BAND	SIGNAL GENERATOR Frequency Setting	Dummy Antenna	Connection to Radio	Position of Band Switch	Variable Condenser Setting	Trimmers Adjusted (in Order Shown)	Trimmer Function	Adjustment
I. F.	465 Kc.	.1 MFD.	Grid of 1R5G 2nd I. F.	Broadcast	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Output I. F.	Adjust to maximum output
	465 Kc.	.1 MFD.	Grid of 1A7G, Mixer	Broadcast	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Input I. F.	Adjust to maximum output (See Note "A")
SHORT WAVE BAND	17 Mc.	400 ohms	Antenna lead	Short Wave	Set Dial at 17 Mc.	Trimmer C6 (See Fig. 3)	Short Wave oscillator	Adjust to maximum output
	17 Mc.	400 ohms	Antenna lead	Short Wave	Set Dial at 17 Mc.	Trimmer C3 (See Fig. 3)	Short Wave antenna	Adjust to maximum output
	6 Mc.	400 ohms	Antenna lead	Short Wave	Set Dial at 6 Mc.	Trimmer C3 (See Fig. 3)	Short Wave oscillator series pad	Adjust to maximum rock dial. (See note "B")
BROAD-CAST BAND	1720 Kc.	200 mmf.	Antenna lead	Broadcast	Rotor full open (Plates out of mesh)	Trimmer C7 (See Fig. 3)	Broadcast oscillator	Adjust to maximum output
	1400 Kc.	200 mmf.	Antenna lead	Broadcast	Set Dial at 1400 Kc.	Trimmer C2 (See Fig. 3)	Broadcast antenna	Adjust to maximum output
	600 Kc.	200 mmf.	Antenna lead	Broadcast	Set Dial at 600 Kc.	Trimmer C8 (See Fig. 3)	Broadcast oscillator series pad	Adjust to maximum rock dial. (See note "B")

NOTE "A" Do not re-adjust the trimmers on the output I. F. Transformer.  
 NOTE "B" Turn the dial back and forth slightly (rock) and adjust trimmer until the peak of greatest intensity is obtained.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
 After each band is completed, repeat the procedure as a final check.

**Model No. 93BR-460A and 93BR-1460A**

Power Consumption . . . "A" Battery 260 MA; "B" Battery 11.5 MA.  
 Power Output . . . . . 150 Milliwatts, Undistorted  
 Sensitivity (for .05 Watts) . . . . . 45 Microvolts Average

Selectivity . . . . . 45 Kc. Broad at 1000 Times Signal at 1000 Kc.  
 Tuning Range . . . . . 535 to 1730 Kc.  
 Intermediate Frequency . . . . . 465 Kc.  
 Speaker . . . . . 5 in. P. M. Dynamic

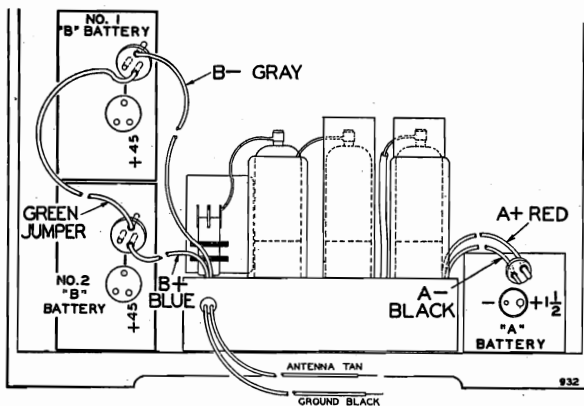

**ALIGNMENT PROCEDURE**

- Volume control—Maximum all adjustments.
- Connect radio chassis to ground post of signal generator with a short heavy lead.
- Connect dummy antenna value in series with generator output lead.
- Connect output meter across primary of output transformer.
- Allow chassis and signal generator to "heat up" for several minutes.

- The following equipment is required for aligning:
- An all wave signal generator which will provide an accurately calibrated signal at the test frequencies as listed.
- Output indicating meter.
- Non-metallic screwdriver.
- Dummy antennas—1 mf., 200 mmf.

BAND	SIGNAL GENERATOR Frequency Setting	Dummy Antenna	Connection to Radio	Variable Condenser Setting	Trimmers Adjusted (in Order Shown)	Trimmer Function	Adjustment
I. F.	465 Kc.	.1 MFD.	Grid of 1P5G I. F. Tube	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Output I. F.	Adjust to maximum output
	465 Kc.	.1 MFD.	Grid of 1A7G	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Input I. F.	Adjust to maximum output
BROAD-CAST BAND	1730 Kc.	200 mmf.	Antenna lead	Rotor full open (Plates out of mesh)	Trimmer—Top of front section of gang (See Fig. 1)	Oscillator	Adjust to maximum output
	1400 Kc.	200 mmf.	Antenna lead	Set dial at 1400 Kc.	Trimmer—Top of rear section of gang (See Fig. 1)	Antenna	Adjust to maximum output

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
 After each band is completed, repeat the procedure as a final check.

**STEP 1—CONNECTING "A" BATTERY:**

First—Place the "A" Battery in the cabinet as shown, (alongside right hand side of the radio chassis).  
 NEXT—Insert the special two-prong connector plug into the socket on the "A" battery as shown in illustration.

**STEP 2—CONNECTING "B" BATTERIES:**

First—Place both "B" Batteries in the cabinet exactly as shown (alongside left hand side of the radio chassis).  
 NEXT—Insert the special three-prong connector plugs into the sockets on the "B" batteries as shown in illustration.

NOTE: The above procedure and illustration pertains to the new style "B" batteries which have sockets; however, the old style "B" batteries which have terminals can be used by connecting them as follows:

FIRST—Remove the special plugs by cutting the wires off at the plugs.

NEXT—Connect gray colored B minus (—) wire to minus (—) terminal of "B" battery (marked Battery No. 1 in illustration).

NEXT—Connect one end of green connecting wire to plus (+45) terminal of battery No. 1 and other end to the minus (—) terminal of Battery No. 2.

NOW—Connect blue B plus (+) wire to the plus (+45) terminal of Battery No. 2.

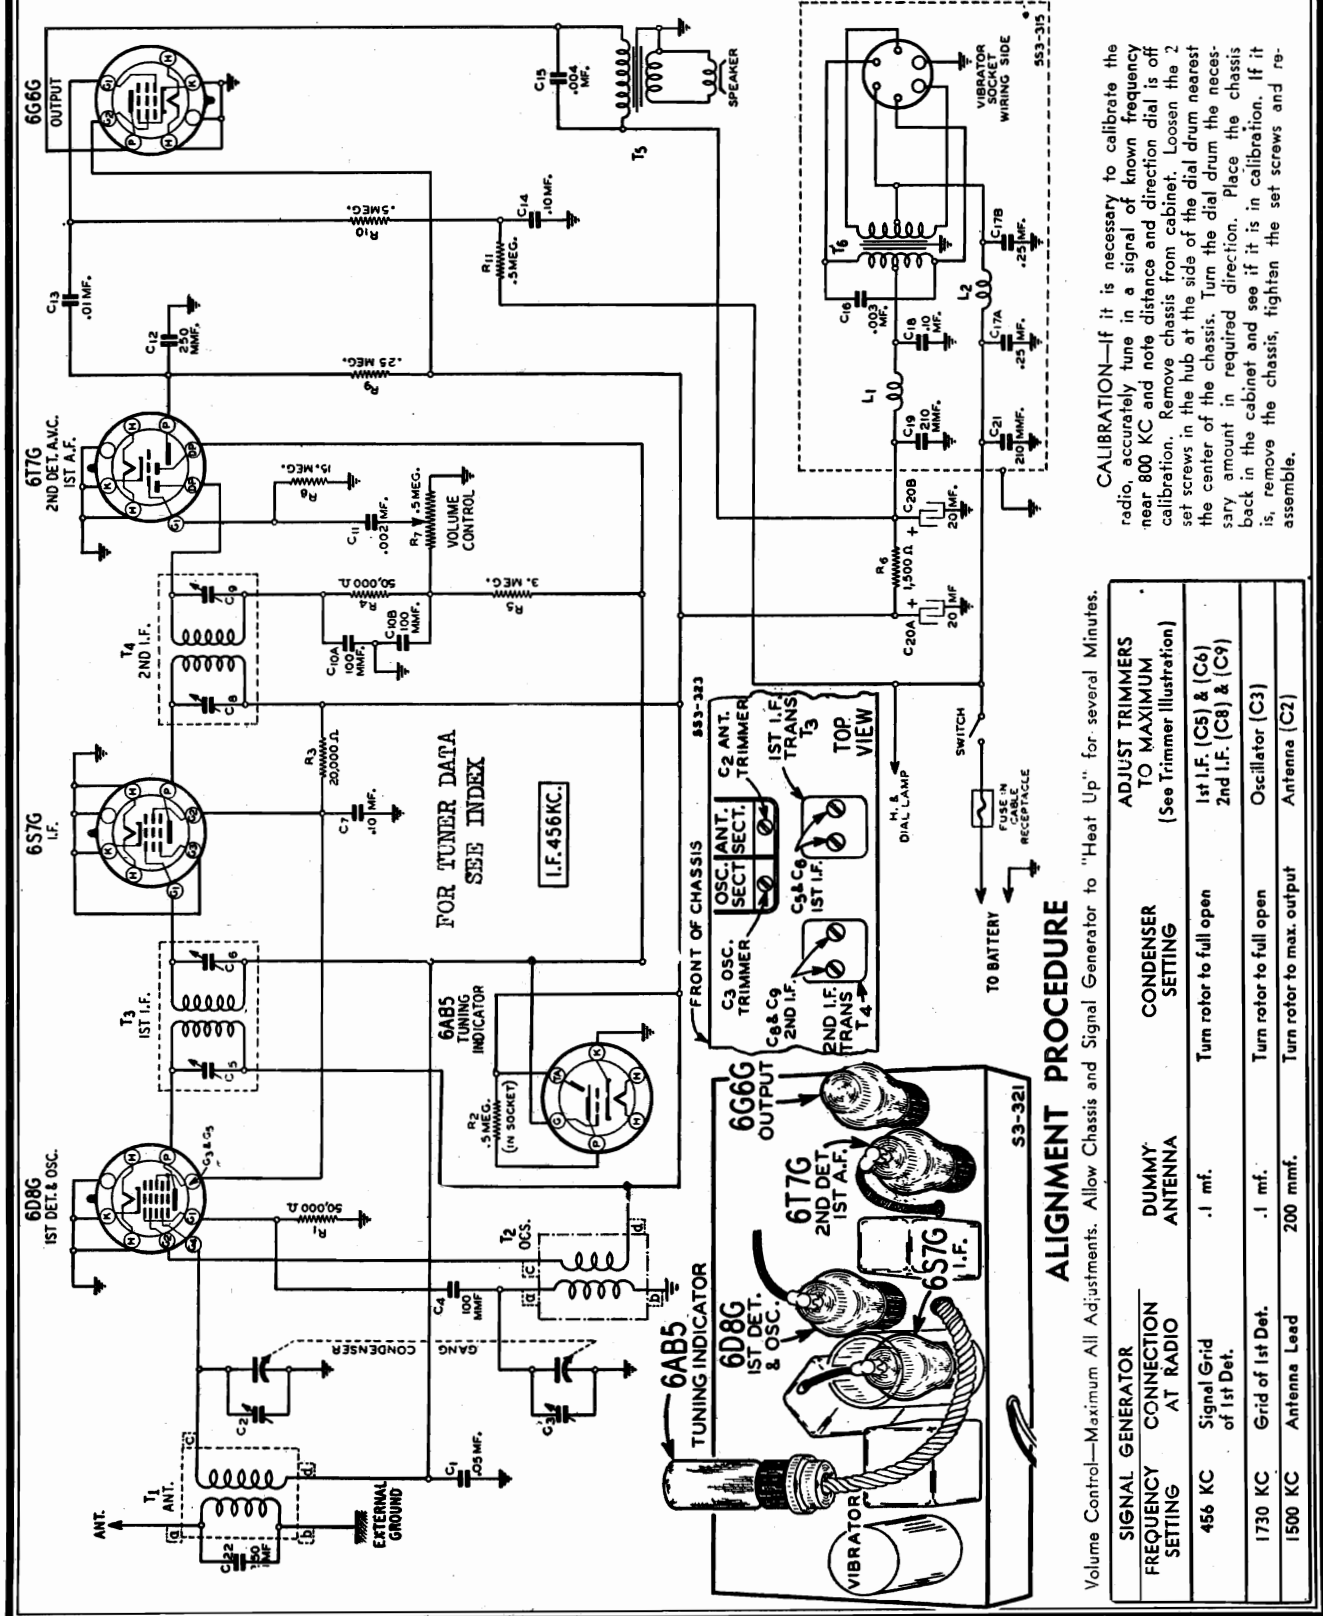

MONTGOMERY WARD & CO.

MODEL 93WG562  
Schematic, Socket  
Alignment, Trimmers

**SPECIFICATIONS**

Power Consumption - 2.2 Amperes at 6.3 Volts  
Power Output - .5 Watt Undistorted  
1.0 Watt Maximum  
Selectivity - 41 KC Broad at 1000 times Signal

Intermediate Frequency - 456 KC  
Speaker - 5" P. M. Dynamic  
Tuning Frequency Range - 528 to 1730 KC.  
Sensitivity (For .05 Watt Output) 15 Microvolts Average

**CALIBRATION**—If it is necessary to calibrate the radio, accurately tune in a signal of known frequency near 800 KC and note distance and direction dial is off calibration. Remove chassis from cabinet. Loosen the 2 set screws in the hub at the side of the dial drum nearest the center of the chassis. Turn the dial drum the necessary amount in required direction. Place the chassis back in the cabinet and see if it is in calibration. If it is, remove the chassis, tighten the set screws and re-assemble.

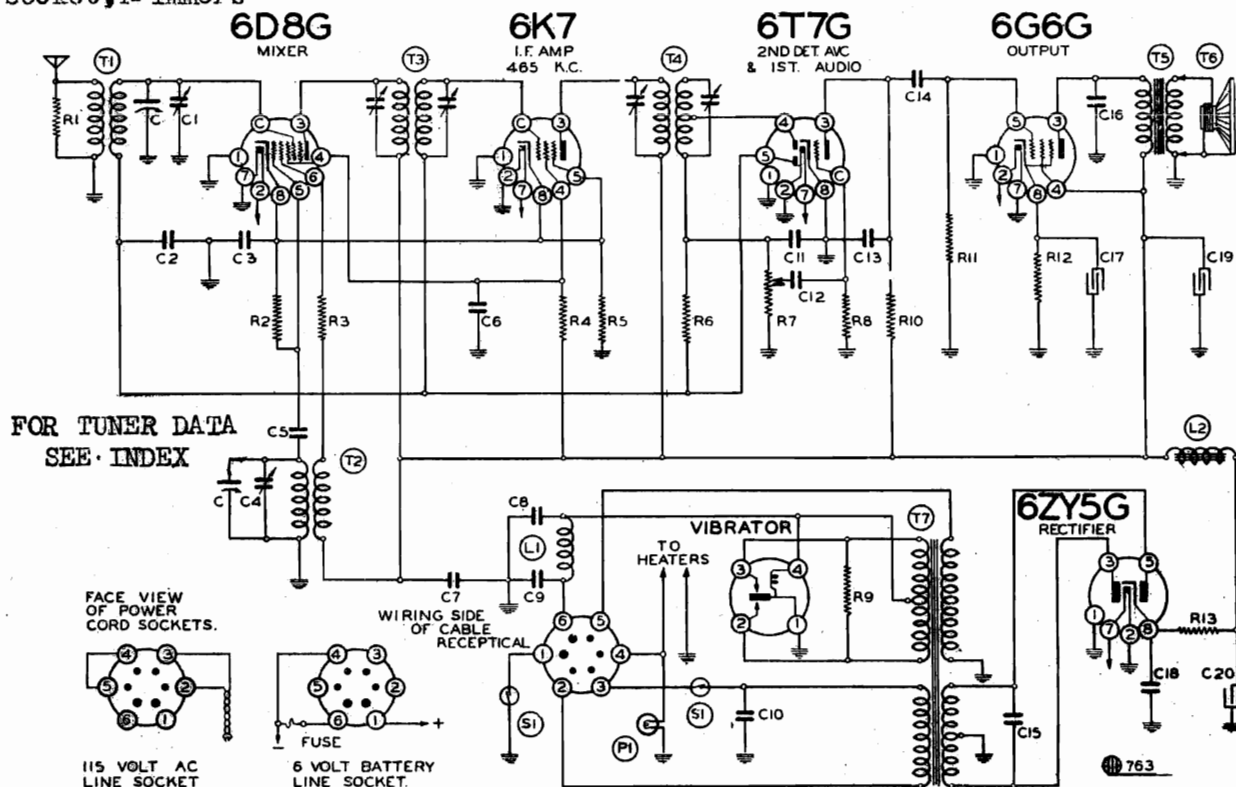

**ALIGNMENT PROCEDURE**

Volume Control—Maximum All Adjustments. Allow Chassis and Signal Generator to "Heat Up" for several Minutes.

SIGNAL GENERATOR FREQUENCY SETTING	DUMMY ANTENNA CONNECTION AT RADIO	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM (See Trimmer Illustration)
456 KC	Signal Grid of 1st Det.	Turn rotor to full open	1st I.F. (C5) & (C6) 2nd I.F. (C8) & (C9)
1730 KC	Grid of 1st Det.	Turn rotor to full open	Oscillator (C3)
1500 KC	Antenna Lead	Turn rotor to max. output	Antenna (C2)

Schematic, Voltage  
Socket, Trimmers

Power Consumption - 28 Watts (At 117 volts AC Supply)  
Power Output - .8 Watt Undistorted  
Selectivity - 50 KC Broad at 1000 times Signal  
Intermediate Frequency - 456 KC

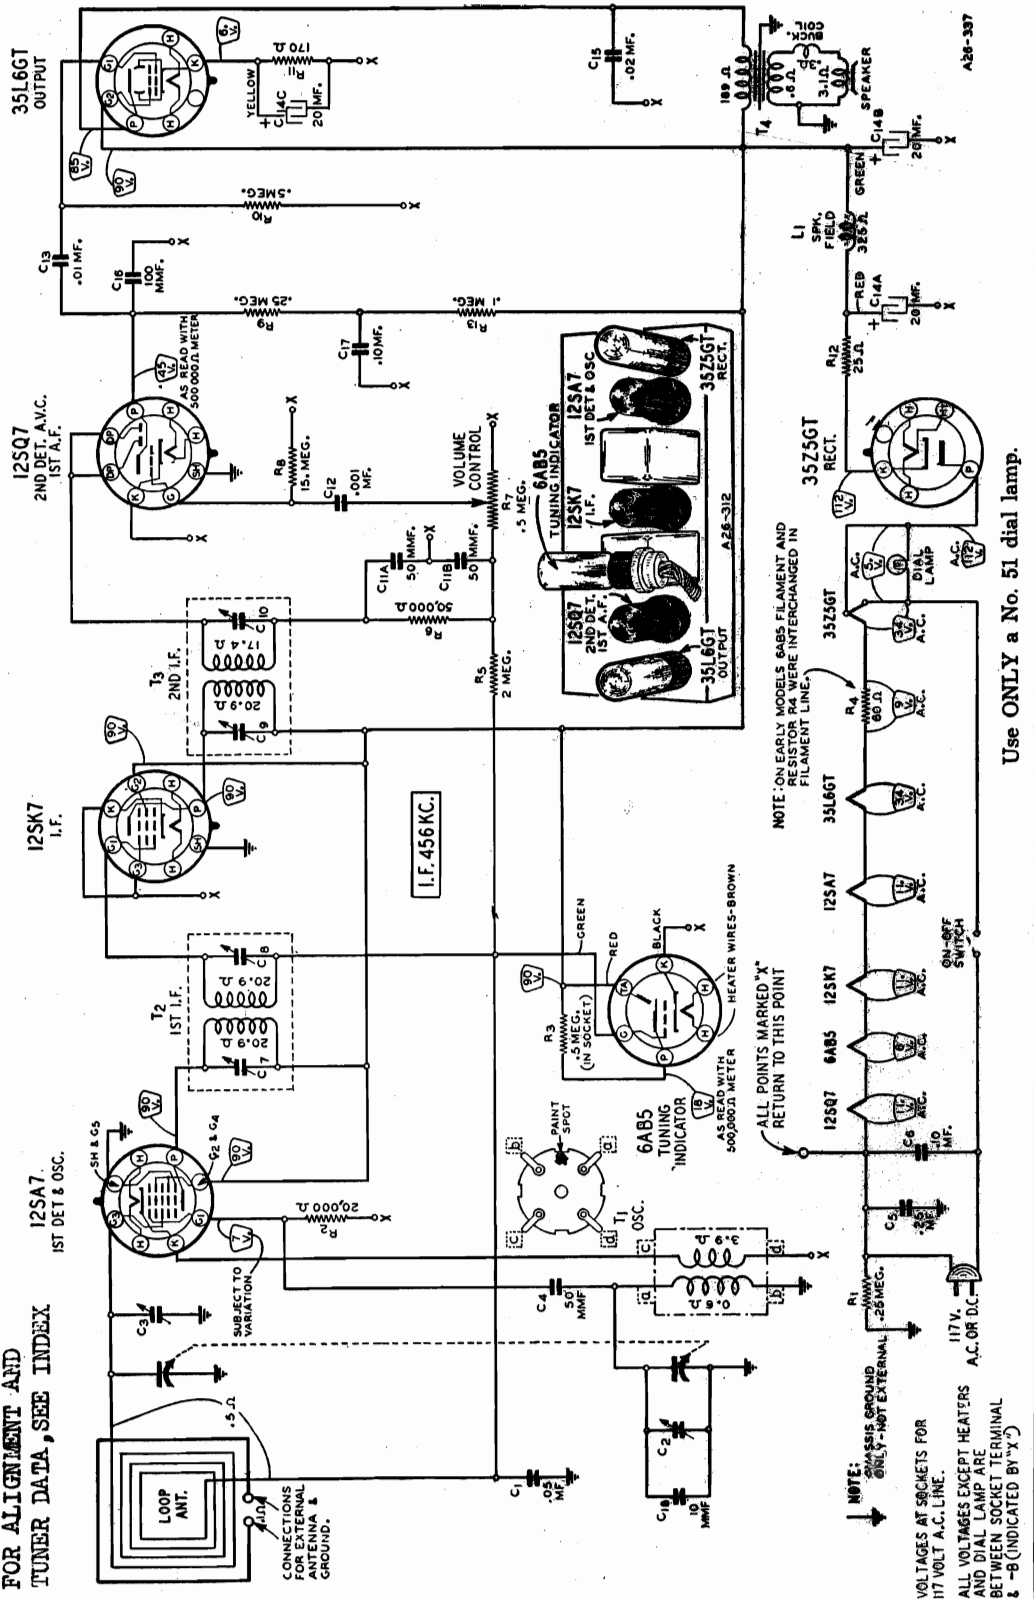

Speaker - 5" Electro Dynamic  
Tuning Frequency Range - 528 to 1730 KC  
Sensitivity - 40 Microvolts per Meter Average  
(For .85 Watt Output)

## Caution

The metal chassis is connected to one side of the line through a .25 mfd. condenser. Both AC and DC power lines are generally grounded on one side. If the side of the line not connected to the metal chassis through this condenser is grounded and the metal chassis comes in contact with an external ground, this condenser will be connected across the line and there will be an increase in hum. Therefore, in any service work on the chassis, keep it on a wood or other insulated surface to avoid contacts with ground. The person working on the set should avoid getting in contact with any ground.

FOR ALIGNMENT AND  
TUNER DATA, SEE INDEX.

NOTE: ON EARLY MODELS 6AB5 FILAMENT AND RESISTOR R4 WERE INTERCHANGED IN FILAMENT LINE.

ALL POINTS MARKED "X" RETURN TO THIS POINT

NOTE: CHASSIS GROUND ONLY - NOT EXTERNAL.  
117 V. A.C. OR D.C.  
ALL VOLTAGES EXCEPT HEATERS AND DIAL LAMP ARE BETWEEN SOCKET TERMINAL & -B (INDICATED BY "X")

Use ONLY a No. 51 dial lamp.

VOLTS MEASURED WITH 1000 OHM PER VOLT VOLTMETER BETWEEN SOCKET TERMINALS AND CHASSIS.

VOLTS MEASURED WITH 1000 OHM PER VOLT VOLTMETER BETWEEN SOCKET TERMINALS AND CHASSIS.

1] CANNOT BE MEASURED WITH VOLTMETER, READ BETWEEN SOCKET TERMINALS AND CHASSIS.

2] 340 VOLTS A.C.

3] 340 VOLTS A.C.

M97.39

MODEL 93BR657A  
Alignment  
MODEL 62-381 S.P.U.  
Chassis

MONTGOMERY WARD & CO.

Chassis No. 98BR657A

Power Consumption . . . . . 2.5 Amp. at 6.3 Volts  
Power Output . . . . . .6 Watts Undistorted  
Sensitivity (for .05 Watts Output) . Shortwave 20 Microvolts Average  
Selectivity 35 KC Broad at 1000 Times Signal at 1600 KC  
Tuning Frequency Range . . . . . 535 to 1730 KC  
Intermediate Frequency . . . . . 5.6 to 18.3 MC  
Speaker . . . . . 8 in. P. M. Dynamic

- Volume control—Maximum all adjustments.
- Connect radio chassis to ground post of signal generator with a short heavy lead.
- Connect dummy antenna value in series with generator output lead.
- Connect output meter across primary of output transformer.
- Allow chassis and signal generator to "heat up" for several minutes.
- The following equipment is required for aligning:
  - An all wave signal generator which will provide an accurately calibrated signal at the test frequencies as listed.
  - Output indicating meter.
  - Non-metallic screwdriver.
  - Dummy antenna—1 mH, 200 mmi. and 400 ohms.

BAND	SIGNAL GENERATOR Frequency Setting	Connection to Radio	Position of Band Switch	Variable Condenser Setting	Trimmers Adjusted (in Order Shown)	Trimmer Function	Adjustment
I. F.	465 Kc.	Grid of 6SK7	Broadcast	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Output I. F.	Adjust to maximum output
	465 Kc.	Grid of 6D8G	Broadcast	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Input I. F.	Adjust to maximum output
SHORT WAVE BAND	17 Mc.	Antenna lead	Short Wave	Set Dial at 17 Mc.	Trimmer (C6) (See Fig. 6)	Short Wave oscillator	Adjust to maximum output
	17 Mc.	Antenna lead	Short Wave	Set Dial at 17 Mc.	Trimmer (C4) (See Fig. 5)	Short Wave antenna	Adjust to maximum output
	6 Mc.	Antenna lead	Short Wave	Set Dial at 6 Mc.	Trimmer (C10) (See Fig. 3)	Short Wave antenna series pad	Adjust to maximum rock dial. (See note "A")
BROAD-CAST BAND	1750 Kc.	Antenna lead	Broadcast	Rotor full open (Plates out of mesh)	Trimmer (C7) (See Fig. 6)	Broadcast oscillator	Adjust to maximum output
	1500 Kc.	Antenna lead	Broadcast	Set Dial at 1500 Kc.	Trimmer (C1) (See Fig. 5)	Broadcast antenna	Adjust to maximum output
	600 Kc.	Antenna lead	Broadcast	Set Dial at 600 Kc.	Trimmer (C3) (See Fig. 5)	Broadcast oscillator series pad	Adjust to maximum rock dial. (See note "A")
	600 Kc.	Antenna lead	Broadcast	Set Dial at 600 Kc.	Trimmer (C2) (See Fig. 5)	Broadcast oscillator series pad	Adjust to maximum rock dial. (See note "A")

FIG. 5—FRONT OF CHASSIS

TUBES:

The following complement of this chassis consists of the following octal base glass and metal tubes:  
The type and function of each tube is as follows:  
1—Type 6D8G First Detector-oscillator.  
1—Type 6SK7 Remote Cut-Off Pentode, I. F. Amplifier (465 K. C.).  
1—Type 6Y7G Duplex Diode Triode Second Detector, A.V.C. and First Audio.  
1—Type 6G6G Output Amplifier.  
1—Type 6AE6G D. C. Amplifier.  
1—Type 6AD6G Cathode-Ray Tuning Eye.  
NOTE:—If the 62-381 A. C. power unit is installed in place of the 6 volt power unit, the tube complement of the radio will consist of one more tube:  
1—Type 5Y3G Rectifier.

NOTE "A" Turn the dial back and forth slightly (rock) and adjust trimmer until the peak of greatest intensity is obtained.  
Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each band is completed, repeat the procedure as a final check.

 MODEL 44C, Chassis RE46

Alignment, Socket  
 Sensitivity  
 Trimmers

**BALANCING INSTRUCTIONS  
 ARVIN MODEL 44C CAR RADIO**

All sensitivities are given for 1 watt output = 1.73 V across speaker voice coil.

**SPECIAL NOTE:** The intermediate frequency transformers in this receiver are coupled so as to secure flat top characteristics and provide semi-high fidelity reception of radio stations. These transformers may be balanced with a standard signal generator and output meter as follows: Feed a signal of 170 kc into the grid of the 6AS tube through 600 ohm capacity, connect a 10,000 ohm resistor across the primary of the second I. F. transformer, connect the secondary of the second I. F. transformer to the primary of the second I. F. transformer, disconnect the resistor and place it across the secondary of the same transformer and adjust screw No. 2.

Then connect the resistor across the primary of the 1st I. F. transformer and adjust screw No. 3 and then after placing the resistor across the secondary, adjust screw No. 4.

Operation No.	Connect Bal. Oscillator To	Bal. Oscillator Frequency	Adjust Fadder No.	Dial Setting	Sensitivity
1	6AS Grid	170 kc	1, 2, 3 & 4	Condenser Closed	700 uv
2	Ant. Coupler Through 20 uf	1570 kc	5	Condenser Open	5 uv
3	Through 20 uf	1400 kc	6 & 7	600 kc	3.5 uv
4	Through 20 uf	600 kc	8		

\*Operation No. 4 adjusts bias on 6AS to obtain 5 uv sensitivity; for metropolitan areas this sensitivity may be set as low as 10 uv, and in mountainous areas as high as 1 uv, to secure the most satisfactory reception.

**BALANCING INSTRUCTIONS  
 ARVIN MODEL 7A CAR RADIO**

All sensitivities given for 1/2 watt output equals 1A V. across Voice Coil

Operation No.	Connect Bal. Oscillator To	Bal. Oscillator Frequency	Adjust Fadder No.	Dial Setting	Sensitivity
1	6AS Grid	455	1, 2, 3 and 4	550 KC	50 uv
2	Ant. Coupler Through 20 uf	1400	5	1400	10 uv
3	"	1400	6	1400	10 uv
4	"	600	7	600	10 uv

MODEL 44C  
Antenna Data

ARVIN 828AT-838AT AUTOMATIC DIAL TUNING INDICATOR

This receiver should first be removed from its carton and the cabinet carefully cleaned with a soft rag to remove packing lint.

The hook bolts or clips which secure the chassis to the cabinet to hold it rigidly during shipment should next be removed. One will be found on each side of the chassis. Do not confuse these with the brackets which suspend the chassis through rubber grommets. These latter brackets should not be loosened unless it is necessary to service the receiver.

The receiver may be prepared for operation by connecting an antenna lead at "A" on the rear terminal strip and connecting a ground lead at "G", leaving the jumper from "D" to "G" in place; or by removing the jumper and connecting the transmission line lead from an Arvin all-wave antenna kit. (Black lead to "D" and red lead to "A".) Plug the line cord into a suitable receptacle.

Make a list of ten stations in your locality which you desire to set up on the station selector, arranging this list so that the stations appear in the order of their frequencies. Cut the call letters of these stations from the sheets supplied with this receiver, leaving a white tab on each end of the piece cut out.

The receiver is placed in operation by turning the right-hand knob in a clockwise direction. This knob also functions as a tone control. The second knob to the left should be turned to the maximum counter-clockwise or manual tuning position.

Tune in the first station on your list, using the tuning indicator to determine whether station is properly tuned in. Change the Manual-Automatic Tuning switch to the automatic tuning position. Unless one of the buttons about to be adjusted happens to be set at this point the receiver will now appear to be inoperative. (In event a button does happen to be set at the proper point—no adjustment is necessary. If the pilot light is not in proper rotation, the sockets may be exchanged from the rear.) Looking at the rear of the dial and on the side toward which the pointer is now pointing, locate the button in the circular slot whose lead goes to the lowest pilot light on that side of the dial. Loosen this button by means of a turn in the counter-clockwise direction and slide the button in its track slowly until a point is reached where the receiver operates. The correct location for this button is directly behind the brass strip carried by the arm behind the plate on which the buttons are mounted. If this correct location cannot be attained by sliding the button in the particular track it now occupies, the button should be slid along this

track to the point where it may be taken out and inserted in a track where this adjustment is possible.

The Manual-Automatic Tuning switch should now be returned to the Manual position; the second station on the list tuned in; the Manual-Automatic Tuning switch again thrown to the Automatic Tuning position; the button at the rear of the dial selected whose lead goes to the second pilot light; this button should be loosened, slid along the track and again tightened at the point where the receiver operates.

This same procedure should be continued for each station successively right around the dial, which then completes the set-up.

The switch may now be turned to the Automatic Tuning position. Tune in each station again, placing the proper call letters in each clip, inserting them from the rear of the receiver and at the edge of the dial frame. Push the call letter strips in so that they properly center in each window when viewed from the front.

This Arvin receiver has special advanced features which must be properly understood in order that full benefit may be derived from this fine instrument.

When the receiver is being operated with the Manual-Automatic Tuning switch in the manual position, the receiver tunes sharply and any station within the range of the receiver may be selected at will. Tonal quality to suit the taste of the listener may be obtained by adjustment of the tone control.

On the other hand, when the Manual-Automatic Tuning switch is in the automatic tuning position, the receiver functions in an entirely different manner. Throwing this switch automatically broadens the selectivity characteristics of the receiver.

It should be noted that this broad selectivity will only function satisfactorily on the louder stations, that is, those which are normally selected for use on the Arvin-Station-Selector. (This broadened selectivity is not practical in the manual tuning position because of inter-station interference which would inevitably result.)

Should the listener so desire, this increased fidelity can be compensated for by readjusting the setting of the tone control.

When this receiver is being operated on the police-amateur or foreign-short wave band, tuning should always be done manually and no attempt made to utilize the station selector feature which has been set up for the broadcast band.

BALANCING INSTRUCTIONS  
MODELS 828AT and 838AT

SENSITIVITY:

- A. Broadcast Band—50 Microvolts Minimum
- B. Police Band—75 Microvolts Minimum
- C. Short Wave Band—100 Microvolts Minimum

NOTE: Standard output is considered 500 milliwatts which is equal to 1.12 R.M.S. AC volts across the voice coil of the speaker. Sensitivity is determined by the amount of input in microvolts required to produce 1.12 volts at the voice coil. Measurement may be made with any AC voltmeter or output meter.

The intermediate frequency transformers embodied in the circuit of Arvin Models 828AT-838AT are of the semi-permatune type, the only adjustment being variable iron cores in the fields of the transformers. It is advisable before attempting to rebalance the intermediate stages of this receiver, therefore, to check the overall intermediate frequency stage sensitivity. This may be accomplished by connecting the 455 K. C. output of a standard signal generator to the grid cap of the 6ABG tube after removing the grid clip. Connection should be made through a standard 200 uuf. dummy antenna. Check sensitivity and perform all balancing procedure with the automatic tuning in the "off" position. The intermediate frequency sensitivity should be at least 75 microvolts for 50 milliwatts output. If the I. F. sensitivity is within the limits prescribed the following instructions for balancing may then be followed.

If the I. F. sensitivity is low then adjust screws 1, 2, 3 and 4 for maximum output.

1. Connect the signal generator to the A and G terminals on the rear of the radio. Rotate the condenser until it is fully in mesh (maximum clockwise position.) The dial pointer should point to the center of the station window which is alongside 550 kilocycles (55 on the American broadcast band.)
2. Rotate dial pointer to 1,400 K. C. Set band switch to Broadcast Position. Adjust padder No. 5 to resonance. Adjust padder No. 6 for maximum output.
3. Rotate dial pointer to 600 K. C. With 600 K. C. input from the signal generator adjust padder No. 7 for resonance.
4. Set band switch to mid-band position. Rotate dial pointer to 5.0 megacycles. With 5,000 K. C. input from signal generator adjust padder No. 8 for resonance. Adjust padder No. 9 for maximum output.
5. Set band switch to short-wave band position. Rotate dial pointer to 15.0 megacycles. With 15 megacycles input from signal generator turn padder No. 10 to the extreme clockwise position. Then rotate padder screw counter-clockwise selecting the second resonance point reached. Then adjust padder No. 11 for maximum output.

ARVIN MODELS 7A, 8A, AND 44C,  
ANTENNAS A22, A23 and A24

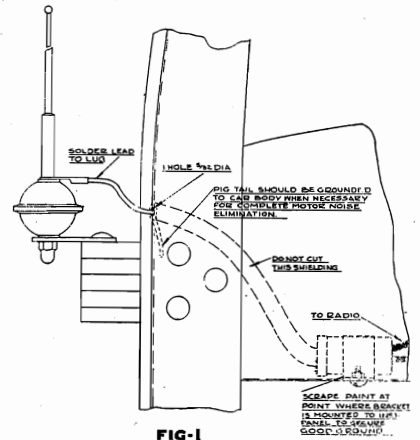

FIG-1  
INSTALLATION FOR DOOR HINGE ANTENNA

Antenna:

Arvin antennae A22, A23 and A24 are recommended for use with the Arvin Model 7A Radio. These antennae are supplied with special connector shield cups to provide for good motor noise elimination.

The use of UNDER CAR or built in ROOF TYPE ANTENNA is not recommended nor will satisfactory reception be obtained if this type antennae is used.

The Phantom Filter should be mounted as shown in Figure 1 if a door hinge type antenna is used. Fig 2 illustrates the proper connections for the side cowl type Arvin Antenna and the Arvin Phantom Filter.

Installation:

A clear space, preferably above the steering column, approximately 8 1/2" square and free of obstructions is required for mounting the model 7A radio chassis.

Remove the cap screw in the rear of the radio chassis and insert the stud, (supplied in the hardware envelope) in its place. Drill a 1/2" hole in the center of the space selected for the chassis.

Scrape the paint from the motor side of the dash around the 1/2" hole to secure a good ground for the mounting stud.

\* Measured with a vacuum tube voltmeter. 600 to 1500 K. C.

No signal applied to receiver: with 100,000 microvolts to input diode voltage approximately 12 volts.

**BALANCING INSTRUCTIONS**

CONNECT an output meter or A. C. Voltmeter across the speaker coil leads.

1. Connect the signal generator to the grid cap of the 1C7G tube and with an input of 456 K. C. adjust padders 1, 2, 3 and 4 for maximum output.
2. Connect the signal generator through a standard 200 micromicrofarad dummy antenna to the antenna (green) lead wire on the rear of the chassis. Ground the generator to the (black) ground wire.
3. Rotate the tuning condenser to the wide

open position. Check the dial pointer to see that it is parallel to the horizontal line across the dial face.

4. Rotate the dial pointer to 1,400 K. C. and with an input of that frequency adjust padder No. 5 to resonance. Adjust padder No. 6 for maximum output.
5. Rotate the dial pointer to 600 K. C. and with an input of that frequency adjust the series padder No. 7 to resonance.
6. Return to 1,400 K. C. and recheck the settings of padders No. 5 and No. 6.

\* Dial pointer should line up with end of broadcast band (dial calibration with tuning condenser fully closed).

\*\* After balancing 600 kc padder, return and recheck the adjustments of padders 6 & 7.

\* NOTE: Signal generator should be connected to A & G terminals on rear of radio chassis. D & G terminals should be connected together.

"Hash" Elimination  
 Changes, Notes

- FIG. 5 BEFORE
- FIG. 6 AFTER
1. Ground the Gang Condenser can as shown in Figure 2.
  2. Bend vibrator prongs away from receiver case as shown in Figure 4.
  3. Tighten power supply mounting nuts.

SUBJECT—VIBRATOR "HASH" NOISE

Caution: Only radios that have a vibrator hash noise should have this correction made. If there is no hash noise and these changes are made to prevent hash development, it will only tend toward driving hash noise into the radio.

CORRECTION

The following procedure to correct vibrator hash is:

Deluxe Model - 982084 ONLY

1. The Bond that grounds the Gang Condenser to the Antenna Coil can should be held against the Gang Condenser bracket and soldered. This is shown in Figure 1 before change, and Figure 2 after change.

1. Ground the Gang Condenser can as shown in Figure 2.
2. Bend vibrator prongs away from receiver case as shown in Figure 4.
3. Tighten power supply mounting nuts.

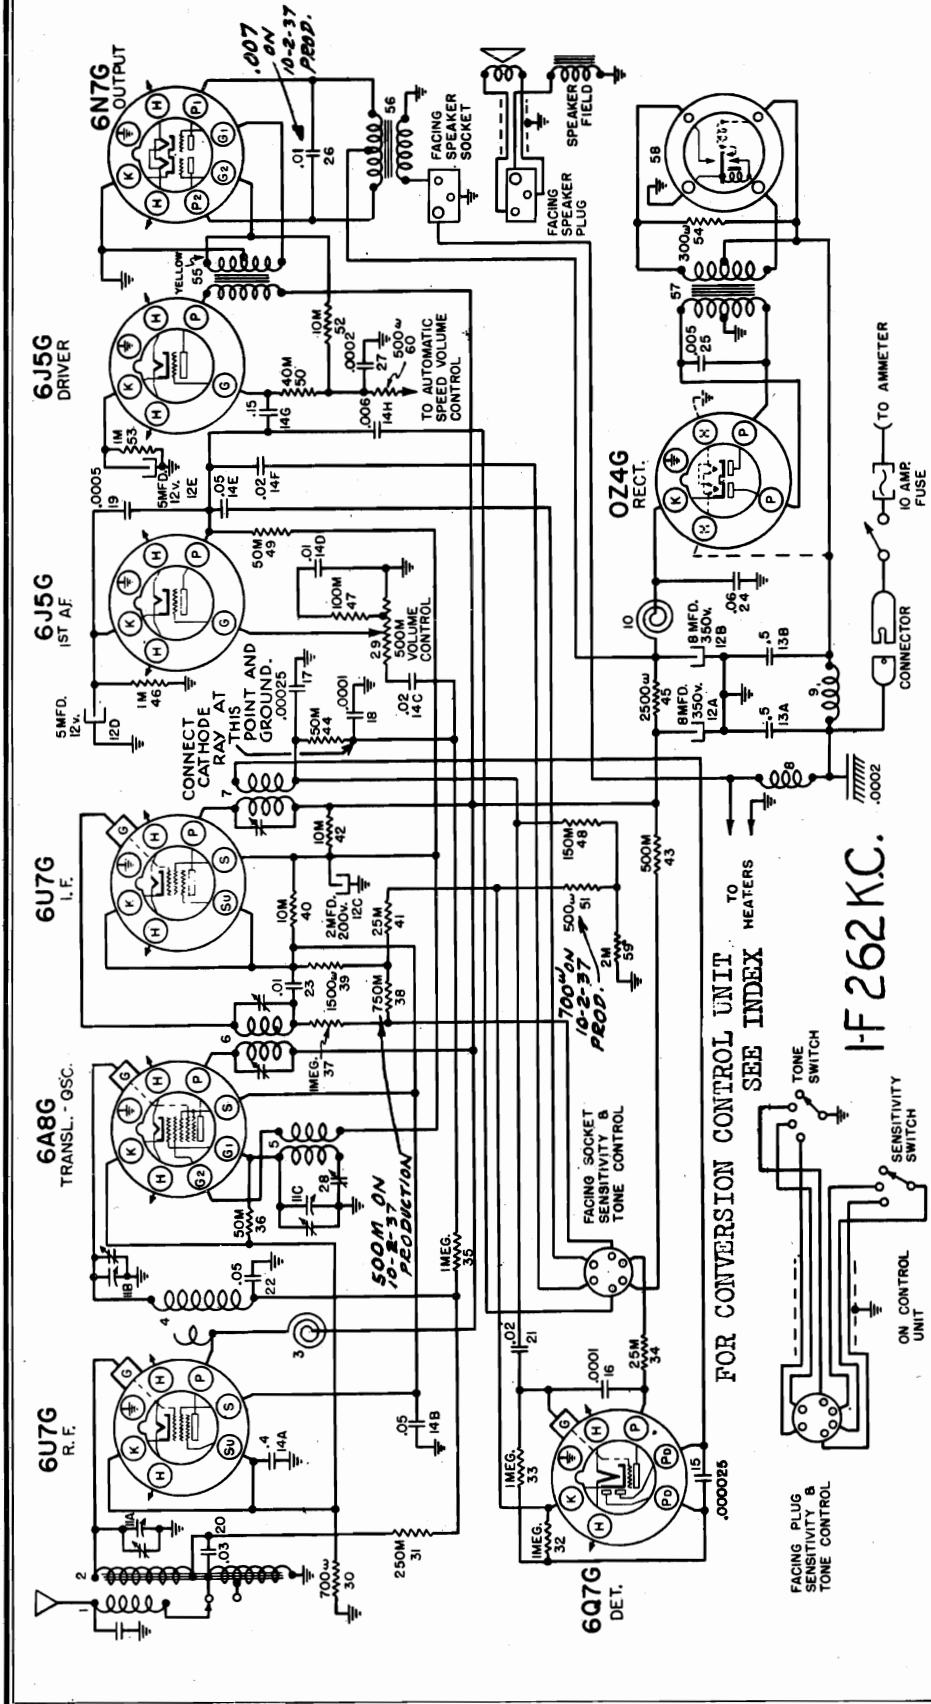

Standard Model - 982083 ONLY

4. Remove the receiver from the car and add a .0002 MFD condenser from the small terminal strip to ground. Solder one end of condenser to the same terminal that the two small resistors are soldered to and solder the other end of the condenser to the chassis ground, as shown in Figure 6.

OLDSMOBILE DIV.—GEN. MOTORS

MODEL 982084  
Early, Late  
Schematic, Notes

The Oldsmobile Model 982084 is an eight tube Dash Speaker Deluxe Receiver, with tone and sensitivity controls. This receiver was designed specifically for 1938 Oldsmobiles and is equipped with an instrument panel tuning control having a sensitivity switch and variable tone control in addition to the tuning and volume controls.

The antenna circuit is directly coupled to the antenna in contrast with the capacity coupled circuit used in some previous Oldsmobile Models. A small adjustable condenser is provided for adjusting the antenna circuit to the antenna. This adjustment is made near the high frequency end of the band (1400 K.C.) instead of at the low frequency end as with the capacity coupled sets. There are two taps provided on the Antenna Coil. One for use with the Running Boards Antenna and the other for use with overhead (Roof) type Antennas.

Early, Late  
Alignment, Voltage

1. Aligning I-F Stages at 262 Kilocycles:
 

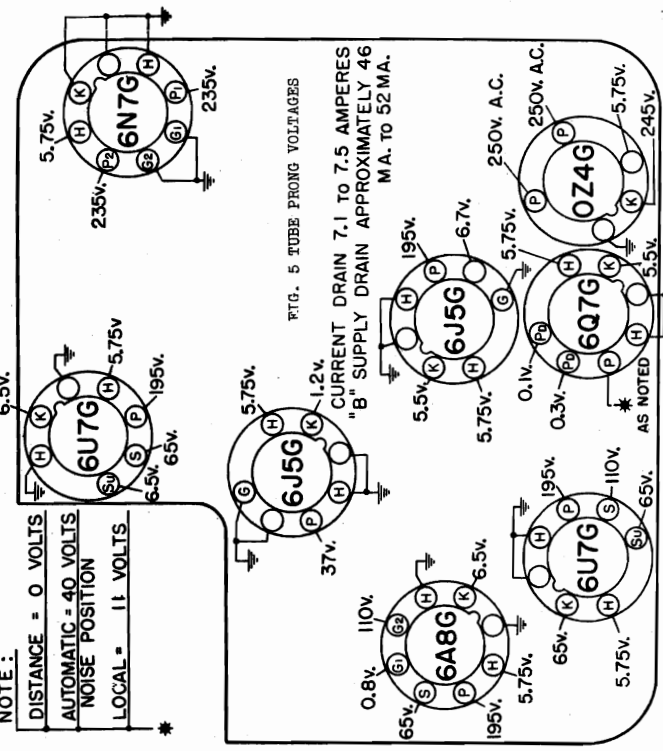

**IMPORTANT:** The sensitivity switch on the tuning control should be in the "distance" position when aligning the receiver, or the cable from the control unit to the receiver disconnected.

  - a. Connect the signal lead of the test oscillator to the grid cap of the 6A8G Tube through a .1 mfd. condenser, leaving the tube's grid clip in place.
  - b. Connect the ground lead of the test oscillator to the chassis frame.
  - c. Connect the output meter across the plate prongs of the output tube. Care should be taken when connecting the output meter to insert a series condenser to protect the meter from D.C. Voltages.
  - d. Set the test oscillator to exactly 262 K.C.
  - e. Adjust the trimmers on the I-F coils (Illustration 6 and 7, Figure 2) for maximum output. These adjustments should be repeated several times and during alignment, the test oscillator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.
2. Aligning at 1520 Kilocycles:
  - a. Leave the test oscillator leads connected the same as for aligning the I-F circuits.
  - b. Turn the rotor plates of the gang condenser all the way out and against the high frequency stop.
  - c. Set the test oscillator to 1520 Kilocycles.
  - d. Adjust the parallel trimmer for the oscillator section of the condenser gang (Illustration 11C, Figure 3) for maximum output. (It is very important that this frequency be set accurately as a slight mis-setting will cause the receiver to be out of track over the entire high frequency end of the dial.)
3. Aligning at 540 Kilocycles:
  - a. Leave test oscillator leads connected the same as before.
  - b. Turn the rotor plates of the gang condenser all the way into mesh so that they rest against the low frequency stop.
  - c. Set the test oscillator to 540 K.C.
  - d. Adjust the oscillator padding condenser (Illustration 28, Figure 2) located on the mounting plate of the receiver to maximum output. (This adjustment sets the low frequency tuning range of the receiver to 540 K.C.)
4. Aligning at 1400 Kilocycles:
  - a. Remove the signal lead of the test oscillator from the grid of the Translator tube and connect to the antenna terminal of the receiver THROUGH A .00085 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used. (It is very important that a .00085 mfd. mica condenser be used in aligning the antenna stage of these receivers in order that this circuit can be made to track properly. Some test oscillators have this condenser included and if the capacity is correct, it will not be necessary to use an external series condenser.)
  - b. Set the test oscillator to 1400 K.C.
  - c. Turn the condenser rotor plates until the frequency is tuned in with maximum output.

**NOTE:** If the entire alignment procedure has been accomplished correctly, the receiver should be very nearly uniformly sensitive over the entire frequency range.

**NOTE:**

DISTANCE = 0 VOLTS
AUTOMATIC = 40 VOLTS
NOISE POSITION
LOCAL = 11 VOLTS

CIRCUIT DESCRIPTION

The circuit used in this receiver is the conventional superheterodyne type and does not employ regeneration.  
An Automatic Speed Volume Control, which increases volume with car speed, is incorporated in the receiver.

 Chassis, Alignment

ANTENNA CIRCUIT

The antenna circuit is directly coupled to the antenna. A small adjustable condenser is provided for adjusting the antenna circuit to the antenna. This adjustment is made near the high frequency end of the band (1400 K.C.) There are two antenna receptacles provided on the receiver. One for use with the running boards antenna and the other for use with the overhead (roof) type antenna.

1. Aligning I-F stages at 260 Kilocycles

- (a) Connect the signal lead of the test oscillator to the grid cap of the 6A8 Tube through a .1 mfd. condenser, leaving the tube's grid clip in place
- (b) Connect the ground lead of the test oscillator to the chassis frame.
- (c) Connect the output meter across the plate prongs of the output tube. Care should be taken when connecting the output meter to insert a series condenser to protect the meter from D. C. voltages.
- (d) Set the test oscillator to exactly 260 Kilocycles.
- (e) Adjust the trimmers "A", "B", "C" and "D" on the I-F Transformers for maximum output. (See parts layout). These adjustments should be repeated several times and during alignment the test oscillator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.

2. Aligning at 1560 Kilocycles

- (a) Leave the test oscillator leads connected as for aligning the I-F Circuits.
- (b) Turn the Rotor plates of the gang condenser (illustration #9) all the way out and against the high frequency stop.

- (c) Set the test oscillator to 1560 kilocycles.

- (d) Adjust the condenser "F" for maximum output. (It is very important that this frequency be set accurately as a slight missetting will cause the receiver to be out of track over the high frequency end of the dial.)

3. Aligning at 540 Kilocycles

- (a) Leave the test oscillator leads connected the same as before.
- (b) Turn the rotor plates of the gang condenser all the way into mesh so that they rest against the low frequency stop.
- (c) Set the test oscillator to 540 kilocycles.
- (d) Adjust the oscillator padding condenser "G" for maximum output. (This adjustment sets the low frequency tuning range of the receiver to 540 K.C.)

4. Aligning at 1400 Kilocycles

- (a) Remove the signal lead of the test oscillator from the grid of the 6A8G tube and connect to the Running Board Antenna receptacle of the receiver THROUGH a .00045 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used. (It is very important that a .00045 mfd. mica condenser be used when aligning the antenna stage of these receivers and that the lead from the test oscillator is in the correct terminal in order that this circuit can be made to track properly.)
- (b) Set the test oscillator to 1400 K.C.
- (c) Turn the condenser rotor plates until this frequency is tuned in with Maximum output.

- (d) Adjust the R-F Parallel trimmer "H" on the condenser gang and the antenna compensating condenser "I" which is the parallel trimmer on the Condenser Gang.

5. Aligning at 600 Kilocycles

- The oscillator padding condenser was previously adjusted at 540 K.C., however, it is necessary in most cases to repeat the oscillator tracking condenser at 600 K.C. in order to make the receiver track properly and to secure full sensitivity.
- (a) Set the test oscillator at 600 K. C.
  - (b) Turn the Condenser rotor plates until the signal from the test oscillator is tuned in with maximum output.
  - (c) Maintain a low output signal from the test oscillator and readjust the oscillator tracking condenser "J" while rocking the variable condenser gang tuning shaft back and forth through the signal.
  - (d) This operation should be continued until no further increase in output can be obtained.

NOTE: If the entire alignment procedure has been accomplished accurately, the receiver should be very nearly uniformly sensitive over the entire frequency range.

5. Aligning at 600 Kilocycles  
The oscillator padding condenser was previously adjusted at 540 K.C., however, it is necessary in most cases to repeak the oscillator padding condenser at 600 K.C. in order to make the receiver track properly and to secure full sensitivity.
- Set the test oscillator at 600 K.C.
  - Turn the condenser rotor plates until the signal from the test oscillator is tuned in with maximum output.
  - Maintain a low output signal from the test oscillator and readjust the oscillator padding condenser "E" while rocking the variable condenser gang tuning shaft back and forth through the signal.
  - This operation should be continued until no further increase in output can be obtained.
- NOTE: If the entire alignment procedure has been accomplished correctly, the receiver should be very nearly uniformly sensitive over the entire frequency range.

LOCATION OF PARTS - OLDS MODEL 982127

Note: For tuning head mechanism parts, refer to Olds Model Radio 982126.

- Connect the signal lead of the test oscillator to the grid cap of the 6A8G Tube through a .1 mfd. condenser, leaving the tube's grid clip in place.
- Connect the ground lead of the test oscillator to the chassis frame.
- Connect the output meter from the plate prong of the output tube to ground. Care should be taken when connecting the output meter to insert a series condenser to protect the meter from D. C. Voltages.
- Set the test oscillator to exactly 455 K.C.
- Turn volume control to maximum.
- Adjust the trimmers "A", "B", "G" and "H" on the I-F Transformers for maximum output. (See parts layout) These adjustments should be repeated several times and during alignment the test oscillator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.

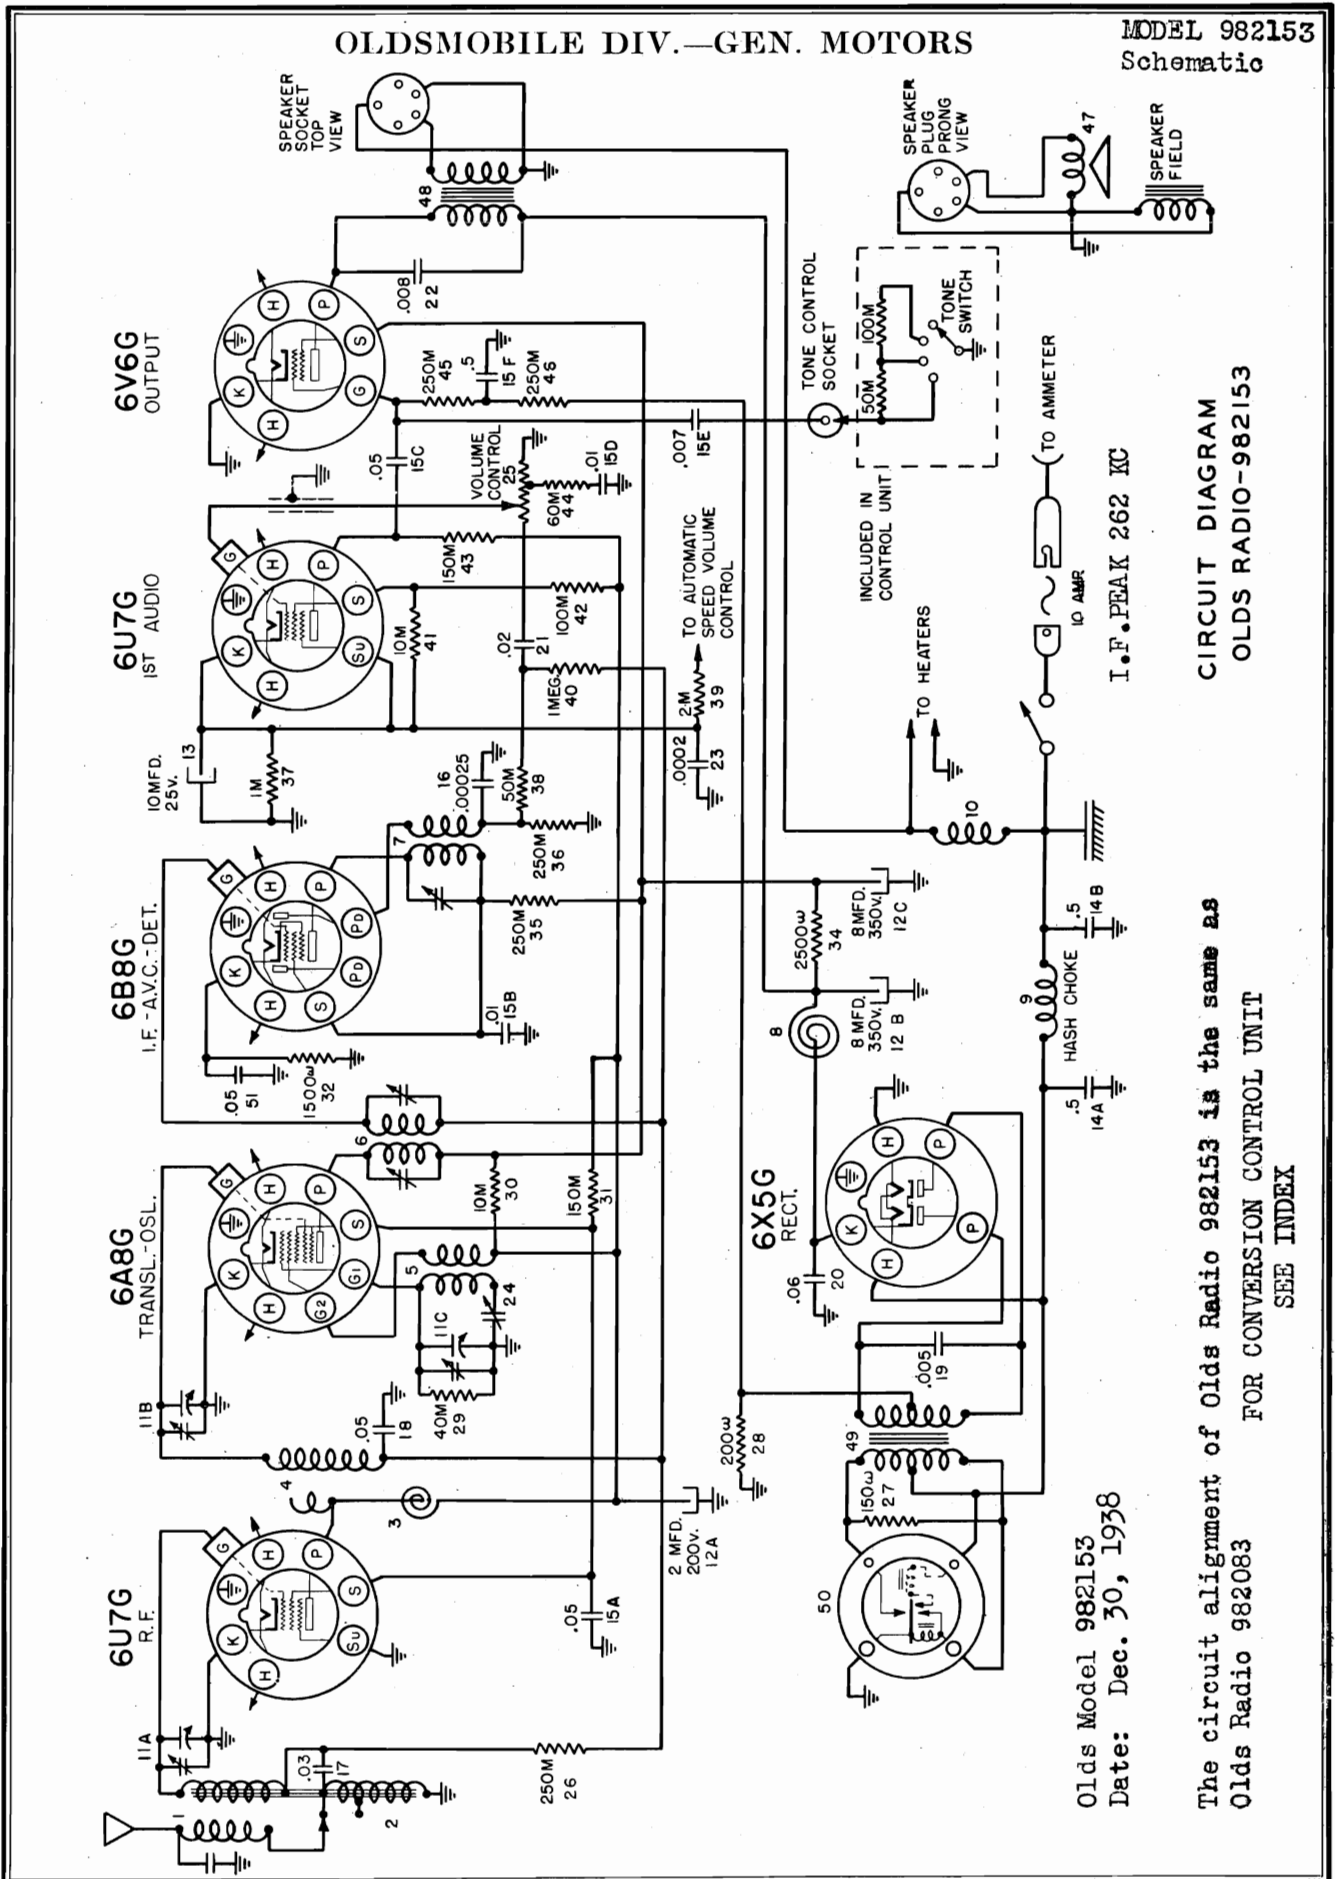

2. Aligning at 550 Kilocycles
- Leave the test oscillator leads connected the same as for aligning the I-F Circuits.
  - Turn the Rotor plates of the gang condenser (illus. #6) all the way out and against the high frequency stop.
  - Set the test oscillator to 550 kilocycles.

- Adjust the condenser "F" for maximum output. (It is very important that this frequency be set accurately as a slight missetting will cause the receiver to be out of track over the entire high frequency end of the dial.)
3. Aligning at 540 Kilocycles
- Leave test oscillator leads connected the same as before.
  - Turn the rotor plates of the gang condenser all the way into mesh so that they rest against the low frequency stop.
  - Set the test oscillator to 540 K.C.
  - Adjust the oscillator padding condenser "E" for maximum output. (This adjustment sets the low frequency tuning range of the receiver to 540 K.C.)

4. Aligning the Antenna Stage
- Remove the signal lead of the test oscillator from the grid of the 6A8G tube and connect to the Running Board Antenna receptacle of the receiver THROUGH a .0004 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used. (It is very important that a .0004 mfd. mica condenser be used when aligning the antenna stage of those receivers and that the lead from the test oscillator is in the correct receptacle in order that this circuit can be made to track properly.)
  - Set the test oscillator to 600 K.C.
  - Adjust antenna trimmer condenser "D" for maximum output.
  - Set the test oscillator to 1400 K.C.
  - Turn the condenser rotor plates until this frequency is tuned in with maximum output.
  - Adjust the Parallel trimmer "C" on the condenser gang for maximum output.

Alignment

MODEL 25  
IF PEAK 465 KC.

**INTERMEDIATE FREQUENCY:** Set oscillator to 465 KC. Feed this to the grid of the pentagrid (6A7) converter tube. Adjust trimmers on the intermediate frequency transformers for peak readings as indicated on the output meter which is to be placed across the output transformer.

**BROADCAST BAND:** Set the band switch for broadcast reception. Adjust oscillator to 1400 KC and connect the output of the generator to the antenna connection at the rear of the chassis through a .0002 mfd. mica condenser. Set the pointer on the dial to 1400 KC making sure that the volume control is set at its maximum position. Adjust the broadcast antenna and broadcast oscillator trimmers for maximum signal (as indicated on the output meter). Re-set the dial pointer on the receiver and on the test oscillator to 600 KC. Slowly increase or decrease the broadcast padding condenser while tuning back and forth across the signal with the station selector knob until the maximum reading is obtained on the output meter. Re-check the 1400 KC alignment as the adjustment at 600 KC may have slightly disturbed the original 1400 KC setting.

**SHORT WAVE:** Set band switch on short wave position. Connect the antenna of the radio receiver to the output of the test oscillator through a 400 ohm carbon resistor. Set oscillator trimming condensers for maximum output as indicated by readings on the output meter. No other adjustments are necessary for aligning this band.

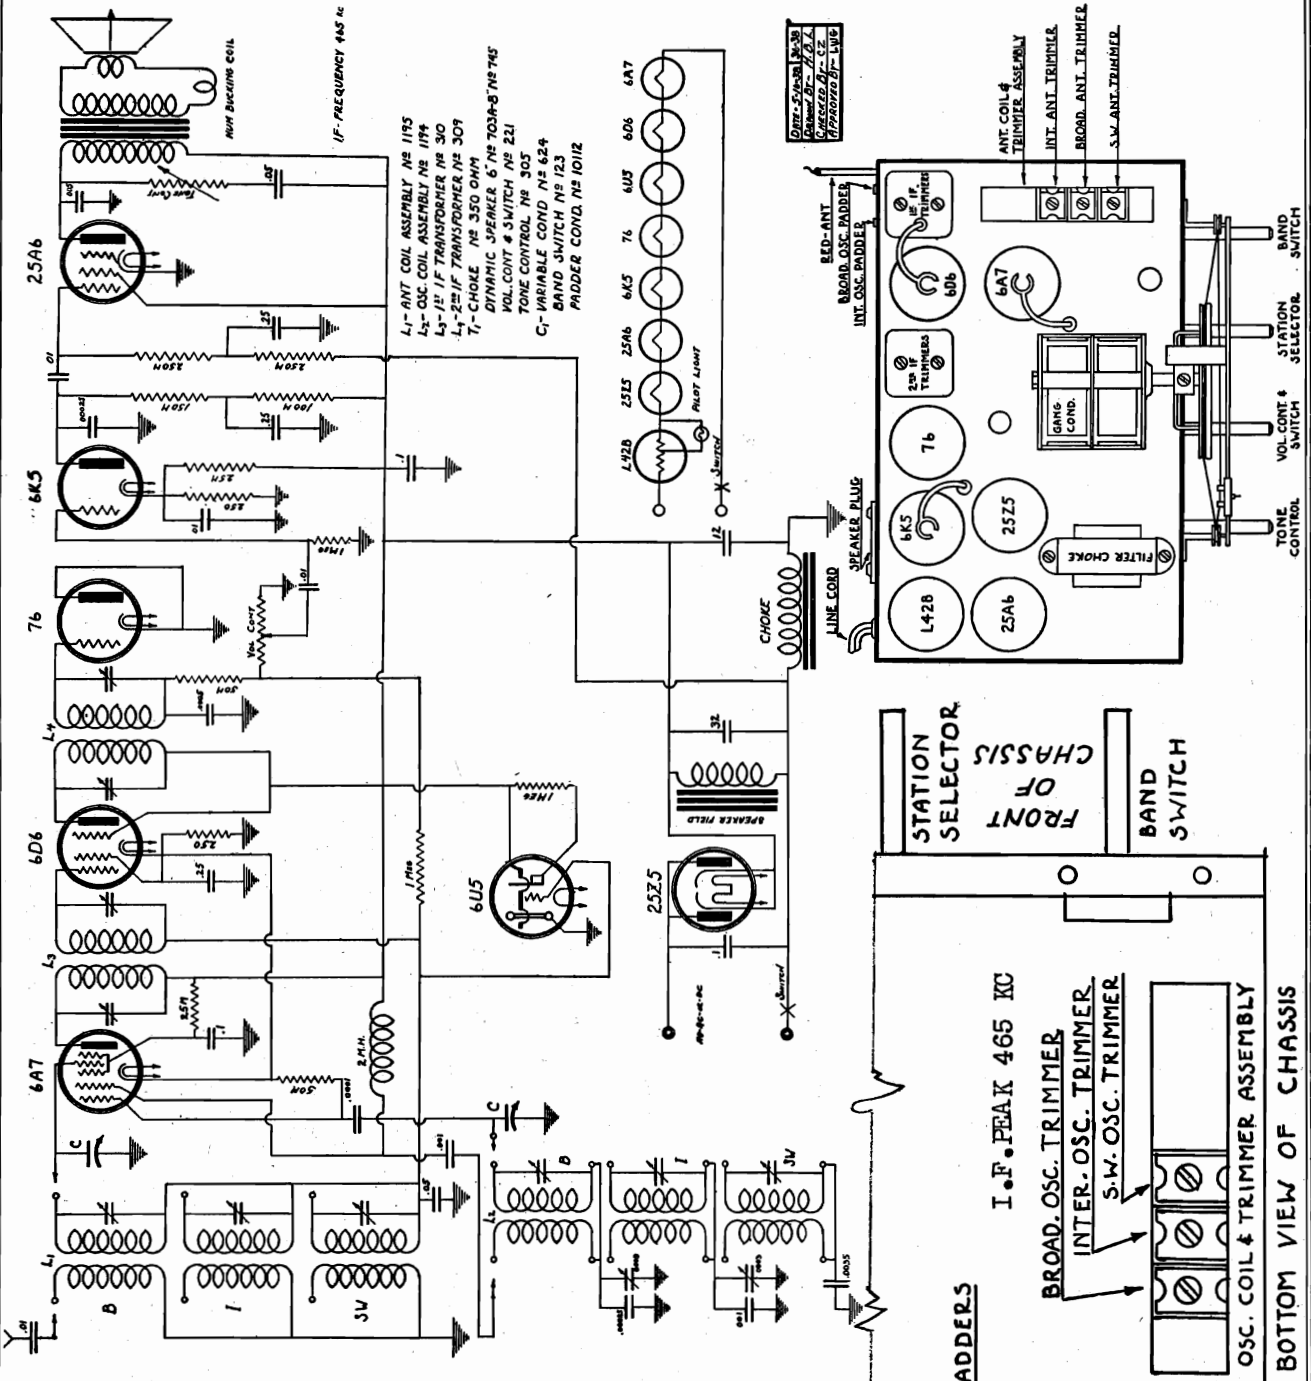

It is advisable to check the sensitivity at 6000 KC to determine whether the circuits are properly aligned. Should the receiver lack sensitivity at this frequency check the .0035 mica condenser for short circuit.

Model 160 Automatic

Alignment Procedure

Turn the dial (manually) to 1740 kc position (plates of tuning condenser completely unmeshed) and set the volume control at maximum. Turn the band switch to broadcast position. Short the cathode of 6B6 tube (now connected to 2 meg. resistor) to chassis so that the automatic frequency control action will be nullified during alignment. Connect the through lead of the signal generator to the control grid of the 6A8 tube through a .006 condenser and set dial of generator to 460 kc. Adjust I.F. trimmers 1-2-3 and 4 until maximum output is obtained, meanwhile maintaining as low a value of signal as will allow obtaining of accurate adjustment.

Now tune signal generator to 1740 kc and connect output lead through .006 condenser to antenna post of receiver. Turn dial pointer of receiver to horizontal position and adjust oscillator trimmer 5, antenna trimmer 7 and first detector trimmer 6 for maximum output. Next tune the generator to 600 kc. Turn dial pointer of radio to point of maximum signal and adjust trimmer 8 for increase in signal. At the same time rock the tuning condenser back and forth through resonance while adjusting the padder until maximum output is obtained. This should occur when the receiver dial is set at approximately 600 kc. Now tune back across the dial and if not exactly on kc at the high frequency end readjust trimmers 5-6 and 7 for correction. Do not attempt to play this receiver with only one speaker as there are two audio channels and the tone quality will be very poor unless both speakers are used.

Band Number 2. (1.8 to 5.6 Mc) Turn knob of waveband switch to Amateur position. Tune signal generator to 5.5 mc and set radio dial to 5.5 position. Adjust oscillator trimmer 9 and antenna trimmer 10 for maximum output. There is no K.F. stage on the Amateur and Foreign bands. Band Number 3. (5.6 to 18.5Mc) Turn knob of waveband switch to Foreign position. Tune signal generator to 18 mc and connect output lead to antenna post through a 200 Mfd condenser and a 400 ohm resistor. Set volume control at maximum. Turn radio dial to 18 mc and adjust oscillator trimmer 11 and first detector trimmer 12 for maximum output. After completing alignment of all bands then disconnect 6B6 cathode jumper so that the AFC will be active again. The discriminator circuit is adjusted at the factory and should not be touched under any circumstances.

Model 160 Automatic

The automatic frequency control in the Model 160 Packard-Bell radio is so adjusted that it does not interfere with the normal selectivity of the receiver. Any station that can be received without automatic frequency control can also be received with it. The only instances where A.F.C. will give preference to a more powerful station is where the stronger station will be heard in the background of the weaker one. From this it is obvious that an A.F.C. switch is unnecessary. This eliminates a control which would have been confusing to most people.

IMPLEMENTATION FOR SETTING MARKERS ON CONTROL PANEL. To begin with, in setting the motor controller (located at center-rear of chassis) one must first determine what stations are desired on the eight station keyboard. To do this examine the stationized dial and determine the location of stations related to each side of dial center. This done, it is then necessary to allot a sufficient number of sliders (station markers) corresponding to push-button switches on station keyboard of receiver panel below large dial.

Let us take for example a choice which would give us 5 stations between center and left hand side of dial, and 3 between center and right hand side of dial. We then consider push-button switches to correlate in numerical order with stations chosen as follows: KECA, KGFJ, KAKD, KMA, KFWB, KHJ, KMPC, and KFI, Giving KECA No. 1 position, others following consecutively, completing with KFI as No. 8. Considering push-buttons on panel from left to right as reading from 1 to 8, a correct sequence will result for control sliders at rear of chassis. Control sliders are set up to correspond with buttons in correct numerical order, (that is, on rear slider rail you will find 4 buttons, and on front slider rail 4 buttons). Buttons or sliders on front are odd numbers, i.e., 1-5-6-7, and on rear rail are the even numbers, i.e., 2-4-6-8. Looking from rear the right hand slider corresponds to left front panel push button looking from the front.

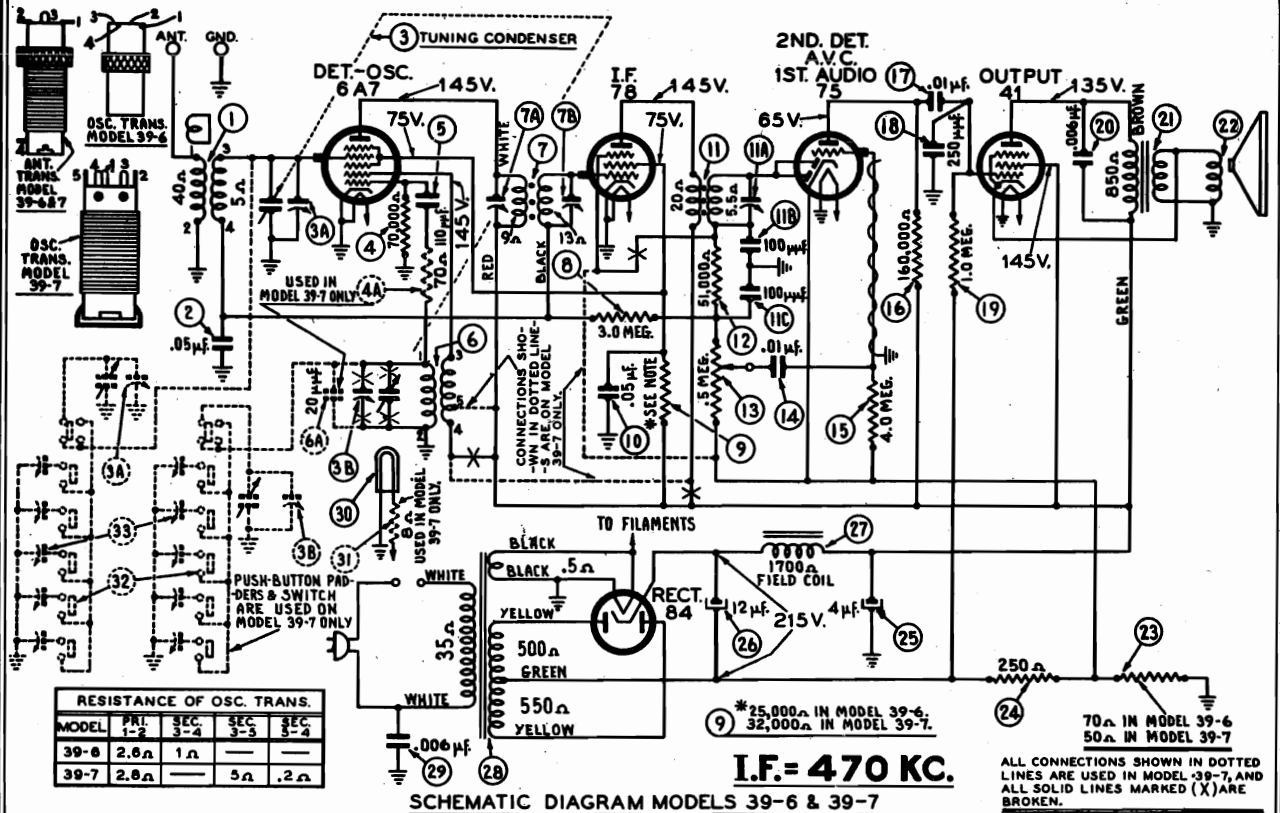

OPERATION: Starting with KECA, push button No. 1 until it locks. We then reach back and push slider No. 1 back and forth until dial pointer comes to rest at KECA as marked on dial. Follow this procedure for all other stations.

The buttons marked R and L are used to tune in stations not set up on the keyboard. For example: If one is listening to KHJ and decides to change to KFOX then all that is necessary is to press the button L down until pointer turns to KFOX, then release the button and the pointer will stop. Or if one is listening to KHJ and wants to change to KEHE just press the button R down and hold until the pointer gets to KEHE, then release. In other words button R controls the motor to the right and button L to the left.

PHILCO RADIO & TELEV. CORP.

# Alignment of Compensators

## EQUIPMENT REQUIRED:

- (1) Signal Generator; Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K.C. is the correct instrument for this purpose.
- (2) Output Meter, Philco Model 027 Circuit Tester, incorporates a sensitive output meter and is recommended.
- (3) Philco Fiber Handle Screw Driver, Part No. 27-7059, and Fiber Wrench, Part No. 3164.

**OUTPUT METER:** The Philco 027 Output Meter is connected to the plate and screen terminals of the type 41 tube and adjusted for the 0 to 30 V.A.C. scale. After connecting the output meter, adjust the compensators in the order as shown in the tabulation below. Locations of the compensators are shown on Fig. 2. If the output meter pointer goes off scale when adjusting the compensators, reduce the strength of the signal from the generator.

**TYPE OF CIRCUIT:** Models 39-6, code 121; and 39-7, code 121, employ a five-tube A.C. operated superheterodyne circuit, covering standard broadcast frequencies; Automatic Volume Control, and Pentode Audio Output. In general the two models are similar but differ in their tuning mechanisms and cabinets.

Model 39-6 is manually tuned and is assembled in cabinet type C.

Model 39-7, code 121, in addition to being manually tuned, is equipped with six Electric Automatic Push-Buttons. Five push-buttons are used for selecting any one of five stations in the standard broadcast range, and one push-button for changing to manual tuning. The procedure for adjusting the push-buttons for reception of stations will be found in the instructions supplied with each set.

Copyright 1938—Philco Radio & Television Corp.

**NOTE A**—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

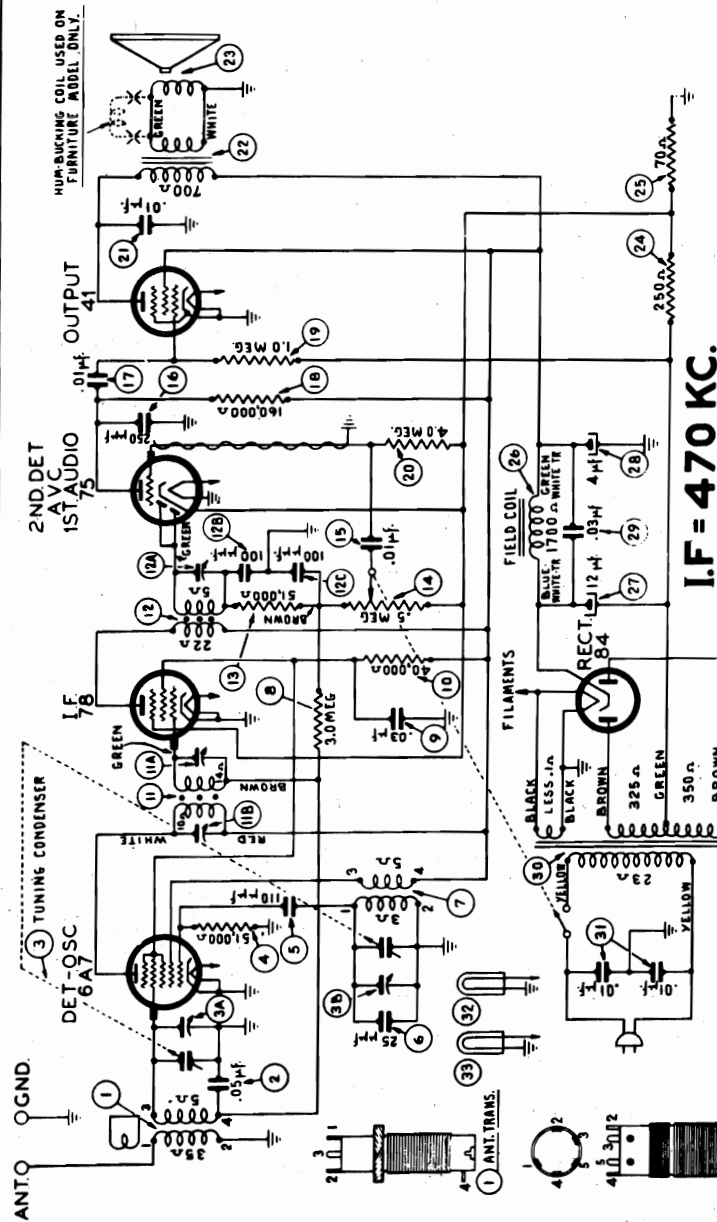

**NOTE B**—**DIAL CALIBRATION:** With the tuning condenser in "maximum capacity" position (plates fully meshed), set the dial pointer between the two horizontal lines at the low frequency end of the scale (550 K.C.).

MODEL 39-17  
Codes 121, 122  
Socket, Trimmers,  
Alignment, Voltage

PHILCO RADIO & TELEV. CORP.

**SPECIFICATIONS**

**TYPE OF CIRCUIT:** A. C. operated; superheterodyne circuit, covering standard broadcast band (540 K. C. to 1720 K. C.); **TUNING RANGE:** 540 to 1720 K. C.; **AUDIO OUTPUT:** 2 watts.

Automatic Volume Control; and pentode output.  
Codes 121 and 122 chassis of this model are similar with the exception of Speaker and Cabinet.

The receiver is designed to operate from a "Philco Utility Aerial," part No. 45-2450. This aerial system should be used to obtain maximum performance from the receiver.

**POWER SUPPLY:** Voltage—115 volts. Frequency—50-60 cycles. Power consumption—40 watts.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**PHILCO TUBES USED:** Five tubes: 1-6A7, 1st detector and oscillator; 1-78, I. F.; 1-75, 2nd detector, Automatic Volume Control, and 1st audio; 1-41, Output; and 1-84, Rectifier.

**TUNING MECHANISM:** Pulley and cable drive for Manual tuning. Push-Button for Automatic Tuning. The procedure for adjusting and operating the Automatic Tuning Push-Buttons will be found in the instructions supplied with each set.

**CABINETS:** Code 121 chassis in type "T" cabinet. Code 122 chassis in type "F" cabinet.

MODEL 39-18  
Codes 121, 122  
Socket, Trimmers

PHILCO RADIO & TELEV. CORP.  
**SPECIFICATIONS**

Alignment, Voltage

**TYPE OF CIRCUIT:** A. C. - D. C. operated; superhetrodyne circuit, covering standard broadcast (540 K. C. to 1720 K. C.) frequency; Automatic Volume Control; and pentode output.

Codes 121 and 122 chassis of this model are similar with the exception of Speaker and Cabinet.

The receiver is designed to operate from a "Philco Utility Aerial," part No. 45-2450. This aerial system should be used to obtain maximum performance from the receiver.

**POWER SUPPLY:** Voltage—115 volts A. C. or D. C. Power consumption—55 watts.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**TUNING RANGE:** 540 to 1720 K. C.

**PHILCO TUBES USED:** 1—6A7, 1st detector and oscillator; 1—78, I. F.; 1—75, 2nd detector, Automatic Volume Control, and 1st audio; 1—43, Output; 1—25Z5, Rectifier; and 1—BKV51DJ, ballast tube.

**TUNING MECHANISM:** Pulley and cable drive for Manual tuning. Push-Button for Automatic Tuning. The procedure for adjusting and operating the Automatic Tuning Push-Buttons will be found in the instructions supplied with each set.

**CABINETS:** Code 121 chassis in type "T" cabinet.  
Code 122 chassis in type "F" cabinet.

Fig. 2. Locations of Compensators

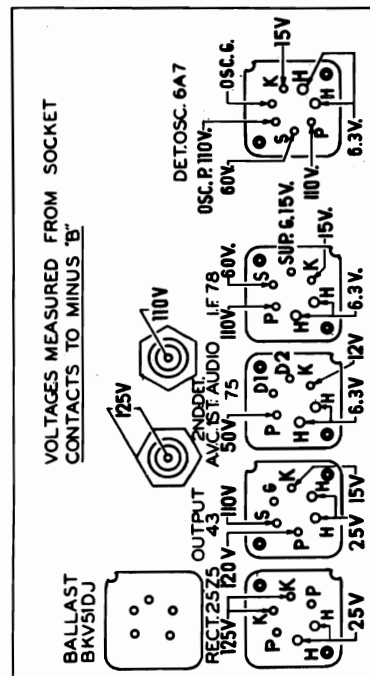

Fig. 1. Socket Voltage—Underside of Chassis View  
The voltages indicated by arrows were measured with a Philco 027 Circuit Tester, which contains a sensitive voltmeter. Volume Control at minimum—Tuning Condenser set for no signal—line voltage 115 A. C.

**Alignment of Compensators**

- (3) Philco Fiber Handle Screw Driver, part No. 27-7059 and Fiber Wrench, part No. 2164.
- (4) Philco Set Transformer, part No. 32-2763.

**OUTPUT METER:**

The Philco 027 Output Meter is connected to the plate and cathode terminals of the Type 43 tube. Set the meter to use the 0-30 volt scale.

**EQUIPMENT REQUIRED:**

- (1) Signal Generator; Philco Model 077 Signal Generator, which has a fundamental frequency range from 115 to 36,000 KC., is the correct instrument for this purpose.
- (2) Output meter; Philco Model 027 Circuit Tester incorporates a sensitive output meter and is recommended.

Operations in Order	Signal Generator			Receiver			Special Instructions
	Output Connections to Receiver	Dummy Antenna (Note A)	Dial Setting	Dial Setting	Control Settings	Adjust Compensators in Order	
1	6A7 Grid	.1 mf.	470 KC	580 KC	Vol. Cont. Max.	(12A) (11A) (11B)	See Note B
2	Ant. Ter.	100 mmf.	1550 KC	1550 KC	Vol. Cont. Max.	(3B) (3A)	See Note C See Note D

**NOTE A**—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

**NOTE B**—Insert the signal generator output lead into the "Med" jack and the ground lead into the "Gnd" jack of the signal generator. Connect the other end of the output lead to terminal No. 1 on the Set Transformer, part No. 32-2763, and the cable ground to terminal No. 2. Nos. 3 and 4 terminals of Set Transformer are then connected to the chassis and 6A7 grid respectively of the receiver with short pieces of wire. Insert the 0.1 mf. in series with the No. 4 lead which connects to the grid.

**NOTE C**—**DIAL CALIBRATION:** In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To

adjust the dial proceed as follows: With the push button unit disconnected from the gang, the pointer is to be set on the extreme left edge of the index line (low frequency end of the scale) with the gang closed. The gang is then opened until the pointer is at the right edge of the index line and, with the push-button shaft at its closed stop, the push-button coupling is tightened on the gang shaft.

**NOTE D**—Insert the signal generator output lead into the "Med" jack and the ground lead into the "Gnd" jack of the signal generator. Connect the other end of the output lead to terminal No. 1 on the Set Transformer, part No. 32-2763, and the cable ground to terminal No. 2. Nos. 3 and 4 terminals of Set Transformer are then connected to the chassis and antenna lead respectively of the receiver with short pieces of wire. Insert the 100 mmf. in series with the No. 4 lead which connects to the antenna lead.

MODEL 39-19  
Codes 121, 122  
Socket, Trimmers.

PHILCO RADIO & TELEVISION CORP. Alignment, Voltage

**SPECIFICATIONS**

**TYPE OF CIRCUIT:** A. C. operated; superhetrodyne circuit with two tuning ranges, covering standard broadcast (540 K. C. to 1720 K. C.) and short wave (5.6 M. C. to 18.0 M. C.) frequencies; Automatic Volume Control; and pentode output.

**TUNING RANGES:** 540 K. C. to 1720 K. C. 5.5 M. C. to M. C. 19.0

**AUDIO OUTPUT:** 2 watts.

Codes 121 and 122 chassis of this model are similar with the exception of Speaker and Cabinet.

**PHILCO TUBES USED:** Five tubes: 1-6A7, 1st detector and oscillator; 1-78, I. F.; 1-75, 2nd detector, Automatic Volume Control, and 1st audio; 1-41, Output; and 1-84, Rectifier.

The receiver is designed to operate from a "Philco Utility Aerial," part No. 45-2450. This aerial system should be used to obtain maximum performance from the receiver.

**TUNING MECHANISM:** Pulley and cable drive for Manual Tuning. Push-Button for Automatic Tuning. The procedure for adjusting and operating the Automatic Tuning Push-Buttons will be found in the instructions supplied with each set

**POWER SUPPLY:** Voltage—115 volts. Frequency—50-60 cycles. Power consumption—40 watts.

**CABINETS:** Code 121 chassis in type "T" cabinet. Code 122 chassis in type "F" cabinet.

**INTERMEDIATE FREQUENCY:** 470 K. C.

Fig. 2. Locations of Compensators

**ALIGNMENT OF COMPENSATORS**

**EQUIPMENT REQUIRED:** (1) Signal Generator. Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K. C. is the correct instrument for this purpose. (2) Output meter: Philco Model 027 Circuit Tester, incorporates a sensitive output meter and is recommended. (3) Philco Fiber Handle Screw Driver, part no. 27-7059 and Fiber Wrench, part no. 3104.

**OUTPUT METER:** The Philco 027 Output Meter is connected to the plate and cathode terminals of the type 41 tube. Set the meter to use the 0-30 volt scale.

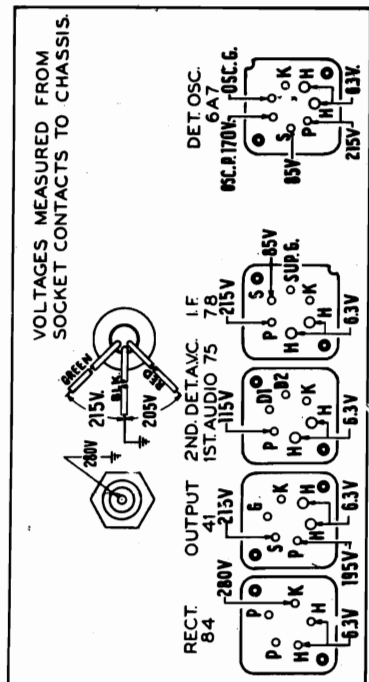

Fig. 1. Socket Voltage—Underside of Chassis View  
The voltages indicated by arrows were measured with a Philco 027 Circuit Tester, which contains a sensitive voltmeter. Volume Control at minimum—Tuning Condenser set for no signal—line voltage 115 A. C.

**EQUIPMENT REQUIRED:** (1) Signal Generator. Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K. C. is the correct instrument for this purpose. (2) Output meter: Philco Model 027 Circuit Tester, incorporates a sensitive output meter and is recommended.

Code 121

Alignment, Chassis  
Tuner Data

PHILCO RADIO & TELEVISION CORP.

Fig. 3. Part Locations, Underside of Chassis

**TUNING MECHANISM:** Pulley and cable drive for Manual tuning. Electric Push-Button for Automatic tuning.

**CABINETS:** Types "T" and "XF."

**Alignment of Compensators**

**EQUIPMENT REQUIRED:** (1) Signal Generator; Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K. C. is the correct instrument for this purpose. (2) Output meter, Philco Model 027 Circuit Tester, incorporates a sensitive output meter and is recommended. (3) Philco Fiber Handle Screw Driver, part No. 27-7059, and Fiber Wrench, part No. 3164.

**OUTPUT METER:** The Philco 027 Output Meter is connected to the plate and cathode terminals of the Type 41 tube. Set the meter to use the 0-30 volt scale. After connecting the output meter adjust compensators in the order as given below.

**TYPE OF CIRCUIT:** A. C. operated; superheterodyne circuit with two tuning ranges, covering standard broadcast (540 K. C. to 1720 K. C.) and short wave (4.9 M. C. to 18.0 M. C.) frequencies; Automatic Volume Control; and pentode output.

The receiver is designed to operate from a "Philco Safety Aerial," part No. 40-6371. This aerial system should be used to obtain maximum performance from the receiver.

**POWER SUPPLY:** Voltage—115 volts. Frequency 50-60 cycles. Power consumption 45 watts.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**TUNING RANGES:** 540 K. C. to 1720 K. C.; 4.9 M. C. to 18.0 M. C.

**PHILCO TUBES USED:** 1-6A8G, 1st detector and oscillator; 1-7S, I. F.; 1-7S, 2nd detector, Automatic Volume Control, and 1st audio; 1-41, Output; and 1-84, Rectifier.

Operations in Order	Signal Generator		Receiver		Special Instructions
	Output Connections to Receiver	Dummy Antenna (Note A)	Dial Setting	Adjust Control Compensators in Order	
1	6A8G Grid	.1 mf.	470 KC	Vol. Cont. max.	(20A) (12B) (12A)
2	Ant. Ter.	100 mmf.	18.0 MC	Vol. Cont. max.	(4B)
3	Ant. Ter.	100 mmf.	1550 KC	Vol. Cont. max.	(5) (4A)
4	Ant. Ter.	100 mmf.	580 KC	Vol. Cont. max.	(5A)
5	Ant. Ter.	100 mmf.	1550 KC	Vol. Cont. max.	(5)

**NOTE A—**The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

These detailed instructions have been prepared to make sure the correct procedure is followed in setting the stations on the Philco Electric Push-Button Tuning models. The work requires the use of a Philco Model 077 Station Setter and a part No. 27-7059 Insulated Screw Driver.

(A) Select eight of the most popular stations received in the locality and remove their call letters from the call letter sheets supplied. Place the call letters in the windows above the buttons, making sure that each respective button covers the frequency of the station for which it is to be used. The frequency range of the circuits are as follows:

Circuits	Frequency Range
1 and 2	540 to 1030 kilocycles
3 and 4	670 to 1160 kilocycles
5 and 6	900 to 1470 kilocycles
7 and 8	1170 to 1600 kilocycles

These numbers are stamped on the unit as seen from the rear. Looking at the front of the cabinet the numbers read from left to right.

(B) Connect the aerial and ground to the "ANT" and "GND" terminals of the receiver.

**NOTE B—DIAL CALIBRATION:** In order to adjust the receiver correctly the dial pointer must be aligned to track precisely with the tuning control. To do this, set the dial pointer on the extreme left index line at the low frequency end of the scale.

(C) Turn the receiver Tuning Range Selector to position two ("Manual Tuning") and tune the receiver to the station to be set on the first button.

(D) Plug the output leads of the Station Setter into the "High" and "Gnd" jacks, and turn the output controls to maximum. Turn the modulation control to "Modulation Off." Connect the output lead of the Station Setter to the "ANT" and "GND" terminals of the receiver and tune to the frequency of the station being received. As the indicator is slowly tuned through the pitched swish will be heard, one above and one below the frequency of the station. When the indicator is on the frequency of the station, minimum high pitched swish will be heard.

(E) Set the modulation control of the Station Setter for "Modulation On." The modulated signal of the Station Setter will then be heard through the receiver.

(F) Turn the receiver Tuning Range Selector to position one (Automatic Tuning) and push in the first button. Using the Part No. 27-7059 Insulated Screw Driver, turn the number 1 "OSC" screw until the modulated signal of the Station Setter is tuned in to maximum volume. Then adjust the number 1 "ANT" screw for maximum signal.

(G) Remove the output lead of the Philco Station Setter from the "ANT" terminal of the receiver and turn its indicator off the frequency of the station. The program of the desired station will then be heard on the receiver.

(H) With the volume of the receiver low, slowly turn the number 1 "OSC" back and forth until maximum output is received. Repeat the same procedure for the number 1 "ANT" screw.

After setting up the first station, the same procedure given under (C) to (H) is used for the other stations.

Wireless Record Player PHILCO RADIO & TELEV. CORP.  
Schematic, Instructions

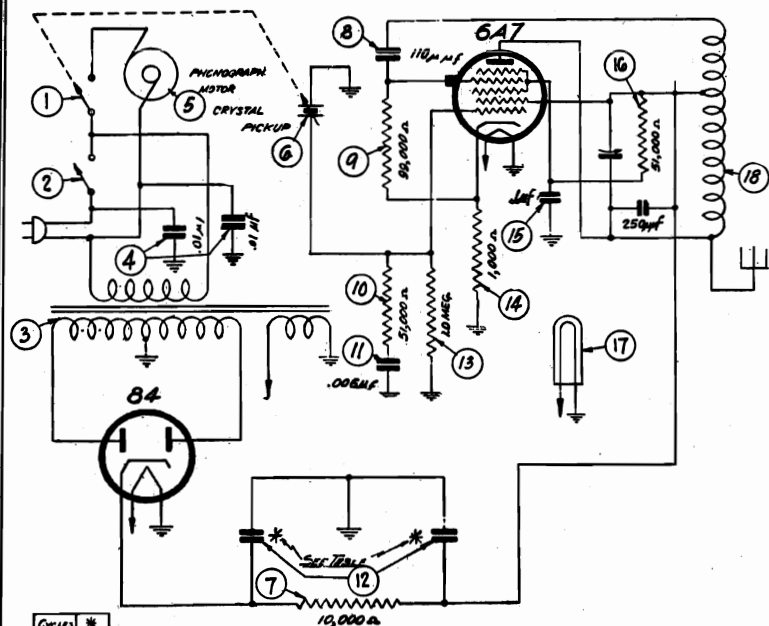

DIAGRAM A

DIAGRAM B

# MODEL RP-1

CODE - 122

## WIRELESS RECORD PLAYER

The Model RP-1 is a remote type record player which can be used in conjunction with any standard broadcast receiver to reproduce phonograph records.

To place unit in operation:

First. Remove all packing material, being sure to save the small envelope attached to the tone arm. This envelope contains needles, needle screw, and rubber bumper.

Second. Lift off record turn-table and remove motor support tape by carefully pulling out tuck and cutting the tape. Replace turn-table.

Third. Disengage tone arm (pickup) by rolling rubber locking ring down along arm rest and pushing sideways on tone arm. **Do not lift arm vertically when locked.**

Fourth. Place rubber bumper (contained in small envelope attached to tone arm) between the jaws of the arm rest, large end up. This forms a suitable rest for tone arm when not in use.

Fifth. Insert needle as far as possible into the tone arm head, and tighten securely with the needle screw, which should be inserted in the head of the tone arm. **A Philco needle (like furnished) is recommended for best results.**

Sixth. Check to make sure your electric supply agrees with that specified on the name label located on under side of cabinet and insert line cord plug into a convenient power outlet.

If in doubt as to the electric supply, check with your local power company.

The unit is now ready for operation. Place record on turn-table and slide "Off-On Switch" (Diagram "A") to "On" position; this will be indicated by pilot light in tone arm.

After allowing sufficient time for tubes to warm up, place tone arm on record; this automatically starts motor.

Next go to your radio and tune to approximately 540 KC (54 on most dials), at which setting the phonograph signal will be picked up. Volume can be regulated by the radio receiver's volume control in the normal way.

At the end of the record, return the tone arm to rest position, which will automatically turn motor off. It is not necessary to slide "Off-On Switch" to the "Off" position between records.

If interference from broadcast stations is encountered the frequency of the unit can be changed to any other frequency between 530 KC and 580 KC by adjusting the small screw indicated in Diagram "B." Turning screw clockwise lowers the frequency, counter-clockwise raises the frequency. **This adjustment is best made while the unit is in operation.**

If hum is experienced it may be necessary to reverse the power plug of the record player, the radio, or both. In some cases it may be advisable to use the same receptacle for record player and radio.

No definite rule can be established for the relative location of the record player to your radio; individual trial will establish best location. However, in general, satisfactory operation may be obtained up to a distance of fifty (50) feet, provided local noise conditions are not too severe.

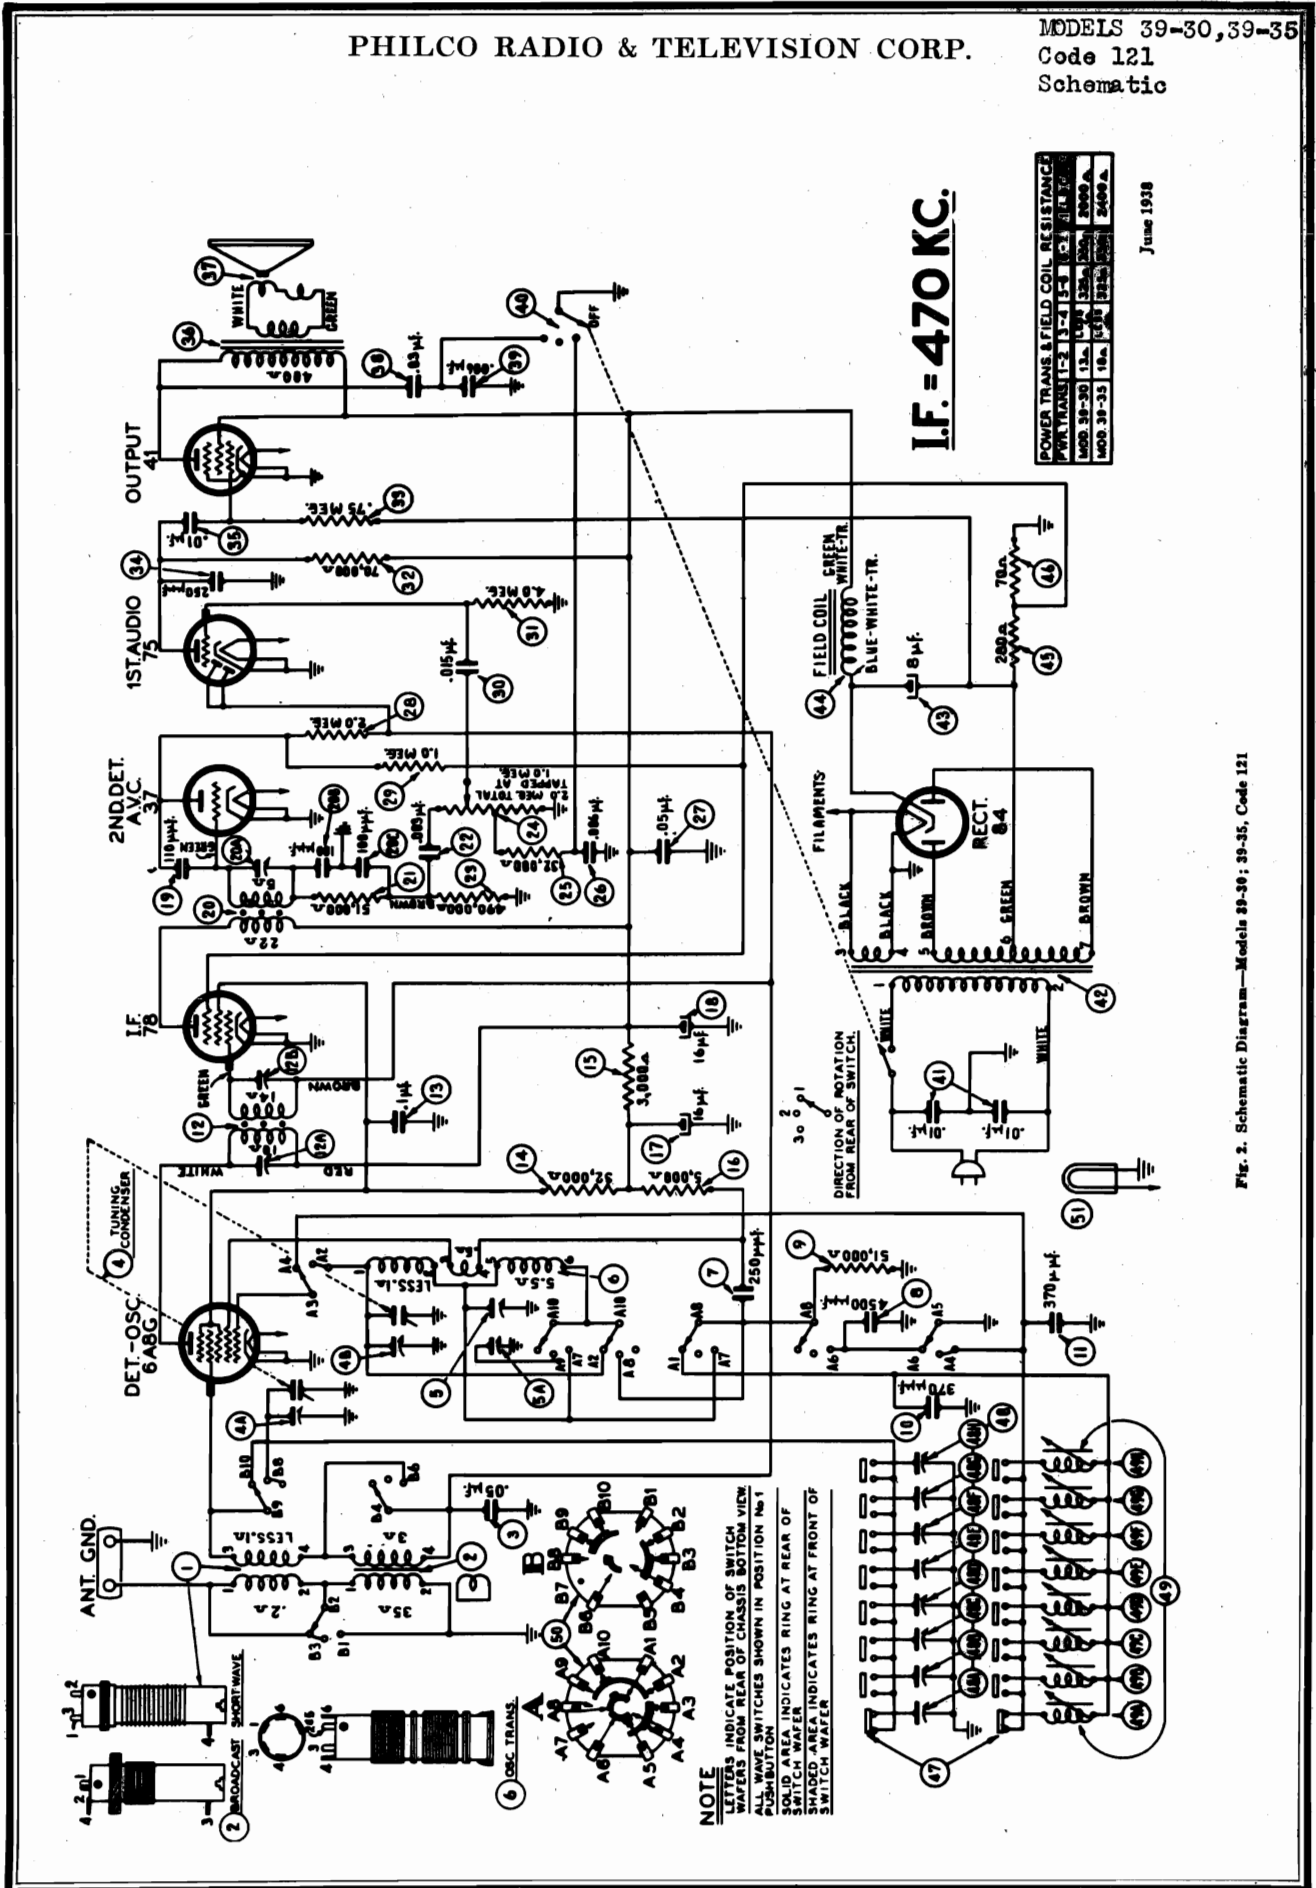

**IMPORTANT . . . Do not attempt to force tone arm past stops.**

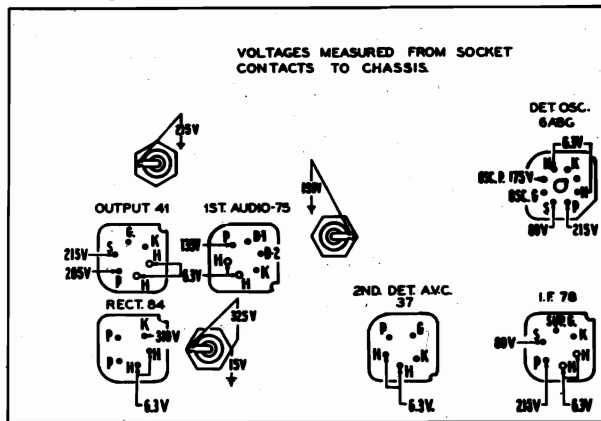

Fig. 1. Socket Voltages—Underside of Chassis

The voltages indicated by arrows were measured with a Philco 027 Circuit Tester which contains an accurate voltmeter. Volume control at minimum, range switch in broadcast position, line voltage 115 A. C.

**TYPE OF CIRCUIT:** A. C. operated; superheterodyne circuit with two tuning ranges, covering standard broadcast (540 K. C. to 1720 K. C.) and short-wave (4.9 M. C. to 18.0 M. C.) frequencies; Automatic Volume Control; and pentode output.

The receiver is designed to operate from a "Philco Safety Aerial," Part No. 40-6371. This aerial system should be used to obtain maximum performance from the receiver.

**POWER SUPPLY:** Voltage, 115 volts. Frequency, 50-60 cycles. Power consumption 45 watts.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**TUNING RANGES:** 540 K. C. to 1720 K. C.; 4.9 M. C. to 18.0 M. C.

**PHILCO TUBES USED:** 1-6A8G, 1st detector and oscillator; 1-78, I. F.; 1-37, 2nd detector, Automatic Volume Control; 1-75, first audio; 1-41, output; and 1-84, Rectifier.

**TUNING MECHANISM:** Pulley and cable drive for Manual tuning. Electric Push-Button for Automatic tuning.

**CABINETS:** Types: "T" for 39-30 and "XX" for 39-35.

\* Replace Speaker

† Model T Cabinet uses two optional speakers. The part numbers of the speakers are the same with the exception of a dash number (2 or 3) following the part number. When ordering a Cone and Voice Coil Assembly, the part number as indicated must be specified.

MODEL S-1622

PHILCO RADIO & TELEVISION CORP.

MODELS 39-30, 39-35

Alignment, Socket, Trimmers

Code 121

Alignment

**ALIGNMENT**

**MODELS 39-30, 39-35 (CODE 121); S1622.**

**Equipment**—Fully charged heavy duty storage battery or 6-volt power pack, 077 or 177 Philco Set Tester, 27-7159 Padding screw driver.

**General**—The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

MODEL S-1622

4	Ant. Ter.	100 mmf.	580 K. C.	580 K. C.	Vol. Cont. Max.	(5A)	
5	Ant. Ter.	100 mmf.	1550 K. C.	1550 K. C.	Vol. Cont. Max.	(5)	

**NOTE A**—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure

**NOTE B—DIAL CALIBRATION:** In order to adjust the receiver correctly the dial pointer must be aligned to track properly with the tuning condenser. To adjust the dial proceed as follows: With the tuning condenser closed, set the dial pointer on the extreme left index line at the low frequency end of the scale.

**MODEL S-1622**

OPERATION	SIGNAL GENERATOR		DUMMY CAPACITY	SPECIAL INSTRUCTIONS	ADJUST PADDER
	FREQUENCY	CONNECTION			
1	Press the Automatic Station Selector button until "DIAL" appears in the window			and stations can be tuned in by Manual Tuning.	
2	470 K.C.	To Antenna Receptacle on Radio	35 Mmfd. See Note 1	Turn Tuning Condenser Plates Out of Mesh as Far as They Will Go.	69 27 21 17
3	1580 K.C.	To Antenna Receptacle on Radio	35 Mmfd. See Note 1	Note 2	67
4	1500 K.C.	To Antenna Receptacle on Radio	35 Mmfd. See Note 1	Set Tuning Condenser at 1500 K.C.	66 Note 3

Make all adjustments for maximum reading on the output meter.

**NOTE 1**—Connect the antenna lead, Part No. L-2765, to the antenna receptacle in the radio. Connect a 35 Mmfd. Condenser in series between the signal generator and the antenna lead.

**NOTE 2**—Turn the condenser rotor plates completely out of mesh as far as they will go.

**NOTE 3**—When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

PHILCO RADIO & TELEV. CORP.

MODEL 108  
 Tuner Data  
 MODELS 40-120,40-125  
 Alignment, Trimmers

EQUIPMENT REQUIRED: MODELS 40-120,40-125.

(1) Signal Generator; Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K. C. is the correct instrument for this purpose.

(2) Output Meter; Philco Models 027 or 028 Vacuum Tube Voltmeters and Circuit Testers incorporate a sensitive output meter and are recommended.

(3) Philco Fiber Handle Screw Driver, Part No. 45-2610. Aligning adapter Part No. 45-2767.

OUTPUT METER: The Philco 027 or 028 Output Meter is connected to the plate and screen terminals of the type 35A5 tube and adjusted for the 0 to 30 V. A. C. scales.

VACUUM TUBE VOLTMETER: To use the vacuum tube voltmeter as an alignment indicator make the following connections:

Remove the 7C6 tube from its socket and insert the aligning adapter, Part No. 45-2767, then replace the tube in the adapter. Connect the negative terminal of the vacuum tube voltmeter to the wire which protrudes from the side of the adapter. Attach the positive terminal of the voltmeter to the chassis. The positive terminal is connected to the chassis.

After connecting the output meter, adjust the compensators in the order as shown in the tabulation below. Locations of the compensators are shown on Fig. 2. If the output meter pointer goes off scale when adjusting the compensators, reduce the strength of the signal from the generator.

Operations in Order	SIGNAL GENERATOR			RECEIVER			SPECIAL INSTRUCTIONS
	Output Connections to Receiver	Dummy Antenna Note A	Dial Setting	Dial Setting	Control Settings	Adjust Compensators in Order	
1	7C7 See Note C	.1 mf.	455 K. C.	580 K. C.	Vol. Cont. Max.	14A, 14B, 15A	Push "IN" Manual Button Model 40-125
2	Ant. Ter.	10 mmf.	1600 K. C.	1600 K. C.	Vol. Cont. Max.	2B	See Note B See Note C
3	Ant. Ter.	10 mmf.	1400 K. C.	1400 K. C.	Vol. Cont. Max.	2A	

NOTE A — The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (High side). Use the capacity or resistance as specified in each step of the above procedure.

NOTE B — DIAL CALIBRATION: In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To do this, proceed as follows: Turn the tuning condenser to the maximum capacity position (plates fully meshed). With the condenser in this position, the tuning pointer is set horizontal at the low frequency end of the scale (540 K. C.).

NOTE C — Compensators 2A and 2B are at the top of the tuning condenser. Compensator 2A is on the front section and compensator 2B on the rear section. When padding the I. F. the signal generator can be attached to the 7C7 grid on the front section of the tuning condenser.

Fig. 1

**Adjusting Push Button Tuning - MODELS 39-30,39-35,108 (CODE 121); 40-150,40-155; 40-160; 40-195,40-200;40-180,40-185,40-190.(FOR BUTTON ADJUSTMENT FREQUENCIES FOR MODELS 39-30,39-35, & 108 (CODE 121); SEE PARTS LISTS OF THESE MODELS).**

In order to adjust the electric push buttons accurately for reception of broadcast stations, a vacuum tube voltmeter such as Philco Model 027 and 028 should be used. In addition, an insulated padding screw driver part No. 45-2610 and Loktal aligning adapter part No. 45-2767 are required. With this equipment at hand proceed as follows:

Insert the station call letters into the windows above the buttons. The station with the lowest frequency is placed in the first button on the left and the highest frequency is placed in the button on the extreme right. Each push button is adjusted by two set screws located on the rear of the push button unit. Each set of screws is numbered and covers a frequency range as follows:

MODEL 40-160

Push Button	Frequency Range
1	540-1000 K.C.
2	650-1100 K.C.
3	740-1300 K.C.

1, 2, 3	540-1060 K. C.
4, 5	650-1110 K. C.
6, 7	920-1600 K. C.

Looking at the front of the cabinet, the first button on the

left is adjusted by set screw No. 1. The next push button by set screw No. 2 and the remaining push buttons in order.

1. Remove the 7C6 A.F. tube from its socket and insert the aligning adaptor, then replace the tube in the adaptor. Connect the negative terminal of the vacuum tube voltmeter to the wire which protrudes from the side of the adaptor. Attach the positive terminal of the voltmeter to the chassis.

2. Turn the receiver on and set the tuning range disc to "Broadcast" (Manual Tuning).

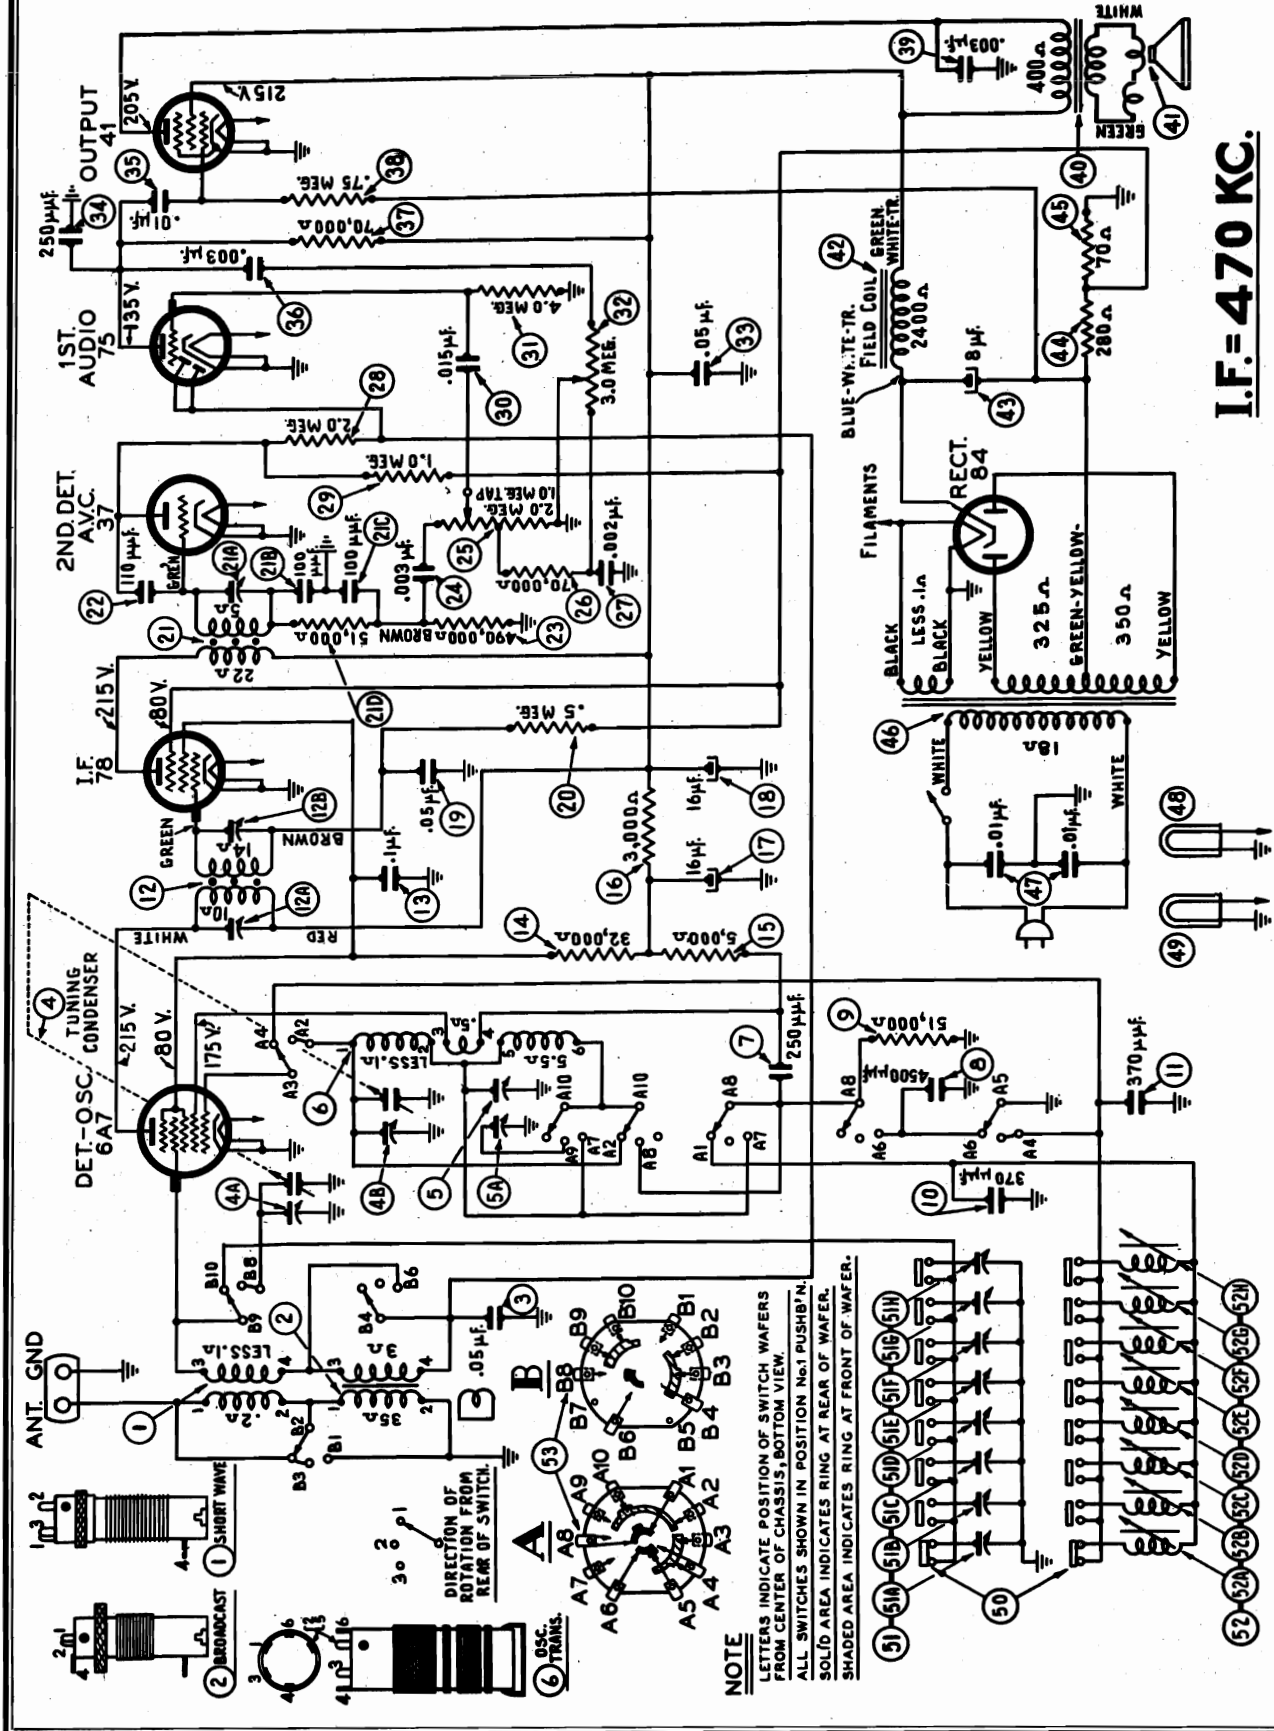

3. Set up the Model 077 Station Setter about 3 feet from the receiver and connect a loop constructed out of about 6 feet of wire to the high and ground output jacks of the signal generator. Turn the output controls to maximum and set the modulation control to "MOD. ON". Manually tune in the first station to be set up on push button No. 1. After doing this set the indicator of the 077 Signal Generator to the frequency of the station being received. As the indicator approaches the frequency of the station a whistle will be heard; leave the indicator at this point. Turn the receiver tuning range disc to "Push Button" and press in No. 1 button. Using the insulated screw driver turn the No. 1 "Osc." screw until the broadcast station identified by the signal generator is heard; at this point, turn the indicator of the signal generator away from the frequency of the station. Readjust No. 1 "Osc." and "Ant." screws for maximum deflection of the vacuum tube voltmeter pointer. Station No. 1 is now adjusted properly. After setting up the first station the same procedure as outlined above is used for the remaining stations.

When this model is to be set up to receive the sound of a television program tuned in by the special type Philco television sets or when it is to be used in conjunction with a Philco Record Player, push-button No. 1 should be used. To tune in these programs, the same procedure as given for ordinary broadcast stations as outlined above is used.

SPECIFICATIONS

**TYPE CIRCUIT:** Philco Model 39-36, code 121 is a six tube, A.C. operated superheterodyne circuit with two tuning ranges covering standard broadcast (540-1720 K.C.) and shortwave (5 M.C. to 18.0 M.C.) frequencies. In addition, the receiver employs Electric Automatic Push-Button Tuning for automatically selecting any of eight standard broadcast stations, continuously variable tone control, automatic volume control, and pentode audio output.

**POWER SUPPLY:** 115 V., 60 cycle A.C. 42 watts. For operation on 115V., 25 to 40 cycles, A.C. current or 220 V. 50 to 60 cycles A.C. cur-

rent, different power transformers are required, and can be obtained from your distributor.

**INTERMEDIATE FREQUENCY:** 470 K.C.

**PHILCO TUBES USED:** 6A7, First Detector Oscillator, 7B, I.F. Amplifier; 87, Second Detector-A.V.C.; 75, First Audio; 41, Audio Output and 84, Rectifier.

**CONTROLS:** The new Philco Disc Controls are used on this model for adjusting tuning, volume, tone and frequency range.

**CABINETS:** Type XX.

Alignment of Compensators

EQUIPMENT REQUIRED:

- (1) Signal Generator; Philco Model 077.
- (2) Output Meter, Philco 027 Circuit Tester.
- (3) Philco Fiber Handle Screw Driver, Part No. 27-7059, and Fiber Wrench, Part No. 8164.

**OUTPUT METER:** The Philco 027 Output Meter is connected to the plate and cathode terminals of the type 41 tube. After connecting the Output Meter, adjust compensators in the order as given in tabulations below. Locations of the compensators are shown in Fig. 1.

Operations	SIGNAL GENERATOR			RECEIVER			Special Instructions
	Output Connections To Receiver	Dummy Antenna (Note A)	Dial Setting	Dial Setting	Control Settings	Adjust Compensators in Order	
1	6A7 Grid.	.1 mf.	470 K.C.	580 K.C.	Vol. Cont. Max. Range Switch (Brdest.)	(21A) (12B) (12A)	
2	Ant. Ter.	100mmf.	18.0 M.C.	18.0 M.C.	Vol. Cont. Max. Range Switch (S.W.)	(4B)	See Note B, C
3	Ant. Ter.	100mmf.	1550 K.C.	1550 K.C.	Vol. Cont. Max. Range Switch (Brdest.)	(5) (4A)	
4	Ant. Ter.	100mmf.	580 K.C.	580 K.C.	Vol. Cont. Max. Range Switch (Brdest.)	(5A)	
5	Ant. Ter.	100mmf.	1550 K.C.	1550 K.C.	Vol. Cont. Max.	(5)	

**NOTE A**—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

**NOTE B**—Dial Calibration: In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows:

With the tuning condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable is shown in Service Bulletin No. 895.

**NOTE C**—Compensators (4A) and (4B) are located on top of the tuning condenser. Compensator (4B) is the first one from the tuning drum side.

Alignment, Tuner Data

ADJUSTING ELECTRIC PUSH-BUTTON TUNING FOR MODELS 39-36, 39-40, AND 39-45

In order to set the Electric Push-Buttons correctly for each station, the procedure as given below should be carefully followed. Accurate adjustment of the buttons requires the use of a Philco Model 077 Station Setter and a part No. 27-7059 insulated screw driver.

(A) Select eight of the most popular stations received in the locality and remove their call letters from the call letter sheets supplied. Place the call letters in the windows above the buttons, making sure that each button covers the frequency of the station for which it is to be used. Two adjustment screws for each button are located on the rear of the push-button unit. Each set of screws is numbered and covers a frequency range as follows:

Push-Button	Frequency Range
1 and 2	540-1030 KC.
3 and 4	670-1160 KC.
5 and 6	900-1470 KC.
7 and 8	1100-1600 KC.

Looking at the front of the cabinet, the first button on the left is adjusted by set screw No. 1, the next button by set screw No. 2, and the remaining buttons in the same order.

(B) Connect the aerial and ground to the "ANT" and "GND" terminals of the receiver.

(C) Turn the receiver Tuning Range Selector to position 2 (Broadcast) and tune the receiver to the station to be set on the first button.

(D) Plug the output leads of the Station Setter into the "High" and "Gnd" jacks, and turn the output controls to maximum.

Turn the modulation control to "Modulation On." Connect the output lead of the station setter to the "ANT" and "GND" terminals of the receiver and tune to the frequency of the station being received. As the indicator is slowly tuned through the frequency of the station, there will be two points at which a whistle will be heard, one above and one below the frequency of the station. When the indicator is on the frequency of the station the whistle will be eliminated and the modulated signal of the station setter will then be clearly heard through the receiver.

(E) Turn the receiver Tuning Range Selector to position 1 (Push-Button) and press in the first button. Using the part No. 27-7059 insulated screw driver; turn the No. 1 "OSC" screw until the broadcast station identified by the station setter signal is tuned to Maximum Volume.

(F) Remove the output lead of the station setter from the "ANT" terminal of the receiver and turn the indicator of the Station Setter off the frequency of the station. The program of the desired station will then be heard in the receiver without the modulated signal.

(G) With the volume of the receiver low, slowly turn the No. 1 "OSC" screw back and forth until maximum output is received. Repeat the same procedure for the No. 1 "ANT" screw.

After setting up the first station, the same procedure given under (C) to (G) is used for the other stations.

ALIGNMENT OF MODEL 39-40

Operations	SIGNAL GENERATOR			RECEIVER			Special Instructions
	Output Connections to Receiver	Dummy Antenna (Note A)	Dial Setting	Dial Setting	Control Setting	Adjust Compensators to Max. Reading	
1	6A7	.1 mf	470 KC.	580 KC.	Vol. Max. Range Switch Broadcast	26B, 26A, 23B, 23A	
2	Ant. Ter.	150 mmf	1550 KC.	1550 KC.	"	15, 7B, 7A	See Note B and C
3	Ant. Ter.	150 mmf	580 KC.	580 KC.	"	17	Roll Tuning Condenser
4	Ant. Ter.	150 mmf	1550 KC.	1550 KC.	"	15	
5	Ant. Ter.	400 ohms	18.0 MC.	18.0 MC.	Range Switch S. W.	15A, 12, 5	

NOTE A—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

NOTE B—Dial Calibration. In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To adjust

the dial, proceed as follows: With the tuning condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable is shown on page 3.

NOTE C—Compensators (7A) and (7B) are located on top of the tuning condenser. Compensator (7A) is the first one from the tuning drum side.

NOTE A—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

NOTE B—Dial Calibration: In order to adjust the receiver correctly the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows: With the tuning condenser closed (maximum

capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable is shown on page 3.

NOTE C—Compensators (8A) and (8B) are located on top of the tuning condenser. Compensator (8A) is the first one from the tuning drum side.

**MODEL 39-71**  
**Schematic, Voltage, Socket PHILCO RADIO & TELEV. CORP.**  
**Alignment, Trimmers, Parts**  
**Chassis**

Operations in Order	SIGNAL GENERATOR			RECEIVER			Special Instructions
	Output Connections to Receiver	Dummy Antenna (Note A)	Dial Setting	Dial Setting	Control Settings	Adjust Compensators in Order	
1	1A7G Grid	.1 mfd.	470 K. C.	580 K. C.	Vol. Cont. Max.	12A, 11B, 11A	Note C
2	Ant. & Grd. Terminals	400 ohms	1550 K. C.	1550 K. C.	Vol. Cont. Max.	2B, 2A	Note B Note C

**NOTE A**—The "Dummy Antenna" consists of a condenser or resistor connected in series with the signal generator output lead (high side). Use the capacity or resistance as specified in each step of the above procedure.

**NOTE B**—**DIAL CALIBRATION:** In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To adjust the dial proceed as follows: Turn the tuning condenser to maximum capacity (plates fully meshed). With tuning condenser in this position set the pointer to the small "black dot" at the low frequency end of the dial scale.

**NOTE C**—To adjust the I. F. compensators, remove the back from the cabinet, which is held in place by four screws. The chassis is then taken out by removing the four screws and two corks underneath the cabinet, and the Tuning and Volume knobs. The I. F. compensators are located on top of the I. F. transformers.

When adjusting the Antenna (2A) and Oscillator (2B) compensators, the chassis must be assembled in the cabinet with the batteries and loop in place. The Signal Generator output lead with the "Dummy Antenna" is then connected to the terminals marked "Ant" and "Grd" underneath the cabinet. The antenna and oscillator compensators are then adjusted through the holes in the bottom of the cabinet.

Schematic, Voltage

NOTE  
SWITCHES SHOWN FROM REAR, BOTTOM VIEW OF CHASSIS, IN POSITION NO. 1. PUSHBUTTON LETTERS INDICATE POSITION OF SWITCH WAFERS FROM CENTER OF CHASSIS. SOLID RING INDICATES FRONT OF SWITCH WAFER. SHADED RING INDICATES REAR OF SWITCH WAFER.

CABINETS: Type "XX." FOR ALIGNMENT AND ADJUSTMENTS OF PUSH-BUTTON TUNER, SEE INDEX

TUNING RANGES: 540 KC. to 1720 KC.; 1.7 MC. to 5.9 MC.; 5.8 MC. to 18.0 MC.  
POWER SUPPLY: Voltage, 115 volts. Frequency, 50-60 cycles. Power consumption, 85 watts.

### Alignment Notes

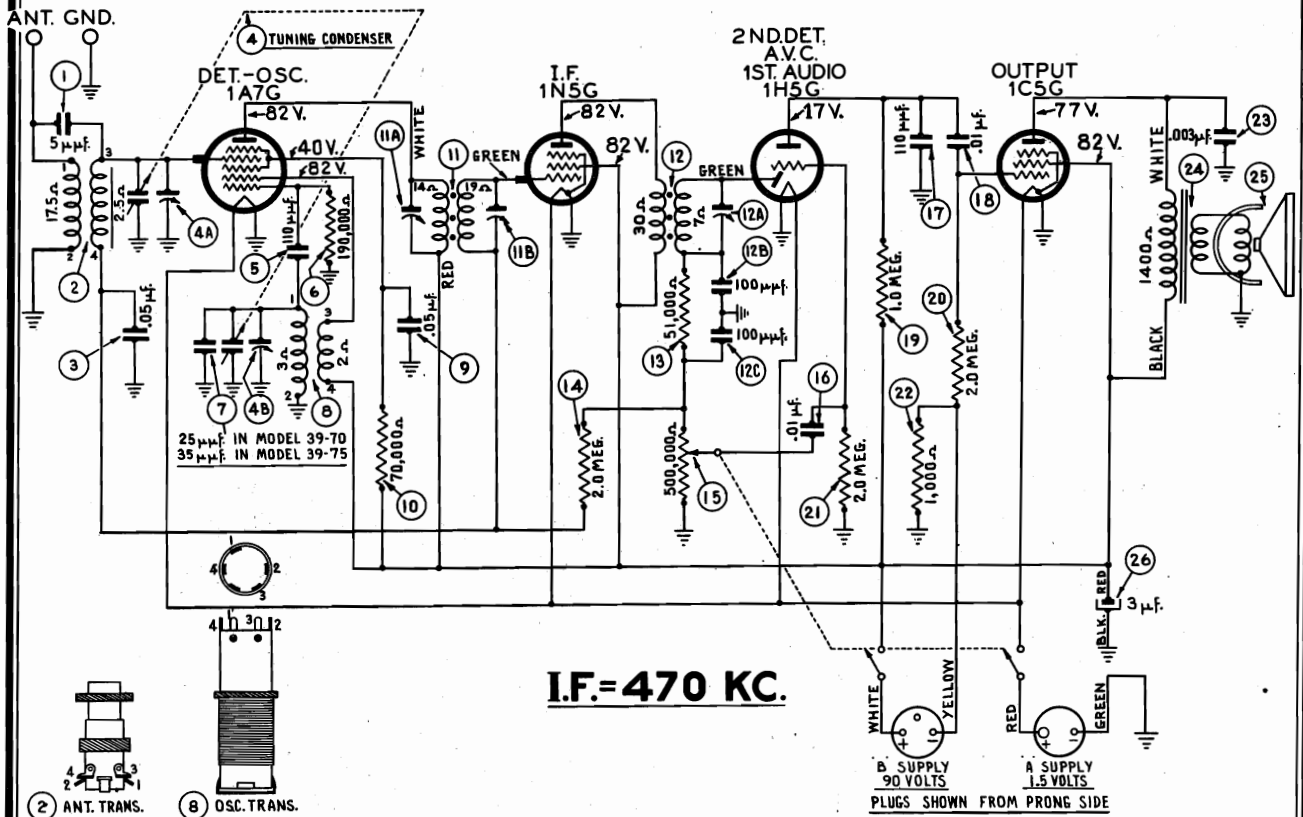

**NOTE A**—The "Dummy Antenna" consists of a condenser or resistor connected in series with the signal generator output lead (high side). Use the capacity or resistance as specified in each step of the above procedure.

**NOTE B**—DIAL CALIBRATION: In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser.

**Model 39-70 and 39-80**—To adjust the dial proceed as follows: Turn the tuning condenser to maximum capacity (plates fully meshed). With the tuning condenser in this position, set the pointer horizontally across the dial.

**Model 39-75**—With the tuning condenser in the maximum capacity position (plates fully meshed), loosen the coupling screws connecting the push-button unit to the condenser. The pointer is then set on the extreme left edge of the index line (low frequency end of the scale) with the tuning condenser fully closed. The gang is then opened until the pointer is at the right edge of the index line. The push-button shaft is then turned counter-clockwise to its "stop." With the tuning condenser and push-button shaft in these positions tighten the coupling set screws.

**NOTE C**—The locations of the compensators in Models 39-70, 39-75 and 39-80 are shown in Figs. (1), (2) and (3) respectively.

**Specifications**

**TYPE OF CIRCUIT:** Models 39-70, 39-75 and 39-80 are four tube battery operated superheterodyne receivers covering standard broadcast and extended broadcast bands. The receivers employ the new Philco Farm Radio Tubes which are designed for low current for operation. Automatic Volume Control and Philco Speaker designed especially for battery radio. In general these models are similar but differ in their tuning mechanisms, speakers and cabinets.

Model 39-70 is manually tuned and is assembled in cabinet type "F" (see model) and "B" (table model).

Model 39-75, codes 121 and 122, is equipped with automatic push-button and manual tuning. The automatic tuning mechanism contains six push-buttons for selecting any of six stations in the standard broadcast band. The procedure for adjusting and operating the push-buttons will be found in the instructions supplied with this model.

Code 122 of this model is assembled in cabinet type "F" (see model); Code 121 in cabinet type "T" (table model).

Model 39-80 is manually tuned and is assembled in cabinet type "B" (table model) and cabinet type "XF" (floor model).

In addition to the new Philco speaker in Model 39-80 a sound chamber is also built into the cabinet. This sound chamber reinforces the sound produced by the speaker and results in greater clarity of tone and intensity of sound output. Bass compensation is also included in the volume control circuit.

**TUNING RANGE:** 530 to 1720 K. C.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**PHILCO TUBES:** One 1A7G, First Detector and Oscillator; one 1N5G, I. F. Amplifier; one 1H5G, Second Detector; First Audio and Automatic Volume Control, and one 1C5G (1A5G Model 39-80) Pentode Output.

**BATTERIES REQUIRED:** One (1) Philco "A" Pack, Part No. 41-8014; one (1) Philco "B" Pack, Part No. 41-8015.

**INSTALLING BATTERIES:** The batteries are arranged in the cabinet in such a manner that they form part of the sound chamber air column.

**Alignment of Compensators**

**EQUIPMENT REQUIRED:**  
(1) Signal Generator: Philco Model 077 Signal Generator which has a fundamental frequency range from 115 to 36,000 K. C. is the correct instrument for this purpose.  
(2) Output Meter, Philco Model 027 Circuit Tester, incorporates sensitive output meter and is recommended.  
(3) Philco Fiber Blaudé Screw Driver, Part No. 27-7059, and Fiber Wrench, Part No. 3104.

Fig. 2 SCHEMATIC DIAGRAM MODELS 40-120 & 40-125

TYPE OF CIRCUIT: FOR ALIGNMENT, SEE INDEX

Models 40-120 and 40-125 are six (6) tube super-heterodyne receivers employing the new Philco built-in super aerial system which eliminates an outside aerial, and Philco High-Efficiency Loktal tubes. In addition, other features of design are: two tuning ranges; special high gain R. F. stage; automatic volume control and a Beam power audio output stage. In general, these models are similar but differ in their tuning mechanisms and cabinets.

Model 40-120 is dial tuned and assembled in cabinet type "C".

Model 40-125 is equipped with six electric push buttons for automatically selecting stations in addition to dial tuning. Five push buttons are used for stations one of which can be used in combination with a Special type PHILCO TELEVISION receiver for reception of television sound programs. The sixth push button selects dial tuning. The procedure for

FOR TUNER ADJUSTMENTS SEE INDEX

The voltages indicated were measured with a Philco Model 027 Voltmeter (1000 ohms per volt) — Power supply 115 volts, 60 cycle — Volume control minimum — No signal being received — Range switch "Brdest."

MODELS 40-150,40-155

PHILCO RADIO & TELEV. CORP.

MODELS 40-180,40-185,40-190

Alignment

**TYPE OF CIRCUIT:** Models 40-150 and 40-155 are Electric Push-button and dial tuned radios incorporating the new Philco Built-in Super Aerial system which eliminates an outside aerial and reduces local static interference to a minimum. The models are also designed to receive the sound of a television program tuned in by special type Philco Television Sets.

**PHILCO BUILT-IN SUPER AERIAL SYSTEM**—Included in the built-in super aerial system is a statically shielded loop for broadcast band reception and a short wave receiving loop. A feature of the built-in broadcast band statically shielded loop is that it may be turned to the position in which it picks up a minimum amount of interference, or if interference is not

present the loop may be set in the position where best reception is obtained.

In general, these models are similar with the exception of the number of tubes used and cabinet design. Model 40-180 employs a seven tube receiver. Models 40-185 and 40-190 employ eight tube receivers assembled in different type cabinets.

Each model is equipped with eight electric tuning push buttons for automatically selecting stations. Six of the push buttons are used for broadcast stations, one for selecting dial tuning and one push button may be set up for use with a Philco wireless Record Player or the sound program tuned in by special Philco Television Sets.

Model 40-150 employs seven (7) tubes and Model 40-155, eight (8) tubes.

**Aligning of Compensating Condensers Equipment Required**

(1) *Signal Generator.* In order to properly adjust this receiver an accurately calibrated signal generator such as Philco Model 077 is required. This signal generator covers a frequency range of 540 to 36,000 K. C. (2) *Indicating Device.* To obtain maximum signal strength and accurate adjustment of the padders a vacuum tube voltmeter and circuit tester such as Philco Models 027 and 028 is

recommended. When using the vacuum tube voltmeter, an aligning adapter, Philco Part No. 45-2767, is necessary for connecting to the A. V. C. circuit. These testers also contain an audio output meter which may also be used as an indicating device. (3) *Aligning Tools.* Fiber handle screw driver, Philco Part No. 45-2610, and fiber wrench, Philco Part No. 7696.

**Connecting Aligning Instruments**

**VACUUM TUBE VOLTMETER**—To use the vacuum tube voltmeter as an alignment indicator make the following connections:

1. Adjusting I. F. Circuit.

Remove the 1232 R. F. tube from its socket and insert the aligning adaptor, then replace the tube in the adaptor. Connect the negative terminal of the vacuum tube voltmeter to the wire (light color) which protrudes from the side of the adaptor. Attach the positive terminal of the voltmeter to the black wire.

2. Adjusting R. F. Circuit.

To adjust the R. F. circuit, the aligning adaptor is inserted in the 7C6 A. F. tube socket. The vacuum tube voltmeter remains connected to the adaptor as given in the above paragraph.

With the voltmeter connected in this manner a very sensitive indication of the A. V. C. voltage is obtained when the padders are adjusted. If an audio output meter is used, connect it to the plate

and socket terminals of the 41 output tube and adjust the output meter for the 0 to 30 A. C. scale.

After connecting the aligning indicator, adjust the compensators in the order as shown in the tabulation below. Locations of the compensators are shown on the schematic diagram, page No. 2. If the output meter pointer goes off scale when adjusting the compensators, reduce the strength of the signal from the generator.

**SIGNAL GENERATOR:** When adjusting the I. F. padders, the high side of the signal generator is connected through a .1 mfd. condenser to terminal No. 1 of the loop terminal panel at the rear of the chassis. The ground or low side of the signal generator is connected to the chassis of the receiver.

When aligning the R. F. padders a loop is made from a few turns of wire and connected to the signal generator output terminals; the loop is then placed two or three feet from the loop in the cabinet. Do not remove the receiver loop from the cabinet. It is necessary when adjusting the padders that the receiver be left in the cabinet.

**Models 40-150, 40-155 40-180 - 185 - 190**

Operations	SIGNAL GENERATOR		RECEIVER			Remarks
	Output Connections	Dial Frequency	Dial Frequency	Control Settings	Adjust Compensators for Max. Signal	
1	High Side to No. 1 Ter. Loop Panel	I. F. 455 K. C.	580 K. C. No Signal	Range Sw. "Brdst." Volume "Max." Push-Button "Dial"	37A, 30, 30A	See Note A.
2	Use Loop on Generator	18 M. C.	18 M. C.	Range Sw. "SW." Volume "Max." Push-Button "Dial."	21A	Note B. Note D.
3	Use Loop on Generator	1400 K. C.	1400 K. C.	Range Sw. "Brdst." Volume "Max."	19A, 21B	
4	Use Loop on Generator	580 K. C.	580 K. C.	Range Sw. "Brdst." Volume "Max."	19	Roll Cond. Note C.
5	Use Loop on Generator	1400 K. C.	1400 K. C.	Range Sw. "Brdst." Volume "Max."	19A, 21B	Roll Cond. Note C.
6	Use Loop on Generator	18 M. C.	18 M. C.	Range Sw. "SW."	3	Roll Cond. Note C.

**NOTE A**—A "Dummy Antenna" consisting of a .1 mfd. condenser is connected in series with the signal generator output lead (high side).

**NOTE B**—**DIAL CALIBRATION:** In order to adjust the receiver correctly the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows: With the tuning condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable in this position is shown in the schematic diagram.

**NOTE C**—When adjusting the low frequency compensator of Range One (Broadcast) or the antenna and R. F. compensators of the high frequency tuning ranges; the receiver Tuning Condenser must be adjusted (rolled) as follows: First tune the compensator for maximum output, then vary the tuning condenser of the receiver for maximum output. Now turn the

compensator slightly to the right or left and again vary the receiver tuning condenser for maximum output. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

**NOTE D**—To accurately adjust the high frequency oscillator compensator to the fundamental instead of the image signal, turn the oscillator compensator to the maximum capacity position (clockwise). From this position slowly turn the compensator counter-clockwise until a second peak is obtained on the output meter. Adjust the compensator for maximum output at this second peak.

If the above procedure is correctly performed, the image signal will be found (much weaker) by turning the receiver dial 910 K. C. below the frequency being used on any high frequency range.

SCHEMATIC DIAGRAM MODEL 101

February, 1939.

Model 101 is a combination Phonograph and Radio Receiver. The phonograph section is designed to play 10 or 12 inch standard records (78 R. P. M.) and includes a manually operated crystal pickup and Turntable Motor.

The radio receiver employs an A. C. or D. C. operated superheterodyne circuit covering standard broadcast and police stations. (540 to 1720 K. C.)

**POWER SUPPLY:** Radio, 115 volts A. C. or D. C. Phonograph, 115 volts — 60 cycles only.

**POWER CONSUMPTION:** 57 watts.

**INTERMEDIATE FREQUENCY:** 470 K. C.

**PHILCO TUBES USED:** Five tubes; 1-7A8, first detector oscillator; 1-7B7, I. F. amplifier; 1-7C6, 2nd detector; A. V. C., first audio; 1-35A5, audio output, and 1-35Z3, rectifier.

 Tuner Unit Chassis  
 Alignment

PHILCO RADIO & TELEV. CORP.

MODEL 40-160  
 Alignment

MODEL 40-160. **Aligning of Compensating Condensers**

**Equipment Required**

(1) Signal Generator. In order to properly adjust this receiver an accurately calibrated signal generator such as Philco Model 077 is required. This signal generator covers a frequency range of 540 to 36,000 K.C. (2) Indicating Device. To obtain maximum signal strength and accurate adjustment of the padders a vacuum tube voltmeter and circuit tester such as Philco Models 027 and 028 is recommended. These testers also contain an audio output meter which may be used as an indicating device. (3) Aligning Tools. Fiber handle screw driver Philco Part No. 45-2610 and when using the vacuum tube voltmeter for adjusting the set, an aligning adaptor Part No. 45-2767 is required.

**Connecting Aligning Instruments**

**VACUUM TUBE VOLTMETER:** To use the vacuum tube voltmeter as an alignment indicator make the following connections:

1. **Adjusting I.F.:** Remove the 7C7 R.F. tube from its socket and insert the aligning adaptor in the socket, then replace the tube in the adaptor. Connect the negative terminal of the vacuum tube voltmeter to the light colored wire which protrudes from the side of the adaptor. Attach the positive terminal of the voltmeter to the black wire.

2. **Adjusting R.F. Padders:** To adjust the R.F. padders, insert the aligning adaptor in the 7C6 socket and place the tube in the adaptor. The vacuum voltmeter remains connected to the adaptor as given in the Adjusting I.F. above.

With the voltmeter connected in this manner a very sensitive indication of the output voltage is obtained when the padders are adjusted. If an audio output meter is used, connect it to the plate and socket terminals of the 41 type tube and adjust the output meter for the 0 to 30 A.C. scale.

After connecting the output meter, adjust the compensators in the order as shown in the tabulation below. Locations of the compensators are shown on the schematic diagram page No. 2. If the output meter pointer goes off scale when adjusting the compensators, reduce the strength of the signal from the generator.

**SIGNAL GENERATOR:** When adjusting the I.F. padders, the high side of the signal generator is connected through a .1 mfd. condenser to terminal No. 1 of the loop terminal panel at the rear of the chassis. The ground or low side of the signal generator is connected to the chassis of the receiver.

When aligning the R.F. padders a loop antenna is made from a few turns of wire and connected to the signal generator output terminals; the loop is then placed two or three feet from the loop in the cabinet. Do not remove the receiver loop from the cabinet. It is necessary when adjusting the padders, that the receiver be left in the cabinet.

SIGNAL GENERATOR			RECEIVER			
Operations in Order	Output Connections to Receiver	Dial Setting	Dial Setting	Control Setting	adjust compensators	Special Instructions
1	High Side to No. 1 Ter. Loop Panel	455 K.C.	580 K.C.	Vol. Max. Range Switch "Broadcast." Dial push button "In"	28A 28B 25 A 25 B	See Paragraph on Signal Generator Above
2	Use Loop on Generator	1500 K.C.	1500 K.C.	Vol. Max. Range Switch "Broadcast"	16A 22	Note A

**NOTE A—Dial Calibration:** In order to adjust the receiver correctly the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows: With the tuning condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable in this position is shown in Schematic Diagram.

MANY OF THE PARTS IN THIS PHILCO, SUCH AS CONDENSERS AND RESISTORS, ARE HELD TO MUCH CLOSER TOLERANCE THAN STANDARD REPLACEMENT PARTS. GENUINE PHILCO REPLACEMENT PARTS MUST BE USED TO OBTAIN SATISFACTORY PERFORMANCE OF THIS MODEL.

MODEL 108, CODE 121. **ALIGNMENT OF COMPENSATORS**

**EQUIPMENT REQUIRED:**

- (1) Signal Generator; Philco Model 077.
- (2) Output Meter, Philco 027 Vacuum Tube Voltmeter and Circuit Tester.
- (3) Philco Fiber Handle Screw Driver, Part No. 27 - 7059, and Fiber Wrench, Part No. 3164.

**OUTPUT METER:** The Philco 027 Output Meter is con-

nected to the plate and cathode terminals of the type 41 tube. The Vacuum Tube Voltmeter can also be used in aligning the receiver by connecting the Negative terminal through a one megohm Resistor to the 6A7 grid. The Positive terminal is connected to the chassis. After connecting the Output Meter, adjust compensators in the order as given in tabulation below. Locations of the compensators are shown in Fig. 1.

Operations in Order	SIGNAL GENERATOR				RECEIVER		SPECIAL INSTRUCTIONS
	Output Connections to Receiver	Dummy Antenna Note A	Dial Setting	Dial Setting	Control Settings	Adjust Compensators in Order	
1	6A7 Grid	.1 mf.	470 K. C.	580 K. C.	*Vol. Cont. Max. Range Sw. (Brdcst)	(21A) (12B) (12A)	
2	Ant. Ter.	100 mmf.	18.0 M. C.	18.0 M. C.	Vol. Cont. Max. Range Sw. (S. W.)	(4B)	See Note B, C
3	Ant. Ter.	100 mmf.	1550 K. C.	1550 K. C.	Vol. Cont. Max. Range Sw. (Brdcst)	(5) (4A)	
4	Ant. Ter.	100 mmf.	580 K. C.	580 K. C.	Vol. Cont. Max. Range Sw. (Brdcst)	(5A)	
5	Ant. Ter.	100 mmf.	1550 K. C.	1550 K. C.	Vol. Cont. Max.	(5)	

**NOTE A**—The "Dummy Antenna" consists of a condenser connected in series with the signal generator output lead (high side). Use the capacity as specified in each step of the above procedure.

**NOTE B**—**DIAL CALIBRATION:** In order to adjust the receiver correctly, the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows: With the tuning

condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable is shown in Service Bulletin No. 305.

**NOTE C**—Compensators (4A) and (4B) are located on top of the tuning condenser. Compensator (4B) is the first one from the tuning drum side.

PHILCO RADIO & TELEV. CORP.

MODELS 40-195, 40-200  
Alignment

**TYPE OF CIRCUIT:** Models 40-195 and 40-200 are Electric Push-Button and dial tuned radios incorporating the new Philco Built-in Super Aerial system which eliminates an outside aerial and reduces local static interference to a minimum. These models are also designed to receive the sound of a television program tuned in by special type Philco Television Sets.

**PHILCO BUILT-IN SUPER AERIAL SYSTEM:**

Included in the built-in aerial system is a statically shielded loop for broadcast band reception and a short wave receiving loop. The feature of the built-in broadcast band statically shielded loop is that it may be turned to the position in which it picks up a minimum amount of interference, or if interference is not present the loop may be set in the position where best reception is obtained.

In general, both radios are similar with the exception of the number of tubes used and cabinet design. Models 40-195 and 40-200 employ ten and eleven tubes respectively.

Each receiver is equipped with eight electric tuning push buttons for automatically selecting stations. Seven of the push buttons are used for broadcast stations and one push button (left hand push button preferably) may be set up for use with a Philco wireless Record Player or the sound programs tuned in by Special Philco Television sets.

**PHILCO TUBES USED: Model 40-195**

1232, R. F.; 7J7, Converter; 7B7, I. F.; 7C6, Second Detector, A. V. C., and First Audio; 37, Phase Inverter; two 37, Drivers; two 42, Audio Power Outputs; 80, Rectifier.

**Model 40-200**

1232, R. F.; 7J7, Converter; 7B7, I. F.; 7A6 Detector A. V. C.; 7C6 First Audio; 37, Phase Inverter; two 37, Audio Drivers; two 42, Power Outputs; 80, Rectifier.

CABINET DIMENSIONS:	Height	Width	Depth
Model 40-195 type "XX".....	38"	29½"	13½"
Model 40-200 type "RX".....	36½"	34½"	14½"

**Aligning of Compensating Condensers**

**Equipment Required**

(1) Signal Generator. In order to properly adjust this receiver an accurately calibrated signal generator such as Philco Model 077 is required. This signal generator covers a frequency range of 540 to 36,000 K. C. (2) Indicating Device, to obtain maximum signal strength and accurate adjustment of the padders a vacuum tube voltmeter and circuit tester such as Philco Models 027 and 028 is recommended. When using

the vacuum tube voltmeter, an aligning adaptor Philco part No. 45-2767 is necessary for connecting to the A. V. C. circuit. These testers also contain an audio output meter which may also be used as an indicating device. (3) Aligning Tools, fiber handle screw driver Philco part No. 45-2610 and fiber wrench Philco part No. 7696.

**Connecting Aligning Instruments**

**VACUUM TUBE VOLTMETER**—To use the vacuum tube voltmeter as an alignment indicator make the following connections:

**1. ADJUSTING I. F. CIRCUIT:**

Remove the 1232 R. F. tube from its socket and insert the aligning adaptor, then replace the tube in the adaptor. Connect the negative terminal of the vacuum tube voltmeter to the wire which protrudes from the side of the adaptor. Attach the positive terminal of the voltmeter to the chassis.

**2. ADJUSTING R. F. CIRCUIT:**

To adjust the R. F. circuit, the aligning adaptor is inserted in the 7C6 A. F. tube socket. The vacuum tube voltmeter remains connected to the adaptor as given in the above paragraph.

With the voltmeter connected in this manner a very sensitive indication of the A. V. C. voltage is obtained when the padders are adjusted. If an audio output meter is used, connect it to the plate and socket terminals of the 42 type tube and adjust the output meter for the 0 to 30 A. C. scale.

After connecting the aligning indicator, adjust the compensators in the order as shown in the tabulation below. Locations of the compensators are shown on the schematic diagram page No. 2. If the output meter pointer goes off scale when adjusting the compensators, reduce the strength of the signal from the generator.

**SIGNAL GENERATOR:** When adjusting the I. F. padders, the high side of the signal generator is connected through a .1 mfd. condenser to terminal No. 1 of the loop terminal panel at the rear of the chassis. The ground or low side of the signal generator is connected to the chassis of the receiver.

When aligning the R. F. padders a loop is made from a few turns of wire and connected to the signal generator output terminals; the loop is then placed two or three feet from the loop in the cabinet. Do not remove the receiving loop from the cabinet. It is necessary when adjusting the padders, that the receiver be left in the cabinet.

6	Use Loop on Generator		18.0 M. C.	18.0 M. C.	Vol. Max. Range Switch "S. W."	25, 4	Check Image Signal Note D

**NOTE A**—A "Dummy Antenna" consisting of a .1 mfd. condenser is connected in series with the signal generator output lead (high side).

**NOTE B**—**DIAL CALIBRATION:** In order to adjust the receiver correctly the dial must be aligned to track properly with the tuning condenser. To adjust the dial, proceed as follows: With the tuning condenser closed (maximum capacity), set the dial pointer on the extreme left index line at the low frequency end of the broadcast scale. The arrangement of the drive cable in this position is shown in Fig. 4.

**NOTE C**—When adjusting the low frequency compensator of Range One (Broadcast) or the antenna and R. F. compensators of the high frequency tuning ranges; the receiver Tuning Condenser must be adjusted (rolled) as follows: First tune the compensator for maximum output, then vary the tuning condenser of the receiver for maximum output. Now

turn the compensator slightly to the right or left and again vary the receiver tuning condenser for maximum output. This procedure of first setting the compensator and then varying the tuning condenser is continued until there is no further gain in output reading.

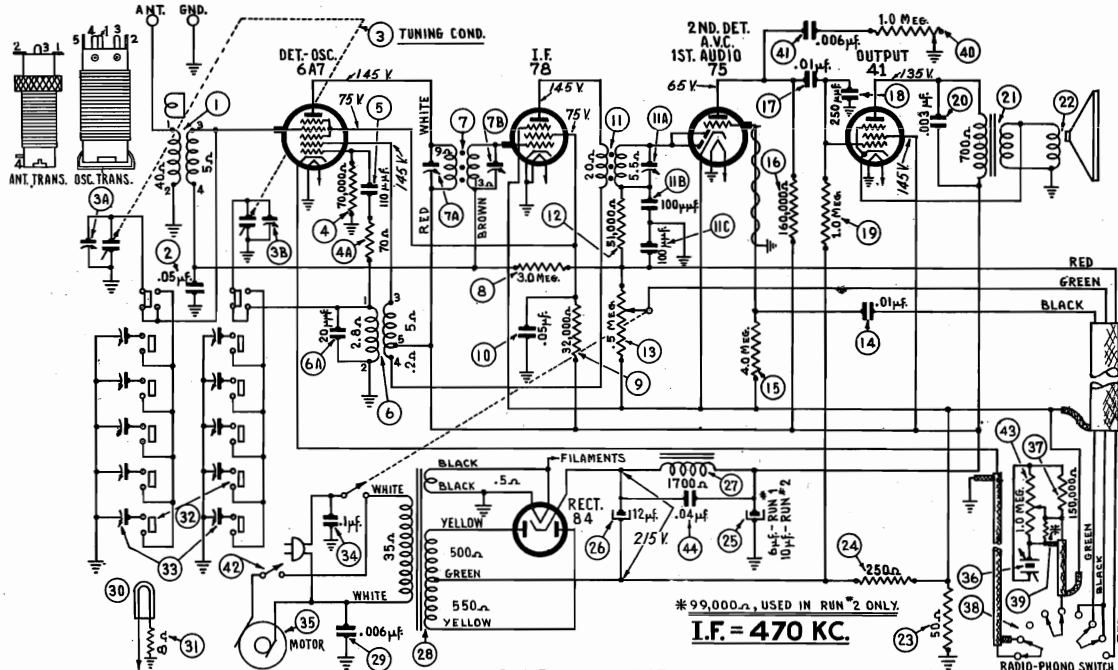

**NOTE D**—To accurately adjust the high frequency oscillator compensator to the fundamental instead of the image signal, turn the oscillator compensator to the maximum capacity position (clockwise). From this position slowly turn the compensator counter-clockwise until a second peak is obtained on the output meter. Adjust the compensator for maximum output at this second peak. If the above procedure is correctly performed, the image signal will be found (much weaker) by turning the receiver dial 910 K. C. below the frequency being used on any high frequency range.

SCHEMATIC DIAGRAM .MODEL 105

March, 1939

RADIO-PHONO SWITCH SHOWN FROM FRONT IN RADIO POSITION

POWER SUPPLY: 115 V., 60 cycle A. C.

POWER CONSUMPTION: 57 watts.

AUDIO OUTPUT: One (1) watt.

Model 105 is a combination Phonograph and Electric Automatic Tuning Radio Receiver. The phonograph is designed to play 10 or 12 inch standard records (78 R. P. M.) and consists of a semi-automatically operated crystal pickup and Turntable Motor.

The radio receiver consists of a five tube A. C. operated superheterodyne circuit, covering standard broadcast frequencies (530 to 1720 K. C.) with Automatic Volume Control and Pentode Audio Output. In addition to being manually tuned, there are six Electric Automatic Push Buttons. Five push buttons are used for selecting any one of five stations and one for changing to manual tuning. The procedure for adjusting the push buttons for reception of stations will be found in the instructions supplied with each receiver.

**NOTE — DIAL CALIBRATION:** With the tuning condenser in "maximum capacity" position (plates fully meshed), set the dial pointer between the two horizontal lines at the low frequency end of the scale (550 K. C.).

MODEL 936  
MODEL 937

PHILCO RADIO & TELEV. CORP.

Trimmers, Alignment

MODEL 936 — ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6 volt power pack, 077 or 177 Philco Set Tester, 27-7189 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

MODEL 937 — ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6 volt power pack, 077 or 177 Philco Set Tester, 27-7189 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

4	580 K.C.	To Antenna Receptacle on Radio	See Note 1	Set Tuning Condenser at 580 K.C.	Note 3
5	1580 K.C.	To Antenna Receptacle on Radio	See Note 1	Note 2	ⓐ
6	1400 K.C.	To Antenna Receptacle on Radio	See Note 1	Set Tuning Condenser at 1400 K.C.	Note 4
7	1200 to 1400 K.C.	To Antenna Receptacle on Radio	Note 5	Note 5	ⓐ

Make all adjustments for maximum reading on the output meter.

**NOTE 1** — Connect the antenna lead, Part No. 41-3191, to the antenna receptacle in the radio. Connect a 50 Mmfd. Condenser in series between the signal generator and the antenna lead.

**NOTE 2** — Turn the condenser rotor plates completely out of mesh as far as they will go.

**NOTE 3** — Rock the tuning condenser while adjusting the low frequency paddler. Tune the condenser to the signal and adjust the paddler for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the paddler for maximum output. Repeat this procedure until no further improvement is noticed.

**NOTE 4** — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

**NOTE 5** — When installing the radio in the car, follow the installation instructions carefully. Tune in a weak broadcast signal between 1200 and 1400 Kilocycles on the control scale. Remove the plug button on the end of the radio and adjust the antenna compensator ⓐ (See Figure 2) for maximum signal.

MODEL 938K  
Socket, Trimmers  
Alignment

PHILCO RADIO & TELEV. CORP.

**Alignment MODEL 938K**

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6 volt power pack, 077 or 177 Philco Set Tester, 27-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 6Y7G output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

8	1200 to 1400 K.C.	Note 5	Note 5	Note 5	④

Make all adjustments for maximum reading on the output meter.

- 1 — Connect the antenna lead, Part No. 41-3191, to the antenna receptacle in the radio. Connect a 50 Mmfd. Condenser in series between the signal generator and the antenna lead.
- 2 — Turn the condenser rotor plates completely out of mesh as far as they will go.
- 3 — Rock the tuning condenser while adjusting the low frequency padder. Tune the condenser to the signal and adjust the padder for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the padder for maximum output. Repeat this procedure until no further improvement is noticed.
- 4 — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.
- 5 — When installing the radio in the car, follow the installation instructions carefully. Tune in a weak broadcast signal between 1200 and 1400 Kilocycles on the control scale. Remove the plug button on the end of the radio and adjust the antenna compensator ④ (See Figure 2) for maximum signal.

ADJUSTMENTS MODEL C-1606

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.  
**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 077A or 177 Philco Set Tester, 27-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

FIGURE 3

OPERATION	SIGNAL GENERATOR		DUMMY CAPACITY	SPECIAL INSTRUCTIONS	ADJUST PADDER
	FREQUENCY	CONNECTION			
1	400 K.C.	To Grid of 6A7 Tube	.5 Mfd.	Turn Variator to the Indexed Position	24 17 15
2	950 to 1500 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 1 and adjust No. 1 Antenna Padder and No. 1 Oscillator Coil (Fig. 4)	Note 2 Fig. 4
3	950 to 1500 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 2 and adjust No. 2 Antenna Padder and No. 2 Oscillator Coil (Fig. 4)	Note 2 Fig. 4
4	750 to 1250 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 3 and adjust No. 3 Antenna Padder and No. 3 Oscillator Coil (Fig. 4)	Note 2 Fig. 4
5	750 to 1250 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 4 and adjust No. 4 Antenna Padder and No. 4 Oscillator Coil (Fig. 4)	Note 2 Fig. 4
6	550 to 950 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 5 and adjust No. 5 Antenna Padder and No. 5 Oscillator Coil (Fig. 4)	Note 2 Fig. 4
7	550 to 950 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Press Push Button No. 6 and adjust No. 6 Antenna Padder and No. 6 Oscillator Coil (Fig. 4)	Note 2 Fig. 4

FIGURE 4

Make all adjustments for maximum reading on the output meter.  
**NOTE 1** — Connect the antenna lead, Part No. L-2765, to the antenna receptacle in the radio. Connect a 25 Mmfd. Condenser in series between the signal generator and the antenna lead.

**Special Note:** — When the cowl antenna is used follow the above procedure. Be sure the lead to the antenna transformer is plugged into the "SKY" socket of the Antenna Transformer.

\*When the undercar is used, connect the antenna lead, Part No. 41-3191 to the antenna receptacle in the Radio. Connect a 250 Mmfd. condenser in series between the signal generator and the antenna lead. Be sure the lead to the antenna transformer is plugged into the "ROAD" socket of the antenna transformer.

**NOTE 2** — The antenna padder screw is on the right, the oscillator coil screw is on the left (see Figure 4).

ALL ADJUSTMENTS MUST BE REPEATED.

ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 077A or 177 Philco Set Tester, 37-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 41 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

MODEL C-1608

MODEL C-1608

ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 048A or 099 Philco Set Tester, 37-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 42 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

OPERATION	SIGNAL GENERATOR CONNECTION		DUMMY CAPACITY	SPECIAL INSTRUCTIONS	PADDERS ADJUST

1	470 K.C.	To Grid of 6A7 Tube	.5 Mfd.	Press the "DIAL" button and stations can be tuned in by "DIAL" tuning.	① ② ③
2	1580 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Turn Tuning Condenser Plates Out of Mesh as Far as They Will Go. Note 2	④ ⑤
3	1400 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1		⑥ ⑦
4	580 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Set Tuning Condenser at 1400 K.C.	⑧ ⑨
5	1580 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Set Tuning Condenser at 580 K.C.	⑩ ⑪
6	1400 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Note 2	⑫ ⑬
7	1400 K.C.	To Antenna Receptacle on Radio	*25 Mmfd. See Note 1	Set Tuning Condenser at 1400 K.C.	⑭ ⑮

Make all adjustments for maximum reading on the output meter.  
NOTE 1 — Connect the antenna lead, Part No. L-2765, to the antenna receptacle in the radio. Connect a 25 Mmfd. Condenser in series between the signal generator and the antenna lead.

**Special Note:** — When the cowl antenna is used follow the above procedure. Be sure the lead to the antenna transformer is plugged into the "SKY" socket of the Antenna Transformer.  
When the undercar is used, connect the antenna lead, Part No. 41-3191 to the antenna receptacle in the Radio. Connect a 250 Mmfd. condenser in series between the signal generator and the antenna lead. Be sure the lead to the antenna transformer is plugged into the "ROAD" socket of the antenna transformer.

NOTE 2 — Turn the condenser rotor plates completely out of mesh as far as they will go.  
NOTE 3 — Rock the tuning condenser while adjusting the low frequency paddler. Tune the condenser to the signal and adjust the paddler for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the paddler for maximum output. Repeat this procedure until no further improvement is noticed.

NOTE 4 — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

MODEL P-1630

**ADJUSTMENTS**  
 All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 048A or 099 Philco Set Tester, 27-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 42 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

**ADJUSTMENTS**

DECEMBER 20, 1938

MODEL P-1635 Packard  
 Socket, Trimmers  
 Alignment

PHILCO RADIO & TELEV. CORP.

ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 077 or 177 Philco Set Tester, 27-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 6Y7G output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

7	1400 K.C.	To Antenna Receptacle on Radio	*250 Mmfd. See Note 1	Set Tuning Condenser at 1400 K. C.	84 Note 4

Make all adjustments for maximum reading on the output meter.

NOTE 1 — Connect the antenna lead, Part No. 41-3191, to the antenna receptacle in the radio. Connect a 250 Mmfd. Condenser in series between the signal generator and the antenna lead.

Special Note: — When the roof or undercarriage antenna is used follow the above procedure. Be sure the lead to the antenna transformer is connected to the red terminal of the Antenna Transformer.

\*When the cowl antenna is used, connect the antenna lead, Part No. L-2765, to the antenna receptacle in the Radio. Connect a 20 mmfd. condenser in series with the signal generator and the antenna lead. Be sure the lead to the antenna transformer is connected to the black terminal of the antenna transformer.

NOTE 2 — Turn the condenser rotor plates completely out of mesh as far as they will go.

NOTE 3 — Rock the tuning condenser while adjusting the low frequency padder. Tune the condenser to the signal and adjust the padder for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the padder for maximum output. Repeat this procedure until no further improvement is noticed.

NOTE 4 — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

**MODEL F-1640 Ford  
Socket, Trimmers  
Alignment**

**PHILCO RADIO & TELEV. CORP.**

Make all adjustments for maximum reading on the output meter.

- NOTE 1 — Connect the antenna lead, Part No. 95-0063, to the antenna receptacle in the radio. Connect a 30 Mmfd. Condenser in series between the signal generator and the antenna lead.
- NOTE 2 — Turn the condenser rotor plates completely out of mesh as far as they will go.
- NOTE 3 — Rock the tuning condenser while adjusting the low frequency padder. Tune the condenser to the signal and adjust the padder for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the padder for maximum output. Repeat this procedure until no further improvement is noticed.
- NOTE 4 — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

FIGURE 3

**ADJUSTMENTS**

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty storage battery or 6-volt power pack, 048A or 099 Philco Set Tester, 27-7189 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 42 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

The shielding on the generator output lead must be connected to the Radio housing.

PHILCO RADIO & TELEV. CORP.

Alignment

Make all adjustments for maximum reading on the output meter.

NOTE 1 — Connect the antenna lead, Part No. 41-3191, to the antenna receptacle in the radio. Connect a 800 Mmfd. Condenser in series between the signal generator and the antenna lead.

Special Note: — When the tire compartment door antenna is used follow the above procedure. Be sure the lead to the antenna transformer is connected to the red terminal of the Antenna Transformer.

\*When the cowl antenna is used, connect the antenna lead, Part No. 41-3191, to the antenna receptacle in the Radio. No dummy capacity is necessary. Be sure the lead to the antenna transformer is connected to the black terminal of the antenna transformer.

NOTE 2 — Turn the condenser rotor plates completely out of mesh as far as they will go.

NOTE 3 — Rock the tuning condenser while adjusting the low frequency padder. Tune the condenser to the signal and adjust the padder for maximum output. Rotate the tuning condenser back and forth slightly for maximum output. Then readjust the padder for maximum output. Repeat this procedure until no further improvement is noticed.

NOTE 4 — When the antenna stage adjustment is made with the Radio installed in the car, the Radio antenna lead must be connected to the car antenna in the usual manner. Connect the signal generator output lead to a wire placed near the car antenna but not connected to it.

FIGURE 3

ADJUSTMENTS

All padding adjustments are carefully made at the factory and ordinarily no readjustments are necessary. However, when readjustments are required, the procedure given below must be followed in detail.

**Equipment** — Fully charged heavy duty shortage battery or 6-volt power pack, 048A or 099 Philco Set Tester, 27-7159 Padding screw driver.

**General** — The output meter must be connected by means of an adapter to the plate of the type 42 output tube and to the Radio chassis.

With the Radio and signal generator set up for operation at the prescribed frequency, turn the Radio volume control on full and set the signal generator attenuator so that a half scale reading is obtained on the output meter. The signal in the speaker should be audible but not loud.

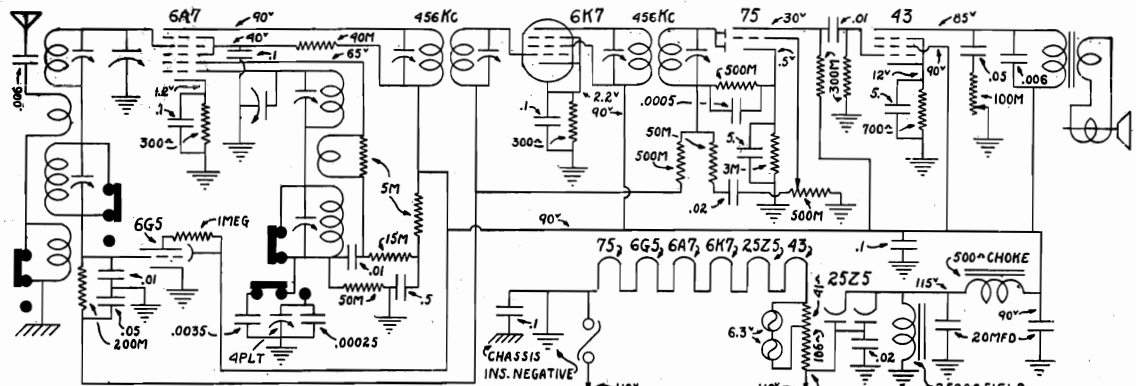

The shielding on the generator output lead must be connected to the Radio housing.

Alignment Procedure

## PILOT RADIO CORP.

PILOTUBES Required.

One 6K7	R.F. Amplifier
One 6K8	1st Detector-Oscillator
One 6K7	I.F. Amplifier
One 6R7	2nd Detector-AVC-1st Audio Amplifier
Four 25L6-G	Output Tubes
Two 25Z6-G	Power Supply Rectifiers
One 6U5	Cathode Ray Tuning Beacon

<u>Power Supply.</u>	A.C. or D.C.		
<u>Voltage</u>		<u>Ballast Tubes</u>	<u>Watts</u>
110-125		81973	110

Intermediate Frequency. 455 kc.

Panel Controls. Volume with On-Off switch, Tone, Band Selector Switch, Manual Tuning Control and an 8 key mechanically operated PIANO TUNING mechanism, with key locking knob. The PIANO TUNING mechanism is only on the H-320 series.

TUNING RANGES. The models H-324 and H-224 chassis have the following tuning ranges:

Band 1	8.72 - 25.5 mc. or 11.8 - 34.4 meters
Band 2	2.96 - 9.95 mc. or 30.2 - 101.4 meters
Band 3	520 - 1725 kc. or 174 - 577 meters

Maximum Power Output. 6 watts

SERVICE DATA

Removal of the chassis from the cabinet, when necessary is done as follows:

1. Remove the power supply cord from the supply outlet.
2. Remove the knobs and felt washers from all shafts on the front of the cabinet. These knobs, except the "locking" knob, are of the "push-on" type.
3. Remove the back of the cabinet.
4. Remove the speaker cord from the socket on the speaker.
5. Remove the four mounting screws located under the cabinet, and carefully slide the chassis out of the cabinet.

RECEIVER ALIGNMENTEquipment Required.

1. Signal Generator. One using fundamental frequencies for all the frequencies used in the receiver is preferred.
2. Output Meter. Generally a copper-oxide rectifier meter is the most convenient.

Dummy Antennas. .1 mfd. condenser  
.0002 mfd. mica condenser  
400 ohm, non-inductive resistor

Alignment Connections.

The posts marked "D" and "G" on the rear of the chassis should be connected to the ground side of the signal generator.

Connect the "hot" post of the signal generator through the .1 mfd. condenser to the grid of the 6K8 detector-oscillator tube or the 6K7 I.F. Amplifier tubes when aligning the I.F. amplifier.

Connect the "hot" post of the signal generator through the 200 mfd. condenser to the post marked "A" on the rear of the chassis when aligning the Long-Wave and Broadcast Bands. Use the same connections for both short-wave bands, but replace the 200 mfd. condenser with the 400 ohm, non-inductive resistor.

In all measurements, connect the output meter through .1 mfd. 600 volt condensers, from plate to plate terminals of the 25L6-G tubes, as this is a push-pull amplifier.

Procedure.

The volume and tone controls should be turned to the extreme clockwise positions, before starting.

The location of all trimmers is shown in the accompanying figure. Always keep the output from the signal generator at the lowest value which will give a readable deflection on the output meter.

I.F. Amplifier Alignment.

Turn the Band Selector Switch to Band 3 and turn the ROTOR dial to the low frequency end.

Connect the output meter as described under "Connections" and connect the "hot" post of the signal generator to the grid of the 6K8 tube through the .1 mfd. condenser. Then proceed with the alignment as follows:

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.

2. Adjust the screws 1, 2, 3, and 4 (see figure), for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the I.F. amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the I.F. amplifier tube, and align the last I.F. transformer. Always finish the alignment with the signal input to the 6K8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

R.F. AlignmentBand 3 (Model H-324 and H-224)

Connect the "hot" terminal of the generator to the antenna post marked "A" through the .0002 mfd. condenser.

Set the generator frequency to 1500 kc., and the ROTOR dial to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #8 for maximum reading of the output meter. (This trimmer is adjusted by moving the brass rod in or out, with a hooked wire, and with a twisting motion. First loosen the lock nut). Then without touching any tuning controls adjust trimmers #9 and #10 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc. and accurately set the ROTOR dial to the 600 kc. mark. Then adjust trimmer #11 for maximum reading of the output meter. Do not move the tuning control while making this adjustment. Finally return and repeat the 1500 kc. adjustments and then tighten the lock nut on trimmers #8 and #9.

Band 2 (Model H-324 & H-224 Short-Wave)

Remove the .0002 mfd. dummy antenna used in aligning the lower frequency bands and substitute the 400 ohm resistor.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator, and the ROTOR dial to 9 mc. Adjust trimmer #15 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmers #16 and #17 for maximum reading of the output meter, while slightly "rocking" the gang condenser. Readjust trimmer #15 if necessary to correct the calibration.

Band 1 (Model H-324 & H-224 Short-Wave)

Connections and dummy antenna are the same as on Band 1 above.

Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 23 mc. and the ROTOR dial to 23 mc. Adjust trimmer #18 to 23 mc. for maximum reading of the output meter. Be careful that the receiver is not adjusted to the Image Frequency. Then adjust trimmers #19 and #20 while "rocking" the gang condenser, for maximum reading of the output meter. Reset trimmer #18 so that calibration is correct if necessary.

Image Frequency

All bands in these two models must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on the Long-Wave and Broadcast Bands. However, on the higher frequency bands it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the Image Frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, set the ROTOR dial to that one which comes in at the higher frequency marking on the ROTOR dial.

Miscellaneous Service Notes.

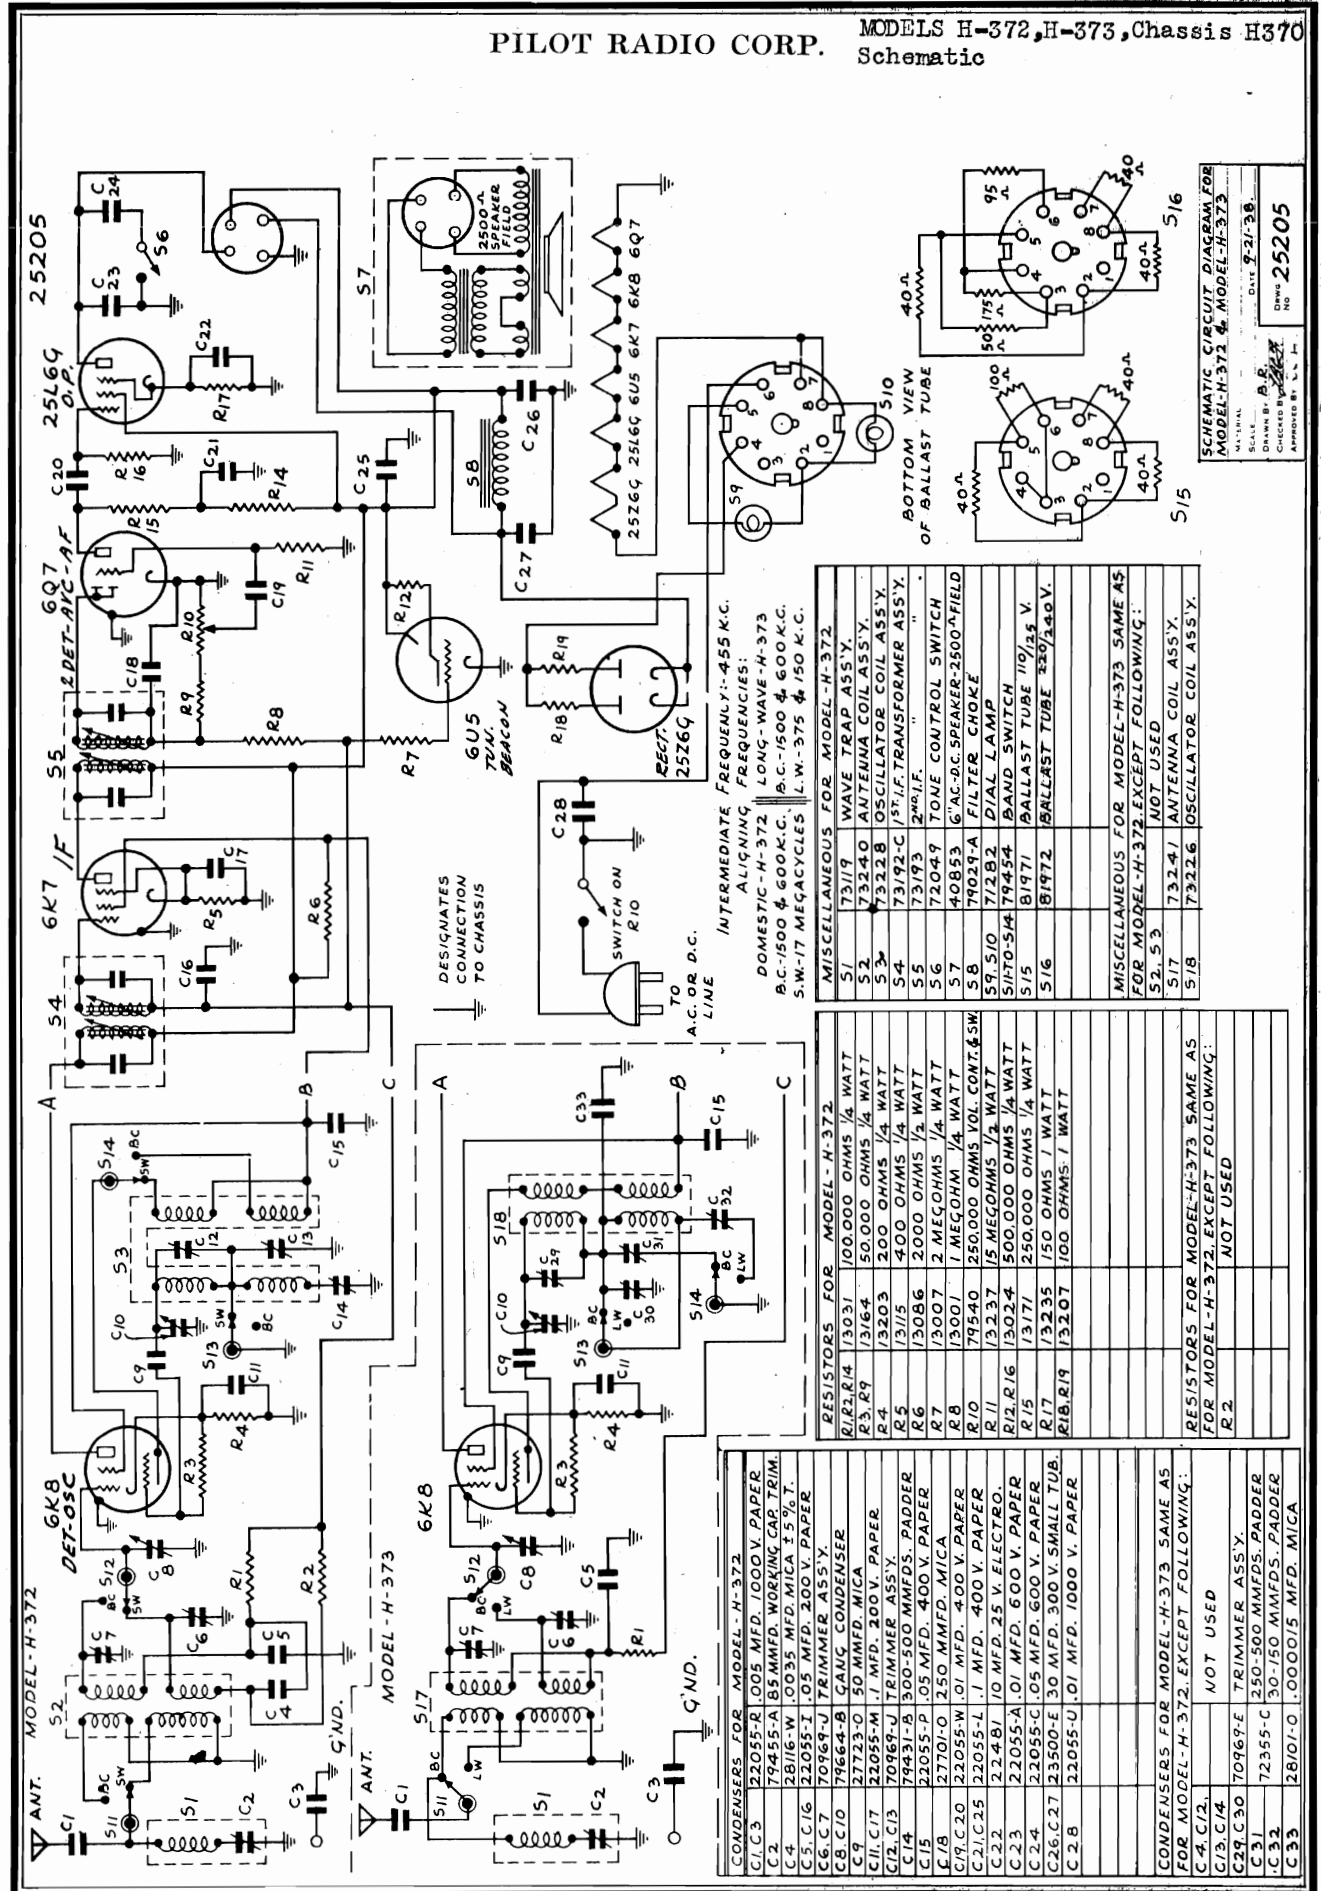

If a howling noise (sometimes referred to as Microphonic Howl) is heard, it is very probably because the four red screws under the cabinet have not been removed, along with the two narrow metal strips between the chassis and the bottom of the cabinet. These strips and screws are only intended as additional bracing during shipment, and must be removed before the receiver is put in operation.

The howl can also be caused by a defective tube, or when some part of the receiver which is rigidly fastened to the chassis rubs against the cabinet. The remedy is obvious.

PILOT RADIO CORP.

Voltage, Socket, Trimmers  
Alignment

IF Amplifier Alignment

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.
2. Adjust the trimmer screws 1, 2, 3, and 4, (see to the blue antenna wire through the .0002 mfd. condenser. Set the generator frequency to 375 kilocycles and with the Band Selector Switch set to the Long Wave Band, turn the pointer of the receiver to 375 kilocycles. Adjust trimmer #8 for maximum reading of the output meter. Do likewise with trimmer #7. Then set the generator frequency to 150 kilocycles and the receiver dial pointer to approximately the same frequency. Adjust the screw of trimmer #10 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 375 kilocycle alignment.

R.F. Alignment  
Long Wave Band

(Model H-373)

Connect the "hot" terminal of the generator antenna wire through the .0002 mfd. condenser. Set the generator frequency to 375 kilocycles and with the Band Selector Switch set to the Long Wave Band, turn the pointer of the receiver to 375 kilocycles. Adjust trimmer #8 for maximum reading of the output meter. Do likewise with trimmer #7. Then set the generator frequency to 150 kilocycles and the receiver dial pointer to approximately the same frequency. Adjust the screw of trimmer #10 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 375 kilocycle alignment.

Broadcast, or Medium Wave, Band (Models H-373 and H-372)

Connections are the same for the alignment of this band as they are for the Long Wave Band. Set the generator frequency to 1500 kilocycles, and the receiver dial pointer to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #9 of Model H-373, or trimmer #8 of Model H-372 for maximum reading of the output meter. Also adjust trimmer #6 of Model H-373, or trimmer #7 of Model H-372 for maximum reading of the output meter. Next, set the generator frequency to 600 kilocycles. Then with the receiver dial pointer set at approximately the same frequency, adjust trimmer #10 for maximum reading of the output meter while carefully "rocking" the gang condenser. Finally, return and repeat the 1500 kilocycle adjustment.

Short Wave Band (Model H-372)

When aligning this band connect the "hot" terminal of the signal generator to the blue antenna wire of the receiver through the 400 ohm resistor. Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 17 mc., and also tune the receiver to this frequency, as marked on the dial. Carefully adjust trimmer #9 for maximum reading of the output meter. Be careful you do not adjust to the "Image Frequency". Then adjust trimmer #6 for maximum output meter reading, while slightly "rocking" the gang condenser. Readjust trimmer #9, if necessary, to keep the calibration correct.

Image Frequency

The Short Wave Band in model H-372 must be aligned with the oscillator frequency lower than the signal frequency. On the high frequency band, it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the Image Frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, turn the tuning knob so that the dial pointer points to that one which comes in at the lower frequency marking on the dial.

Wave Trap Alignment

With the Band Selector Switch set on the Broadcast or Medium Wave position, connect the generator to the blue antenna wire, with the .0002 mfd. condenser. Set the generator frequency to 455 kilocycles and adjust trimmer #5 for minimum reading of the output meter. There must always be sufficient output from the Signal Generator to have a reading on the output meter to make this adjustment.

## PILOT RADIO CORP.

Alignment Procedure

IF Amplifier Alignment Turn the Band Selector Switch to Band 3 and turn the receiver dial pointer to the low frequency end.

Connect the output meter as described under "Connections", and connect the "hot" post of the signal generator to the grid of the 6K8 tube through the .1 mfd condenser. Then proceed with the alignment as follows:-

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.

2. Adjust the screws 1, 2, 3, and 4 (see figure), for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the IF amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the IF amplifier tube, and align the last IF transformer. Always finish the alignment with the signal input to the 6K8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

Wave Trap Alignment With the Band Selector Switch set on the Broadcast Band, replace the .1 mfd dummy antenna with the .0002 mfd dummy antenna. Set the generator frequency at 455 kc and tune trimmer #11 for minimum reading of the output meter. There must be sufficient output from the signal generator to always have a reading on the output meter; do not allow the meter to go to zero and call that the correct adjustment point.

R.F. Alignment

Band 3 (Model 455 Long-Wave) Connect the "hot" terminal of the generator to the blue wire and clip through the .0002 mfd condenser.

Set the generator frequency to 300 kc and with the Band Selector Switch set to Band 3, turn the receiver dial pointer to 300 kc. Adjust trimmer #5 for maximum reading of the output meter. Do likewise with trimmer #13. Then set the generator frequency to 175 kc and the receiver dial pointer to approximately the same. Adjust trimmer #6 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 300 kc alignment.

Band 2 (Model 455) Band 3 (Model 454) (Standard Broadcast)

Connections are the same for the alignment of this band as they are for the long-wave band.

Set the generator frequency to 1500 kc., and the receiver dial pointer to the same frequency, with the band selector switch set appropriately. Adjust trimmer #7 for maximum reading of the output meter. (This trimmer is adjusted by moving the brass rod in or out, with a hooked wire, and with

a twisting motion. First loosen the lock nut). Then without touching any tuning controls adjust trimmer #12 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc., and accurately set the receiver dial pointer to the 600 kc mark. Then adjust trimmer #15 for maximum reading of the output meter. Do not move the tuning control while making this adjustment. Finally return and repeat the 1500 kc adjustments and then tighten the lock nut on trimmer #7.

Band 1 (Model 455 Short-Wave)

Remove the .0002 mfd dummy antenna used in aligning the lower frequency bands and substitute the 400 ohm resistor.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator frequency to 18 mc and also set the receiver dial pointer to this frequency. Carefully adjust trimmer #8 for maximum reading of the output meter; be careful you do not tune in at the Image Frequency.

Then adjust trimmer #14 for maximum output meter reading, while slightly "rocking" the gang condenser. Readjust trimmer #8 if necessary to keep the calibration correct. These are the only adjustments on this band.

Band 2 (Model 454 - Short-Wave)

Connections and dummy antenna same as on Band 1 above.

Before aligning this band refer to the paragraph headed, "Image Frequency".

Set the generator and the receiver dial pointer to 9 mc. Adjust trimmer #9 for maximum reading of the output meter; be careful you do not tune in at the Image Frequency.

Then adjust trimmer #13 for maximum reading of the output meter while slightly "rocking" the gang condenser. Readjust trimmer #9 if necessary to correct the calibration.

Band 1 Alignment (Model 454 Short-Wave)

Connections and dummy antenna are the same as on Band 2 of model 554.

Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 24 mc and the receiver dial pointer to 24 mc. Adjust trimmer #10 to 24 mc for maximum reading of the output meter. Be careful that the receiver is not adjusted to the Image Frequency. Then adjust trimmer #14 while "rocking" the gang condenser, for maximum reading of the output meter. Reset trimmer #10 so that calibration is correct if necessary.

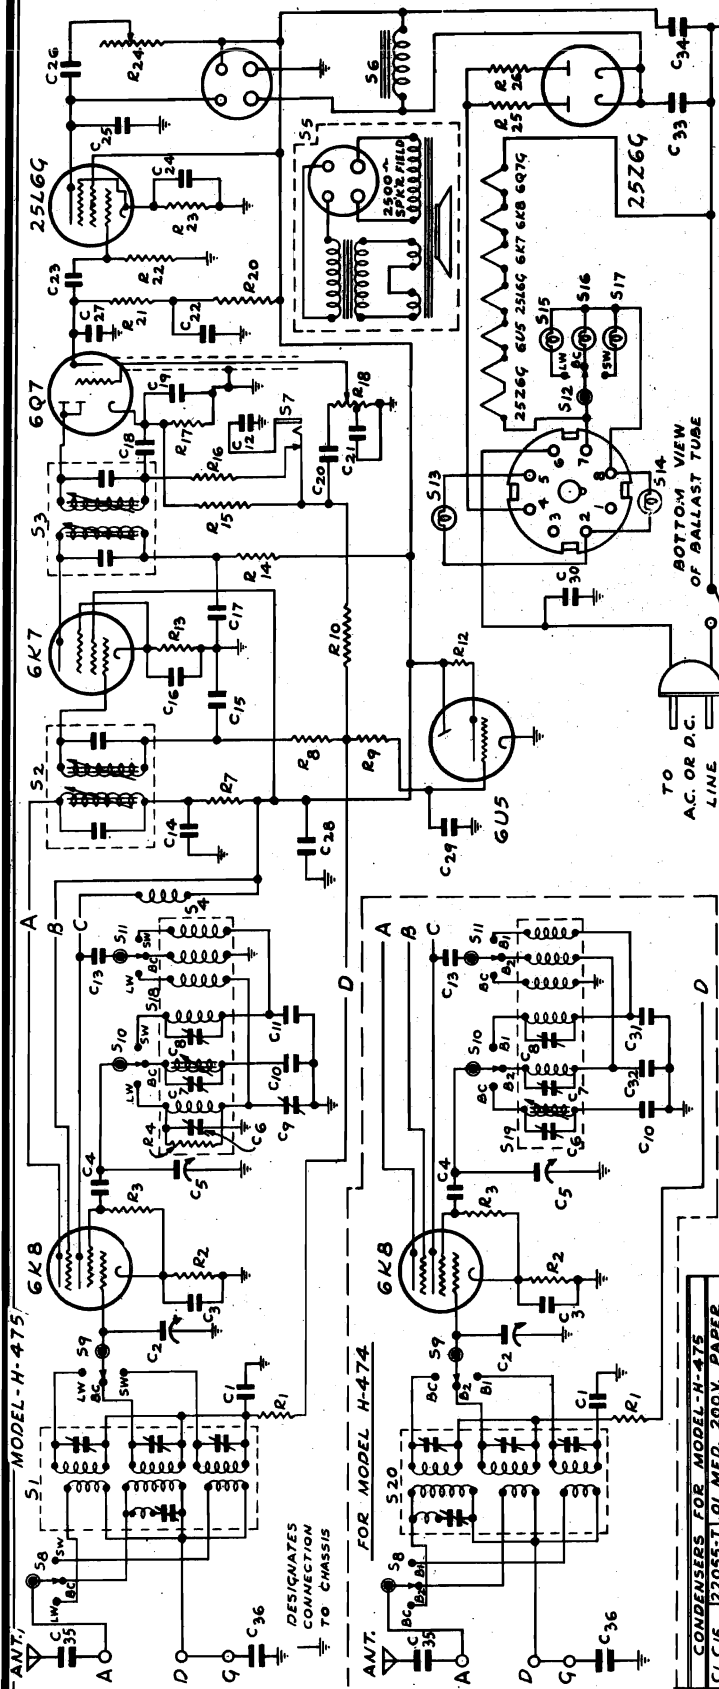

IMAGE FREQUENCY

All bands in these two models must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on the long-wave and Broadcast Bands. However, on the higher frequency bands it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the image frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the intermediate frequency, set the receiver dial pointer to that one which comes in at the higher frequency marking on the receiver dial pointer.

## Alignment Procedure

## PILOT RADIO CORP.

MODELS H-474, H-475

Chassis H-470

Alignment Connections

Connect the Black and Yellow wires together and to the ground post of the signal generator.

Connect the "hot" post of the generator through the correct dummy antenna or condenser to the appropriate point as noted hereafter. In all the measurements to follow, the output meter should be connected to the plate and screen grid terminals of the 25L6-G through .1 mfd. condensers in any convenient manner.

IF Amplifier Alignment Turn the Band Selector Switch to Band 3 and turn the ROTOR dial to the low frequency end.

Connect the output meter as described under "Connections", and connect the "hot" post of the signal generator to the grid of the 6K8 tube through the .1 mfd. condenser. Then proceed with the alignment as follows:-

1. Adjust the Signal Generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.

2. Adjust the screws 1, 2, 3, and 4, (see figure) for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the IF amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the IF amplifier tube, and align the last IF transformer. Always finish the alignment with the signal input to the 6K8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

Wave Trap Alignment With the Band Selector Switch set on the Broadcast Band, replace the .1 mfd. dummy antenna with the .0002 mfd. dummy antenna. Set the generator frequency at 455 kc. and tune trimmer #11 for minimum reading of the output meter. There must be sufficient output from the signal generator to always have a reading on the output meter. Do not allow the meter to go to zero and call that the correct adjustment point.

R.F. Alignment

Band 3 (Model H-475 - Long-Wave) Connect the "hot" terminal of the generator to the blue wire and clip through the .0002 mfd. condenser.

Set the generator frequency to 300 kc., and with the Band Selector Switch set to Band 3, turn the ROTOR dial to 300 kc. Adjust trimmer #6 for maximum reading of the output meter. Do likewise with trimmer #13. Then set the generator frequency to 175 kc., and the ROTOR dial to approximately the same. Adjust trimmer #5 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 300 kc. alignment.

Band 2 (Model H-475)      Band 3 (Model H-474)  
(Standard Broadcast)

Connections are the same for the alignment of this band as they are for the Long-Wave Band.

Set the generator frequency to 1500 kc., and the ROTOR dial to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #7 for maximum reading of the output meter. (This trimmer is adjusted by moving the brass rod in or out, with a hooked wire, and with a twisting motion. First loosen the lock nut). Then without touching any tuning controls adjust trimmer #12 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc. and accurately set the ROTOR dial to the 600 kc. mark. Then adjust trimmer #15 for maximum reading of the output meter. Do not move the tuning control while making this adjustment. Finally, return and repeat the 1500 kc. adjustments and then tighten the lock nut on trimmer #7.

Band 1 (Model H-475 - Short-Wave)

Remove the .0002 mfd. dummy antenna used in aligning the lower frequency bands and substitute the 400 ohm resistor.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator frequency to 18 mc. and also set the ROTOR dial to this frequency. Carefully adjust trimmer #8 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmer #14 for maximum output meter reading, while slightly "rocking" the gang condenser. Re-adjust trimmer #8 if necessary to keep the calibration correct. These are the only adjustments on this band.

Band 2 (Model H-474 - Short-Wave)

Connections and dummy antenna same as on Band 1 above.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator and the ROTOR dial to 9 mc. Adjust trimmer #9 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmer #13 for maximum output meter reading, while slightly "rocking" the gang condenser. Re-adjust trimmer #9 if necessary to correct the calibration.

Band 1 (Model H-474 - Short-Wave)

Connections and dummy antenna are the same as on Band 1 above.

Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 24 mc. and the ROTOR dial to 24 mc. Adjust trimmer #10 to 24 mc. for maximum reading of the output meter. Be careful that the receiver is not adjusted to the Image Frequency. Then adjust trimmer #14, while "rocking" the gang condenser for maximum reading of the output meter. Reset trimmer #10 so that calibration is correct if necessary.

Image Frequency

All bands in these two models must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on the Long-Wave and Broadcast Bands. However, on the higher frequency bands it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the Image Frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator, to pick up two signals with the receiver, separated by twice the Intermediate Frequency, set the ROTOR dial to that one which comes in at the higher frequency marking on the ROTOR dial.

Miscellaneous Service Notes

If a howling noise (sometimes referred to as Microphonic howl) is heard, it is very probably because the four red screws under the cabinet have not been removed along with the two narrow metal strips between the chassis and the bottom of the cabinet. These strips and screws are only intended as additional bracing during shipment and must be removed before the receiver is put in operation.

The howl can also be caused by a defective tube, or when some part of the receiver which is rigidly fastened to the chassis rubs against the cabinet. The remedy is obvious.

In replacing or resetting the ROTOR dial, always set the gang condenser at maximum capacity.

To reset the dial, loosen the set screws in the ROTOR dial pinion gear. Then, adjust the dial so that the low frequency end of the calibration line, at the base of the arrow tip, is directly under the indicator wire. Then, tighten the pinion gear set screws.

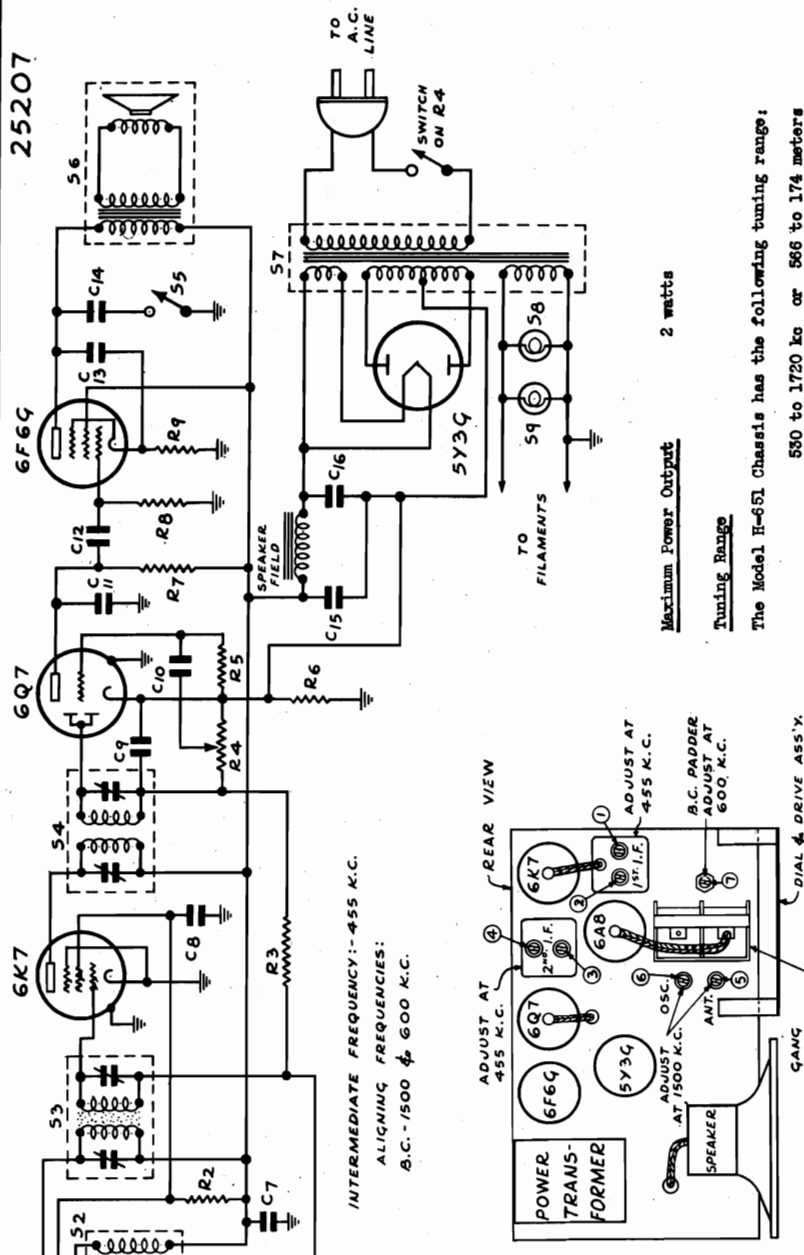

If it should be necessary to remove the ROTOR dial, first remove the top plate which carries the Tuning Beacon Clamp. Next, remove the bearing plates which hold the dial shaft in place, and lift out the whole dial assembly.

In replacing the dial, be sure to compress the "back lash" springs in the double gear approximately 1/16 of an inch.

Never loosen the set screws which connect the link motion to the gang condenser. If this should be done, the calibration of the receiver will be affected.

Tuning Range

The Model H-651 Chassis has the following tuning range:  
 550 to 1720 kc or 566 to 174 meters

Power Supply	Voltage	Frequency	Watts
110 to 125 volts	60	50	50
150 volts	60	50	50
220 to 240 volts	60	50	50
110 to 125 or 220 to 240 volts	60	50	50

- TUBES Required
- One 6A8 1st detector-oscillator
  - One 6K7 IF amplifier
  - One 6F6-G 2nd detector-AVC-1st audio amplifier output tube
  - One 5Y3-G power supply rectifier
- Total 5 tubes

GENERAL SPECIFICATIONS.

Circuit Super-heterodyne, with Class A output stage. Tuning range as listed below. Continuously variable tone control and automatic volume control.

TOP VIEW OF CHASSIS

D.C. SOCKET VOLTAGES

All voltages are those between the indicated tube terminal and the chassis, and are made with a 1000 ohm per volt voltmeter. Make measurements with no signal input to the receiver and with the volume control set at minimum volume.

Make sure that the A.C. supply voltage is correct for the transformer tap being used at the time of measurement.

**Band 2 (Model H-484 Short-Wave)**  
Connections and dummy antenna same as on Band 1 above.  
Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator, and the ROTOR Dial to 9 mc. Adjust trimmer #15 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency. Then adjust trimmers #16 and #17 for maximum reading of the output meter, while slightly "rocking" the gang condenser. Readjust trimmer #15 if necessary to correct the calibration.

**Band 1 (Model H-484 Short-Wave)**  
Connections and dummy antenna are the same as on Band 1 above  
Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 23 mc. and the ROTOR dial to 23 mc. Adjust trimmer #18 to 23 mc. for maximum reading of the output meter. Be careful that the receiver is not adjusted to the Image Frequency. Then adjust trimmers #19 and #20 while "rocking" the gang condenser, for maximum reading of the output meter. Reset trimmer #18 so that calibration is correct if necessary.

FRONT VIEW

RIGHT SIDE OF CHASSIS

REAR VIEW OF CHASSIS (MODEL H-485)

TOP VIEW OF CHASSIS

REAR VIEW OF CHASSIS (MODEL H-484)

**IF Amplifier Alignment.** Turn the Band Selector Switch to Band 3 and turn the ROTOR dial to the low frequency end. "Connections", and connect the "hot" post of the signal generator to the grid of the 6K8 tube through the .1 mfd. condenser. Then proceed with the alignment as follows:

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.
2. Adjust the screws 1, 2, 3, and 4 (see figure), for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

**R.F. ALIGNMENT**

**Band 3 (Model H-485, Long-Wave)** Connect the "hot" terminal of the generator to the blue wire and clip through the .0002 mfd. condenser.

Set the generator frequency to 300 kc., and with the Band Selector Switch set to band 3, turn the ROTOR dial to 300 kc. Adjust trimmer #5 for maximum reading of the output meter. Do likewise with trimmer #6 and #7. Then set the generator frequency to 160 kc. and the ROTOR dial to approximately the same. Adjust trimmer #21 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 300 kc. alignment.

**Band 2 (Model H-485) Band 3 (Model H-484) (Standard Broadcast)**

Connections are the same for the alignment of this band as they are for the Long-Wave Band.

Set the generator frequency to 1500 kc., and the ROTOR dial to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #8 for maximum reading of the output meter. (This trimmer is adjusted by moving the brass rod in or out, with a hooked wire, and with a twisting motion. First loosen the lock nut.) Then without touching any tuning controls adjust trimmers #9 and #10 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc. and accurately set the ROTOR dial to the 600 kc. mark. Then adjust trimmer #11 for maximum reading of the output meter. Do not move the tuning control while making this adjustment. Finally return and repeat the 1500 kc. adjustments and then tighten the lock nut on trimmers #8 and #9.

**Band 1 (Model H-485 Short-Wave)**

Remove the .0002 mfd. dummy antenna used in aligning the lower frequency bands and substitute the 400 ohm resistor.

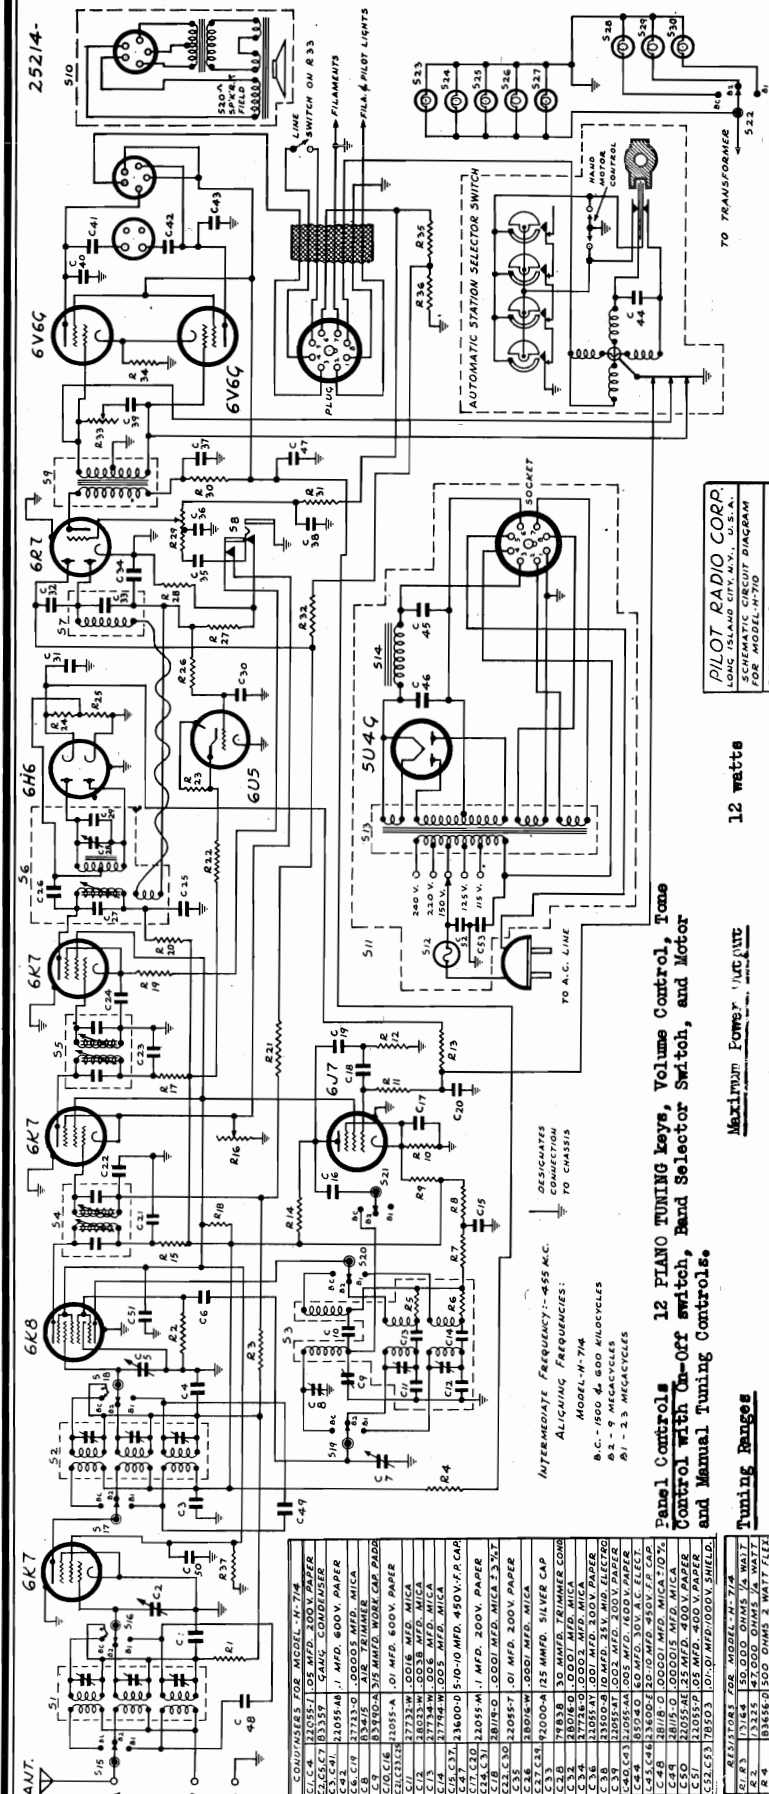

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator frequency to 17.6 kc. and also set the ROTOR dial to this frequency. Carefully adjust trimmer #12 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmers #13 and #14 for maximum output meter reading, while slightly "rocking" the gang condenser. Readjust trimmer #12 if necessary to keep the calibration correct. These are the only adjustments on this band.

- 6U4-G 2nd Detector-AFU-1st Audio Amplifier
- 6V6-G Power Supply Rectifier
- 6U5 Cathode Ray Tuning Beacon

Power Supply	Watts	Frequency
117.5	12	60 cycles
115, 125, 150, 220, 240*	90	60 cycles
Universal transformer	90	60 cycles

\* (Not supplied in the United States).

Super-Heterodyne, with push-pull output stage, and with Automatic Frequency Control of the oscillator on the Standard Broadcast Band. An R.F. stage is used on all bands. Iron Core, Permeability Tuned IF and Discriminator Transformers, which use, in addition, Silver-Mica Condensers. Continuously variable Tone Control, Tone Compensated Volume Control, Visible Indicators on all controls, Motor operated PLANO TUNING on the Broadcast Band. Manual Tuning is instantly available without extra switching. Motor Tuning, without the keys is also available on all bands. These receivers are supplied with a fuse in the power supply circuit, and a Jack is provided for plugging in a high impedance phonograph pick-up. There is also provision for an external speaker.

12 PLANO TUNING keys, Volume Control, Tone Control with On-Off switch, Band Selector Switch, and Motor and Manual Tuning Controls.

Maximum Power Output  
12 watts

MODEL H-710  
Socket, Trimmers  
Alignment

PILOT RADIO CORP.

25215-

**Receiver Alignment**

1. Signal Generator. One using fundamental frequencies for all the frequencies used in the receiver is preferred.
2. Output meter. Generally a copper-oxide rectifier meter is the most convenient.
3. Dummy Antennas. .1 mfd. condenser  
.0002 mfd. mica condenser  
400 ohm non-inductive resistor

**IF Amplifier Alignment.**

Turn the Band Selector Switch to Band 3 and turn the ROTOR dial to the low frequency end.

Connect the output meter as described under "Connections", and connect the "hot" post of the generator to the grid of the 6K8 tube through the .1 mfd. condenser. See that none of the PLANO KEYS is down. Then proceed with the alignment as follows:-

1. Adjust the Signal Generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.
2. Adjust the screws 1, 2, 4, 5, 6, and 7, (see figure) for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the IF amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the last IF amplifier tube, and then to the first IF amplifier tube, while aligning the transformers following these tubes. Always finish the alignment with the signal input to the 6K8 tube and, with this connection, readjust all screws in the IF amplifier, except the discriminator trimmer #3.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

If the receiver is placed in a noisy location when the above adjustments are being made, it may be convenient to reduce the sensitivity of the amplifier by means of the sensitivity control.

**Discriminator Alignment**

**CAUTION:** The discriminator compensator #3 has been accurately adjusted during manufacture. It will probably never need adjustment, even when tubes are replaced, and for these reasons should never be touched unless there is no doubt about its being out of adjustment, in which case, the following procedure should be followed carefully. The adjustment is quite critical and cannot be done correctly in a hasty manner.

1. Set compensator (3) at the minimum position. This is the setting when the screw slot is vertical and when the red half of the adjusting screw is at the left.
2. Tune the IF amplifier to 455 kc as described under "IF Amplifier Alignment".
3. With the signal generator connected to the grid of the 6K8 tube and with the output of the generator at a low value, note the reading of the output meter. Then very carefully turn compensator (3) until the output meter reading reaches a minimum value. That is the correct setting of this compensator.

It will be necessary to use a screw driver made from some insulating material in making this adjustment. If a metal tool is used, the adjustment will not be correct.

If the adjustment is not correctly made, the oscillator control tube will not function properly. It may even detune the oscillator instead of tuning it.

**R.F. Alignment.**

**Band 3 (Standard Broadcast)**

Connect the "hot" terminal of the generator to the post marked "A" on the rear of the chassis through the .0002 mfd. condenser.

Set the generator frequency to 1500 kc., and the ROTOR dial to the same frequency, with the Band Selector Switch set to Band 3. Adjust trimmer #6 for maximum reading of the output meter. (This trimmer is adjusted by drawing the brass rod up or pushing it down with a hooked wire, and with a twisting motion. First loosen the lock nut). Then, without touching the tuning controls, adjust trimmer #12 and trimmer #15 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc., and the ROTOR dial to approximately the same. Adjust trimmer #9 for maximum output reading while "rooking" the gang condenser. Then go back and repeat the 1500 kc. adjustment, and tighten the lock nut on trimmer #6.

**Band 2 (Short-Wave)**

Remove the .0002 mfd. dummy antenna used in aligning Band 3 and substitute the 400 ohm resistor.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator frequency to 9,000 kc. (9 mc.) and also set the ROTOR dial to this frequency. Carefully adjust the oscillator trimmer #10 for maximum reading of the output meter. Be very careful that this trimmer is not set on the Image Frequency.

After the oscillator is set, trimmers #13 and #16 are adjusted for greatest reading of the output meter, resetting trimmer #10 if necessary to keep the calibration correct.

The adjustments on this band are more critical than the similar ones on the lower frequency bands and must be more carefully made.

The above adjustments, at the high frequency end of the band, are the only ones to be made on this band.

**Band 1 (Short-Wave)**

Connections and dummy antenna are the same as on Band 2.

Set the generator, and the ROTOR dial to 23 mc. Adjust trimmer #11 for maximum reading of the output meter, when the lower frequency peak of the two which can be located coincides with the 23 mc. calibration point on the dial. Then adjust trimmers #14 and #17 while "rooking" the gang condenser, until the maximum reading is obtained on the output meter, resetting trimmer #11 if necessary to keep the calibration correct.

These are the only adjustments on this band.

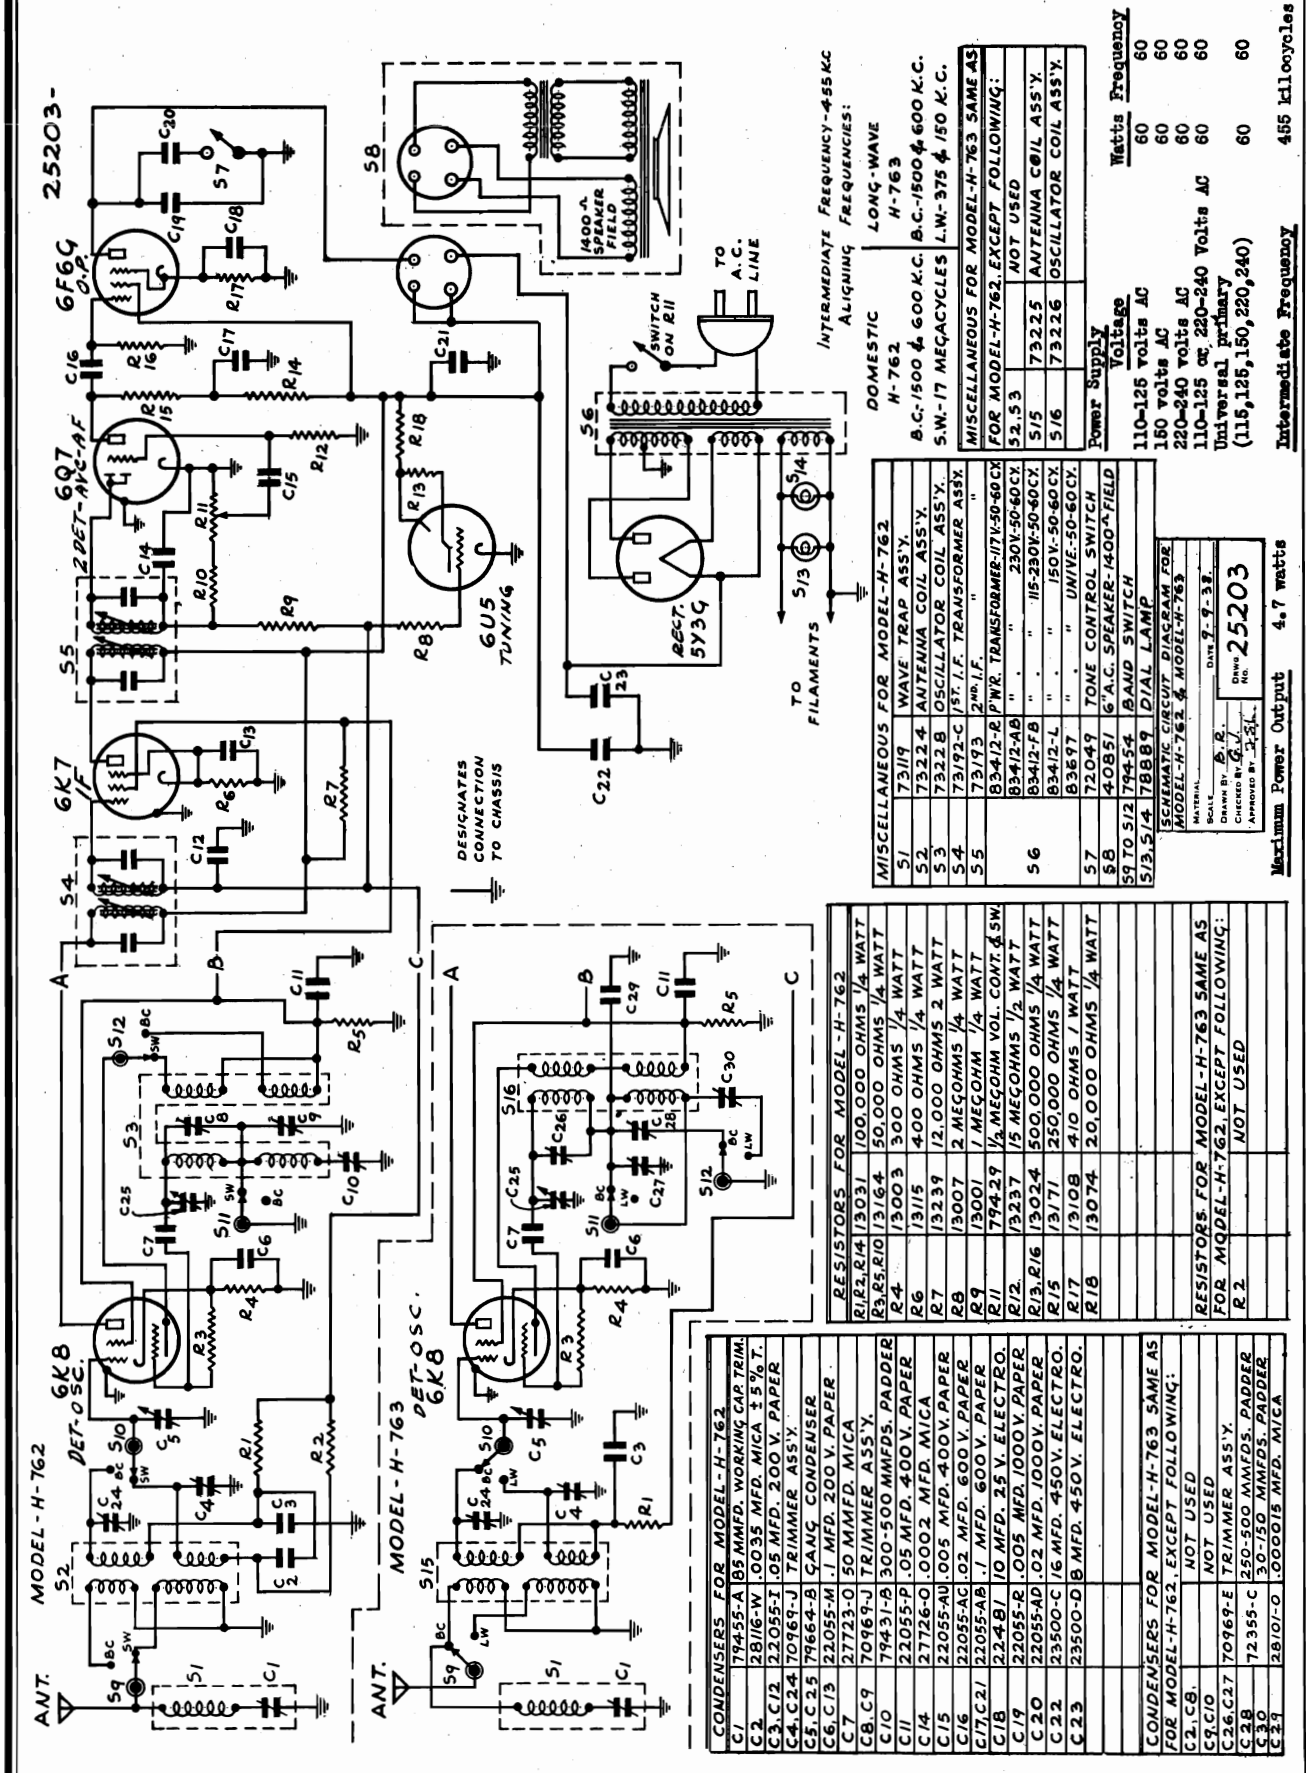

**Image Frequency**

All bands in this receiver, except Band 1 must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on Band 3. However, on the two high frequency bands it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the Image Frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, set the dial on Band 2 to that one which comes in at the higher frequency marking on the ROTOR dial. That is, on Band 2 the two frequencies which will be picked up when the generator is set at 9 mc., will be at 9 mc. and at 8 mc. on the ROTOR dial. Adjust the oscillator trimmer so that the 9 mc. frequency one coincides with 9 mc. on the dial. Exactly the reverse is true on Band 1.

Voltage, Socket, Trimmers  
Alignment

D.C. SOCKET VOLTAGES

Tube	Socket Terminals							
	1	2	3	4	5	6	7	8
6X8	-	-	240	95	-	95	-	2.8
6X7	-	-	240	95	3.5	-	-	3.3
6Q7	-	-	*105	-	-	-	-	1.4
6T6-G	-	-	225	245	-	-	-	16.
5Y3-G	-	-	-	-	-	-	340	340
6U5	Voltages at the prongs of this tube cannot be measured, however, if the tube is removed from the socket, the voltages on the various terminals may be measured. As all these measured voltages would be measured through a high resistance, except the Cathode which is grounded, none of them are noted here.							

\* Not true value, but as measured with voltmeter.

IF Amplifier Alignment

Turn the Band Selector Switch to the Broadcast, or Medium Wave Band, and tune the gang condenser to the low frequency end of the dial. That is the condenser plates completely emmeshed.

Connect the output meter as described under "Connections" and connect the "hot" post of the signal generator to the grid of the 6X8 tube through the .1 mfd condenser. Then proceed with the alignment as follows:

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.

2. Adjust the trimmer screws 1, 2, 3, and 4, (see Figure for maximum reading of the output meter. Keep reducing the generator output as the output meter reading increases. When the reading of the output meter cannot be increased by adjusting the four screws of the IF transformers, the IF amplifier is aligned.

If the output of the generator is too great, while aligning the receivers, the alignment will be incorrect. It is very important that this be kept in mind.

It will seldom, if ever, be found necessary to

more than touch up the alignment of the IF amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the IF amplifier tube, and then align the last IF amplifier transformer. Always finish the alignment of the IF amplifier with the signal input to the grid of the 6X8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

Wave Trap Alignment

With the Band Selector Switch set on the Broadcast, or Medium Wave, position connect the generator to the blue antenna wire with the .0002 mfd. condenser. Set the generator frequency to 455 kilocycles and adjust trimmer #5 for minimum reading of the output meter. There must always be sufficient output from the signal generator to have a reading on the output meter to make this adjustment.

R.F. ALIGNMENT

Long Wave Band (Model H-763). Connect the "hot" terminal of the generator to the blue antenna wire through the .0002 mfd. condenser.

Set the generator frequency to 375 kilocycles and with the Band Selector Switch set to the Long Wave Band turn the pointer of the receiver to 375 kilocycles. Adjust trimmer #8 for maximum reading of the output meter. Do likewise with trimmer #7. Then set the generator frequency to 150 kilocycles and the receiver dial pointer to approximately the same frequency. Adjust the screw of trimmer #10 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 375 kilocycle alignment.

Broadcast, or Medium Wave, Band (Models H-763 & H-762)

Connections are the same for the alignment of this band as they are for the Long Wave Band.

Set the generator frequency to 1500 kilocycles, and the receiver dial pointer to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #9 of Model H-763, or trimmer #8 of Model H-762 for maximum reading of the output meter. Also adjust trimmer #6 of Model H-763, or trimmer #7 of Model H-762 for maximum reading of the output meter. Next, set the generator frequency to 600 kilocycles. Then with the receiver dial pointer set at approximately the same frequency, adjust trimmer #10 for maximum reading of the output meter while carefully "rocking" the gang condenser. Finally return and repeat the 1500 kilocycle adjustment.

Short Wave Band (Model H-762)

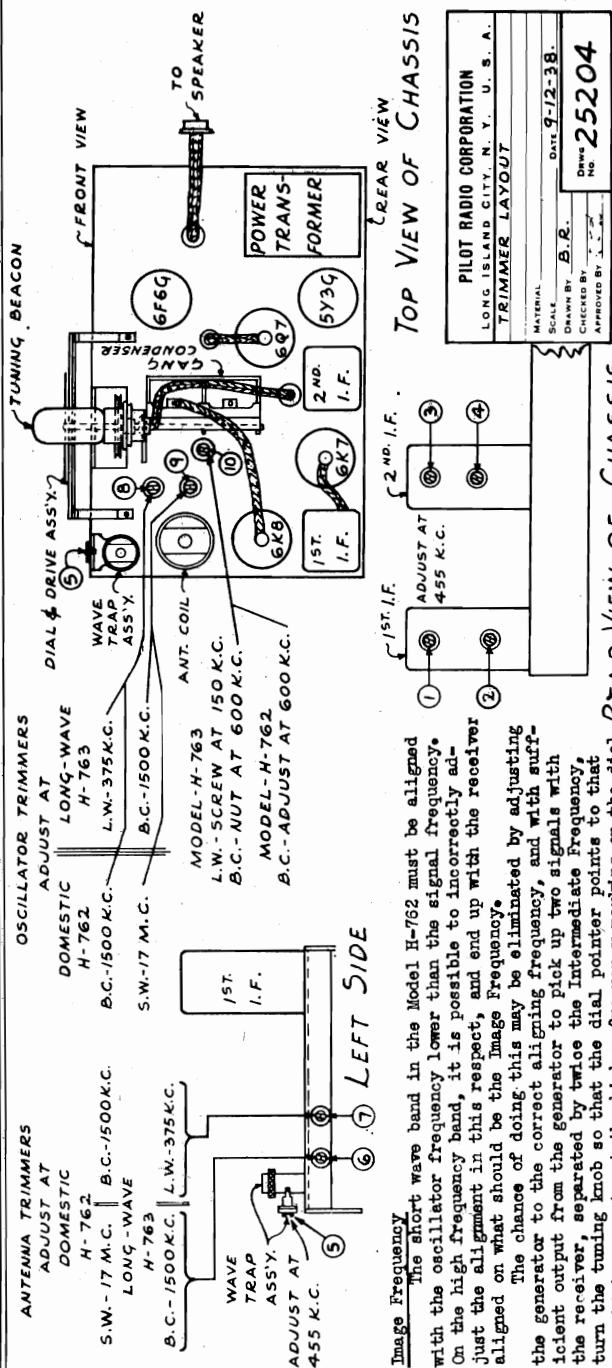

When aligning this band connect the "hot" terminal of the signal generator to the blue antenna wire of the receiver through the 400 ohm resistor.

Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 17 mc., and also the receiver to this frequency, as marked on the dial. Carefully adjust trimmer #9 for maximum reading of the output meter. Be careful you do not adjust to the Image Frequency.

Then adjust trimmer #6 for maximum output meter reading, while slightly "rocking" the gang condenser.

Adjust trimmer #9, if necessary, to keep the calibration correct.

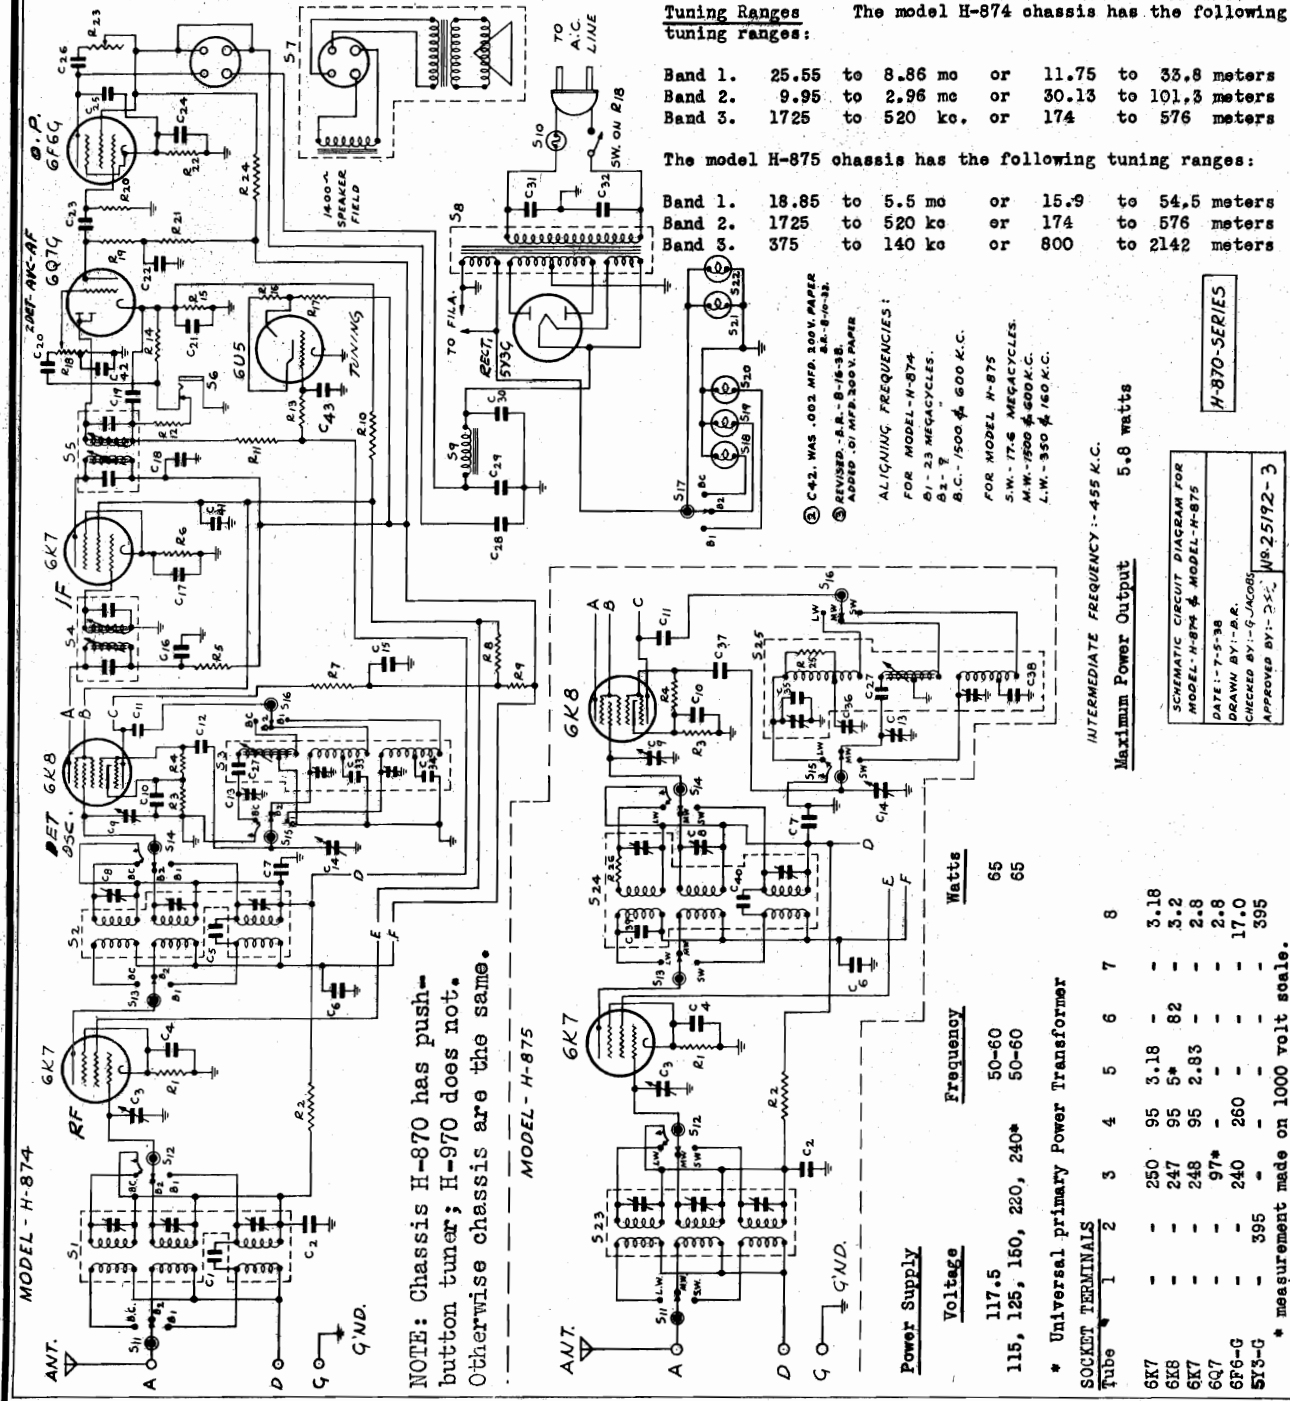

**Image Frequency**  
The short wave band in the Model H-762 must be aligned with the oscillator frequency lower than the signal frequency. On the high frequency band, it is possible to incorrectly adjust the alignment in this respect, and end up with the receiver aligned on what should be the Image Frequency. The chance of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, turn the tuning knob so that the dial pointer points to that one which comes in at the higher frequency marking on the dial.

Chassis H-870

PILOT RADIO CORP.

MODELS H-974, H-975  
Chassis H-970  
Alignment Procedure

PILOT RECEIVERS OF THE H-870 SERIES

SERVICE DATA

Removal of the chassis from the cabinet, when necessary, is done as follows:-

1. Remove the power supply cord from the supply outlet.
2. Remove the knobs and felt washers from all shafts on the front of the cabinet. These knobs, except the "locking" knob, are of the "push-on" type.
3. Remove the speaker cord from the socket on the speaker.
4. Remove the four mounting screws located under the cabinet, and carefully slide the chassis out of the cabinet.

Receiver Alignment

Equipment Required.

1. Signal Generator. One using fundamental frequencies for all the frequencies used in the receiver is preferred.
2. Output Meter. Generally a copper-oxide rectifier meter is the most convenient.
3. Dummy Antennas.
  - .1 mfd. condenser
  - .0002 mfd. mica condenser
  - 400 ohm, non-inductive resistor

Alignment Connections

The posts marked D and G on the rear of the chassis should be connected to the ground side of the signal generator.

Connect the "hot" post of the signal generator through the .1 mfd condenser to the grid of the 6K8 detector-oscillator tube or the 6K7 I.F. amplifier tubes when aligning the I.F. amplifier.

Connect the "hot" post of the signal generator through the 200 mmf condenser to the post marked A on the rear of the chassis when aligning the Long-Wave and Broadcast Bands. Use the same connections for both short-wave bands, but replace the 200 mmf condenser with the 400 ohm non-inductive resistor.

In all measurements connect the output meter, through .1 mfd 600 volt condensers, to the plate and screen terminals of the 6F6-G tube.

Procedure The volume and tone controls should all be turned to the extreme clockwise positions, before starting.

The location of all trimmers is shown in the accompanying figure. Always keep the output from the signal generator at the lowest value which will give a readable deflection on the output meter.

I.F. Amplifier Alignment Turn the Band Selector Switch to Band 3 and turn the ROTOR-DIAL to the low frequency end.

Connect the output meter as described under "Connections" of the output meter, while slightly "rocking" the gang condenser. Readjust trimmer #15 if necessary to correct the calibration as follows:-

1. Adjust the signal generator frequency to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.
2. Adjust the screws 1, 2, 3, and 4 (see figure), for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the I.F. amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the I.F. amplifier tube, and align the last I.F. transformer. Always finish the alignment with the signal input to the 6K8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

R.F. ALIGNMENT

Band 3. (model 875, Long-Wave) Connect the "hot" terminal of the generator to the blue wire and clip, through the .0002 mfd condenser.

Set the generator frequency to 350 kc., and with the Band Selector Switch set to Band 3 turn the ROTOR-DIAL to 350 kc. Adjust trimmer #5 for maximum reading of the output meter. Do likewise with trimmer #6 and #7. Then set the

generator frequency to 160 kc and the ROTOR-DIAL to approximately the same. Adjust trimmer #21 for maximum reading of the output meter, while "rocking" the gang condenser carefully back and forth. Then go back and repeat the 350 kc. alignment.

Band 2. (Model 875) Band 3. (Model 874) (Standard Broadcast)

Connections are the same for the alignment of this band as they are for the Long-Wave Band.

Set the generator frequency to 1500 kc., and the ROTOR-DIAL to the same frequency, with the Band Selector Switch set appropriately. Adjust trimmer #8 for maximum reading of the output meter. (This trimmer is adjusted by moving the brass rod in or out, with a hooked wire, and with a twisting motion. First loosen the lock nut.) Then without touching any tuning controls adjust trimmers #9 and #10 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc. and set the ROTOR-DIAL to the 600 kc. mark. Then adjust trimmer #11 for maximum reading of the output meter, while "rocking" the gang condenser. Finally return and repeat the 1500 kc. adjustments and then tighten the lock nut on trimmers #8 and #9.

Band 1. (Model 875 Short-Wave)

Remove the .0002 mfd dummy antenna used in aligning the lower frequency bands and substitute the 400 ohm resistor.

Before aligning this band refer to the paragraph head "Image Frequency".

Set the generator frequency to 17.6 mc and also set the ROTOR-DIAL to this frequency. Carefully adjust trimmer #12 for maximum reading of the output meter. Be careful you do not tune in at the image frequency.

Then adjust trimmers #13 and #14 for maximum output meter reading, while slightly "rocking" the gang condenser. Readjust trimmer #12 if necessary to keep the calibration correct. These are the only adjustments on this band.

Band 2. (Model 874 Short-Wave)

Connections and dummy antenna same as on Band 1 above.

Before aligning this band refer to the paragraph head "Image Frequency".

Set the generator, and the ROTOR-DIAL to 9 mc. Adjust trimmer #15 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmers #16 and #17 for maximum reading of the output meter, while slightly "rocking" the gang condenser. Readjust trimmer #15 if necessary to correct the calibration.

Band 1. Alignment (Model 874 Short-Wave)

Connections and dummy antenna are the same as on Band 2 of Model 874.

Before aligning this band, refer to the paragraph head "Image Frequency".

Set the generator frequency to 23 mc and the ROTOR-DIAL to 23 mc. Adjust trimmer #18 to 23 mc for maximum reading of the output meter. Be careful that the receiver is not adjusted to the Image Frequency. Then adjust trimmers #19 and #20 while "rocking" the gang condenser, for maximum reading of the output meter. Reset trimmer #18 so that calibration is correct if necessary.

Image Frequency

All bands in these two models must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on the Long-Wave and Broadcast Bands. However, on the higher frequency bands it is possible to incorrectly adjust the alignment in this respect and end up with the receiver aligned on what should be the Image Frequency.

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency, and with sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, set the ROTOR-DIAL to that one which comes in at the higher frequency marking on the ROTOR-DIAL.

  - 2nd Detector
  - A.F. Amplifier
  - Output Tube
  - Power Supply Rectifier

The howl can also be caused by a defective tube, or when some part of the receiver which is rigidly fastened to the chassis rubs against the cabinet. If the vibrator noise becomes loud or objectional, it is probably because the battery connections are not clean, or because the battery is old and its internal resistance is high, or because the vibrator is wearing out.

**Miscellaneous Service Notes**  
(MODEL H-6204)

If a howling noise (sometimes referred to as Microphonic howl) is heard, it is probably because the four red screws under the cabinet and the two narrow metal strips between the chassis and the bottom of the cabinet, have not been removed. These strips and screws are only intended as additional bracing during shipment and must be removed before the receiver is put in operation.

**I.F. Alignment**

Turn the Band Selector Switch to the Broadcast Band and tune the receiver to the low frequency end of the Band.

Connect the output meter as described under "Connections", and connect the "hot" post of the signal generator to the grid of the 6K8 tube through the .1 mfd. condenser. Then proceed with the alignment as follows:-

1. Adjust the signal generator to 455 kilocycles, and adjust the generator output to the lowest value which will give a readable signal on the output meter.
2. Adjust the trimmer screws #1, 2, 3 and 4 (see figure), for maximum reading of the output meter. Keep reducing the output from the generator if the output meter reading increases too much.

If the output of the generator to the receiver is too great, the alignment of the receiver will not be correct, as the AVC action will become too great, and the amplifier will appear broad in tuning.

It will seldom, if ever, be found necessary to more than touch up the alignment of the I.F. Amplifier. Of course, if the amplifier adjustment screws have been tampered with, it will probably be necessary to completely realign the amplifier. In this case, connect the generator to the grid of the 6S7-G I.F. tube, and align the last I.F. transformer. Always finish the alignment with the signal input to the 6K8 tube.

A cathode ray oscilloscope is not necessary in making the above adjustments. One may be used, however, if desired.

**R.F. ALIGNMENT**  
**Standard Broadcast Band**

Connect the "hot" terminal of the generator to the post marked "A" on the rear of the chassis, through the .0002 mfd. condenser.

Set the generator frequency to 1500 kc., and the dial pointer of the receiver to the same frequency with the Band Selector Switch set appropriately. Adjust trimmer #5 for maximum reading of the output meter. Loosen the lock nut and adjust trimmer by moving the brass rod in or out with a hooked wire, and with a twisting motion. Then without touching the tuning controls adjust trimmers #6 and #12 for maximum reading of the output meter.

Next, set the generator frequency to 600 kc., and move the receiver pointer to the same frequency. Adjust trimmer screw #7 for maximum reading of the output meter, while "rocking" the gang condenser. Finally, repeat the 1500 kc. adjustments, and tighten the lock nuts on trimmers #5 and #6.

**Band #2**

Remove the .0002 mfd. dummy antenna used in aligning the Broadcast Band and substitute the 400 ohm non-inductive resistor in its place.

Before aligning this band refer to the paragraph headed "Image Frequency".

Set the generator frequency to 9 mc. and the receiver dial pointer to the same frequency with the Band Selector Switch set appropriately. Adjust trimmer #8 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency.

Then adjust trimmer #10 for maximum output meter reading, while slightly "rocking" the gang condenser. Readjust trimmer #8 if necessary to correct the calibration, and finally adjust trimmer #13 for maximum output meter reading.

**Band #1**

The connections and Dummy Antenna are the same as used in aligning Band #2.

Before aligning this band, refer to the paragraph headed "Image Frequency".

Set the generator frequency to 23 mc. and the receiver dial pointer to the same frequency. Adjust trimmer #9 for maximum reading of the output meter. Be careful you do not tune in at the Image Frequency. Then adjust trimmer #11, while "rocking" the gang condenser, for maximum reading of the output meter. Readjust trimmer #9, if necessary, to correct the calibration, and then adjust trimmer #14 for maximum reading of the output meter.

**Image Frequency**

All bands in this receiver must be aligned with the oscillator frequency higher than the signal frequency. There can be no error in doing this on the Broadcast Band. However, on the higher frequency bands it is possible to incorrectly adjust the alignment in this respect and end up with the receiver aligned on what should be the Image Frequency.

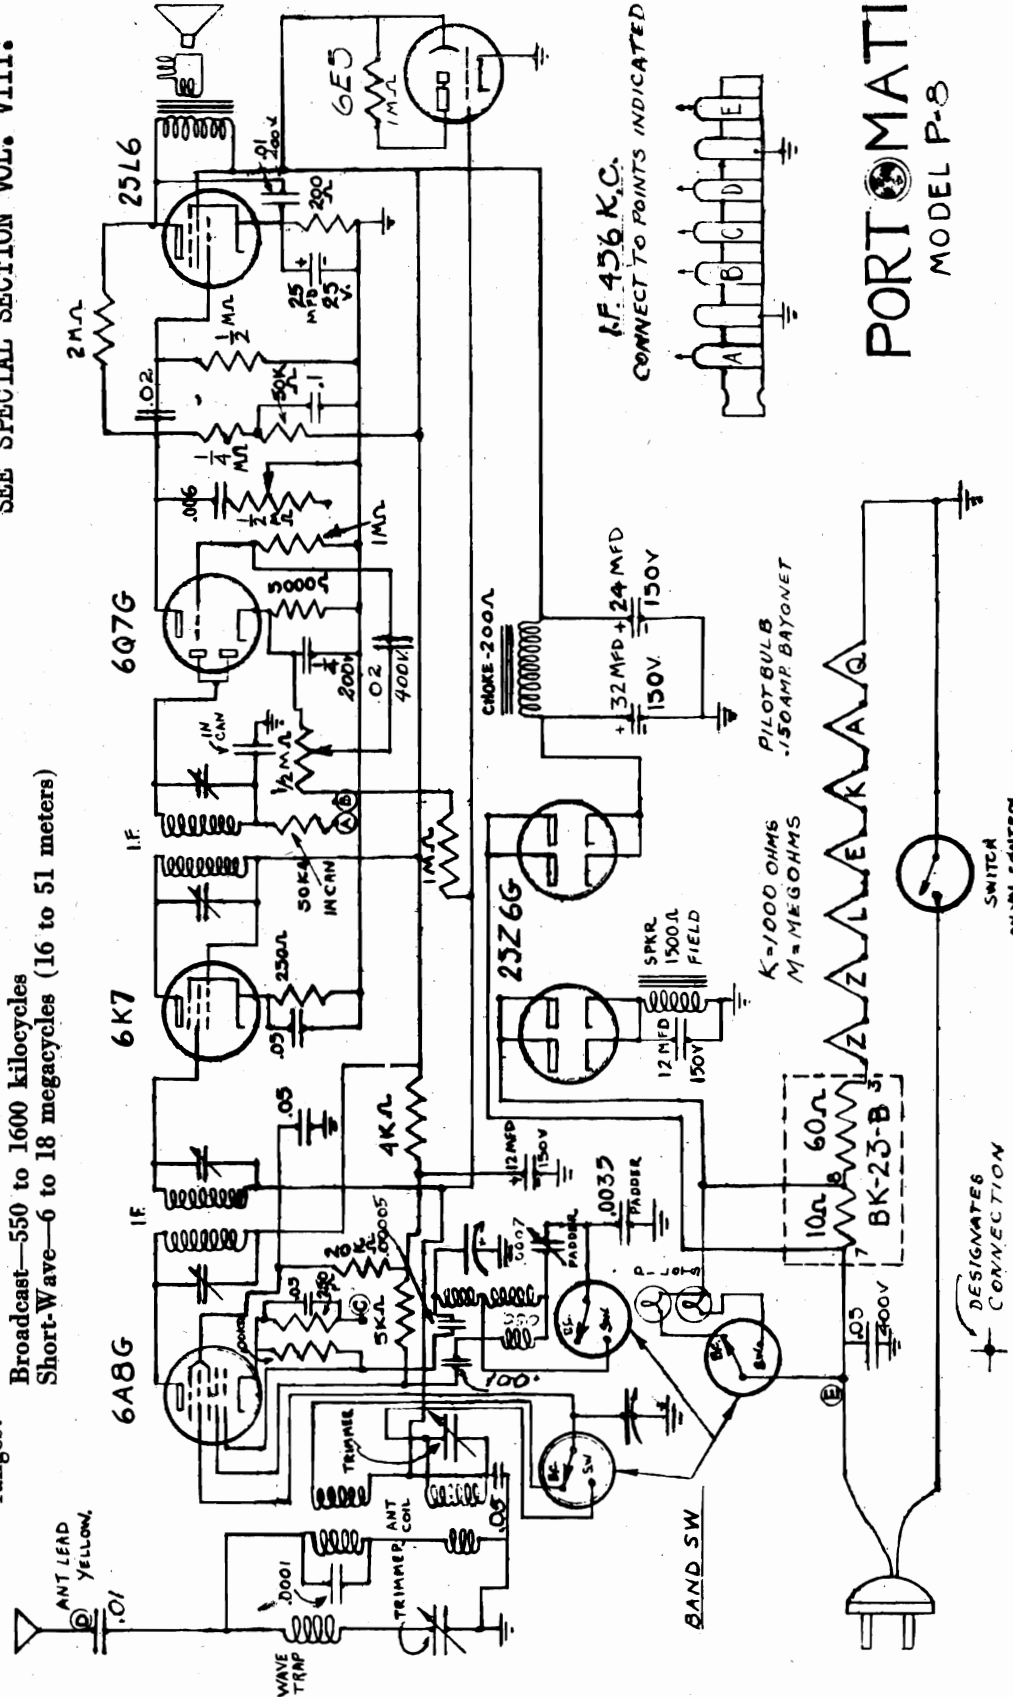

The chances of doing this may be eliminated by adjusting the generator to the correct aligning frequency. With sufficient output from the generator to pick up two signals with the receiver, separated by twice the Intermediate Frequency, set the receiver dial pointer to that one which comes in at the higher frequency marking on the receiver dial calibration.

AC or DC Current  
40-60 Cycles  
65 Watts

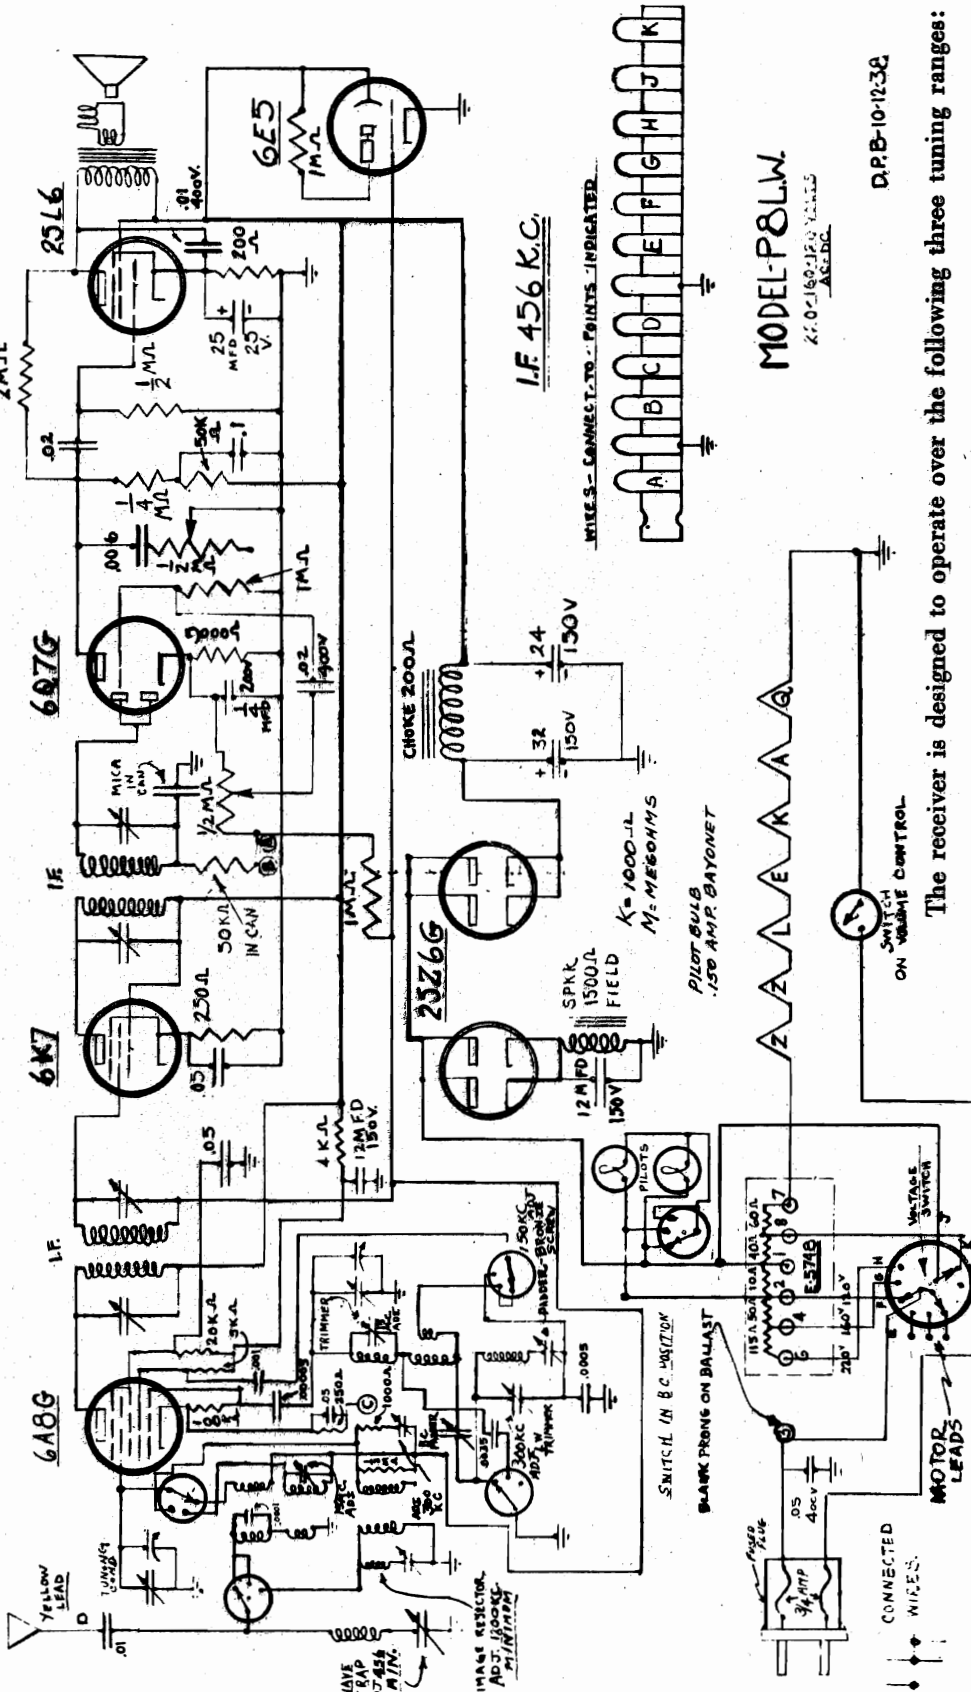

**EUROPEAN MODEL**—A special switch is provided on the motor-plated indicated underneath the pick-up arm, and is marked "110-220." With this switch in 220 Volt position, the PORT-O-MATIC will operate safely on voltages from 200 to 250. To avoid damage, if switch is accidentally placed in wrong position, this particular model is equipped with a fused plug at the end of the electric cord. Should these fuses blow, replace same with no higher than 3/4 to 1 amp. standard automobile cartridge fuses.

### Operation Model TRK-5

The power-volume control on the broadcast radio receiver turns on the power for the complete receiver. Pushing the button marked "Television" on the push button panel turns on the Television receiver, if the above power control is "On." The volume control of the broadcast receiver also controls the Television sound volume level.

**Station Selector and Fine Tuning.**—The outer ring "O" section of the central dual control knob on the Television panel selects the station from which it is desired to receive television transmission.

Five television channels are covered as follows:

- (1) 84 to 90 M.C.
- (2) 78 to 84 M.C.
- (3) 66 to 72 M.C.
- (4) 50 to 56 M.C.
- (5) 44 to 50 M.C.

Set the station selector to the number corresponding to the frequency of the station from which it is desired to receive Television Broadcasts.

The inner section "I" of this knob is used for fine tuning and may eliminate moving ripples or distortion if due to interfering radio signals. A slight inward pressure must be exerted on the knob while turning.

Before the Television portion of the receiver is turned "ON" it is advisable to turn the Brightness and Contrast controls completely counter-clockwise to reduce the illumination of the spot which appears on the Kinescope before the sweep circuits have started functioning.

**Contrast and Brightness Controls.**—The inner "I" section of the "Contrast" "Brightness" controls is the "Contrast" control and varies the black and white tones of the picture being received. Too little contrast makes the picture all half-tones or grays. Turning clockwise increases contrast from grays, to black and white. See Test Patterns Figs. 2, 4, and 5, Page 10-21.

The outer ring "O" is the Brightness Control and affects the average illumination of the picture. Turning clockwise increases the brightness. See test pattern Figs. 2, 4, 5.

**Hold Controls.**—The dual knobs on the Television panel marked "Horizontal" and "Vertical" Hold, control the picture stability. The inner section designated by a "I" is the Horizontal Hold Control and when being set should be turned slowly to the point at which the picture "locks in" horizontally. See test pattern Fig. 6, Page 10-21.

The outer ring section designated by "O" is the Vertical Hold Control and when being set should be turned to the point where the picture "locks in" vertically. Pattern Fig. 7.

These two controls on this dual knob should not ordinarily require readjustment after good picture reception has once been obtained. An occasional resetting may be necessary due to changing to a different station, and to the gradual ageing of the tubes.

**Focus Control.**—This control is located on the rear of the Video chassis, and controls the electron beam focus of the Kinescope. Ordinarily, after once being focused the Kinescope should not require re-focusing for a considerable length of time. See test pattern Fig. 3.

Figure 1—Control Panel Model TRK-5

### Operation Model TT-5

The operation of Model TT-5 is the same as that for the Model TRK-5 except that there is a separate "ON-OFF" switch, and a separate sound volume control because the broadcast radio receiver is not included in this model. When Model TT-5 is connected to a broadcast receiver for the Television sound reproduction, the broadcast receiver volume control should be turned to maximum and the Television sound volume controlled with the control on the Television Receiver.

Figure 2—Control Panel Model TT-5

### SERVICE DATA

Figure 3—Kinescope Installation

Kinescope Installation Models TRK-5, TT-5: Refer to figure 3.

1. Remove back cover from cabinet.
2. Remove Kinescope mounting shield from shipping carton.
3. Using gloves and goggles remove Kinescope from shipping carton and place in the cone-shaped mounting shield.
4. Guide the Kinescope and mounting shield carefully into the cabinet, placing the Kinescope firmly up against the mask and viewing window. Fasten the mounting shield firmly in place with the thumb screw provided, so that it holds the Kinescope firmly against the mask. If the Kinescope does not line up properly with the mask, loosen the screws "A" and nut "B" and adjust in the direction desired.
5. After the receiver is operating, the Kinescope may be rotated to properly square up the picture with the mask.

**CAUTION:** When rotating tube the power should be turned "OFF."

**Adjustments.**—There are a series of screwdriver slot adjustments at the rear of the Video chassis used to obtain the proper picture size and centering. These adjustments are explained fully in the receiver operating instructions, and also in the booklet: *Practical Television* by RCA.

When the receiver is moved from one location to another, some readjustment of these controls may be necessary.

Voltage

RCA MFG. CO., INC.

### Antenna Installation:

In most cases, the antenna should not be installed permanently on the apartment or residence roof until the quality of the picture reception has been observed on a Television Receiver. A temporary transmission line can be run between receiver and the antenna allowing sufficient slack to permit moving the antenna. Then, with a telephone system connecting an observer at the receiver and an assistant on the roof to find an antenna location, the antenna can be positioned to give the most satisfactory results on the received signal. A shift of only a few feet in antenna position or direction may effect a tremendous difference in picture reception. Whenever possible, the antenna location should be chosen or erected so the antenna is not only broadside to the transmitter but removed as far as possible from highways, hospitals and doctors' offices, and similar sources of interference. Auto ignition and diathermy apparatus may cause noise interference which spoils the picture.

In mounting any antenna, care must be taken to keep the antenna rods or pickup wires proper at least 1/4 wave length (at least 6 feet) away from other antennas, metal roofs and gutters or metal objects.

Under certain extremely unusual conditions, it may be possible to rotate or position the antenna so it receives the

cleanest picture over a reflected path. If such is the case, the antenna should be so positioned. However, such a position may give variable results as the nature of reflecting surfaces may vary with weather conditions, as a wet surface has been known to have different reflecting characteristics than a dry surface.

In short, a television receiving antenna and its installation must conform to much higher standards than an antenna for reception of International Short Wave and Standard Broadcast signals because:

(1) Intervening obstacles have a pronounced shielding effect on the ultra-high frequency waves producing low intensity signals. Severe trouble with multi-path transmissions may be experienced, especially in congested city areas.

(2) The picture signal is comprised of a very wide band or range of frequencies, all of which must be received with good efficiency.

(3) It must be continually remembered that the discernment of the eye is much more critical than that of the ear.

### The Transmission Line

RCA Victor has made available two types of exterior transmission lines. One is a special low loss weather-proofed line having the correct surge impedance to match the RCA Victor Television antennas and the RCA Victor Television receivers. It is carried as Stock No. 9882 in 1,000 foot rolls. The second type is a standard weather-proofed line also having the correct surge impedance for proper antenna and receiver matching. It is carried as Stock No. 12430 in 90 ft. rolls, Stock No. 12429 in 40 ft. rolls and is available in

1,000 ft. spools as Stock No. 9881. Use of improper lines may result in excessive loss or may lead to line reflections, resulting in multiple images or "ghosts," thus marring the reception.

For transmission line runs up to 200 feet, and where the signal strength on the antenna is relatively high, the Stock No. 12430, or Stock No. 12429 transmission line may be used. For all other applications the Stock No. 9882 transmission line is recommended.

Video Chassis KC-3 (TT-5)  
KC-3A (TRK-5)

No attempt should ever be made to measure the high (2,000 volts) voltage, because of the dangers and difficulties involved. If at any time it becomes necessary to service the high voltage circuit, the suspected parts should be replaced by parts known to be in good operating condition.

Always replace the red can over the 879 high voltage rectifier.

The most dangerous portion of the receiver is the plate (top cap) lead for the 879 high voltage rectifier. Always be very careful when working near or with this lead.

When working on the high voltage supply portion of this chassis, the following precautions should be observed:

1. Remove power supply cord from the power supply socket.
2. Use only one hand at a time.
3. Connect a shorting lead between ground (firstly) and to the high voltage side.
4. Whenever working with the oil-filled high voltage filter capacitors, keep a constant short across the capacitor, as these capacitors do not completely lose their charge after being discharged a single or several subsequent times.
5. Only one person at a time should work on the unit to prevent any misunderstanding which may result in an accident.

When any changes are made on the Video portion of the chassis, the locations of leads and parts should be returned as closely as possible to their original positions.

Service Hints:

1. In some cases the horizontal sweep oscillator circuit will radiate energy to nearby broadcast receiving antennas and lead-ins, causing interference with standard broadcast receivers. It has been found that this trouble has been cleared up in some cases by use of an RCA "Magic Wave" antenna for the broadcast receiver receiving the interference.
2. If the picture "tears out" when the receiver is jarred it may be due to microphonic 1852, 1853, or 6J5 tubes.
3. The 6J5 oscillator tube should be removed without rocking it in its socket to loosen it, as the motion may cause the 80.5 mmf capacitor C16 to break off.
4. The coils or straps in the h.f. oscillator circuits should not be touched or moved or the alignment of the receiver will be disturbed.
5. The two Video coupling capacitors C44, 45, should be kept clear of chassis.
6. In some cases the metal Kinescope mounting shield may become magnetized by the earth's or some nearby magnetic field, and thus distort the picture on the screen towards the magnetized portion of the shield. The shield can be demagnetized by passing it slowly through a solenoid which is energized by an a.c. current.

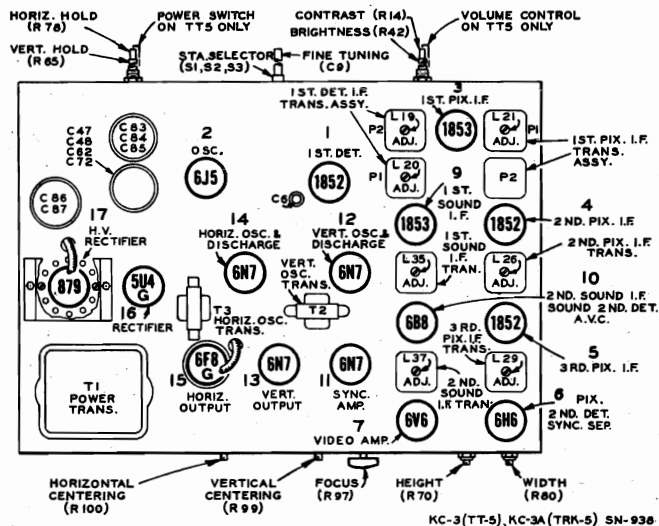

Figure 5—Top View Television Chassis

Figure 6—Rear View Model TRK-5

Antenna

The finest television receiver built may be said to be only as good as the antenna design and installation. It is therefore important to use a correctly designed antenna, and use care in its installation.

The RCA Double Dipole Antenna, Stock No. 9871, is recommended for use with these receivers. Both this antenna and the "V" antenna described below are especially designed for a sufficient broad frequency response to cover the contemplated television spectrum, with good efficiency and are therefore superior to a single Dipole type antenna.

When greater signal pickup, or where a shielding effect from noise pickup or image reflections are desired, a reflector assembly Stock No. 9872 may be added to the Stock No. 9871 Antenna to obtain an improved signal-to-noise ratio.

The RCA Double "V" Wire type Television Antenna is alternative type of antenna designed for television sight and sound reception. Two points of support are necessary. It serves adequately in suburban areas but may not be sufficiently flexible and efficient for congested city areas where bad reflections and interference are encountered.

### General Description

Radio receiver chassis No. RC-429 is used in RCA Victor Television console Model TRK-5.  
The audio output of the television chassis is connected to the audio input of the RC-429 chassis by means of jack X-8 and the left-hand push-button switch (S44, S45, S46).  
A separate plug-in power supply unit, RS-89A, is used to supply heater and plate voltage to the RC-427 chassis. Service data and diagrams for the power unit are contained in the following pages.

Location of Controls (Radio)

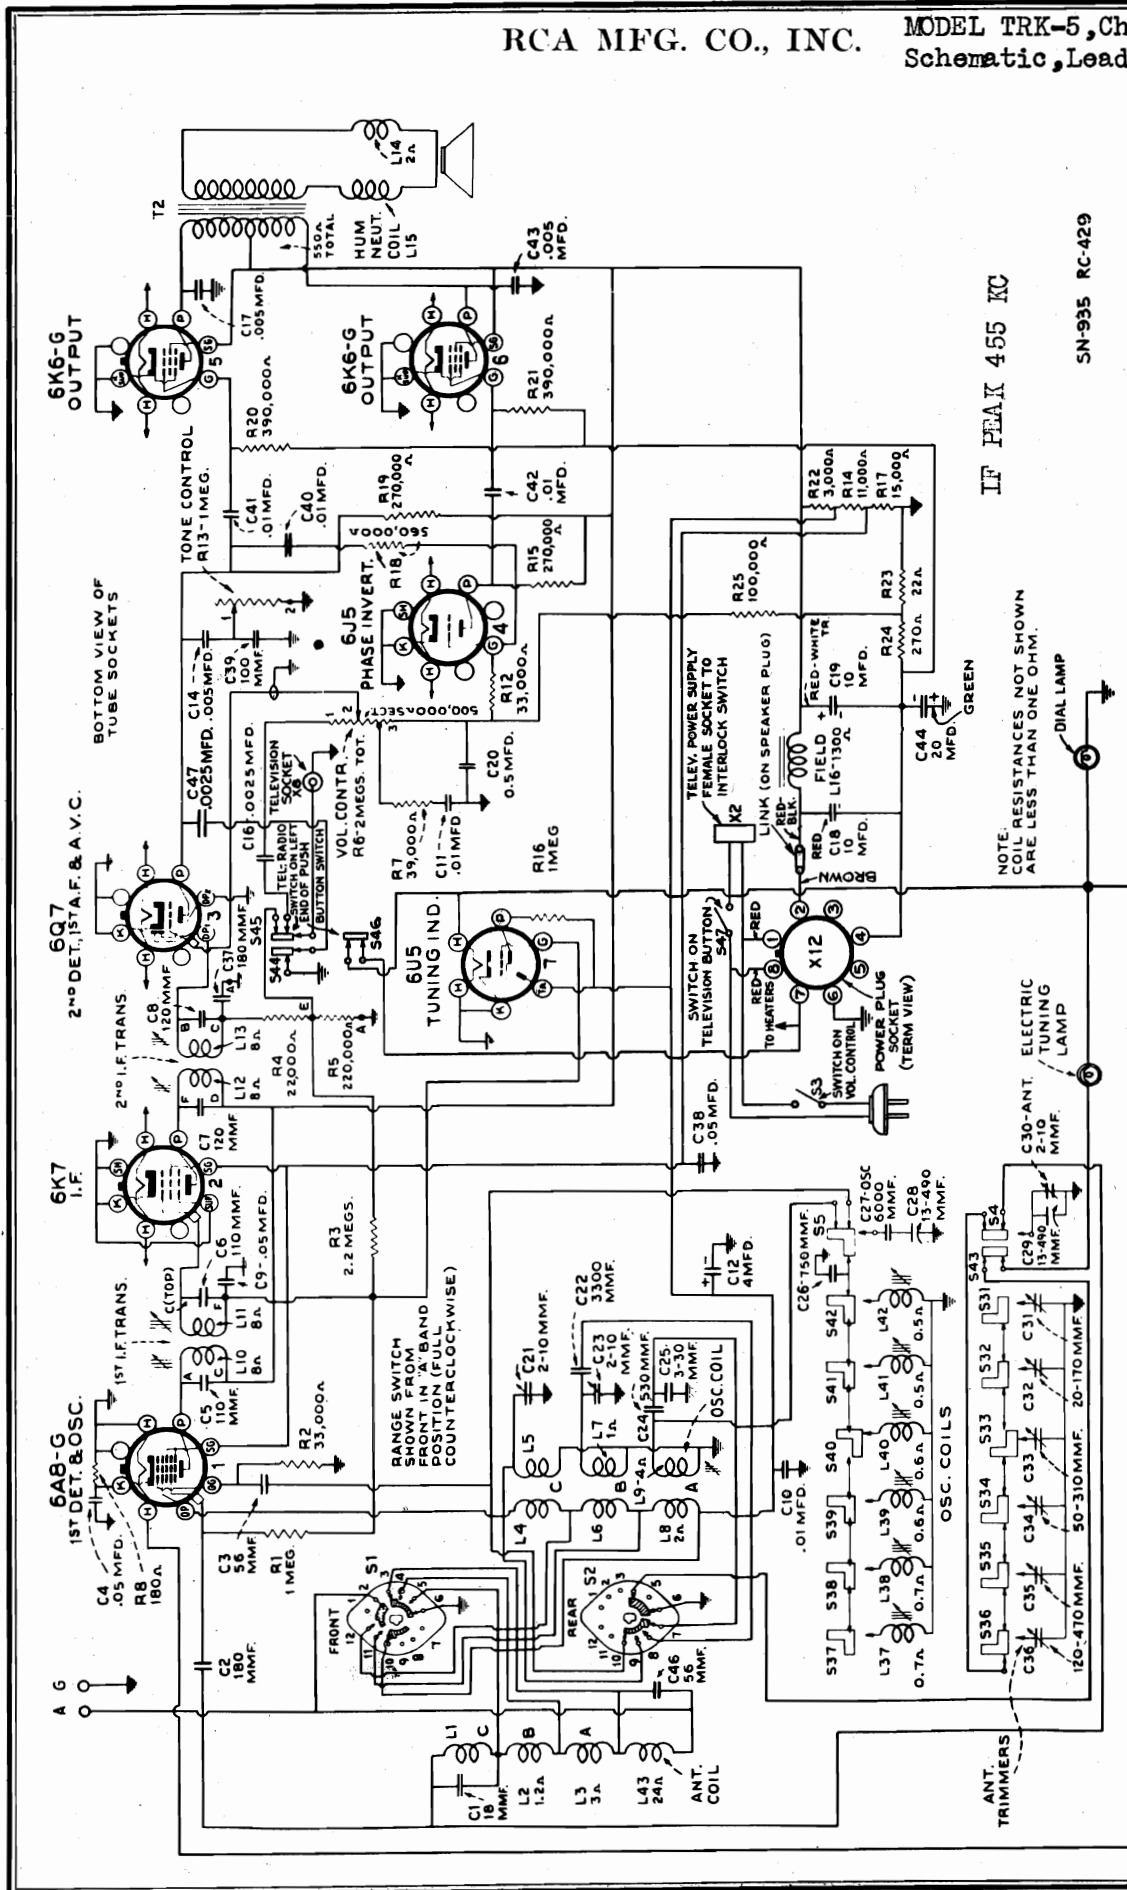

Reduced Reproduction of Receiver Dial, and Corresponding 0-180° Calibration Scales

The corresponding position of the dial indicator for any setting of the calibration scale can be determined by drawing a line from this point on the bottom calibration scale to the same point on the top calibration scale. For example, 28° on the calibration scale corresponds to 1,500 kc on "A" band. Read instructions under "Alignment Procedure."

**Precautionary Lead Dress:**

1. Electric tuning lamp leads to S43 must be dressed in front of the range switch.
2. Dress leads away from antenna coil.

3. Leads across back of chassis must be dressed away from television jack (X8).
4. C26 (750 mmfd.) on push-button switch assembly must be dressed carefully to prevent shorts.

MODEL TRK-5, Chassis RC-429  
 Socket, Trimmers, Tuner  
 Alignment

RCA MFG. CO., INC.

## Alignment Procedure (RADIO CHASSIS)

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver ground terminal (G), and keep the output as low as possible to avoid a-v-c action.

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial if fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed 3/8-inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-

condenser frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Step	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6A8-G 1st-Det. grid cap, in series with .01 mfd.			L10 and L11 (1st I-F Trans.)
3	Antenna terminal, in series with 200 mmfd.	600 kc	600 kc 150.5°	L9 (osc.)
4		1,500 kc	1,500 kc 28°	C25 (osc.) C30 (ant.)
5	Repeat steps 3 and 4.			
6	Antenna terminal, in series with 300 ohms	6 mc	6 mc 26.5°	C23 (osc.)*
7		20 mc	20 mc 22°	C21 (osc.)*
8	Follow "Adjustments for Electric Tuning."			

\* Use minimum capacity peak if two peaks can be obtained, and check for image by tuning radio approximately 910 kc lower.  
 Note: The oscillator tracks above the signal on all bands.

## Adjustments for Electric Tuning

These models have eight push buttons. The left-hand button is a Television switch. The right-hand button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

The procedure is as follows:

1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.

3. Push in station button No. 1 (second from left) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

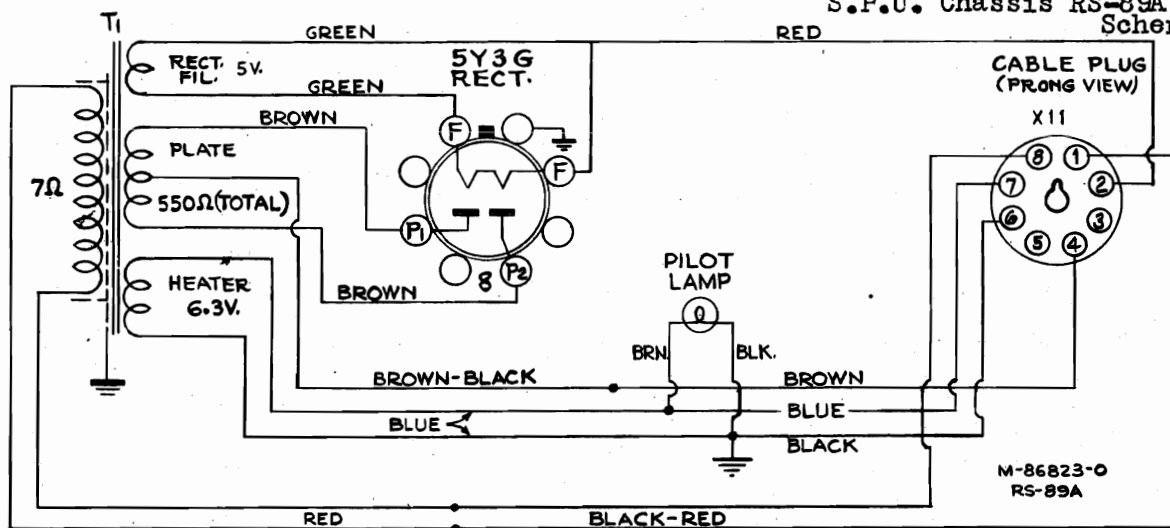

Clockwise adjustment of cores and trimmers tunes the circuits to lower frequencies.

5. Adjust for each of the remaining five stations in the same manner.
6. Make a final careful adjustment of the oscillator cores and antenna trimmers. Use the "Magic Eye" to ensure sharp peaking.

Chassis Wiring

2. Use only one hand at a time. It is advisable to keep the other hand in one's pocket.
3. Connect a shorting lead between ground (first) and the high voltage side of C-114.
4. Whenever working with the oil-filled capacitors, keep a constant short across the capacitor, as these capacitors do not completely lose their charge after being discharged a single or several subsequent times.
5. Only one person at a time should work on the unit to prevent any misunderstanding which may result in an accident.

**Socket Power Units KK7, KK7A**  
These precautions should be observed when any work on the SPU is being done:

1. Remove power supply cord from the power supply socket. S\*33244

No attempt should ever be made to measure the high (7,500 volts) voltage because of the difficulties and dangers involved. If, at any time it becomes necessary to service the SPU, the suspected parts should be replaced by parts known to be in good operating condition.

1. Remove power supply cord from the power supply socket. S\*33244

**CAUTION**  
DISCONNECT BOTH OF THESE LEADS, AND CONNECT THE TERMINAL OF C114 TO GROUND BEFORE MAKING ANY VOLTAGE MEASUREMENTS EITHER ON THIS CHASSIS, OR THE TELEVISION CHASSIS

MODELS TRK-9, TRK-12  
Operating Data

RCA MFG. CO., INC.

1. Turn the Fidelity-Selector Control on the radio panel to "Television," fully clockwise.
2. Turn Power-Volume Control on radio panel clockwise and advance about half way.
3. Set the Station Selector on the Television panel to the desired television station 1-2-3-4 or 5.
4. Turn the Contrast Control fully counterclockwise and then turn Brightness Control slowly until illumination of the screen almost disappears. Advance the Contrast Control until the picture appears at its best as viewed in the mirror on the lid. The Contrast Control turned too far clockwise causes blurring. Make final adjustment for best picture by adjusting both the Contrast and Brightness Controls.
5. The illustrations shown in Figures 2, 4 and 5 give an idea of the effect of the Brightness and Contrast Controls. Incorrect setting has effects somewhat similar to under and over exposure on photographic prints.
6. If the picture is not steady, the "Hold" controls will require slight readjustment. If the picture is moving sideways the Horizontal Hold (inner "H" section of the knob) requires readjustment. If the picture is moving up or down or is off position, then the outer ring "O" of the knob, Vertical Hold Control, requires readjustment. See Figures 6 and 7.
7. Adjust the Volume Control and the Tone Control (Fidelity-Selector knob) for best sound reception.
8. If an interfering ripple is observed in the picture, adjustment of the Fine Tuning knob may reduce or eliminate the distortion.
9. If the picture appears out of focus, carefully turning the Focusing Control knob on the back of the cabinet will remedy the condition.

As long as the Television Receiver is not moved in any way, only an occasional setting of the other controls will be required.

A spot in the center and also a slight discoloration of the television screen may occasionally appear as the Kinescope ages. This is normal and in no way affects good picture reproduction.

Television Fixed Controls

1. Horizontal Centering.—This is a screwdriver adjustment at the top of the horizontally on the Kinescope screen and is made at the time of installation of the receiver. It may require resetting due primarily to the earth's magnetic field, if the receiver location is changed, the cabinet turned around, or the Kinescope replaced. Figure 8 shows the effect of incorrect setting of this control.
2. Width.—The next screwdriver control determines the width of the picture and is adjusted when the receiver is installed. Further adjustment may occasionally be required in order to compensate for the gradual reduction in horizontal deflection with tube life. See Figure 10.
3. Vertical Linearity.—The third control is adjusted in conjunction with the Height Control, No. 4, to give the correct vertical proportions to the picture. It may require readjustment due to changing of the Height Control and due to the gradual ageing of the tubes. See Figures 12 and 13. If the picture fills the frame but is crowded near the top, turn Vertical Linearity Control clockwise and Height Control counterclockwise. If crowded towards the bottom, turn these two controls in the reverse directions.
4. Height.—The fourth control determines the height of the picture and is adjusted in conjunction with Vertical Linearity when the receiver is installed. Further adjustment will occasionally be necessary in tube life. See Figure 11.
5. Vertical Centering.—The screwdriver adjustment at the bottom of the row serves to center the picture vertically on the Kinescope screen and is made at the time of installation. It will require resetting whenever the receiver location is changed, the cabinet turned around, or the Kinescope replaced. See Figure 9.

Figure 15—Fixed Television Controls

- (1) Fully counterclockwise modifies tone, reducing surface noise on old recordings and emphasizing low tones.
- (2) The middle Victrola point minimizes bass response, thus emphasizing higher tones.
- (3) The next point in a clockwise direction sets the instrument for full tone phonograph reproduction.

The position, marked "Radio," sets the instrument for Radio reception and provides four variations of radio tone control. Turning clockwise these are:

- (1) Reduction of static and circuit hiss, and emphasis on low tones.
- (2) Speech point with a modification of low tones.
- (3) Full tone reception for normal reproductions.
- (4) High Fidelity reception for special musical programs giving all the tone values possible.

The position marked "Television" sets the instrument for Television reception. The first and second points, give modified tones as for "Victrola" position, points (1) and (2), and the third point (3) gives full tone reception.

**Horizontal and Vertical Hold Controls.**—The dual knob at the back of the panel on the right controls the picture stability. The inner section designated by a "H" is the Horizontal Hold Control and when being set should be turned slowly to the point at which the picture "locks in" horizontally. Figure 6 shows the effect of incorrect setting of the control. The outer ring section designated by "O" is the Vertical Hold Control and when being set should be turned to the point where the picture "locks in" vertically. See Figure 7.

These two controls on this dual knob should not ordinarily require readjustment after good picture reception has once been obtained. An occasional resetting will be necessary due to changing to a different station, and to the gradual ageing of the tubes.

**Station Selector and Fine Tuning.**—The outer ring "O" section of the central dual control knob on the right hand side of the panel selects the station from which it is desired to receive television transmissions. The range covers five television channels:

- (1) 84 to 90 M.C.
- (2) 78 to 84 M.C.
- (3) 66 to 72 M.C.
- (4) 50 to 56 M.C.
- (5) 44 to 50 M.C.

The inner "H" section of this knob is used to obtain best picture reception by elimination of distortion resulting from interfering radio signals. These interfering signals may be moving in the picture. A slight downward pressure must be exerted on the knob while turning.

**Contrast and Brightness Controls.**—The inner "C" Contrast section of the dual knob near the front of the cabinet on the right regulates the sensitivity of the receiver, varying the black and white tones of the picture being received. Too much contrast gives blurred details and a lack of half-tones, while too little contrast makes it all half-tones or grays. Turning clockwise increases contrast from grays, to black and white. See Figures 2, 4 and 5.

The outer ring "O" is the Brightness Control and affects the average illumination of the picture. Turning clockwise increases the brightness. See Figures 2, 4 and 5.

**Focusing Control.**—This control is a knob located on the back of the cabinet near the bottom and is used for adjustment of the picture focus. This adjustment affects the sharpness (detail observable) of the picture and must be carefully made when the receiver is first placed in operation. It may be checked occasionally to insure continuous best focusing. See Figure 3.

**Pilot Light.**—A little jewel pilot light at the bottom of the front of the cabinet tells when current is on.

**Other Controls.**—There are five other controls on the television chassis. All of these will be permanently adjusted at the time the TRK 12 is installed, but may require occasional resetting. These controls are accessible from the back of the cabinet. See Figure 15. They are adjustable by means of a screwdriver through a vertical row of holes in the left side of the back of the cabinet towards the top.

Receiving the Picture

To obtain picture reception, open the lid of the cabinet and:

Antenna

A television receiving antenna and its installation must conform to much higher standards than an antenna for reception of International Short Wave and Standard Broadcast signals because:

- (1) At the short wave lengths employed, intervening obstacles have a pronounced shielding effect, causing low intensity signals, and often severe trouble with multi-path transmissions; these produce blurring and image-imagés.
- (2) The picture signal is comprised of a very wide band of range of frequencies, all of which must be received with good efficiency.

Only an RCA Television Antenna which has been designed for the particular installation should be used with the TRK 12 to insure best results. Three types are available.

1. The Double "Y" Type, Stock No. 9870.
2. The Double Dipole, Stock No. 9871.
3. The Double Dipole, Stock No. 9871, with Reflector, Stock No. 9872.

Under favorable conditions, good pictures may be obtained with the Double "Y" Wire Type. In areas of weak signals or where interference or double images mar the picture a Double Dipole or Double Dipole and Reflector become necessary.

Full instructions accompany all RCA Television antennas and these instructions must be followed implicitly.

The two leads from the antenna transmission line are for connection to the terminals A1 and A2 showing at the back of the cabinet of the television receiver. Terminal C must be connected to a good ground such as a cold water pipe. Terminals A3 and G are connected to the Radio chassis and the circuit is designed so that the Television Antenna is also used for Standard Broadcast and Short-Wave Radio Reception.

An RCA Radio Antenna such as the RCA Magic Wave or RCA Spider-Jag may be installed.

The connection from "A" on the terminal board on the radio chassis to "A3" on the terminal board on the radio chassis must then be removed and the leads from the antenna connected to the radio chassis in accordance with the instructions accompanying the radio chassis.

The connection from "C" on the Radio chassis to "C" on the Television chassis must be made.

A good ground connection must be made to the antenna "good ground" is absolutely necessary to avoid possible danger from electric shock.

TELEVISION

The picture is formed on the Kinescope screen under the lid and is reflected in the mirror on the lid. The lid when opened must be set at the correct angle for best viewing of the picture. Once your TRK 12 is installed and giving good reception, the controls on the panel under the lid are all that are necessary for satisfactory pictures and sound. If the instrument is moved to another location in the home, the screwdriver-operated controls in the back, and also the Kinescope yoke, may have to be reset. The ground connection to the antenna terminal board must always be reconnected.

Controls

There are three dual control knobs for Television to the right of the screen, and four single control knobs in the Radio section to the left. Two of these single control knobs are all purpose controls and are used on Television, Radio and Phonograph reproductions. See Figure 1.

**Power-Volume Control.**—The knob nearest the front of the cabinet on the left hand side turns on the power to the receiver when rotated clockwise from its extreme "Off" position. Rotating it further increases sound volume for Television, Radio, or Phonograph (when an attachment is used).

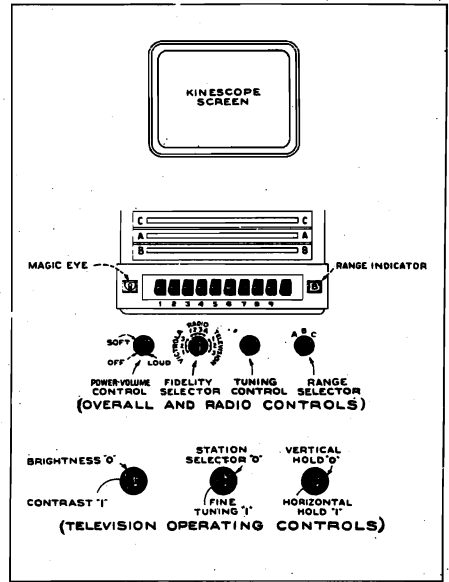

**Fidelity-Selector.**—The second knob from the front in the Radio section selects the type of entertainment i.e. "Victrola," "Radio," or "Television."

Turned to the position marked "Victrola" it provides for operation of a Victrola Attachment such as the RCA R-100 or R-93-C. There are three variations of tone possible:

Victrola Attachment

A jack (X-16) is located near the antenna terminal board for convenience in plugging in a Victrola Attachment.

## Electric Tuning Mechanism

When a station button is pushed in, it completes the 24-volt circuit through the corresponding station-setting contact and one-half of the brass selector disc, which is connected to one side of the motor field coil. This energizes the motor, and the rotor is pulled forward, engaging with the gear train that drives the tuning condenser and selector disc. The condenser and disc rotate until the insulation line comes under the particular station-setting contact, and the motor circuit is broken.

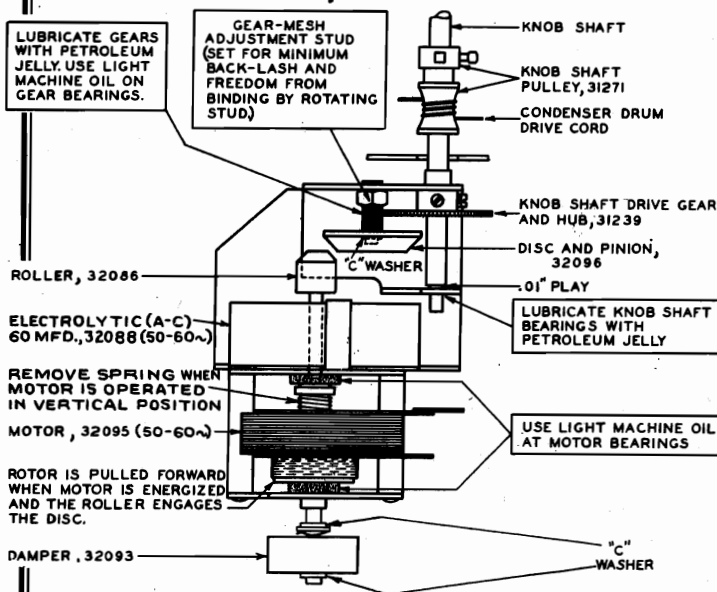

When the electric tuning mechanism is in action, the motor-supply voltage is fed into a diode rectifier circuit which applies a high bias to the first-audio amplifier. This prevents audio amplification and makes the set quiet or "mute" while the mechanism is operating.

The brass selector disc is fastened to the rear shaft of the tuning condenser by means of two set-screws. When the condenser is at maximum (plates fully meshed) the insulation line should be horizontal, with the operating end at the left (viewed from rear). The brass is beveled at this end.

The selector disc should be set so that the contact-tip plungers in the station-setting contacts project not more than 1/16-in. from the body of the contacts.

### LUBRICATION

**Motor bearings and gear bearings;** use light machine oil.  
**Gear faces;** use "Pure Oil No. 611" or petroleum jelly.  
**Dial-indicator pulleys and rails;** use "Castordag" or petroleum jelly.  
**Selector disc;** apply thin film of petroleum jelly.

## Adjustments for Electric Tuning

With power turned off, disconnect the antenna transmission line and ground connection, turn fidelity control to radio (3rd. radio position—6th position from full counter-clockwise). Remove the back from the cabinet and reconnect the antenna transmission line and ground connection. The two interlock switches on the side panels should not be touched and care should be taken not to press on them when making the push-button set-up. Then turn on power, set range selector to "A," allow a few moments warm-up period and proceed as follows:

1. Make a list of the desired nine stations, arranged in order from low to high frequencies.
2. Turn on power-volume control, turn range selector to "A" band, and allow a few minutes for warming up.
3. Press down the "dial-tuning" (right-hand) button.

4. Manually tune in the first station on the list, using the "Magic Eye" for accurate tuning.
5. Hold down the "dial-tuning" button and press down station button No. 1 (left-hand). Both buttons will stay down. Move station adjuster contact pin No. 1 to the insulating line on the disc at rear of gang. When the pin is correctly centered on the insulating line, the central dial lamp will go out completely.
6. Press down any other button in order to release the dial-tuning button and station button No. 1. Tune to some other section on the dial, and then press down station button No. 1 again; the electric tuning mechanism will function to tune in the first station, and the central dial lamp will stay on.
7. Repeat this process for the remaining stations.

Kinescope Data  
Parts List

RCA MFG. CO., INC.

Precautions in Handling Kinescopes

The Kinescope bulb encloses a high vacuum and, due to its large surface area, is subjected to considerable air pressure. For these reasons, Kinescopes must be handled with more care than ordinary receiving tubes.

The large end of the Kinescope bulb — particularly that part at the rim of the viewing surface — must not be struck, scratched or subjected to more than moderate pressure at any time. If the tube sticks, or fails to slip into its socket or deflecting yoke smoothly, investigate and remove the cause of trouble. Do not force the tube.

All RCA Kinescopes are shipped in special cartons and should always be left in the cartons until ready for installation in the receiver. Keep the carton for future use.

The RCA-1803-P4 (12-inch) Kinescope is equipped with a protective lid and shield. Do not at any time remove the close-fitting cone-shaped section of the protective shield from the Kinescope. This section should be installed with the tube in the cabinet and is designed to protect the user while handling the glass bulb.

**General Description**

Models 5Q5, 5Q55, 5Q56 and 6Q7 are three-band table type superheterodyne receivers. They are designed to cover the standard broadcast range of 540 to 1,720 kilocycles, and the short-wave range from 2.3 to 22 megacycles.  
 Models 5Q5 and 6Q7 are Export Types.

Features of design include: Magnetite-core I-F transformers; magnetite-core "A" band oscillator coil; automatic volume control; continuously-variable high-frequency tone control on Model 6Q7; edge-lighted straight-line dial; band indicator in dial; jack for Victrola Attachment; and dust-proof electrodynamic loudspeaker.

D-C Resistance { Primary No. 1..... 13 ohms  
 Primary No. 2..... 15 ohms  
 H. V. Secondary (Total)..... 500 ohms

Connections of Universal Power Transformer Primary for 220 and 110 Volts

**Miscellaneous Service Data**

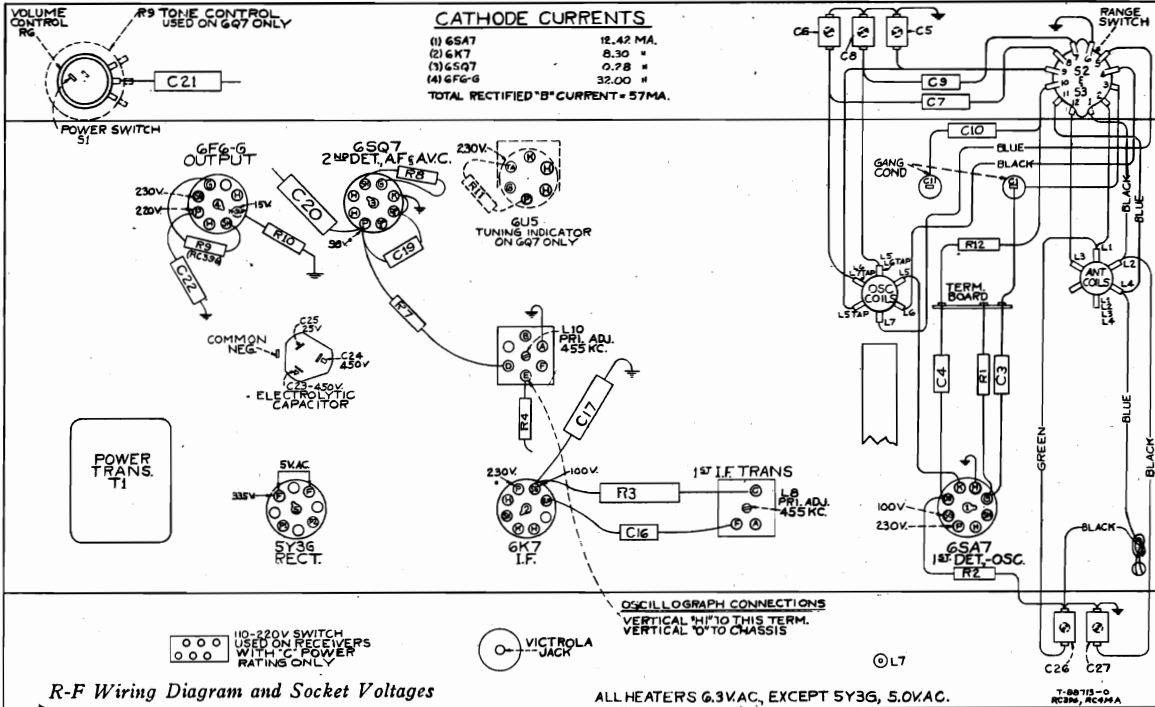

- Precautionary Lead Dress**
- Lead from 2nd I.F. (E) to volume control should be kept close to chassis.
  - R.F. coil leads should be kept short and away from coil.
  - Leads to 6,000 mmf. (C10) should be as short as possible and condenser dressed away from chassis, bearing against 10 ohm (R12) resistor.

**Victrola Attachment.**—A jack is provided on the rear of chassis for connection to a Victrola Attachment. The cable from the attachment should be terminated in a Stock No. 31048 plug to fit the jack.  
**Loudspeaker.**—To center the loudspeaker voice coil, first remove the front dust cover, then loosen the screws holding the spider assembly. Insert three narrow feelers into the air gap, and tighten the spider screws. Remove the feelers and fasten a dust cover in place with loudspeaker cement.

Socket, Trimmers, Voltage  
 Drive Cord Data, Scale

Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within  $\pm 20\%$  with 117-volt a-c supply.  
 \*NOTE: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

Alignment, Parts List

Alignment Procedure

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-Oscillator.—For all alignment operations, connect the low side of the test-oscillator to the ground terminal, and keep the output as low as possible to avoid a-v-c action.

Calibration Scale on Indicator-Drive-Cord Drum.—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment. Therefore a calibration scale is attached to the rear of the drum, which is mounted on the shaft of the gang condenser. The setting of the gang condenser is in degrees on this scale, which is calibrated in degrees. The correct settings for the gang condenser, for each alignment frequency is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 45 degree mark on the drum scale (see "Drum Drive and Indicator Cord Assembly" drawings) must be in a horizontal position when the plates are fully meshed. The distance from the edge of the scale to the drum must not exceed 8-inch. The drum is held to the shaft by means of a set screw, which must be tightened securely when the drum is in the correct position.

Pointer for Calibration Scale.—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "0" mark on the calibration scale when the plates are fully meshed.

Dial-Indicator Adjustment.—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn tuning dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap. in series with .01 mfd.	455 kc	"A" Band quiet point between 550-750 kc	L10 and L11 (2nd I.F. trans.)
2	Tuning condenser in series with .01 mfd. *	455 kc		L8 and L9 (1st I.F. trans.)
3	Antenna lead (blue) in series with 200 mmfd.	600 kc	600 kc (33%) "A" Band	L7†
4	Repeat steps 3 and 4	1,500 kc	1,500 kc (152.4°) "A" Band	C2 (ant.) C8 (osc.)
5	Antenna lead (blue) in series with 400 ohms	20 mc	20 mc (156.4°) "C" Band	C5 (osc.) * C26 (ant.)
6	Antenna lead (blue) in series with 200 mmfd.	6 mc	6 mc (149°) "B" Band	C6 (osc.) * C27 (ant.)
7	Antenna lead (blue) in series with 200 mmfd.	1,500 kc	1,500 kc (152.4°) "A" Band	C8 (osc.)

\* Use minimum capacity peak if two peaks can be obtained.  
† Rock gang condenser slightly while adjusting L7.  
\* Make test-oscillator connection to lug on tuning condenser stator (oscillator section) in series with .01 mfd. condenser.  
Note.—Oscillator tracks 455 kc above signal on all bands.

RCA MFG. CO., INC.

## Model 5X5 Series (Chassis No. RC-406)

### Five-Tube, Single-Band, AC-DC Multiplex Superheterodyne Receiver

### Model PLF-10

### Power Line Filter Coupling Unit

#### General Description

The following features are incorporated in the design of the Little Nipper Multiplex 5X5 Series Receiver:

First, it is a "standard broadcast" receiver. Second, it will operate any other radio in the home by "remote control" without the use of connecting wires. Third, records may be reproduced through the Little Nipper when used with Victrola Attachment. Fourth, the Model 5X5 (when used with Victrola Attachment) will reproduce records

through any other radio in the home without the use of connecting wires.

When using the 5X5 as a remote control, the Model PLF-10 Power Line Filter Coupling Unit should be used in conjunction with the receiver to be controlled. The filter is connected between the power line receptacle and the receiver being controlled, as shown in accompanying drawing.

#### Alignment Procedure

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mfd. capacitor, and keep the output as low as possible.

The Remote Control Oscillator in the 5X5 is set at the factory to approximately 540 kc. The frequency may be varied between 540 and 800 kc to suit local conditions by adjusting the trimmer condenser C7.

**Power-Supply Polarity.**—For operation on d-c, the power plug must be inserted in the outlet for correct polarity. If the set does not function, reverse the plug. On a-c, reversal of the plug may reduce hum.

If the electric supply circuit is a three-wire system, it may be necessary to connect a ½ mfd 700-volt capacitor between the two outside lines of the three-wire system.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	Tuning condenser stator (osc.) in series with .01 mfd.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna term. of ant. trans. in series with 100 mmfd.	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal	C6 (antenna)

#### Replacement Parts

Insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

Model 5X5W Walnut Finish  
Model 5X5I Ivory Finish

Set-up Procedure for Remote Control

1. Install the 5X5 and tune in any desired station.
2. Turn the control switch on the back of the 5X5 to its clockwise position marked "Remote." The 5X5 becomes silent. The 5X5 now becomes a small relay station for signalling to the controlled receiver via the power line wiring.
3. Next tune the main receiver to the exact frequency of transmission of the 5X5, usually 540 kc. Tune carefully to this frequency, setting the volume control as high as permissible with regard to hum and noise conditions. The station to which the 5X5 was tuned will be heard. If the receiver is equipped with tuning indicator (Magic Eye) the correct point will most easily be obtained by observing the indicator.
4. Now any station tuned in on the 5X5 dial will be heard on the controlled receiver. The volume will also be controlled with the 5X5 volume control.
5. If it is desired to operate the controlled receiver on its own controls it is only necessary to set the switch on the Power Line Filter Coupling Unit to its position marked "Radio."
6. In the event that, with the 5X5 being used as a remote control, other receivers in the home are in use, trouble may be experienced due to noise and hum. To avoid this, connect a Power Line Filter Coupling Unit, RCA Victor PLF-10, to each of these other receivers, as shown in accompanying drawing.

Precautionary Lead Dress

1. Dress 1st I-F plate and grid leads against chassis and away from each other. Dress plate lead from 12C8 close to chassis.
2. Dress A.V.C. condenser (0.1) close to chassis and tight to 0.25 mmfd. condenser.

PLF-10 COUPLING UNIT

**Antenna.**—The set is equipped with length of antenna wire. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mmf. capacitor in series with the lead-in.

**Victrola Attachment.**—A jack is provided on the rear of chassis for connecting a Victrola Attachment into the audio-amplifying circuit. The cable from the Victrola Attachment should be terminated in a Stock No. 31048 plug to fit the jack.

 Weight (net) ..... 11½ pounds

Alignment Procedure

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.  
**Test-Oscillator.**—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mfd. capacitor, and keep the output as low as possible.  
**Antenna.**—The set is equipped with length of antenna wire. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mmf. capacitor in series with the lead-in.

Precautionary Lead Dress

1. Dress 1st I-F plate and grid leads against chassis and away from each other. Dress plate lead from 12SK7 close to chassis.
2. Dress electrolytic capacitor against chassis apron.

Phonograph Service Data

The motor is started by turning the radio-phono tone control to either 3rd or 4th position clockwise and giving the turntable a clockwise spin with the hand. Smooth starting and running will be insured by keeping the bearings well cleaned and oiled.

**Hum and Vibration.**—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. If excessive vibration occurs it may be due to:

1. Insufficient lubrication, or any failure that will cause binding.
2. Leather washer not oiled. (Check to make certain that the leather washer is above the steel washer.)
3. Motor not properly supported from motor board.
4. Burrs on poles of rotor or stator. Remove with fine emery cloth.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	Tuning condenser stator (osc.) in series with .01 mfd.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna term. of ant. trans. in series with 100 mmfd.	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal	C6 (antenna)

**Power Supply.**—Although this model employs an ac-dc chassis, it is not suitable for use on dc, as this would damage the motor.

5. The damper spring must fit without binding or chattering in the slot in the stator. The stator must be free to deflect in either direction between the limits of the damper spring. The damper spring must exert approximately equal force in restoring the stator to its mid-position when the stator is deflected manually in each direction.

**Removing Rotor.**—The rotor and turntable assembly simply rests on the ball bearing at bottom of vertical bearing. Remove by lifting up.

**Rotor Adjustment.**—Loosen the three screws that hold the rotor to the turntable, insert three 16-mil shims at equal distances around the gap between the rotor and stator, and then carefully tighten the three screws. The top of rotor must be flush with top of stator; add additional steel washers beneath the stator if necessary.

**Lubrication.**—Oiling points are indicated in the diagram.

**POWER SUPPLY RATINGS**  
 A-C Rating..... 105-125 volts, 50-60 cycles, 50 watts  
 D-C Rating..... 105-125 volts, direct current, 50 watts  
 Power Output (125 volt, 60 cycle supply)  
 Undistorted..... 1.5 watt  
 Maximum..... 2.0 watts  
**LOUDSPEAKER**  
 Type..... 4-inch Electrodynamic

- 1938 No. 41
- Model 9SX-1, Molded cabinet, walnut finish, ivory knobs.
  - Model 9SX-2, Molded cabinet, walnut body, ivory front, walnut knobs.
  - Model 9SX-3, Molded cabinet, ivory finish, red knobs.
  - Model 9SX-4, Molded cabinet, red body, ivory front, red knobs.
  - Model 9SX-5, Molded cabinet, black body, marble front, jet knobs.
  - Model 9SX-6, Molded cabinet, blue body, onyx front, blue knobs.
  - Model 9SX-7, Molded cabinet, onyx finish, maroon knobs.
  - Model 9SX-8, Molded cabinet, marble finish, jet knobs.

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.  
**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis through .01 mfd., and keep the output as low as possible to avoid a-v-c action.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	6K7 I-F grid cap, in series with .01 mfd.	456 kc	Quiet point between 1,650-1,720 kc, with range switch at broadcast position (counter-clockwise from rear).	Two trimmers on 2nd I-F trans.
2	6A8 1st-Det. grid cap, in series with .01 mfd.	456 kc		Two trimmers on 1st I-F trans.
3	Antenna Term. on antenna trans., in series with 400 ohms.	6,250 kc	Max. clockwise (out of mesh) "B" band	C2 (osc. gang trimmer)*
4		6,000 kc	Resonance on 6,000 kc signal	C1 (ant. gang trimmer)**
5	Antenna Term. on antenna trans., in series with 90 mmf.	1,720 kc	Max. clockwise (out of mesh)	C3
6		1,500 kc	Resonance on 1,500 kc signal.	C4

- TUBE COMPLEMENT**
- (1) RCA-6A8..... 1st-Detector—Oscillator
  - (2) RCA-6K7..... I-F Amplifier
  - (3) RCA-6Q7..... 2nd-Det., 1st A-F, and A.V.C.
  - (4) RCA-25L6..... Power Output
  - (5) RCA-25Z6..... Half-Wave Rectifier
  - Dial Lamp (1)..... Mazda 40, 6.3 volts, .15 amp.

Bottom view of tube sockets

\* Use minimum capacity peak if two peaks can be obtained.  
 \*\* After this adjustment, check for image by leaving test oscillator at 6,000 kc, and shifting receiver dial to 5,088 kc, where a weaker signal should be received.

**Cabinet Dimensions.**..... Height 4 1/2 inches .. Width 8 inches .. Depth 4 1/2 inches  
**Weight.**..... 7 pounds (shipping)

**Power-Supply Polarity.**—For operation on d-c, the power plug must be inserted in the outlet for correct polarity. If the set does not function, reverse the plug. On a-c, reversal of the plug may reduce hum.

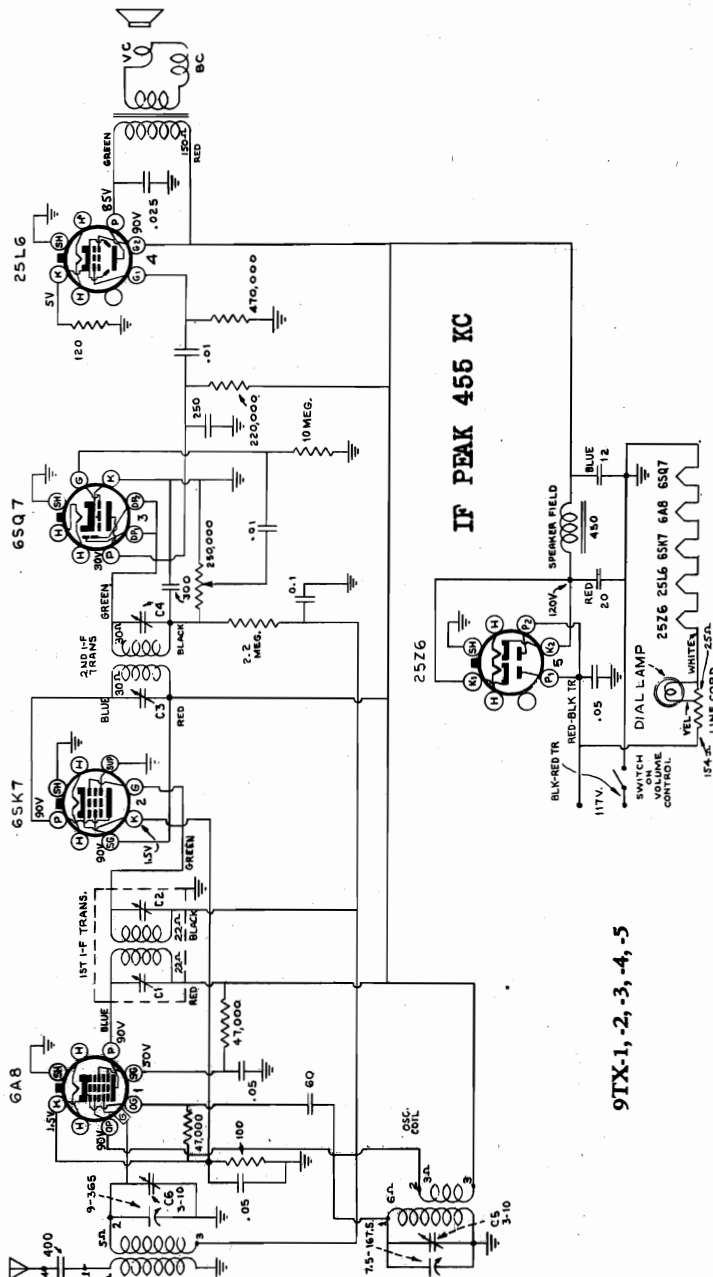

**Resistor in Power Cord.**—The power cord contains a resistor which becomes warm during operation.

**Antenna.**—The set is equipped with length of antenna wire. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mmf. capacitor in series with the lead-in.

MODELS 9TX-1 to 9TX-5 incl.  
Little Nipper-2nd

RCA MFG. CO., INC.

Schematic, Voltage, Socket  
Trimmers, Alignment

**Precautionary Lead Dress**

1. Dress 1st I-F plate and grid leads against chassis and away from each other. Dress plate lead from 6SK7 close to chassis.
2. Dress electrolytic capacitor against rear apron.
3. Keep leads away from adjusting screws to allow easy access.
4. Dress output plate lead along front apron and away from 6A8.
5. Dress parts at ends of chassis to clear cabinet bosses.

**Electrical and Mechanical Specifications**

Antenna.—The set is equipped with length of antenna wire. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mmf. capacitor in series with the lead-in.

POWER SUPPLY RATINGS

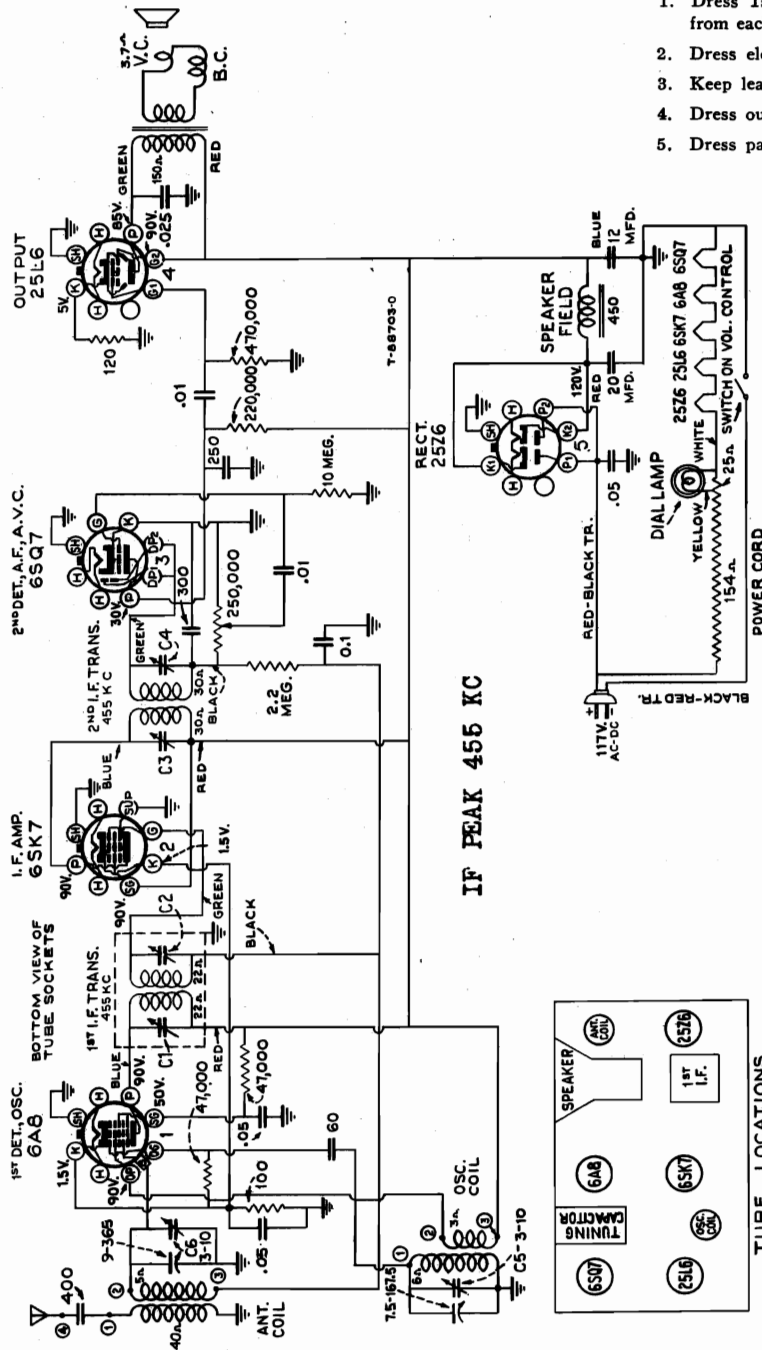

A-C Rating ..... 105-125 volts, 50-60 cycles, 50 watts  
D-C Rating ..... 105-125 volts, direct current, 50 watts

Power-Supply Polarity.—For operation on d-c, the power plug must be inserted in the outlet for correct polarity. If the set does not function, reverse the plug. On a-c, reversal of the plug may reduce hum.

Resistor in Power Cord.—The power cord contains a resistor which becomes warm during operation.

Precautionary Lead Dress

1. Dress 1st I-F plate and grid leads against chassis and away from each other. Dress plate lead from 6SK7 close to chassis.
2. Dress electrolytic capacitor against rear apron.
3. Keep leads away from adjusting screws to allow easy access.
4. Dress output plate lead along front apron and away from 6A8.
5. Dress parts at ends of chassis to clear cabinet bosses.

— 1939 No. 5 —

Alignment Procedure

Test-Oscillator.—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mid. capacitor, and keep the output as low as possible. The antenna should be rolled up and kept at least one foot from chassis during alignment.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	6A8 1st-Det. grid cap, in series with .01 mid.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna term. of ant. trans. in series with 100 mmfd.	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal.	C6 (antenna)

Output Meter Alignment.—Connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Alignment Procedure**

- Precautionary Lead Dress**  
 1. Dress 1st I-F plate and grid leads against chassis and away from each other. Dress plate lead from 12SK7 close to chassis.  
 2. Dress electrolytic capacitor against rear apron.

**Power-Supply Polarity.**—For operation on d-c, the power plug must be inserted in the outlet for correct polarity. If the set does not function, reverse the plug. On a-c, reversal of the plug may reduce hum.

**Antenna.**—The set is equipped with length of antenna wire. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mmf. capacitor in series with the lead-in.

**Victrola Attachment.**—A jack is provided on the rear of chassis for connecting a Victrola Attachment into the audio-amplifying circuit. The cable from the Victrola Attachment should be terminated in a Stock No. 81048 plug to fit the jack.

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.  
**Test-Oscillator.**—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mfd. capacitor, and keep the output as low as possible.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	Tuning condenser stator (osc.) in series with .01 mfd.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna term. of ant. trans. in series with 100 mmfd.	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal	C6 (antenna)

RCA MFG. CO., INC.

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mfd. capacitor, and keep the output as low as possible.

**Pre-Setting Dial.**—With gang condenser in full mesh, the pointer should be adjusted so that top edge of pointer just touches rivet in dial plate.

**Antenna.**—The set is equipped with a built-in loop antenna. If an outdoor antenna is used, it may be connected to the "ANT" terminal on rear of cabinet. It should not be longer than 100 feet, including lead-in. If it is longer, connect a 100 to 200 mfd. capacitor in series with the lead-in.

**Power-Supply Polarity.**—For operation on d-c, the power plug must be reversed in the outlet for correct polarity. If the set does not function, invert the plug. On a-c, reversal of the plug may reduce hum.

**Victrola Attachment.**—A jack is provided on the rear of cabinet for connecting a Victrola Attachment into the audio-amplifying circuit. The cable from the Victrola Attachment should be terminated in a Stock No. 31048 plug to fit the jack.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	Tuning condenser across (osc.) in series with .01 mfd.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna term. of ant. loop in series with 100 mfd.	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal	C6 (antenna)

**Precautionary Lead Dress**

1. Dress 2nd I-F green lead close to chassis and under other parts.
2. Dress lead from gang condenser to grid of 12SA7 close to chassis and away from 12SQ7 socket.
3. Dress blue 1st I-F lead under volume control close to chassis.
4. Dress blue 2nd I-F lead close to chassis and behind 12SK7 socket.

MODEL D22-1A

Model D22-1A

Service Data for Model D22-1 are directly applicable to these instruments except as follows:

- (1) The schematic circuit diagram for Model D22-1A is shown by figure 5.
- (2) The metal rectifier socket wiring for tube No. 14 is shown by figure 2.
- (3) Figure 3 shows the Pickup details.
- (4) The phonograph motor is of the capacitor type. Light machine oil should be used to lubricate the motor bearings. The motor is wired in this instrument as follows: One power-supply lead connects to one terminal of switch S201. The other terminal of S201 connects to one terminal of the brake switch S202. The other terminal of S202 connects to the yellow motor lead. The green motor lead connects to one lead of the motor capacitor. The red motor lead connects to the other capacitor lead and also to the remaining power-supply lead.
- (5) The Radiotron socket voltages (figure 4 herein) apply to all Models D22-1 or D22-1A and should be used in place of figure 4 of the D22-1 Service Data.
- (6) The resistor assembly R44 and R45 is mounted on the front chassis apron instead of the rear chassis apron.
- (7) Change price on Stock No. 11879 Transformer from \$3.50 to \$8.15.
- (8) Change price on Stock No. 11541 Arm from \$0.82 to \$8.15.

- (9) Change price on Stock No. 11480 Microphone from \$7.05 to \$7.50.
- (10) Refer to Substitute and Additional Replacement Parts contained herein for other parts changes.

Bottom View - Rear of Chassis  
Maximum chassis height (inches)..... 8 1/4  
Chassis Base (inches)..... 15 1/2 x 8 1/2 x 3 1/8

Measurements made to chassis unless otherwise indicated, with set tuned to quiet point, volume control at minimum. Values should hold within approximately  $\pm 20\%$  with 117-volt a-c supply.

\* NOTE: Values with star (\*) are operating voltages in circuits with high series-resistance, and when measured with a-voltmeter.

The phonograph has a self-starting motor, crystal pickup, and may be set to play ten-inch and twelve-inch records singly, or automatically. In the automatic position, seven ten-inch; eight ten-inch; or a mixed group of seven, ten- and twelve-inch records, may be played in succession. The output of the pickup is "shorted" out when the pickup is on the pickup rest.

General Description

These receivers employ a ten-tube, three-band, "Magic Brain" superheterodyne circuit. Features of design include: "Electric Tuning" for eight broadcast stations; a link-coupled antenna circuit; magnetite-core i-f transformers and "A" band oscillator coil; full automatic volume control; "Magic Eye" tuning tube; improved 12-inch dust-proof electro-dynamic loudspeaker; aurally compensated audio volume control; continuously variable high-frequency tone control; provision for armchair control attachment; illuminated band indicator; noise-reducing antenna adjustment on "A" band;

RCA MFG. CO., INC.

MODELS U-30, Chas. RC-335KR,  
U-129, Chas. RC-335K  
Alignment, Socket, Trimmers  
Tuner Data, Antenna Data

### ALIGNMENT PROCEDURE

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment, therefore a calibration scale is attached to the rear of the indicator-drive-cord drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in rf alignment, check the position of the drum. The "0" mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "0" mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

### Service Data

**Loudspeaker.**—Centering of the loudspeaker is made in the usual manner with three narrow celluloid or paper feelers after first removing the front dust cover. A dust cover

### ADJUSTMENTS FOR ELECTRIC TUNING

1. Make a list of the desired eight stations, arranged in order from low to high frequencies.
2. Turn range selector to "A" band, turn power on, and allow a few minutes for warming up.
3. Press down the "dial-tuning" (right-hand) button.
4. Manually tune in the first station on the list, using the "Magic Eye" for accurate tuning.
5. Hold down the "dial-tuning" button, and press down station button No. 1 (second from left). Both buttons will stay down. Move adjusting pin No. 1 to the insulating line on the disc at rear of gang. When the pin is correctly centered on the insulating line, the central dial lamp will go out.
6. Press down any other button in order to release the dial-tuning button and station button No. 1. Then press down station button No. 1 again. The electric tuning mechanism will function to tune in the station, and the central dial lamp will stay on.
7. Repeat this process for the remaining stations.

### Antenna Connections

**RCA Victor Master Antenna Kit.**—Connect the twisted-pair transmission line to terminals A1 and A2 on the terminal board at rear of chassis. Connect the counter-poise to A3. Terminal G may be connected to ground, but this connection is not necessary for correct operation.

**Noise-Reducing Adjustment.**—After the RCA Victor Master Antenna Kit is connected to the receiver, tune the receiver to a point near 900 kc where no station is heard. Turn volume control clockwise until noise is heard. If no noise of a regular character is audible, start any brush-type motor-driven appliance, such as a vacuum cleaner, electric razor, refrigerator, etc., but do not bring it too near the receiver. This will generate noise as a continuous crackling, or buzz. Adjust C5, which is mounted behind the antenna terminal board, to a point where this noise is reduced to a minimum.

Adjustment of the noise reducing trimmer C5 should be made in the customer's home, with the RCA Victor Master Antenna connected to the receiver.

This adjustment is effective only when the RCA Victor Master Antenna is used. For all other types of antenna, the noise-adjustment trimmer C5 should be screwed all the way down.

**Other Antennas.**—Use terminals A1 and A3 on the receiver terminal board as antenna and ground connecting points respectively. Terminal A3 may be connected to terminal G, unless this causes interference, in which case this connection should be omitted.

should be cemented in place upon completion of adjustment.

**Precautionary Lead Dress.**—(1) The lead from the left pilot light should be kept behind the bulb and toward the "Magic Eye," to keep it away from the 6F5 grid cap, (2) leads from mica trimmers to coil should be kept away from the coil and other parts, (3) leads on oscillator coil which are an extended part of the coil winding should be as short as possible, (4) "C" band series capacitor C31 must have leads as short as possible, (5) all leads from antenna board to antenna coils should be dressed toward back apron, (6) the one lead of the line cord and the primary lead of the power transformer which run to the power switch should be twisted together, (7) shielding on leads to Victrola switch should be kept away from the switch terminals and jack.

Steps	Connect the high side of test-oscillator to — 6K7 I-F grid cap in series with .01 mfd.	Tune test-oscillator to — 455 kc	Range Selector	Set tuning gang to — Quiet point between 550-750 kc	Adjust the following for max. peak output (2nd I-F Transformer)
No. 1	6K7 I-F grid cap in series with .01 mfd.	455 kc	"A"	Quiet point between 550-750 kc	L10, L11
No. 2	6A8 Det. grid cap in series with .01 mfd.	455 kc	"A"	between 550-750 kc	L8, L9 (1st I-F Transformer)
No. 3	Connect A1 to chassis.	20 mc	"C"	20 mc (147.5°)	C24 (osc.)* C8 (det.†)
No. 4	A2, in series with 100 mmfd. Connect A3 to chassis.	6,100 kc	"B"	6,100 kc (145.5°)	C25 (osc.)**
No. 5	A2, in series with 100 mmfd. Connect A3 to chassis.	1,500 kc	"A"	1,500 kc (151.5°)	C29 (osc.) C3 (ant.)
No. 6	A2, in series with 100 mmfd. Connect A3 to chassis.	600 kc	"A"	600 kc (29.5°)	L17 (osc.)
No. 7	A2, in series with 100 mmfd. Connect A3 to chassis.	1,500 kc	"A"	1,500 kc (151.5°)	C29 (osc.)

\* Use minimum capacity peak if two peaks can be obtained. Check to determine that the correct peak has been used by turning to 141.5° (19,090 kc), at which point a weaker signal should be received.  
 \*\* Use minimum capacity peak if two peaks can be obtained. Check to determine that the correct peak has been used by turning to 124° (5,190 kc), at which point a weaker signal should be received.  
 † Rock gang condenser and use maximum capacity peak if two peaks can be obtained with C8.

RCA MFG. CO., INC.

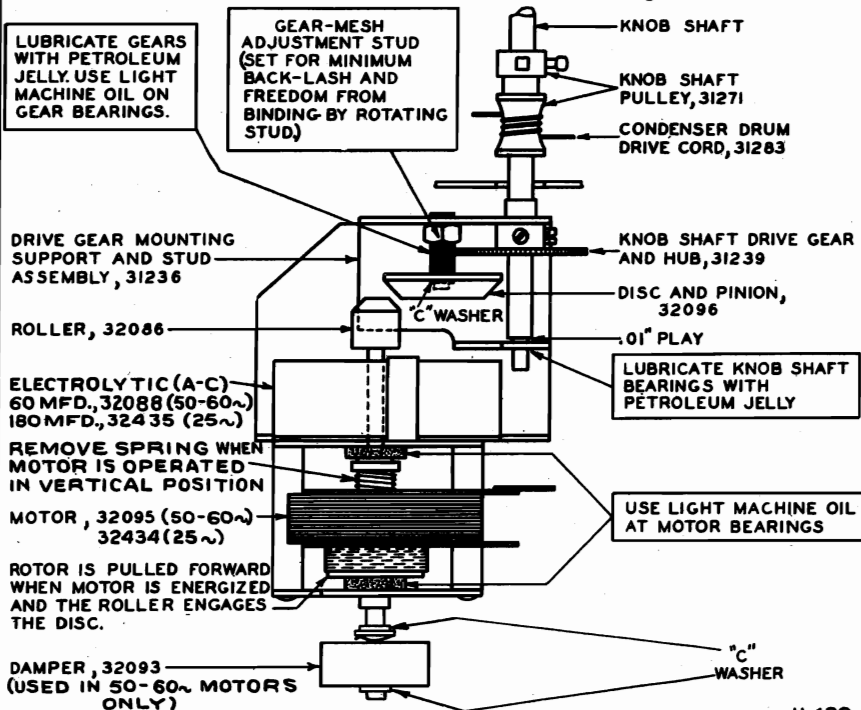

Tuning Mechanism, Data  
Armchair Cont. Unit Data

Component Parts of Station-Setting Contact

At left—Dial Mechanism

Electric Tuning Mechanism

When a station button is pushed in, it completes the 24-volt circuit through the corresponding station-setting contact and one-half of the brass selector disc, which is connected to one side of the motor field coil. This energizes the motor, and the rotor is pulled forward, engaging with the gear train that drives the tuning condenser and selector disc. The condenser and disc rotate until the insulation line comes under the particular station-setting contact, and the motor circuit is broken.

When the electric tuning mechanism is in action, the motor-supply voltage is fed into a diode rectifier circuit which applies a high bias to the first-audio amplifier. This prevents audio amplification and makes the set quiet or "mute" while the mechanism is operating.

The brass selector disc is fastened to the rear shaft of the tuning condenser by means of two set-screws. When the condenser is at maximum (plates fully meshed) the insulation line should be horizontal, with the operating-end at the left (viewed from rear). The operating-end has dark insulating material and the brass is beveled at this end.

The selector disc should be set so that the contact-tip plungers in the station-setting contacts project not more than 1/16-in. from the body of the contacts.

Lubrication

Motor bearings and gear bearings; use light machine oil.

Gear faces; use "Pure Oil No. 611" or petroleum jelly.

Dial-indicator pulleys and rails; use "Castorag" or petroleum jelly.

Selector disc; apply thin film of petroleum jelly.

Armchair Control Unit

U-129  
SN-923

Station-Setting Contacts and Selector Disc

This illustration shows connections for a G8A Armchair Control Unit. This unit is not supplied with the receiver but may be added as an accessory.

Station Button	Color of Lead To Station-Setting Contact
No. 1	Black
No. 2	Brown
No. 3	Blue
No. 4	Green
No. 5	Red
No. 6	Red-black
No. 7	Brown-black
No. 8	Red-yellow

When a Model G8A Armchair Control is connected to the receiver it duplicates the action of the push-buttons on the front panel when No. 1 button is pressed down. The black lead from push-button No. 1 is unsoldered from No. 1 station-setting contact and soldered to a terminal board which is to be mounted on the frame of selector mechanism. If desired one of the other seven station buttons on the set may be used in place of No. 1 button.

This arrangement allows the use of only seven of the eight buttons when tuning in stations at the set, but allows the use of the entire eight buttons on the Armchair Control. In operating the G8A Armchair Control the push-button must be held down until the station has been tuned in. Care must be taken not to hold two of the station-buttons down at one time as both windings of the motor may be engaged instantaneously causing the motor to be inoperative and overheated.

## Automatic Record Changer Data, Adjustments

RCA MFG. CO., INC.

MODELS U-30, Chas. RC-335KR

fully toward turntable; rotate mechanism through cycle until needle is just ready to land on the record; then see that pin "V" on lever "14" is in contact with "Step I" on lever "17". The correct point of landing is 4-11/16 inches from the nearest side of the turntable spindle; loosen the two screws "D" and adjust horizontal position of tone arm to proper dimension, being careful not to disturb levers "14" and "17". Leave approximately 1/32 inch end play between hub of lever "20" and pickup base bearing, and tighten the blunt nose screw "D"; run mechanism through several cycles as a check, then tighten cone pointed screw "D".

After adjusting for needle landing on a 10 inch record, place 12 inch record on turntable; push index lever to reject and return to 12 inch position; rotate mechanism through cycle until needle is just ready to land on the record; the correct point of landing is 5-11/16 inches from nearest side of spindle. If the landing is incorrect, turn stud "E" until the eccentric end adjusts lever "14" to give correct needle landing. The eccentric end of the stud must always be toward the rear of the motor board, otherwise incorrect landing may occur with 10 inch records.

**F. & G. Record Separating Knife.**—The upper plate (knife) "25" on each of the record posts serves to separate the lower record from the stack and to support the remaining records during the change cycle. It is essential that the spacing between the knife and the rotating record shelf "27" be accurately maintained. The spacing for the 10 inch record is nominally .038 inch, and for the 12 inch record is .075 inch.

To adjust, rotate the knife to the point of minimum vertical separation from the record shelf and turn screw and locknut "F" to give .055-.061 inch separation. Screw "G" must not be depressed during this adjustment. After setting screw "F", adjust screw "C" so that when its tip is depressed flush with top of record shelf, the vertical spacing between the knife, in its lowest rotational position, and the shelf, is .072-.078 inch.

**H. Record Support Shelf.**—The record shelf revolves during the change cycle to allow the lower record to drop onto the turntable. Both posts are rotated simultaneously by a gear and rack coupled to the main lever "15", and it is necessary that adjustments be such that the record is released from both shelves at the same instant. To adjust, place a 12 inch record on the turntable, rotate mechanism into cycle to the point where tone arm is at maximum distance outward from turntable; lift record upward until it is in contact with both separating knives, then loosen screws "H" and shift record shelves so that the curved inner edges of the shelves are uniformly spaced at least 1/16 inch from record edge. Tighten the blunt nose screw "H", run mechanism through cycle several times to check action, then tighten cone pointed screw "H".

If record shelves or knives are bent, or not perfectly horizontal, improper operation and jamming of mechanism will occur.

**J. Tone Arm Rest Support (not shown).**—When the changer is out-of-cycle, the front lower edge of the pickup head should be 5/16 inch above surface of motor board. This may be adjusted by bending the tone arm support bracket, which is associated with the tone arm mounting base, in the required direction.

**K. Trip Pawl Stop Pin.**—The position of the trip pawl stop pin "K" in relation to the main lever "15" governs the

point at which the roller enters the cam. By bending the pin support either toward or away from trip pawl bearing stud, the roller can be made to enter the cam later or earlier, respectively. This adjustment should be made so that the roller definitely clears the cam outer guide as well as the nose of the cam plate.

**Lubrication.**—Petrolatum or petroleum jelly should be applied to cam, main gear, spindle pinion gear, and gears of record posts.

Light machine oil should be used in the tone arm vertical bearing, record post bearings, and all other bearings of various levers on underside of motor board.

The felt washer between the turntable and spindle bearing should be soaked in light engine oil whenever the turntable is removed, or as required for proper operation.

Do not allow oil or grease to come in contact with, rubber mounting of tone arm base, rubber bumper, or flexible coupling of drive motor.

### MISCELLANEOUS SERVICE HINTS

Incorrect adjustment of a particular mechanism of the changer is generally exhibited in a specific mode of improper operation. The following relations between effects on operation and the usual mis-adjustments will enable ready adjustment in most cases.

1. For any irregularity of operation, the adjustment of the main lever "15" should be checked first as in "A".
2. Needle does not land properly on both 10 and 12 inch records—Make complete adjustments "D" and "E".
3. Needle does not land properly on 12 inch record but correct on 10 inch—Effect adjustment "E".
4. Failure to trip at end of record—Increase clutch "5" friction by means of screw "B". Also, see that levers "7" and "12" are free to move without touching each other.
5. Pickup strikes lower record of stack or drags across top record on turntable—Adjust lift cable per adjustment "C".
6. Needle does not track after landing—Friction clutch "5" adjustment "B" may be too tight; bind in tone arm vertical bearing; levers "7" and "12" fouled; or pickup output cable twisted.
7. Cycle commences before record is complete—Record is defective, or adjustment "B" of friction clutch "5" is too tight.
8. Wow in record reproduction—Record is defective; flexible coupling between motor and changer mechanism not correctly assembled; or instrument is not being operated at normal room temperature (65° F).
9. Record knives strike edge of records—Records warped; record edges are rough; or knife adjustments "F" and "G" are incorrect.
10. Record not released properly—Adjust record shelf assemblies in respect to shaft by means of adjustment "H".
11. Needle lands in 10 inch position on 12 inch record or misses record when playing both types mixed—Increase tension of pickup locating lever spring "34".

### Automatic Record Changer GENERAL INFORMATION

Before servicing the automatic record changer, inspect the assembly to see that all levers, parts, gears, springs, etc. are in good order and are correctly assembled.

A bind or jam in the mechanism can usually be relieved by rotating the turntable in the reverse direction.

The changer can be conveniently rotated through its change cycle by pushing the index lever to "Reject" and revolving the turntable by hand. Six turntable revolutions are required for one change cycle.

The turntable, spindle, and pinion gear are assembled by means of a 3/32 inch straight pin. This pin may be removed by gently driving with a standard pin punch.

If the record changer or cabinet is not perfectly level, normal operation is likely to be affected.

The 10 and 12 inch records must be absolutely flat for smooth operation when using a mixture of the two sizes.

A shorting switch, located in the pickup head, operates due to pressure when the pickup is placed on the pickup rest.

### ADJUSTMENTS

**A. Main Lever.**—This lever is basically important in that it interlinks the various individual mechanisms which control needle landing, tripping, record separation, etc. One adjustment is provided for the main lever. Rotate the turntable until the changer is out-of-cycle; and adjust rubber bumper bracket (A) so that the roller clears the nose of the cam plate by 1/16 inch.

**B. Friction Clutch.**—The motion of the tone arm toward the center of the record is transmitted to the trip pawl "22" by the trip lever "7" through a friction clutch "5". If the motion of the pickup is abruptly accelerated or becomes irregular due to swinging in the eccentric groove, the trip finger "7" moves the trip pawl "22" into engagement with the pawl on the main gear, and the change cycle is started. Proper adjustment of the friction clutch "5" occurs when movement of the tone arm causes positive movement of the trip pawl "22" without tendency of the clutch to slip. The friction should be just enough to prevent slippage, and is adjustable by means of screw "B". If adjustment is too tight, the needle will repeat grooves; if too loose, tripping will not occur at the end of the record.

**C. Pickup Lift Cable Screw.**—During the record change cycle, lever "16" is actuated by the main lever "15" so as to raise the tone arm clear of the record by means of the pickup lift cable. To adjust pickup for proper elevation, stop the changer "in-cycle" at the point where pickup is raised to the maximum height above turntable plate, and has not moved outward; at this point adjust locknuts "C" to obtain 1 inch spacing between needle point and turntable top surface.

**D. & E. Needle Landing on Record.**—The relation of coupling between the tone arm vertical shaft and lever "20" determines the landing position of the needle on a 10 inch record. Position of eccentric stud "E" governs the landing of the needle on a 12 inch record; this, however, is dependent on the proper 10 inch adjustment.

To adjust for needle landing, place 10 inch record on turntable; push index lever to reject position and return to the 10 inch position; see that pickup locating lever "17" is tilted

### General Description

Model M50 is a five-tube superheterodyne receiver with loudspeaker and radio chassis in the same case. It is equipped with five push buttons, for tuning your five favorite broadcast stations, as well as the standard method of dial tuning. Adjustments for push button tuning are explained under the heading "Push Button Tuning Mechanism." The receiver is designed to be mounted under the dash panel. The operating controls are integral with the radio and speaker case.

**Loudspeaker.**—The loudspeaker voice coil should be centered in the usual manner with three narrow paper feelers, after first removing the front dust cover. The dust cover should be cemented back in place with ambroid cement after adjustment has been completed.

Position of Dial Pointer	Generator Frequency	Dummy Antenna	Generator Connection	Adjustment Symbol	Circuit Adjusted
No Signal 550-750 kc	455 kc	.001 mfd.	6K7 Grid	L-10	2nd I.F. Trans.
No Signal 550-750 kc	455 kc	.001 mfd.	6A8 Grid	L-8, L-9	1st I.F. Trans.
1,400 kc	1,400 kc	.0001 mfd. †	Ant. Lead	C-3	Ant.
600 kc	600 kc	.0001 mfd. †	Ant. Lead	L-2	Ant.
1,400 kc	1,400 kc	.0001 mfd. †	Ant. Lead	C-3*	Ant.

**NOTE:** No oscillator alignment adjustments are required in this receiver.

† Make the generator connection to the receiver thru a shielded lead-in having not more than 50 mmf. (.00005) capacity with a male connector attached for connection to antenna socket. If C-2 has been changed, as outlined under "Antenna Circuit," for reason of a high capacity antenna, the Dummy Antenna should be the same value as the antenna itself.

\* Re-adjust C-3 after installation as outlined under "Antenna Circuit"

Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the A.V.C. action of the receiver from interfering with accurate alignment.

Alignment adjustment locations are shown on the top and bottom parts location views of chassis.

Only the dummy antenna indicated in the chart for any particular frequency should be used. Grid cap leads should remain in place during alignment.

Oscillator circuit alignment is not required in this receiver at either end of the band; the oscillator coil is pre-adjusted for inductance in the factory.

Since the oscillator coil is unshielded, the case has some effect on its inductance. Therefore alignment must be done either with the chassis in the case or with a steel plate (covering the bottom of chassis), substituting for the case.

**MODEL M60 Chassis No. RC 357K**

† Make the generator connection to the receiver through a shielded lead-in having not more than 50 mmf. (.00005) capacity with a male connector attached for connection to antenna socket. If a capacitor has been added in series with the lead from antenna filter L-1 to the antenna coil, as outlined under "Antenna Circuit," for reason of a high capacity antenna, the Dummy Antenna should be the same value as the antenna itself.

\* Re-adjust C-3 after installation as outlined under "Antenna Circuit";

Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the A.V.C. action of the receiver from interfering with accurate alignment.

Alignment adjustment locations are shown on the top and bottom parts location views of chassis.

Only the dummy antenna indicated in the chart for any particular frequency should be used. Grid cap leads should remain in place during alignment.

**\*\* OSCILLATOR CIRCUIT**

A magnetite core is used to provide temperature stability. The conventional high frequency trimmer has been replaced with a fixed temperature-compensating capacitor (C-12) which determines the high frequency range. Since the inductance of L-7 is adjustable, the conventional series trimmer has been replaced with a fixed capacitor (C-10). C-10 is a special capacitor having zero temperature coefficient to provide for oscillator stability in the low frequency range. Aligning the receiver for 600 kc is accomplished by adjusting L-7 to the antenna and det. circuits (gang condenser must be rocked while making this adjustment). The 1,400 kc alignment is accomplished by adjusting the antenna and the det. trimmers (C-3 and C-5) to the oscillator.

 Antenna Data,  
 Tuner Data

RCA MFG. CO., INC.

### Antenna Circuit

#### M50

The antenna circuit is designed to work with a low capacity antenna having a total capacity including the shielded lead-in not to exceed 150 mmf. If larger antennas, such as screened top or a double under the running-board having a total capacity of 200 to 550 mmf. is to be used, it will be necessary to reduce the value of the antenna coupling capacitor C-2 from .01 to approximately 200 mmf. (.0002). For even larger antennas such as insulated steel tops, a correspondingly smaller value of C-2 (approximately 125 to 150 mmf.) should be used keeping in mind to use the largest value possible with which the antenna circuit can be aligned.

#### M60

The antenna circuit is designed to work with an antenna having a total capacity including the shielded lead-in not to exceed 150 mmf. If an antenna having a larger capacity is to be used, it will be necessary to add a capacitor in series with the lead from antenna filter L-1 to the antenna coil terminal ("A"). Where a "Double Under the Running Board" type of antenna is to be used having a capacity of approximately 200 mmf. the capacitor added should be approximately 300 mmf. The insulated running board type having an approximate capacity of 550 mmf. will require a capacitor of approximately 200 mmf. Cars using an insulated steel top of approximately 3,500 mmf. will require a series capacitor of 150 mmf.

#### M50 M60

After installation, and with antenna connected, tune in a weak station near 1,400 kc and adjust compensator trimmer (C-3) for maximum signal output. This trimmer is accessible by prying off the nameplate between the control knobs.

### Antenna Filter

A filter is included in the antenna circuit. Being completely shielded, it prevents radiating ignition interference within the set. It also reduces the possibility of picking up vibrator interference. The filter unit is mounted inside a steel shell which in turn is welded to the chassis. The shielded antenna lead-in makes contact with the filter unit within the steel shell and is held in place by a bayonet type connector.

## Push Button Tuning Mechanism

The push button tuning mechanism used in this receiver is of the mechanical type, wherein the movement of the button actually turns the tuning condenser to any pre-determined setting. The movement is actuated thru a Push-Arm, Cam, Rocker Plate and Sector Gear, which meshes with a Scissors Gear directly fastened to the tuning condenser shaft. The scissors gear prevents backlash between the sector gear and the tuning condenser. Since the sector gear is mounted directly on the rocker plate shaft, the position of the rocker plate will accurately determine the position of the tuning condenser.

### Setting Up Stations

The push buttons should be adjusted for five favorite stations after the receiver is installed and operating.

Any standard broadcast stations may be chosen. The preferable arrangement is to adjust for stations in the order of frequency, from low to high. Proceed as follows:

1. Loosen the push buttons one-half turn.
2. Using the tuning control, accurately tune in the first station.

Tuning Mechanism

3. With station accurately tuned in, press the first push button fully in and then gently release so as not to jar mechanism.
4. Tighten the push button securely with fingers. Do not force with pliers.
5. Proceed in same manner to adjust the other four push buttons.

### Adjustments

The mechanism should be adjusted so that when using either manual or push-button tuning, it operates positively and without backlash or bind. The following hints will be found helpful in adjusting the mechanism properly.

1. With the gang condenser in full mesh, the sector gear should have the two end teeth fully meshed in the scissor gear.
2. The position of the sector gear on the rocker-plate shaft should be adjusted so that there is clearance between the rocker-plates and the frame of the push-button mechanism at both extremities of gang rotation. Thus correct adjustment prevents the rotation of the gang being limited by the rocker plates touching the frame.
3. The drive cord should have  $8\frac{1}{2}$  turns around the tuning shaft as shown in the illustration. Three degrees of adjustment of the tension on the drive cord may be obtained by use of the three positions for connecting the drive-cord-tension spring to the drive-cord drum on the condenser shaft as shown.
4. The push-arms, rocker-plate shaft, and pulleys should be lubricated with light grease (sparingly). Care should be taken to keep the lubricant off the drive cord.

### Manual Tuning

A manual tuning knob is provided so that additional stations may be tuned in as desired. The manual tuning shaft is connected thru a cord drive to a drum on the rocker plate shaft. This same cord drives the dial drum by passing over a pulley on the drum shaft. A sketch shows the complete cord drive assembly and the correct number of turns which the cord should be wrapped around the drive shaft and dial drum pulley. Stops are provided on the dial drum so that dial scale adjustment is made by tuning the set to the extreme ends of the band.

R-F Wiring Diagram and Socket Voltages

Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within ± 20% with 117-volt a-c supply.

\*NOTE: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

MODEL U50, Chas. RC-414C  
 Socket, Trimmers, Dial Data  
 Alignment, Phono, Data

RCA MFG. CO., INC.

Reduced Reproduction of Receiver Dial, and Corresponding 0-180° Calibration Scales

The corresponding position of the dial indicator for any setting of the calibration scale can be determined by drawing a line from this point on the bottom calibration scale to the same point on the top calibration scale. For example: 33° on the calibration scale corresponds to approximately 7.9 mc on "C" band, and 600 kc on "A" band, etc. Read instructions under "Alignment Procedure."

**Calibration Scale On Indicator-Drive-Cord Drum.**—In most cases it will not be necessary to remove the chassis from the dial scale for alignment, allowing the dial scale to be used for calibration. However, if alignment is made with the receiver chassis removed, the calibration scale attached to the rear of the drum which is mounted on the front shaft of the gang condenser must be used. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 135° mark on the drum scale must be vertical, and directly under the center of the gang-condenser shaft when the plates are fully meshed. The drum is held in place by one set-screw, which must be securely tightened when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the 0° mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

RANGE SWITCH C5 20MC C8 1500KC C6 6.0MC TONE CONTROL, VOLUME CONTROL, & POWER SWITCH

Phonograph Mechanism:

The phonograph motor is a self-starting, constant-speed induction type. It should be lubricated every six months by applying a few drops of light machine oil to the spindle bearing and oil hole.

The motor spindle is tapered, and a conical rubber piece fits snugly on the spindle. The hole in the turntable bushing is tapered to fit the rubber. This provides an excellent self-centering floating mounting.

A metal washer is placed on the spindle under the rubber piece. The washer has ears on the under side which fit over a pin that projects through the spindle.

The motor switch is automatic for both starting and stopping, and when properly adjusted, will turn the motor on as the pickup is moved from the pickup rest toward the turntable. The switch should be adjusted so that it will snap into the "off" position when the pickup needle is 1 1/4 inches from the center line of the spindle

\* Use minimum capacity peak if two peaks can be obtained  
 † Rock gang condenser slightly while adjusting L7.  
 \*\* Make test-oscillator connection to lug on tuning condenser stator (oscillator section) in series with .01 mfd. condenser.  
 Note.—Oscillator tracks 455 kc above signal on all bands.

Tuning Drive Ratio..... 11 to 1

shaft. The motor may be shut off at any time by placing the pickup on the pickup rest.

Power-Line Antenna:

At the back of the motorboard is a terminal board for antenna and ground connections. When it is desired to use the power line antenna, a jumper should be placed across the two outside binding-posts, thus connecting the antenna input of the receiver through a capacitor to the power line. The center binding-post is for the ground connection. When an external antenna is used, it should be connected to the post marked "ANT"

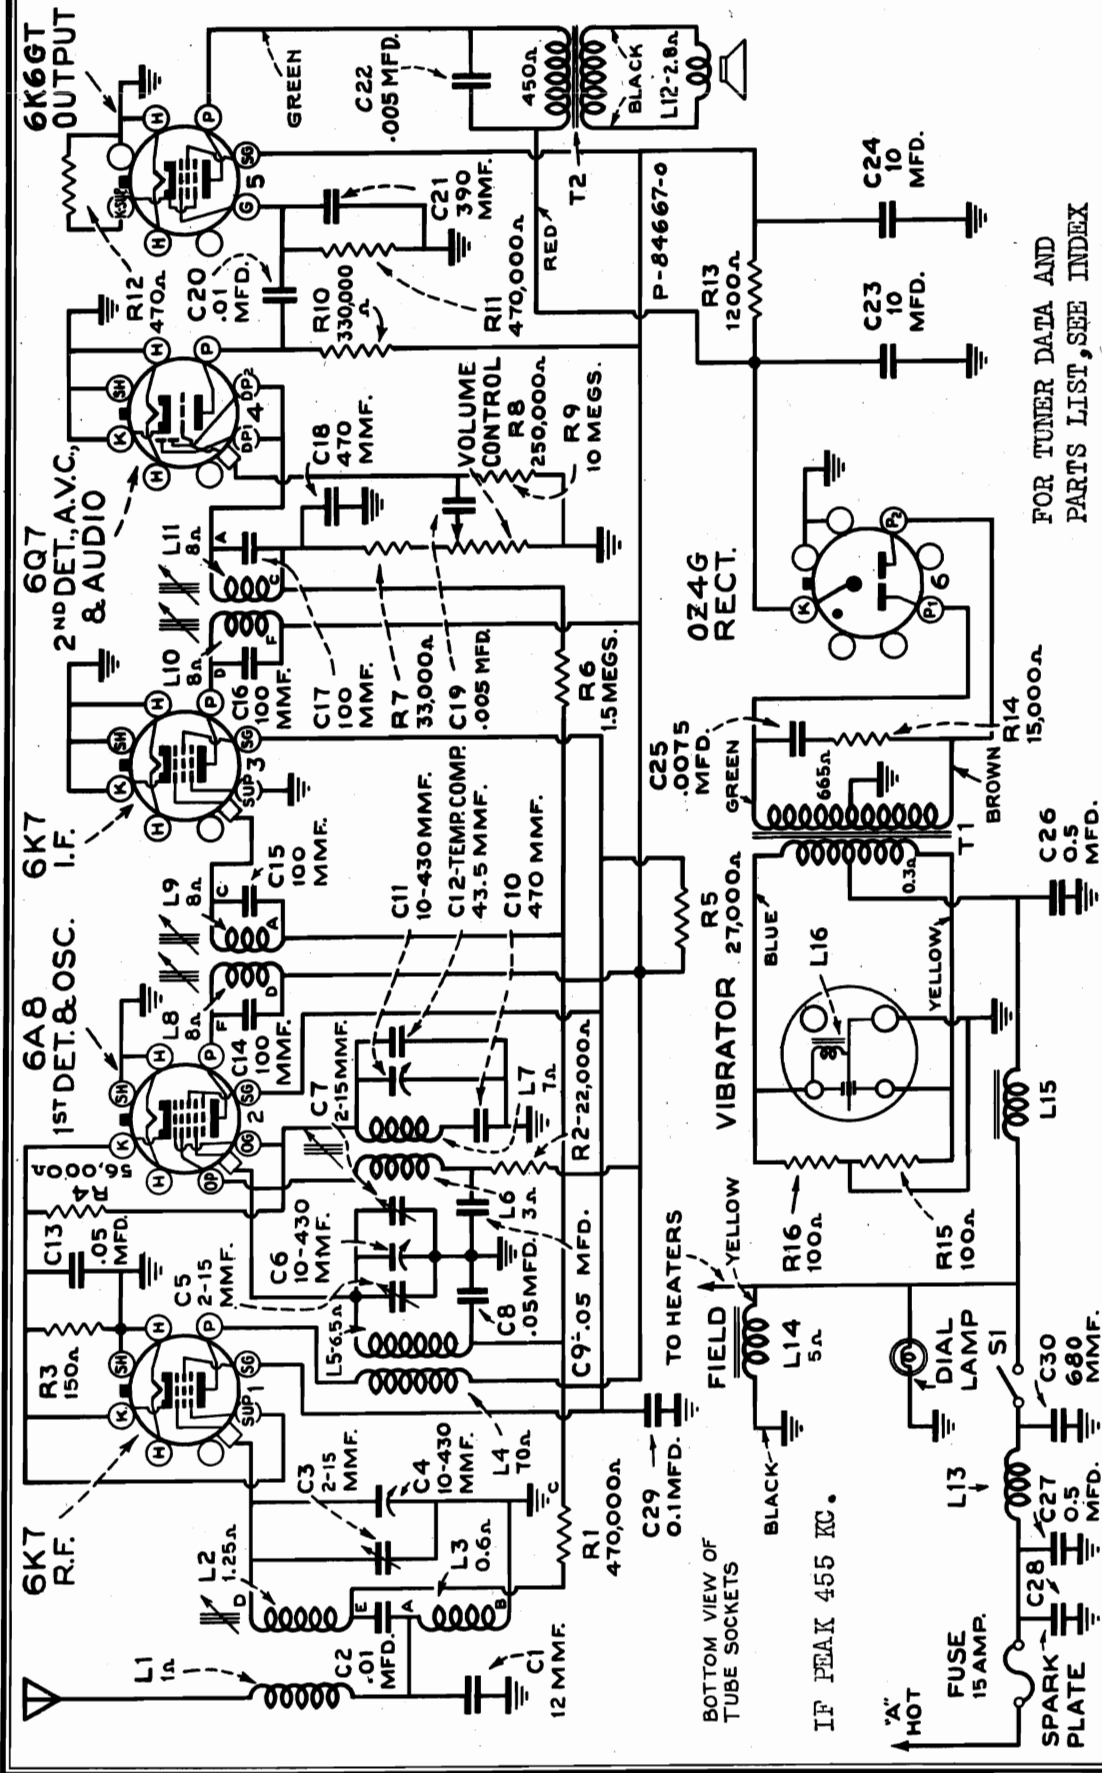

Precautionary Lead Dress:

1. Lead from 2nd I-F transformer to volume control should be kept close to the chassis and dressed against front apron.
2. C-10 should be dressed away from the antenna section of the variable condenser (C-1).

### General Description

Model M60 is a six-tube superheterodyne receiver with loudspeaker and radio chassis in the same case. It is equipped with five push buttons, for tuning your five favorite broadcast stations, as well as the standard method of dial tuning. Adjustments for push button tuning are explained under the heading "Push Button Tuning Mechanism." The receiver is designed to be mounted under the dash panel. The operating controls are integral with the radio and speaker case.

**Loudspeaker.**—The loudspeaker voice coil should be centered in the usual manner with three narrow paper feelers, after first removing the front dust cover. The dust cover should be cemented back in place with ambroid cement after adjustment has been completed.

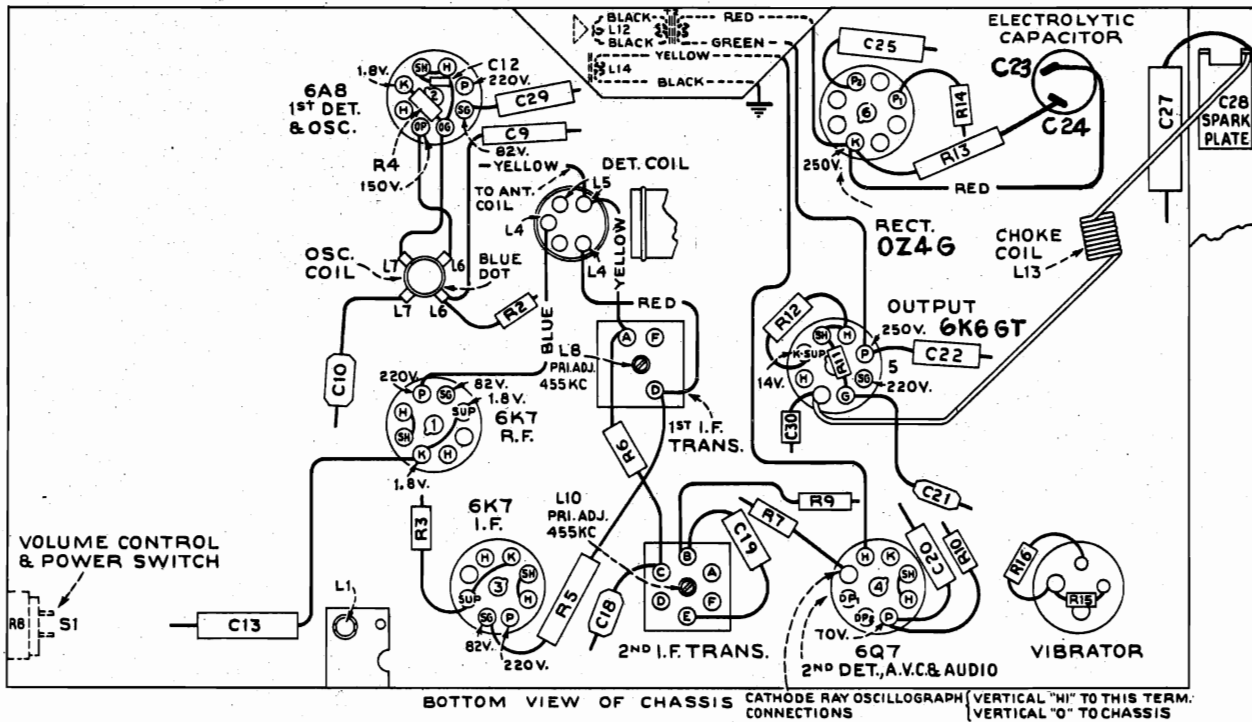

#### ALIGNMENT FREQUENCIES

I-F	455 kc
Antenna	1,400 kc
R-F	1,400 kc
Oscillator	600 kc

#### TUBES AND FUNCTIONS

- (3) RCA-6K7..... I-F Amplifier
- (4) RCA-6Q7.. Second Detector, A-F Amplifier and A.V.C.
- (5) RCA-6K6GT ..... Output
- (6) RCA-0Z4G..... Rectifier

Top View of Chassis

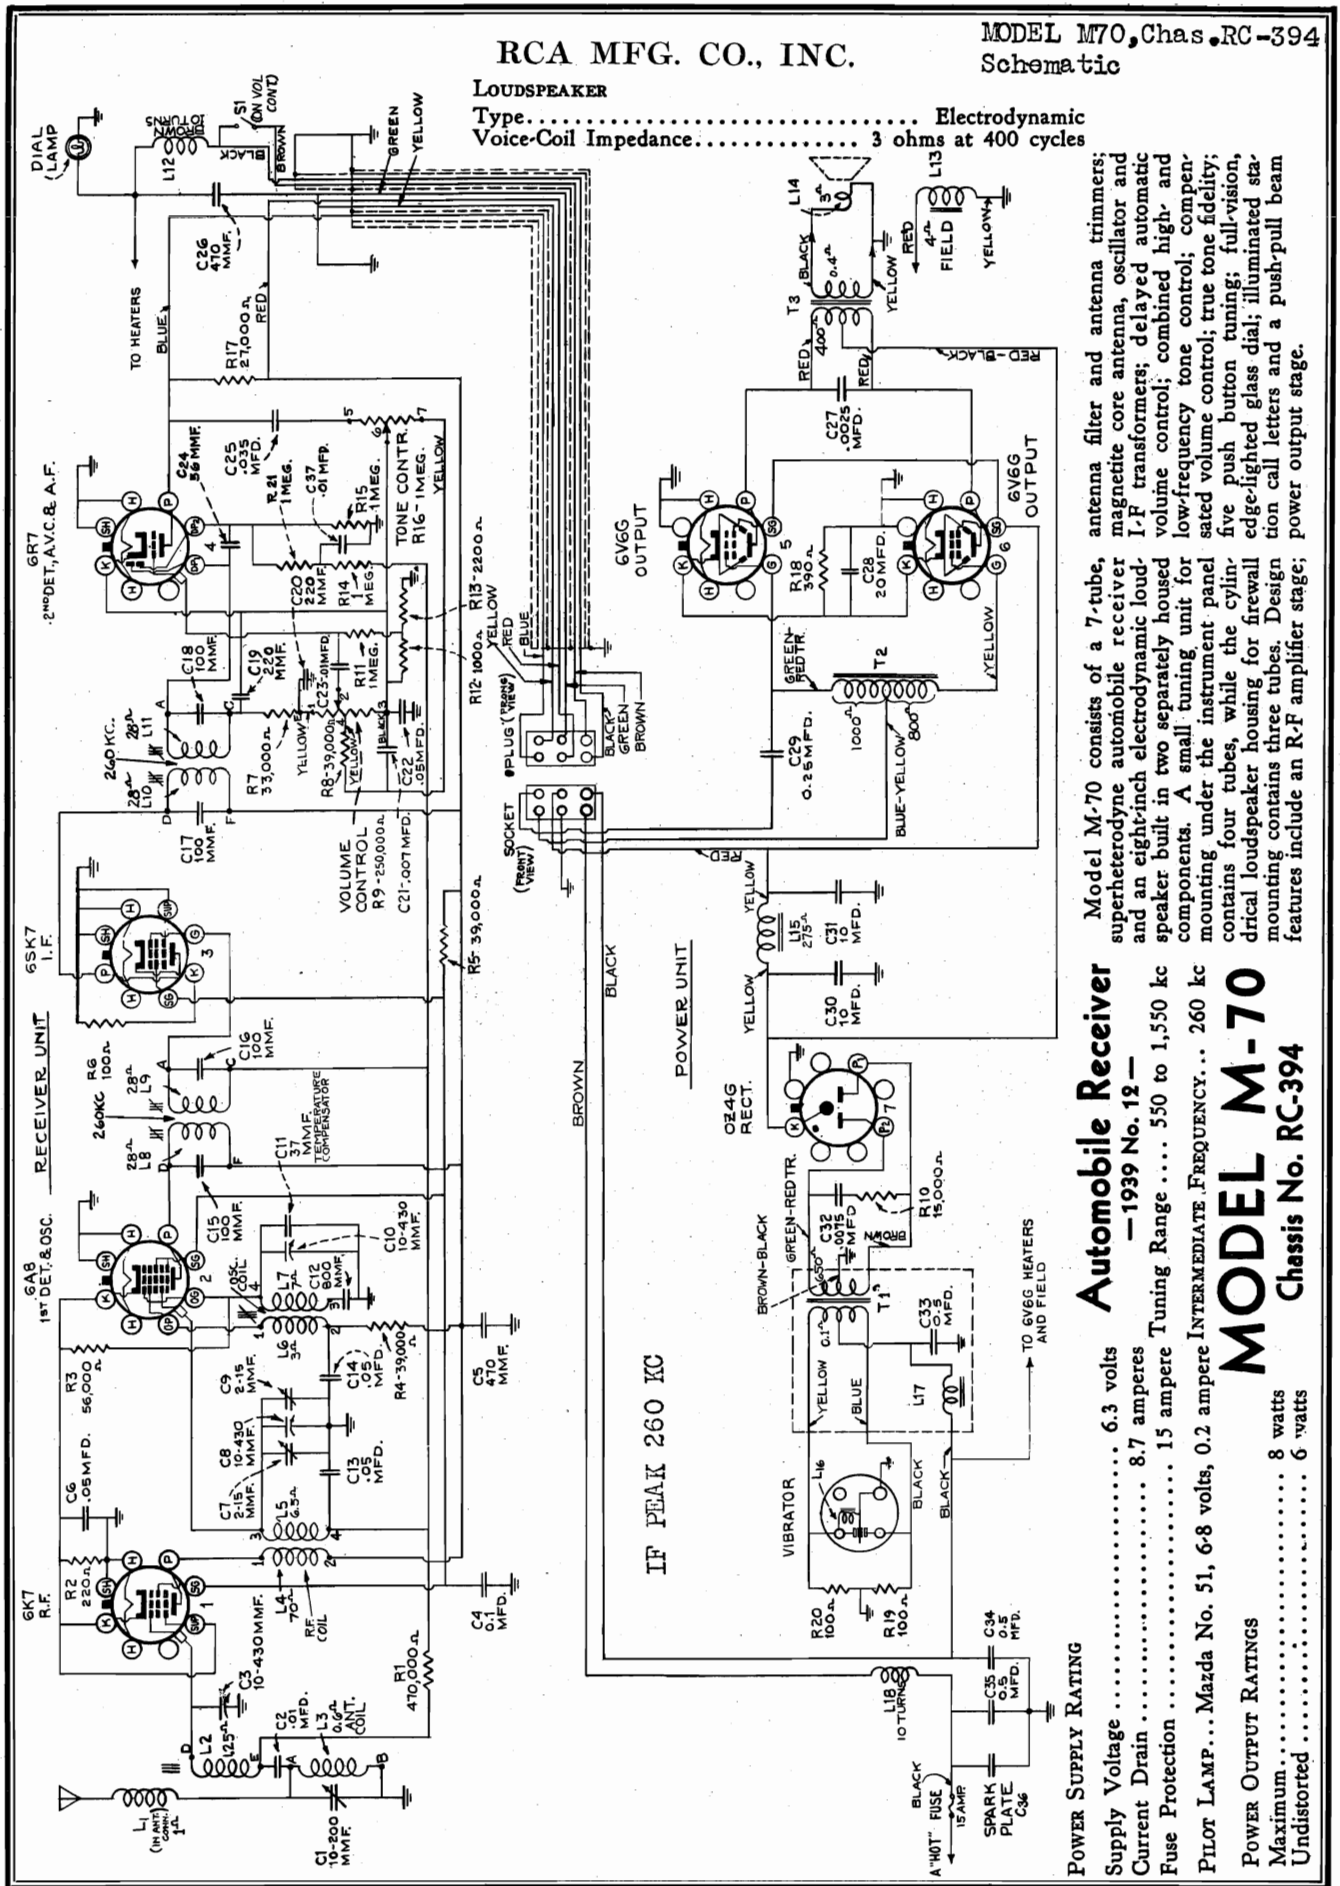

Bottom View of Parts and Socket Voltages

(Measured at 6.3 volts battery supply—Volume control minimum—No signal input—)

To duplicate the conditions under which the above voltages were measured requires a 1,000-ohm-per-volt d-c meter having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the indicated voltage value. Each value should hold within  $\pm 20\%$  when the receiver is normally operative at its rated battery voltage.

RCA MFG. CO., INC.

MODEL M70, Chas. RC-394  
Schematic

Model M-70 consists of a 7-tube, superheterodyne automobile receiver and an eight-inch electrodynamic loudspeaker built in two separately housed components. A small tuning unit for mounting under the instrument panel contains four tubes, while the cylindrical loudspeaker housing for firewall mounting contains three tubes. Design features include an R-F amplifier stage; antenna filter and antenna trimmers; magnetite core antenna, oscillator and I-F transformers; delayed automatic volume control; combined high- and low-frequency tone control; compensated volume control; true tone fidelity; five push button tuning; full-vision, edge-lighted glass dial; illuminated station call letters and a push-pull beam power output stage.

### Adjustment of Push-Button Mechanism

The mechanism should be adjusted so that when using either manual or push-button tuning, it operates positively and without backlash or bind. The following hints will be found helpful in adjusting the mechanism properly.

1. With the gang condenser in full mesh, the sector gear should have the two end teeth fully meshed in the scissor gear, as shown in the illustration.
2. The position of the sector gear on the rocker-plate shaft should be adjusted so that there is clearance between the rocker-plates and the frame of the push-button mechanism at both extremities of gang rotation. Thus correct adjustment prevents the rotation of the gang being limited by the rocker plates touching the frame.
3. The drive cord should have 6 1/2 turns around the tuning shaft as shown in the illustration. Three degrees of adjustment of the tension on the drive cord may be obtained by use of the three positions for connecting the drive-cord-tension spring to the drive-cord drum on the condenser shaft as shown.
4. The push-arms, rocker-plate shaft, and pulleys should be lubricated with light grease (sparingly). Care should be taken to keep the lubricant off of the drive cord.

### Push Button Adjustment

The push buttons should be adjusted for five favorite stations after the receiver is installed and operating.

Any standard broadcast stations may be chosen. The preferable arrangement is to adjust for stations in the order of frequency, from low to high. Proceed as follows:

1. Loosen the push buttons one-half turn.
2. Using the tuning control, accurately tune in the first station.
3. With station accurately tuned in, press the first push button fully in and then gently release so as not to jar mechanism.
4. Tighten the push button securely with fingers. Do not force with pliers.
5. Proceed in same manner to adjust the other four push buttons.

TURN FREE GEAR CLOCKWISE ONE TOOTH TO OBTAIN SCISSOR ACTION BEFORE MESHING GEAR

M-70

### Alignment Procedure

**Test Oscillator.**—For all alignment operations, connect the low side of the test oscillator to the receiver chassis, and keep the output signal as low as possible to avoid a-v-c action.

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are as follows: Vertical "HI" to terminal "C" on 2nd I-F transformer; vertical "0" to chassis.

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6SK7 I-F grid (No. 4 pin) in series with .01 mfd.	260 kc	No Signal 550-750 kc	L10 and L11 (2nd I-F Trans.)
2	6A8 Det. grid cap in series with .01 mfd.	260 kc	600 kc	L8 and L9 (1st I-F Trans.)
3 †	* Ant. connector in series with 60 mmfd.	600 kc	1,400 kc signal	L7 (osc.)
4 †	* Ant. connector in series with 60 mmfd.	1,400 kc	600 kc (rock)	C7 (det.) C1 (ant.)
5 †	* Ant. connector in series with 60 mmfd.	600 kc	1,400 kc signal	L7 (osc.)
6 †	* Ant. connector in series with 60 mmfd.	1,400 kc		C7 (det.) C1 (ant.)**

\* Note 1.—This 60 mmfd. capacitor must be inserted at the antenna connector of the receiver. The lead from the test oscillator to the 60 mmfd capacitor may be shielded if desired, but no shielding should be used between capacitor and antenna connector.

† Note 2.—These adjustments should be made with unit enclosed in its shielded case, through holes provided for adjustment purposes.

\*\* Note 3.—Final adjustment of C1 must be made after the receiver has been installed and the antenna connected. See "Antenna Circuit." steel top of approximately 3,500 mmf will require a series capacitor of 150 mmf.

### Antenna Circuit

It is very important that these instructions be followed when installing the M-70 receiver.

The antenna circuit is designed to work with an antenna having a total capacity including the shielded lead-in not to exceed 150 mmf. If an antenna having a larger capacity is to be used, it will be necessary to add a capacitor in series with the lead from the antenna filter L-1 to the antenna coil terminal ("A"). Where a "Double Under the Running Board" type of antenna is to be used having a capacity of approximately 200 mmf., the capacitor added should be approximately 500 mmf. The insulated running board type having an approximate capacity of 550 mmf. will require a capacitor of approximately 150 mmf. Cars using an insulated

**Output Meter.**—Connect the output meter across the speaker voice-coil and turn the receiver volume control to maximum. (fully clockwise) and tone control to middle of range.

**Dial Calibration.**—Rotate the gang condenser to its full-mesh (maximum-capacity) position and then adjust dial scale so that the pointer is aligned to the last calibration mark at the low-frequency end of the scale.

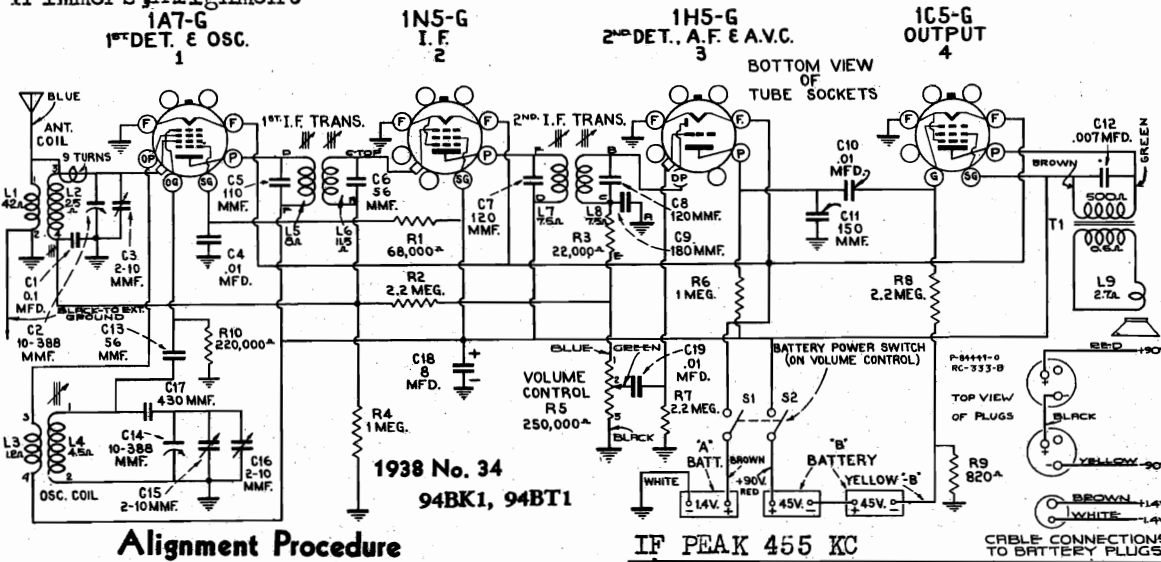

After installation and with antenna connected, tune in a weak station near 1,400 kc and adjust compensator trimmer C-1 for maximum signal output. This trimmer is accessible by removing plug button near antenna jack on top of receiver. If a maximum (peak) signal output cannot be obtained in the range of the antenna trimmer, the effective capacity should be checked and compensated for by varying series capacity as described above.

### Loudspeaker

The loudspeaker cone may be centered in the usual manner with three celluloid or paper feelers after gently cutting away the front dust cover. A new cover should be cemented in place upon completion of the adjustment.

Chassis RC-333B  
Schematic, Voltage, Socket  
Trimmers, Alignment

RCA MFG. CO., INC.

**Alignment Procedure**

Cathode-ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action. For additional details, refer to booklet "RCA Victor Receiver Alignment."

**Pre-setting Dial.**—With gang condenser in full mesh, the pointer should be horizontal.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
No. 1	1N5-G I-F grid cap, in series with 0.01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L8 (2nd I-F transformer)
No. 2	1A7-G 1st-det. grid cap, in series with 0.01 mfd.	455 kc		L5 and L6 (1st I-F transformer)
No. 3	Antenna lead, in series with 200 mmfd.	600 kc	600 kc	L4 (oscillator) L2 (antenna)
No. 4	Antenna lead, in series with 200 mmfd.	1,500 kc	1,500 kc	C15† (oscillator) C3 (antenna)

† Trimmer C16 on gang condenser should be unscrewed one complete turn from tight, before adjusting C15.

**Precautionary Lead Dress**

1. Red lead from second i-f transformer to screen terminal of 1N5-G must be dressed close to and along edge of chassis.
2. Twisted green wire from antenna coil to gang must be 9 turns and kept clear of rotor.
3. Blue and green leads to volume control must be dressed close to chassis and between gang and front apron.

The 94BK2 is a console model; the 94BT2 a table model. Each of these receivers is a low-drain, battery-operated superheterodyne. The design features include gang-tuned push button coils for single control electric tuning adjustments; magnetite-core i-f transformers and "A" band r-f coils; automatic volume control; and permanent magnet dynamic speaker. Push button electric tuning is provided for four favorite broadcast stations; two additional push-buttons provide dial tuning for "Standard-broadcast" and "Short-wave" bands.

### Alignment Procedure

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are shown on the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test Oscillator.**—For all alignment operations, connect the low side of the test oscillator to the chassis, and keep the output as low as possible to avoid a-v-c action.

**Calibration Marks.**—The tuning dial is fastened in the cabinet and can not be used for reference during alignment. Therefore calibration marks corresponding to dial readings of 600 kc, 1,500 kc, and 15.2 mc have been stamped in the plate on the front of the chassis as shown in the accompanying drawing. These marks are used for reference during alignment.

**Dial Indicator Adjustment.**—With the gang condenser in full mesh, the indicator should point to the extreme left (low frequency) mark on the dial scale.

For additional details, refer to booklet "RCA Victor Receiver Alignment".

Tube and Trimmer Locations

Steps	Connect the High Side of Test Oscillator to:	Tune Test Oscillator to:	Push Button	Turn Radio Dial to:	Adjust for Maximum Peak Output:
1	1N5-G I-F grid cap in series with .01 mfd.	455 kc	B.C. (5)	No Signal between 550—750 kc.	L13 and L14 (2nd I-F Trans.)
2	1A7-G Det. grid cap in series with .01 mfd.	455 kc	B.C. (5)		L11 and L12 (1st I-F Trans.)
3	Antenna Lead (blue) in series with 200 mmfd.	1,500 kc	No. 4		L20-L26 (No. 4 Push Button Adj.) C2 (ant.)
4	Antenna Lead (blue) in series with 200 mmfd.	600 kc	No. 1		* (No. 1 Push Button Adj.) L6 (osc.)
5	Antenna Lead (blue) in series with 200 mmfd.	1,500 kc	No. 4		L20-L26 (No. 4 Push Button Adj.) C2 (ant.)

10	Antenna Lead (blue) in series with 300 ohms	15.2 mc	S.W. (6)	Signal Near 15.2 mc Cal. Mark†	**C3 (ant.)
11	Follow the "Adjustments for Electric Tuning."				

\* Adjust L23—L29 (No. 1 push button adjustment) and L6 at the same time, rocking in for maximum signal.

\*\* Use maximum capacity peak if two peaks can be obtained, rock in for maximum signal. A weaker signal (image) should be received about one-quarter inch to the left on the dial plate.

† If two signals are received, set the dial to the higher frequency (right hand) position.

Note: The oscillator tracks 455 kc above the signal on all bands. After the receiver has been installed and the antenna connected, it is sometimes advisable to make a slight change in the adjustment of the antenna trimmer, C2. In most cases it is desirable to make this adjustment while receiving a station on No. 4 push button. However, if a station received on one of the other buttons is especially weak, it may be advisable to make the adjustment while receiving the weak station on this button.

Dial Drive Hookup and Alignment Marks

### Precautionary Lead Dress

- Green lead to first detector grid cap should be pulled out of the chassis as far as possible, and dressed away from the tube envelope.
- Blue lead from push button switch to gang condenser must be dressed over the top of the switch.
- Leads to push button coils must be dressed close to the coils.
- Red and blue leads to gang condenser must be dressed away from chassis.
- Blue antenna lead must be dressed in the end of the chassis away from gang leads and coil windings.

RCA MFG. CO., INC.

MODELS 94BK2, 94BT2  
Chassis RC-390  
Tuner Data, Parts

Adjustments for Electric Tuning

These models have six push buttons. The right-hand button connects the receiver for dial tuning on the "Short-wave" band, the next button connects for dial tuning on the "Standard-broadcast" band, and the other four buttons are for electric tuning of four different stations in the standard-broadcast band. Each station button connects separate oscillator and antenna coils which are tandem-tuned by ganged magnetite cores, and may be adjusted for the desired stations. Use a small screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments. Use a regular antenna for the preliminary adjustments.

The procedure is as follows:

1. Make a list of the four desired stations, arranged in order from low to high frequencies.

Location of Controls

2. Push in the broadcast dial-tuning button (second from right), and manually tune in the first station on the list.
3. Push in station button No. 1 (left-hand) and adjust No. 1 push button adjustment to receive this station. Turn the adjusting screw all the way in, to lowest frequency, and then unscrew slowly until the station is received.
4. Adjust for each of the remaining three stations in the same manner. (Clockwise adjustment of the screw tunes the circuits to lower frequencies.)
5. After installation, and with antenna properly connected, re-adjust C2 as outlined in Note under "Alignment Procedure."

Miscellaneous Service Data

To center the loudspeaker voice coil, first remove the front dust cover, then loosen the screws holding the spider assembly. Insert three narrow feelers into the air gap, and tighten the spider screws. Remove the feelers and fasten a dust cover in place with loudspeaker cement.

The push button switch and coil assembly may be removed from the chassis by removing two screws from the front apron, one from the rear apron, removing the 1A7-G grid connector from the grid cap, and disconnecting the seven leads indicated on the Wiring Diagram.

REPLACEMENT PARTS

Insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

With batteries.....	12 1/2 pounds		
Tuning Drive Ratio.....	10 to 1		

REMOVE THIS BLOCK-PLACE BATTERIES  
IN CABINET AS INDICATED

**Alignment Procedure**  
Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.  
Test-oscillator.—For all alignment operations, keep the output as low as possible to avoid a-v-c action.  
Pre-setting Dial.—With gang condenser in full mesh, the pointer should be horizontal.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	1A7G 1st-DET. grid cap. in series with .01 mfd.	455 kc	Quiet point at 1,600 kc end of dial	C1, C2, C3, C4 (1st and 2nd I-F transformers)
2	Antenna coil loop by means of one turn of wire placed near loop	1,720 kc	Full clockwise (out of mesh)	C5 (oscillator)
3		1,500 kc	Resonance on 1,500 kc signal	C6 (antenna)

The following models comprise the 94BPI Series— all contain the No. RC-407 chassis. FIL.

MODEL 94BP4, Chassis RC-410  
Schematic, Voltage, Alignment  
Chassis Wiring, Socket  
Trimmers, Lead Dress

94BP4  
—1938 No. 40—

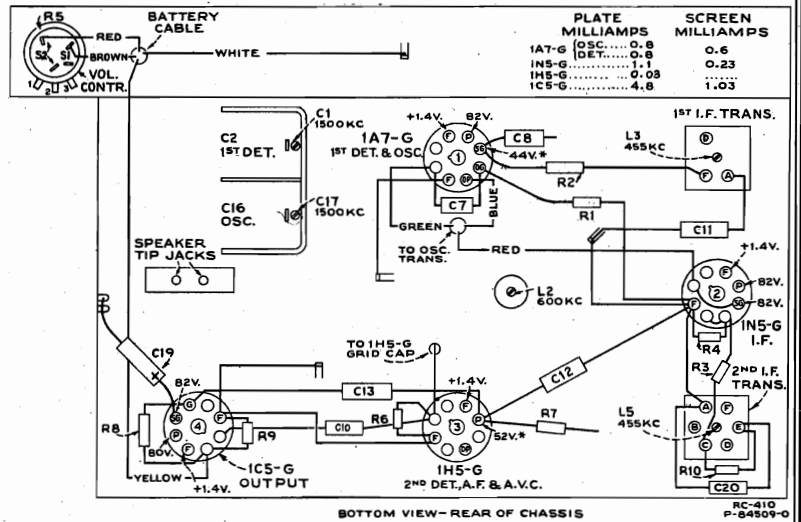

POWER OUTPUT  
Undistorted..... 0.10 watt  
Maximum..... 0.21 watt

CURRENT CONSUMPTION  
"A" 0.24 ampere—  
9.0 milliamperes  
"B" two 45 volt dry  
plug-type "B,"  
2 1/2-in. x 4-in. x 5 1/2-in.  
BATTERIES REQUIRED  
"A," one 1.5 volt dry  
plug-type "A,"  
(No. 742)  
"B," two 45 volt dry  
plug-type "B,"  
(No. 732)

Tube Location

Note: Values with star (\*) are operating voltages. Values not starred are actual measured voltages. Measurements are made to chassis unless otherwise indicated, with set tuned to quiet point. Values should hold within approximately ± 20% with rated battery voltage.

R-F Wiring Diagram and Socket Voltages

### Alignment Procedure

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-oscillator.**—For all alignment operations, keep the output as low as possible to avoid a-v-c action.

**Pre-setting Dial.**—With gang condenser in full mesh, the pointer should be horizontal.

#### Precautionary Lead Dress.

1. Dress speaker leads down to chassis.
2. The green lead from the loop to the antenna section of the gang should be dressed between the output and detector tube shields and pulled toward the far corner of the loop by means of the rubber band.
3. The spiral shield on the 1st-A.F. grid lead should be brought as close as possible to the grid cap.
4. Leads to the high side and tap of the volume control should be dressed down to the chassis and away from the output tube plate lead.

**Antenna.**—An antenna and ground may be connected to "A" and "G" at bottom of cabinet. If total length of antenna and lead-in is more than 150 feet, connect a 300 mmf capacitor in series with lead-in.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	1N5-G grid cap, in series with .001 mfd.	455 kc	Quiet point between 550-750 kc	L5 and L6 (2nd I-F transformer)
2	1A7-G grid cap, in series with .001 mfd.	455 kc		L3 and L4 (1st I-F transformer)
3	Assemble chassis and batteries in correct position in cabinet, and fasten rear cover (loop) in place while making the following adjustments, which are accessible through holes in the bottom of the cabinet.			
4	Antenna terminal, in series with 200 mfd. Connect low side of test-osc. to "G" term.	1500 kc	1500 kc*	C17 (osc.) C1 (ant.)
5		600 kc	600 kc*	L2 (osc.) Rock in
6	Repeat steps 4 and 5.			

\* Use bottom of "1" in "150" for 1500 kc calibration point, and use center of "0" in "60" for 600 kc calibration point.

Width 10 1/8 in.  
Height 12 3/8 in.  
Cabinet Dimensions... 2 in.  
Chassis Base.....

Socket Voltages and Location of Parts

\* NOTE: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.  
Measurements made to chassis unless otherwise indicated, with the set tuned to a quiet point and the volume control at minimum. Values should hold within approximately ± 20% with 6 volts "A."

Alignment Procedure

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
No. 1	6S7-G I-F grid cap, in series with .01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L8 (2nd I-F transformer)
No. 2	6D8-G 1st-det. grid cap, in series with .01 mfd.	455 kc		L5 and L6 (1st I-F transformer)
No. 3	Antenna lead, in series with 200 mmfd.	600 kc	600 kc	L4 (oscillator)
No. 4	Antenna lead, in series with 200 mmfd.	1,500 kc	1,500 kc	C23† (oscillator) C3 (antenna)

† Adjust C24 on gang condenser to one complete turn from tight before adjusting C23.

Frequency Range..... 540 to 1,720 kc  
R-F Alignment Frequencies... 600 kc (osc.), 1,500 kc (osc., ant.)  
Intermediate Frequency..... 455 kc

Cathode-ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-oscillator.—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Pre-setting Dial.—With gang condenser in full mesh, the pointer should be horizontal.

BATTERY REQUIRED  
6-volt Storage "A" Battery.  
POWER OUTPUT (6 volts "A")  
Undistorted..... 0.45 watt  
Maximum..... 0.8 watt

CURRENT CONSUMPTION  
At 6 volts, 1.6 amperes.

MODELS 96BK6, 96BT6  
Chassis RC-392  
Socket, Trimmers  
Alignment Procedure

# MODELS 96BK6 and 96BT6

Chassis No. RC-392 Alignment Procedure

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown on the chassis drawing.

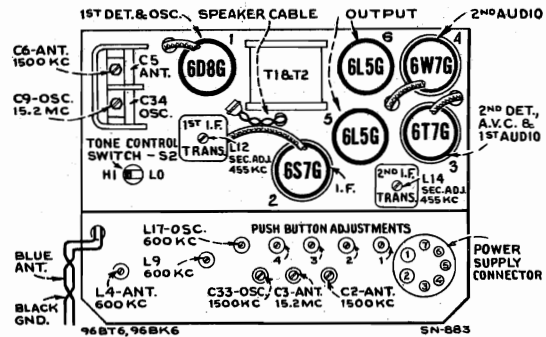

**Output Meter Alignment.**—If this method is used, connect the output meter across the voice coil, and turn the receiver volume control to maximum.

**Test Oscillator.**—For all alignment operations, connect the low side of the test oscillator to the receiver chassis, and keep the oscillator output as low as possible to avoid a-v-c action.

**Calibration Marks.**—The tuning dial is fastened in the cabinet and can not be used for reference during alignment. Therefore calibration marks corresponding to dial readings of 600 kc, 1,500 kc, and 15.2 mc have been stamped in the plate on the front of the chassis as shown in the accompanying drawing. These marks are used for reference during alignment.

**Dial Indicator Adjustment.**—With the gang condenser in full mesh, the indicator should point to the extreme left (low frequency) mark on the dial scale.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

### Tube and Trimmer Locations Miscellaneous Service Data

To center the loudspeaker voice coil, first remove the front dust cover, then loosen the screws holding the spider assembly. Insert three narrow feelers into the air gap, and tighten the spider screws. Remove the feelers and fasten a dust cover in place with loudspeaker cement.

The push button switch and coil assembly may be removed from the chassis by removing two screws from the front apron, one from the rear apron, removing the 6D8-G grid connector from the grid cap, and disconnecting the seven leads indicated on the Wiring Diagram.

Location of Controls

## MODEL 94BT61 Chassis No. RC-333-C

### Precautionary Lead Dress

- Capacitors C20 and C26 must be grounded with as short a lead as possible. C4 and C27 are soldered direct (no leads).
- The "A" supply choke (L13) must be dressed clear of chassis. The H.V. secondary leads (brown and green), C18, and R12 must be dressed clear of the chassis and away from other leads.
- The H.V. secondary mid-tap (brown-black) lead, and the brown lead from L13 to 6G6-G filament must be dressed close to the chassis and away from other parts.

- The lead from the antenna coil (L1 and L2) to the gang must be 9 turns and kept clear of the rotor.
  - The I-F plate lead (blue) must be dressed close along edge of chassis.
  - R10 must be wired with body as close to terminal board as possible.
- Battery Charger Connections.**—The positive side of the 6-volt "A" circuit is connected to the receiver chassis, and the chassis is normally grounded. If the charger has a ground on the negative side, the ground should be removed, or changed to the positive. Do not change the length of the leads from the receiver to the battery.

MODELS 96BK6, 96BT6  
Chassis RC-392  
MODEL CV-9 A-C S.P.U.

Schematic Circuit Diagram for Models 96BK6, 96BT6 and CV-9 A-C Power Unit

**FREQUENCY RANGES**

Standard Broadcast ("A" Band)..... 540—1,720 kc  
Short Wave ("C" Band)..... 5.8—18 mc  
Four Electric Tuning Positions..... 550—1,500 kc  
One station between approximately 550—950 kc (Button No. 1)  
One station between approximately 610—1,090 kc (Button No. 2)  
One station between approximately 750—1,370 kc (Button No. 3)  
One station between approximately 845—1,500 kc (Button No. 4)  
Intermediate Frequency..... 455 kc

**POWER SUPPLY RATINGS**  
With CV-9 a-c power supply unit:  
100-130/140-160/195-250 volts, 25-60 cycles, 45 watts

**Adjustment for Electric Tuning**

These models have six push buttons. The right-hand button connects the receiver for dial tuning on the "Short-wave" band, the next button connects for dial tuning on the "Standard-broadcast" band, and the other four buttons are for electric tuning of four different stations in the standard-broadcast band. Each station button connects separate oscillator and antenna coils which are tuned by ganged magnetite cores, and may be adjusted for the desired stations. Use a small screw-driver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments. Use the regular antenna for all adjustments.

The procedure is as follows:

1. Make a list of the four desired stations, arranged in order from low to high frequencies.
2. Push in the broadcast dial-tuning button (second from right), and manually tune in the first station on the list.
3. Push in station button No. 1 (left-hand) and adjust No. 1 push button adjustment to receive this station. Turn the adjusting screw all the way in, to lowest frequency, and then unscrew slowly until the station is received.
4. Adjust for each of the remaining three stations in the same manner. (Clockwise adjustment of the screw tunes the circuits to lower frequencies.)
5. After installation, and with antenna properly connected, re-adjust C2 as outlined in note under "Alignment Procedure."

Dial Drive Hookup and Alignment Marks

With RS-79B d-c power supply unit:  
6.3 volts; total current drain 1.85 amps.

**POWER OUTPUT**

	Undistorted	Maximum
With a-c power unit	2.2 watts	3.5 watts
With d-c power unit	1.7 watts	2.2 watts

**LOUDSPEAKER**  
Type..... Permanent Magnet Dynamic  
Voice Coil Impedance..... 2.2 ohms at 400 cycles  
Diameter..... 96BK6, 8 inches; 96BT6, 6 inches

	Model 96BT6	Model 96BK6
Height	10 1/2 inches	39 1/2 inches
Width	20 1/2 inches	26 inches
Depth	9 1/2 inches	12 1/2 inches
Net Weight	17 1/2 pounds	21 pounds
Shipping Weight	46 pounds	61 pounds
Chassis Base Dimensions	3 inches x 11 1/2 inches x 5 inches	
Over-all Height of Chassis		7 1/2 inches
Tuning Drive Ratio		12 to 1

The 96BK6 is a console model, the 96BT6 a table model. Each of these receivers is a super-sensitive, six-tube superheterodyne.

**Power Supply Units**

The receiver chassis has a seven-prong male plug for connection to the power-supply unit. Both a-c and d-c power supply units are available, as listed under "Power Supply Ratings." The receivers are shipped with a d-c power unit for use with a 6-volt supply. If an a-c unit is desired, it must be purchased separately as Model CV-9.

If no receiver chassis is available the a-c unit (CV-9) may be tested for proper operation by connecting a 6,500-ohm, 10-watt resistor between terminals 2 and 4 on the cable socket, and shorting terminals 1 and 7. With one voltmeter prod on terminal 2 (ground) the following readings should be obtained: terminal 3, + 200 volts d.c.; terminal 4, + 200 volts d.c.; terminal 5, -5.9 volts d.c.; terminal 6, 6.5 volts a.c. Values should be within ± 20% with rated supply voltage.

**Precautionary Lead Dress.—**

1. Blue lead from push button switch to gang condenser must be dressed over the top of the switch.
2. Leads to push button coils must be dressed close to the coils.
3. Red and blue leads to gang condenser must be dressed away from chassis.
4. Blue antenna lead must be dressed in the end of the chassis away from gang leads and coil windings.
5. Bias cell must be installed with carbon disc connected to chassis.
6. Leads from power switch to connector plug must be dressed away from other leads.
7. Parts under push button coils must be dressed down away from them.
8. Green lead to first detector grid cap should be pulled out of the chassis as far as possible, and dressed away from the tube envelope.

Alignment, Voltage  
Chassis Wiring

Steps	Connect the High Side of Test Oscillator to:	Tune Test Oscillator To:	Press Push Button:	Turn Radio Dial to:	Adjust for Maximum Peak Output:	
1	6S7-G I-F grid cap in series with .01 mfd.	455 kc	B.C. (No. 5)	No Station Point between 550-750 kc.	L13 and L14 (2nd I-F Trans.)	
2	6D8-G Det. grid cap in series with .01 mfd.	455 kc	B.C. (No. 5)		L11 and L12 (1st I-F Trans.)	
3	Antenna Lead (blue) in series with 200 mmfd.	1,500 kc	No. 4		L20-L26 (No. 4 Push Button Adj.) C2 (ant.)	
4	Antenna Lead (blue) in series with 200 mmfd.	800 kc	No. 1		L23-L29* (No. 1 Push Button Adj.) L9 (osc.)	
5	Repeat steps 3 and 4 until maximum signal is obtained.					
6	Unscrew C9 (osc.) to minimum capacity.					
7	Antenna Lead (blue) in series with 200 mmfd.	600 kc	B.C. (No. 5)	600 kc Calibration Mark	L17 (osc.) ** L4 (ant.)	
8	Antenna Lead (blue) in series with 200 mmfd.	1,500 kc	B.C. (No. 5)	1,500 kc Calibration Mark	C33 (osc.) C6 (ant.)	
9	Repeat steps 7 and 8 until maximum signal is obtained.					
10	Antenna Lead (blue) in series with 300 ohms	15.2 mc	S.W. (No. 6)	15.2 mc Calibration Mark	C9 (osc.) † C3 (ant.) ††	
11	Antenna Lead (blue) in series with 200 mmfd.	1,500 kc	B.C. (No. 5)	1,500 kc Calibration Mark	C33 (osc.)	
12	Follow the "Adjustments for Electric Tuning."					

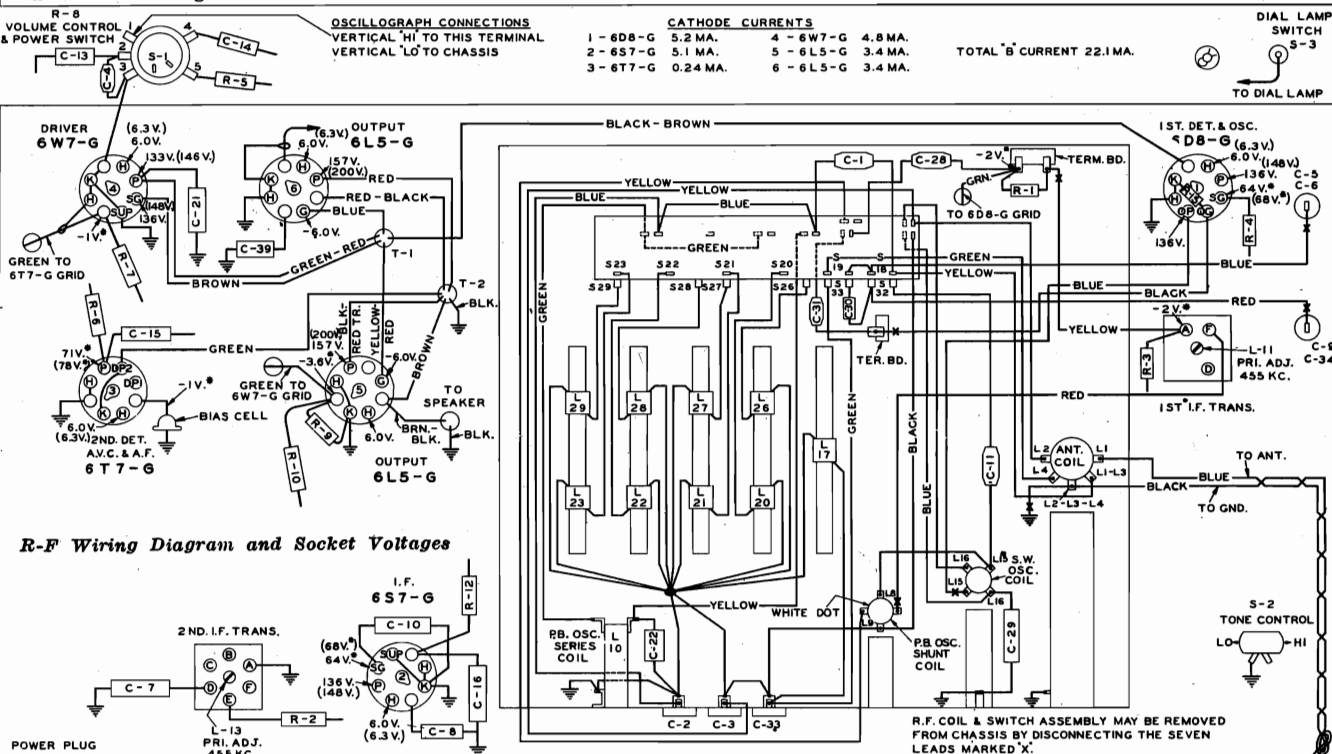

\* Adjust L23-L29 (No. 1 push button adjustment) and L9 at the same time, rocking in for maximum signal.

\*\* Turn L17 adjusting screw all the way out, then turn in slowly until a peak is reached. If two peaks can be obtained the lower inductance setting (screw out) should be used.

† Use minimum capacity peak if two peaks can be obtained. A weaker signal (image) should be received about one quarter inch to the left on the dial plate.

†† Use maximum capacity peak if two peaks can be obtained, rock in for maximum signal.

Note: The oscillator tracks 455 kc above the signal on all bands. After the receiver has been installed and the antenna connected, it is advisable to make a slight change in the adjustment of the antenna trimmer, C2. In most cases it is desirable to make this adjustment while receiving a station on No. 4 push button. However, if a station received on one of the other buttons is especially weak, it may be advisable to make the adjustment while receiving the weak station on that particular button.

R-F Wiring Diagram and Socket Voltages

BOTTOM VIEW - REAR OF CHASSIS

Measurements made to chassis unless otherwise indicated, with set tuned to a quiet point and the volume control at minimum. Values should hold within approximately ± 20% with rated supply voltage.

\* Note: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured values will be lower, depending on the voltmeter loading.

Bracketed voltages ( ) refer to operation with CV-9 a-c power unit.

Alignment, Socket, Trimmers  
 Tuner Adjustments

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed 3/8-inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the left-hand end mark, and gang condenser fully meshed.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6K8 det. grid cap, in series with .01 mfd.	455 kc		L10 and L11 (1st I-F Trans.)
3	Antenna Terminal, in series with 200 mmf.	600 kc	600 kc (150.5°) "A" band	L9
4		1,500 kc	1,500 kc (28°) "A" band	C25 (osc.) C30 (ant.)
5	Repeat steps 3 and 4.			
6	Antenna Terminal, in series with 400 ohms	6 mc	6 mc (26.5°) "B" band	C23 (osc.)*
7		20 mc	20 mc (22°) "C" band	C21 (osc.)*
8	Follow "Adjustments for Electric Tuning."			

\* Use minimum capacity peak if two peaks can be obtained, and rock gang condenser slightly while adjusting C23 and C21.

Note.—Oscillator tracks 455 kc above signal on all bands.

## ADJUSTMENTS FOR ELECTRIC TUNING

These models have eight push buttons. The left-hand button is a Victrola switch. The right-hand button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an in-

sulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

The procedure is as follows:

1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.
3. Push in station button No. 1 (second from left) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

**Clockwise adjustment of cores and trimmers tunes the circuits to lower frequencies.**

5. Adjust for each of the remaining five stations in the same manner.
6. Make a final careful adjustment of the oscillator cores and antenna trimmers.

Location of Controls

The left-hand push button is a Victrola-Attachment switch. The right-hand push button is for dial tuning.

**Loudspeaker.**—Centering of the loudspeaker voice coil is accomplished in the usual manner with three narrow celluloid or paper feelers after first removing the front dust cover. A dust cover should be cemented in place with ambroid upon completion of adjustment.

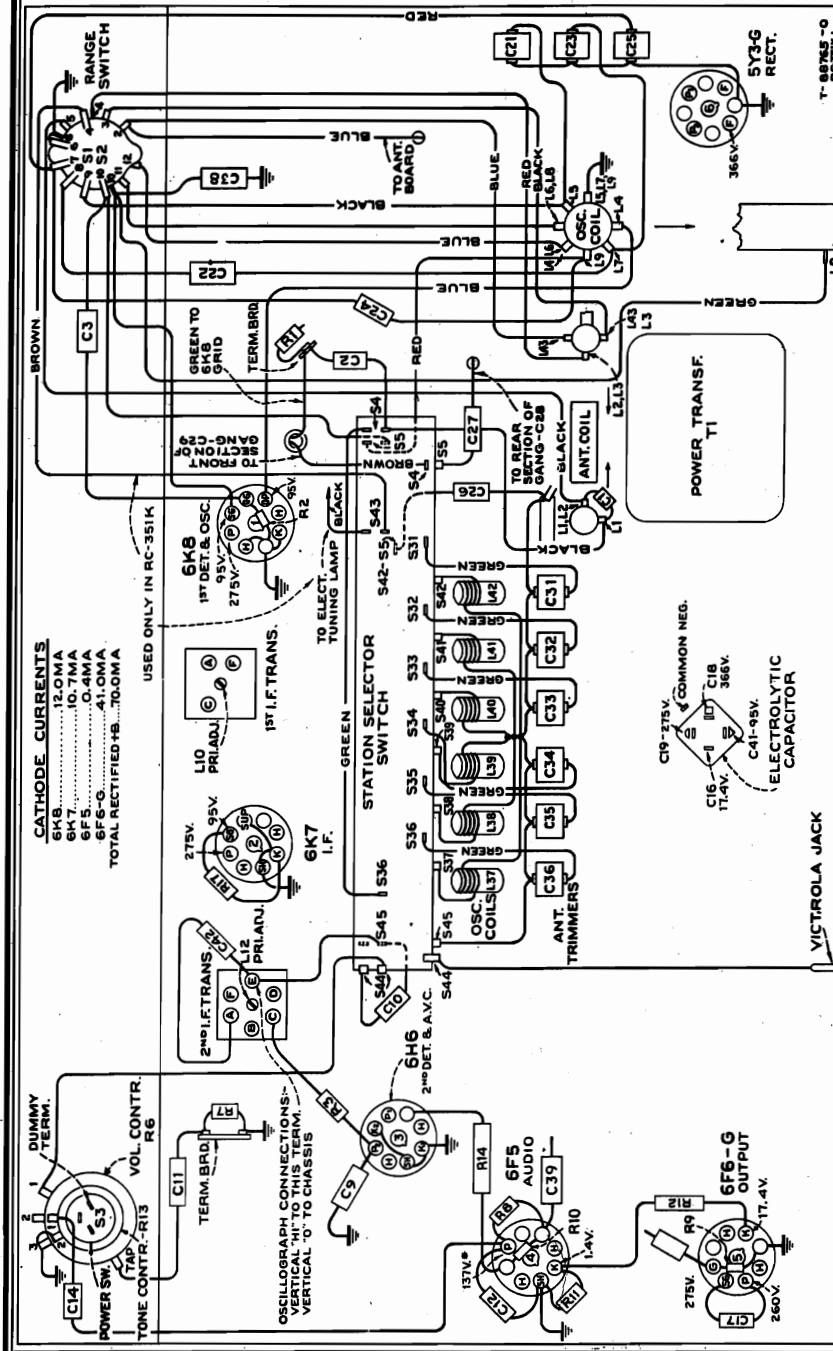

The seven-tube models have a "Magic Eye" tuning tube and illuminated indicator to show when the set is being operated on electric tuning. All models have electric tuning for six stations in the standard broadcast range.

Features of design include: Magnetite-core electric-tuning coils; magnetite-core "A" band oscillator coil; magnetite-core i-f transformers; temperature-compensated capacitor in the oscillator circuit; aural-compensated volume control; high-frequency tone control; jack and switch for Victrola attachment; straight-line dial; dust-proof electrodynamic loudspeaker.

**Victrola Attachment.**—A jack is provided on the rear of the chassis for connection to a Victrola Attachment. The cable from the Victrola Attachment should be terminated in a Stock No. 31048 plug to fit the jack.

Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within  $\pm 20\%$  with 117-volt a-c supply.

\* NOTE: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

Frequency Ranges  
"Standard Broadcast" (A) ..... 540-1,720 kc  
"Short Wave" (C) ..... 5.8-18.0 mc  
Intermediate Frequency ..... 455 kc

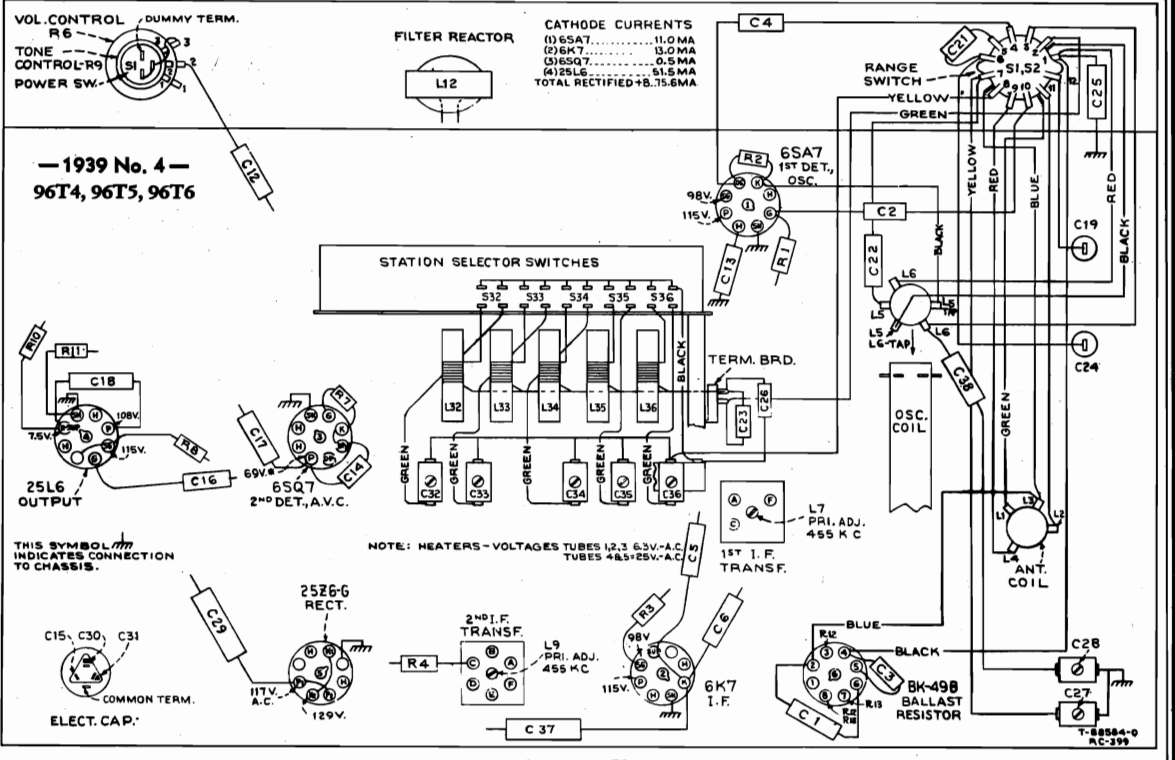

All models have electric tuning for five stations in the standard broadcast range.

Features of design include: Magnetite-core electric-tuning coils; magnetite-core i-f transformers; temperature-compensated capacitor in the oscillator circuit; high-frequency tone

control; straight-line dial; dust-proof permanent magnet dynamic loudspeaker.

Power Supply Polarity.—On d-c operation, the power plug must be inserted in the outlet for correct polarity. If the set does not function, reverse the position of the plug. On a-c operation, a similar reversal of the plug may reduce hum.

Pilot Lamp ..... Mazda 47, 6.3 volts, 0.15 amp.  
Loudspeaker Type ..... Permanent Magnet Dynamic  
Diameter ..... 96T4, 5: 5 inch—96T6: 6 inch  
V.C. Impedance ..... 2 ohms at 400 cycles

Measurements made to low-side of volume control unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within  $\pm 20\%$  with 117 volt a-c supply.

\* Note: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

Chassis Base Dimensions	11 1/8-in. wide, 5-in. deep, 2 7/8-in. high		
Over-all Chassis Height	8 inches		
Tuning Drive Ratio	8 to 1		

### Alignment Procedure

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the black lead and keep the output as low as possible to avoid a-v-c action.

**Calibration Marks.**—The tuning dial is fastened in the cabinet and can not be used for reference during alignment. Therefore calibration marks corresponding to dial readings of 600 kc, 1,500 kc, and 15.2 mc. have been stamped in the plate on the front of the chassis as shown in the accompanying drawing. These marks are used for reference during alignment.

**Dial Indicator Adjustment.**—With the gang condenser in full mesh, the indicator should point to the extreme left mark on the dial scale.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Tube and Trimmer Locations

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L9 and L10 (2nd I-F Trans.)
2	Tuning condenser Stator (osc.) in series with .01 mfd.	455 kc		L7 and L8 (1st I-F Trans.)
3	Antenna Lead (Blue), in series with 200 mmf.	1,500 kc	1,500 kc (Cal. Mark) "A" Band	C28 (osc.) C20 (ant.)
4	Antenna Lead (Blue), in series with 200 mmf.	600 kc	600 kc (Cal. Mark) "A" Band	L6 (osc.)
5	Repeat steps 3 and 4.			
6	Antenna Lead (Blue), in series with 400 ohms	15.2 mc	15.2 mc (Cal. Mark) "C" Band	C27 (osc.)*
7	Follow "Adjustments for Electric Tuning."			

\* Rock gang slightly while peaking C27, and use minimum capacity peak if two peaks can be obtained on C27.  
 Note.—Oscillator tracks 455 kc above signal on both bands.

Dial-Indicator and Drive Mechanism

Refer to "Alignment Procedure" for explanation of the "calibration marks" shown in this drawing.

Push-Button Adjustments

- No. 1—Approximately 550-950 kc.
- No. 2—Approximately 590-1,020 kc.
- No. 3—Approximately 690-1,225 kc.
- Nos. 4, 5—Approximately 890-1,500 kc.

**Removing Push-Button Assembly.**—The push-button assembly is held to the chassis by two nuts on the front apron and may be quickly and easily swung out for convenient access to the sockets and other parts. No unsoldering is required, as flexible leads are used for all connections from the chassis to the assembly.

1. A.C. leads to ballast tube should be dressed away from volume control lead on 2nd I.F. transformer.
2. Coupling condensers C2 and C4 should be dressed away from chassis.

### Miscellaneous Service Data

**Precautinary Lead Dress.**—

1. Volume control lead from 2nd I.F. transformer (E) should be dressed down on chassis.

Adjustments for Electric Tuning

These models have five push buttons for electric tuning of five different stations in the standard broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjust-

ments. Use a regular antenna for the preliminary adjustments.

The procedure is as follows:

1. Make a list of the five desired stations, arranged in order from low to high frequencies.
2. Turn Range Control Knob to "Broadcast" position and tune in station No. 1 (560 kc in example) by Manual Dial Tuning, for reference.
3. Push in station-button No. 1 and turn Range Selector to "PB" position. Adjust No. 1 oscillator core (L32) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until the station is received.
4. Adjust No. 1 antenna trimmer (C32) for maximum output on this station.
5. Adjust for each of the remaining four stations in the same manner.

(Clockwise adjustment of oscillator cores and antenna trimmers tunes the circuits to lower frequencies.)

6. Make a final careful adjustment of the oscillator cores and antenna trimmers, using one or two feet of wire as an antenna to ensure sharp peaking.

Insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

**25 Cycle Operation.**—For 25 cycle operation change filter condensers to 40-40 mfd.

—1939 No. 3—

Alignment Procedure

**Output Meter Alignment.**—Connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—Connect the low side of the test-oscillator to the receiver chassis, through a .01 mfd. capacitor, and keep the output as low as possible.

**Dial Setting.**—To set dial indicator drum, turn tuning condensers fully clockwise and then counter-clockwise.

**Push-button Adjustments.**—Remove bakelite button and loosen screw two turns with a screwdriver or coin. Tune in the desired station by means of the right-hand control knob. Press push lever down as far as it will go and tighten screw. Release lever and put on push-button.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output—
1	Tuning condenser stator (osc.) in series with .01 mfd.†	455 kc	Quiet point between 550-750 kc	C1, C2, C3, C4 (1st and 2nd I-F transformer)
2	Antenna lead (yellow) in series with 400 ohms	19.25 mc	Full clockwise (out of mesh) "C" band	C5* (osc.)
3	Same as step 2	15.0 mc	15.0 mc Test oscillator signal	C6** (ant.) See Note No. 1
4	Antenna lead in series with 200 mfd condenser	1,745 kc	Full clockwise (out of mesh) "A" band	C7 (osc.)

\* Use minimum capacity peak if two peaks can be obtained.  
\*\* Rock gang slightly and check to determine that C5 has been adjusted to the correct peak by tuning to approximately 14.09 mc, where a weaker signal should be received.  
† Make test oscillator connection to lug on tuning condenser stator (oscillator section) in series with .01 mfd. condenser.

Note No. 1.—Accurately tune receiver to the 15.0 mc test oscillator signal. This signal will appear twice (14.09 and 15.0 mc) as dial is turned. Use the higher frequency setting of the tuning condensers (gang furthest out of mesh).

Note No. 2.—Oscillator tracks 455 kc above signal on all bands.

Undistorted..... 2.5 watts  
Maximum..... 4.5 watts

**LOUDSPEAKER**

Type..... 12-inch, electrodynamic  
Voice Coil Impedance at 400 cycles..... 2.2 ohms

### Calibration Scale, RC-351F and RC-351F "M"

The corresponding position of the dial indicator for any setting of the calibration scale can be determined by drawing a line from this point on the lower calibration to the same point on the upper calibration scale. For example, 28° on the calibration scale corresponds to 1,500 kc on "A" band in RC-351F and RC-351F "M."

In RC-351F "R," 27.4° corresponds to 1,500 kc, and 15° corresponds to 18 mc.

## General Description

This receiver employs a two-band superheterodyne circuit which is operated either manually or by electric tuning on standard broadcast, and includes foreign short-wave, aircraft, police, and amateur stations on the short-wave band.

There are three different productions of Model 97K, conveniently identified by rear chassis stamping as RC-351F, RC-351F "M," and RC-351F "R."

Features of design include magnetite-core adjusted i-f transformers and "Electric Tuning" oscillator coils; jack and switch for Victrola attachment; aural-compensated volume control; continuously variable tone-control; automatic volume control; dust-proof electrodynamic speaker; and straight-line dial.

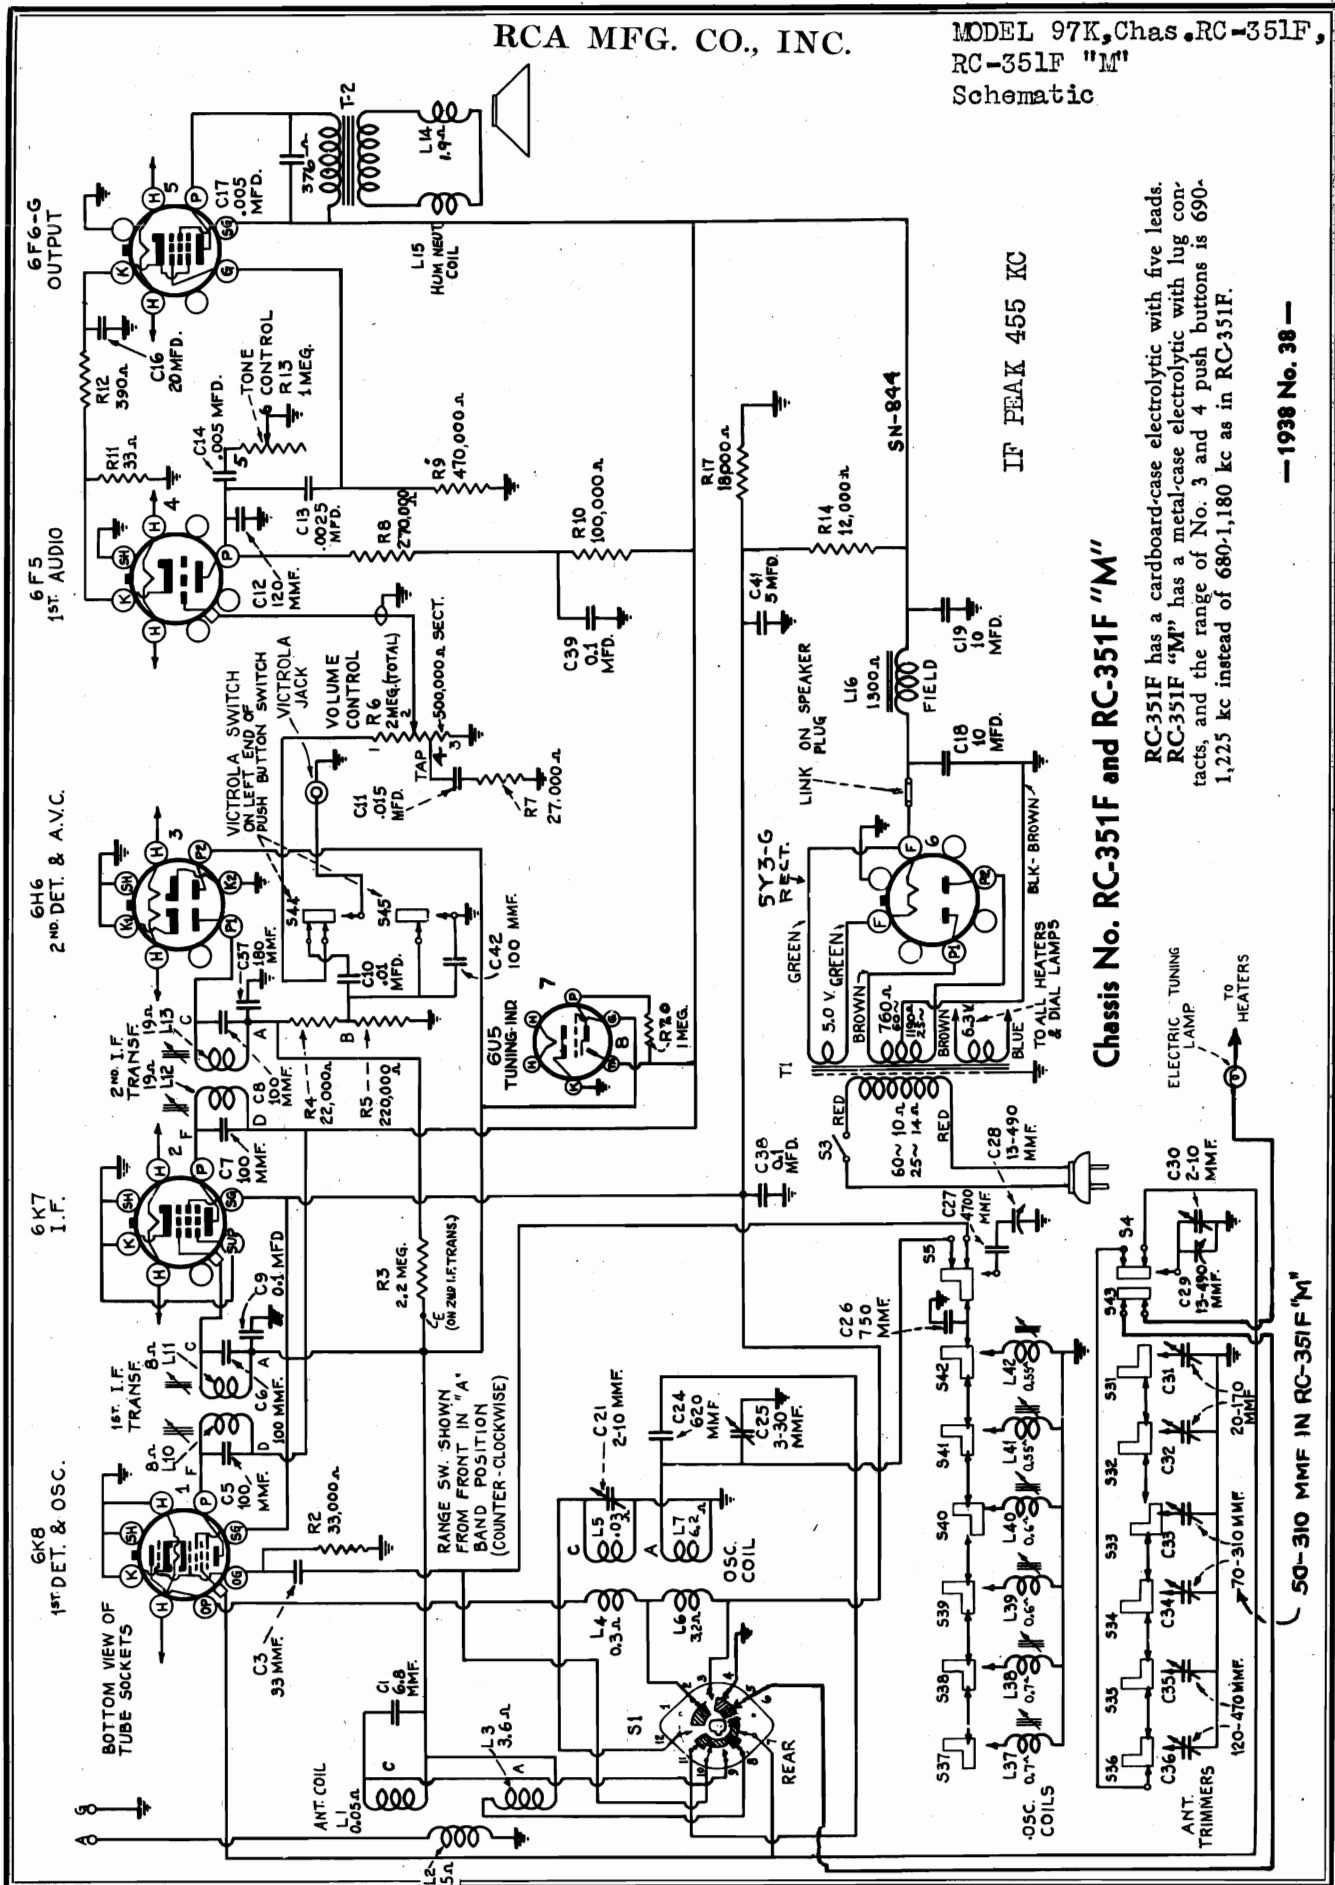

**Precautionary Lead Dress.**—(1) Dress 110-volt leads away from audio wiring. (2) All leads in vicinity of antenna and oscillator coils must be dressed away from the coils. (3) Electric Tuning lamp leads from push-button switch must be dressed against front apron. (4) Keep speaker leads away from Victrola jack. (5) Lead from C19 in electrolytic (RC-351F "R") must be dressed around left-end of push-button switch, and against chassis base. (6) The leads across back of chassis in RC-351F must be dressed under the electrolytic capacitor to prevent approaching the Victrola jack.

**Victrola Attachment.**—A jack is provided on the rear of chassis for connection to a Victrola Attachment. The cable from the attachment should be terminated in a Stock No. 31048 plug to fit the jack.

RCA MFG. CO., INC.

MODEL 97K, Chas. RC-351F,  
RC-351F "M"  
Schematic

Chassis No. RC-351F and RC-351F "M"

RC-351F has a cardboard-case electrolytic with five leads.  
RC-351F "M" has a metal-case electrolytic with lug con-  
tacts, and the range of No. 3 and 4 push buttons is 690-  
1,225 kc instead of 680-1,180 kc as in RC-351F.

MODEL 97K, Chassis RC-351F,  
RC-351F "M", RC-351F "R"  
Alignment, Socket, Trimmers  
Tuner Adjustments

# ALIGNMENT PROCEDURE

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed 3/8-inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire, so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

\* In RC-351F, push buttons 3 and 4 cover 680-1,180 kc.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

## RC-351F and RC-351F "M"

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6K8 det. grid cap, in series with .01 mfd.	455 kc		L10 and L11 (1st I-F Trans.)
3	Antenna Terminal, in series with 400 ohms	15.2 mc	15.2 mc (33.5°) "C" band	C21* (osc.) C30** (ant.)
4	Antenna Terminal, in series with 200 mmf.	1,500 kc	1,500 kc (28°) "A" band	C25 (osc.)
5	Follow "Adjustments for Electric Tuning."			

\* Use minimum capacity peak if two peaks can be obtained.  
\*\* Rock gang slightly while adjusting C30. Check to determine that C21 has been adjusted to the correct peak by tuning to approximately 40.5° (14.29 mc), where a weaker signal should be received.  
Note.—Oscillator tracks 455 kc above signal on both bands.

## RC-351F "R"

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6K8 det. grid cap, in series with .01 mfd.	455 kc		L10 and L11 (1st I-F Trans.)
3	Antenna Terminal in series with 200 mmf.	1,500 kc	1,500 kc (27.4°) "A" band	C25 (osc.) C30 (ant.)
4	Antenna Terminal, in series with 200 mmf.	600 kc	600 kc (148°) "A" band	L7 (osc.)
5	Repeat steps 3 and 4.			
6	Antenna Terminal, in series with 400 ohms	18 mc	18 mc (15°) "C" band	C21 (osc.)*
7	Follow "Adjustments for Electric Tuning."			

\* Rock gang slightly while peaking C21, and use minimum capacity peak if two peaks can be obtained on C21.  
Note.—Oscillator tracks 455 kc above signal on both bands.

## ADJUSTMENTS FOR ELECTRIC TUNING

These models have eight push buttons. The left-hand button is a Victrola switch. The right-hand button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

The procedure is as follows:

1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Use one or two feet of wire as an antenna to ensure sharp peaking.

3. Push in the dial-tuning button, and manually tune in the first station on the list.
4. Push in station button No. 1 (second from left) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
5. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

Clockwise adjustment of cores and trimmers tunes the circuits to lower frequencies.

6. Adjust for each of the remaining five stations in the same manner.
7. Make a final readjustment of the magnetite-cores.

— 1939 No. 20 —

\* NOTE: Values with star are operating voltages in circuits with high series-resistance, and when measured will read lower depending on the voltmeter loading.

Measurements made to chassis unless otherwise indicated, volume control at minimum. Values should hold within approximately ± 20% with 117-volt a-c supply.

LOUDSPEAKER

- Type ..... Eight-Inch Electrodynamic
- Voice Coil Impedance ..... 1.3 ohms at 400 cycles

MOTOR BOARD

- Motor ..... Self-starting Induction
- Turntable Speed ..... 78 r.p.m. (adjustable)

PICKUP

- Type ..... Crystal
- Impedance ..... 100,000 ohms at 1,000 cycles

General Description and Service Data

The model R-98 Victrola consists of a crystal pickup, a five tube audio amplifier, a eight inch dust-proof electrodynamic speaker, and a motor turntable mechanism all combined in a hinged-top, table type walnut veneer cabinet. This instrument will reproduce records up to 12-inches in size.

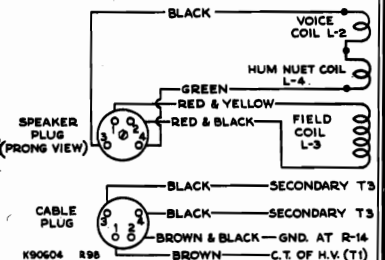

The crystal pickup unit is securely sealed in a metal casing, for protection against extreme changes in atmospheric conditions. If failure occurs, a new replacement crystal unit should be installed.

RCA MFG. CO., INC. MODELS 98T, 98K2, Chas. RC-386A. Schematic, Socket, Trimmers Transformer, Speaker, Data

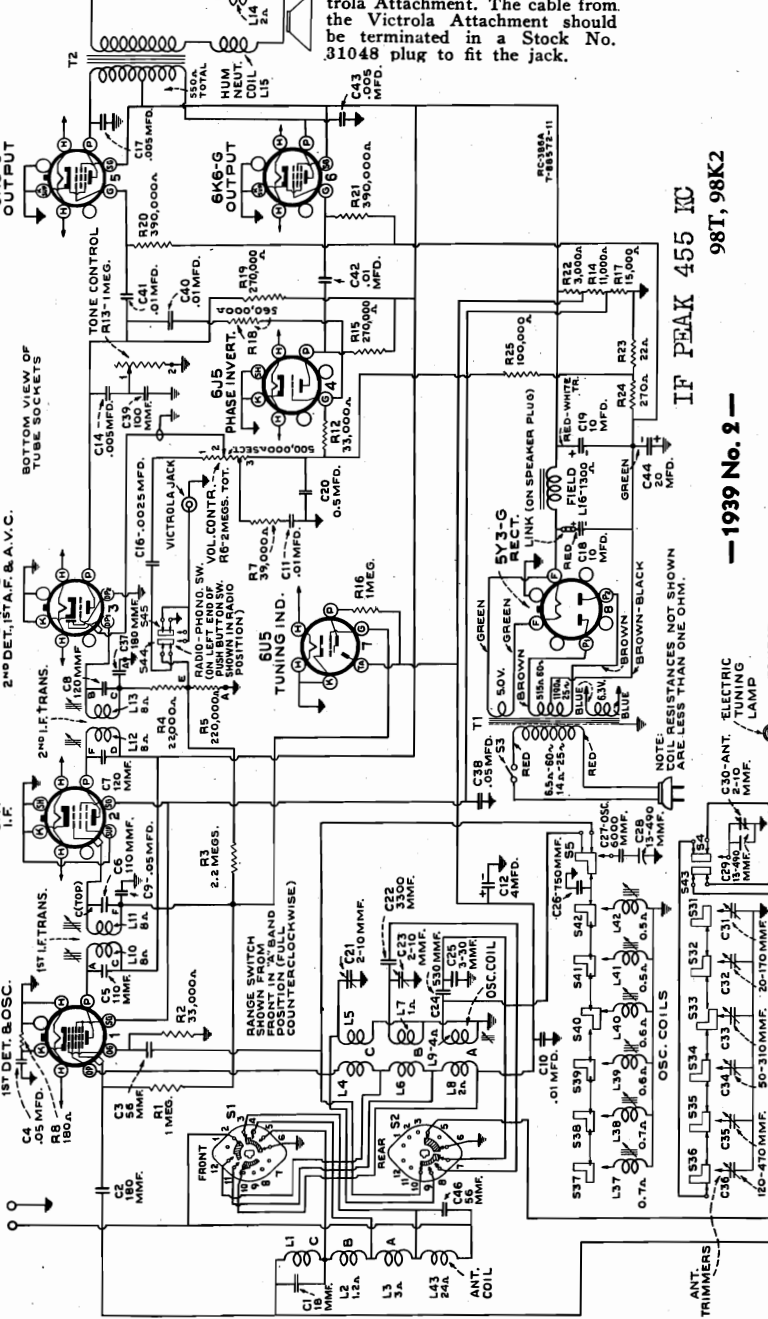

**Connections and Colors of Loudspeaker and Cable**  
**Loudspeaker.**—The loudspeaker cone may be centered in the usual manner with three celluloid or paper feelers after gently cutting away the front dust cover. A new cover should be cemented in place upon completion of the adjustment.  
**Victrola Attachment.**—A jack is provided on the rear of the chassis for connection to a Victrola Attachment. The cable from the Victrola Attachment should be terminated in a Stock No. 31048 plug to fit the jack.

NOTE: INSERT CONNECTOR BETWEEN COMMON CONTACT (CENTER) AND CONTACT CORRESPONDING TO PREVAILING POWER SUPPLY RATING.  
**UNIVERSAL TRANS. CONNECTIONS**  
 Above—Universal Power Transformer Connections. (110-volt supply for a Victrola Attachment may be obtained by connecting the motor to the red and the red-black leads.)

Tube and Trimmer Locations

IF PEAK 455 KC  
 98T, 98K2

—1939 No. 2—

The 98T is a table model; the 98K2 a console model. Both models have a "Magic Eye" tuning tube and illuminated indicator to show when the set is being operated on electric tuning. All models have electric tuning for six stations in the standard broadcast range. Features of design include: Magnete-core electric-tuning coils; magnete-core i-f transformers; temperature-compensated capacitor in the oscillator circuit; aural-compensated volume control; high-frequency tone control; jack and switch for Victrola attachment; straight-line dial; dust-proof electrodynamic loudspeaker.

Location of Controls

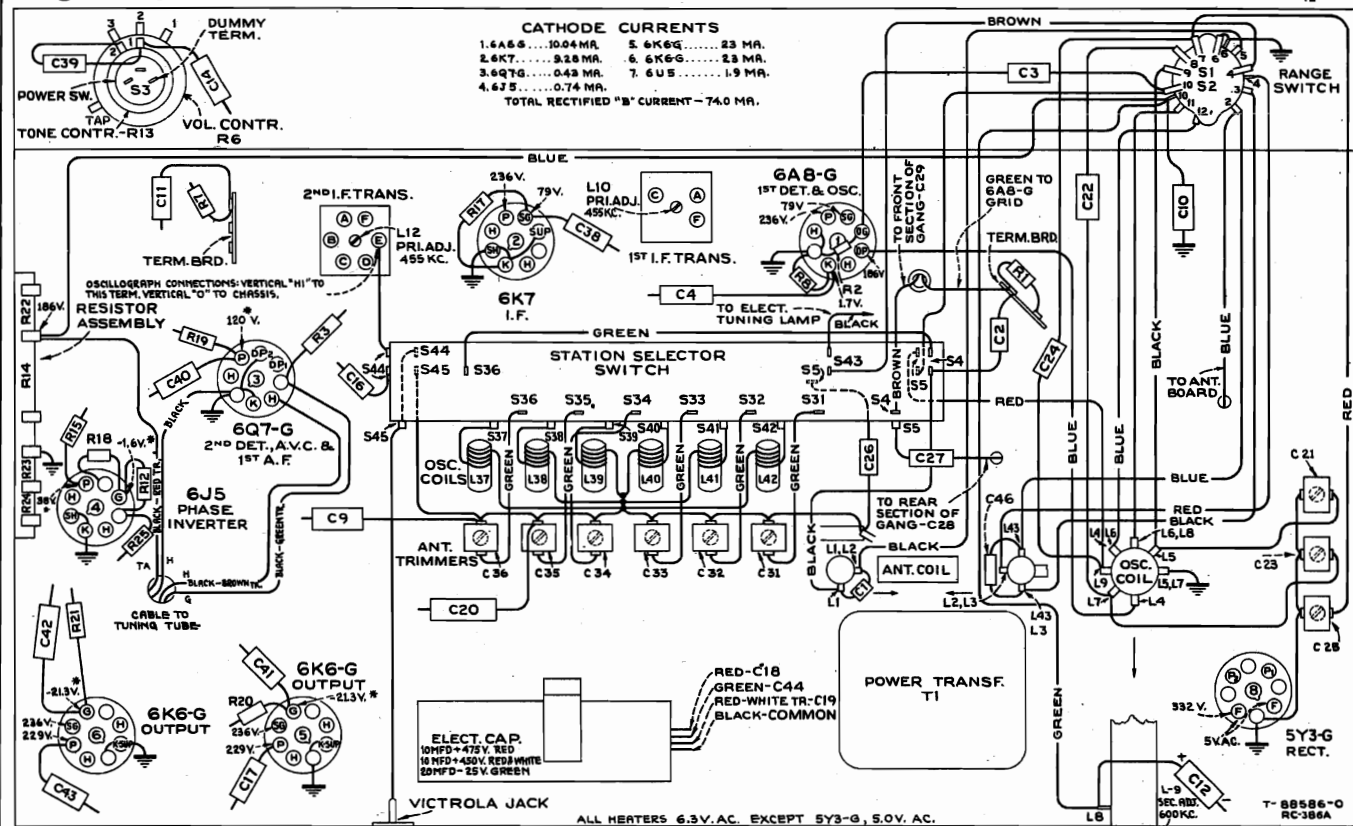

The left-hand push button is a Victrola-Attachment switch. The right-hand push button is for dial tuning.

FREQUENCY RANGES	
"Standard Broadcast" (A)	540-1,720 kc
"Medium Wave" (B)	2.3-7 mc
"Short Wave" (C)	7-22 mc
Six Electric Tuning Positions	
1	550-1,500 kc
2	stations between approximately 550-950 kc (Buttons 1 and 2)
3	stations between approximately 690-1,225 kc (Buttons 3 and 4)
4	stations between approximately 890-1,500 kc (Buttons 5 and 6)
5	Intermediate Frequency
POWER SUPPLY RATINGS	
A	105-125 volts, 50-60 cycles, 115 watts
B	105-125 volts, 25-60 cycles, 115 watts
C	100-130/140-160/200-250 volts, 40-60 cycles, 115 watts
Undistorted	5 watts
Maximum	5.5 watts
LOUDSPEAKER	
Type	Electrodynamic
Diameter	98T, 6 inches; 98K2, 12 inches
Voice Coil Impedance	2.2 ohms at 400 cycles
Model 98T	
Height	12 1/2 inches
Depth	18 1/2 inches
Width	15 1/2 inches
Net Weight	9 1/2 pounds
Shipping Weight	21 pounds
Chassis Base Dimensions	13 in. x 6 1/2 in. x 2 3/4 in.
Over-all Chassis Height	6 1/2 inches
Tuning Drive Ratio	12 to 1

MODELS 98T, 98K2, Chas. RC-386A

Voltage, Chassis Wiring  
Alignment, Drive Data

RCA MFG. CO., INC.

**R-F Wiring Diagram and Socket Voltages**

Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within  $\pm 20\%$  with 117-volt a-c supply.

\*NOTE: Values with star (\*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

**Alignment Procedure**

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed  $\frac{3}{8}$ -inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

\*Use minimum capacity peak if two peaks can be obtained, and rock gang condenser slightly while adjusting C23 and C21.

Note.—Oscillator tracks 455 kc above signal on all bands.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, move the dial indicator on the drive cable to the left-hand end mark on dial, with gang condenser fully meshed.

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio-dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Transformer) L10 and L11 (1st I-F Transformer)
2	6A8G det. grid cap, in series with .01 mfd.	455 kc		
3	Antenna Terminal, in series with 200 mmf.	600 kc	600 kc (150.5°) "A" band	L9
4		1,500 kc	1,500 kc (28°) "A" band	C25 (osc.) C30 (ant.)
5	Repeat steps 3 and 4.			
6	Antenna Terminal, in series with 400 ohms.	6 mc	6 mc (26.5°) "B" band	C23 (osc.)*
7		20 mc	20 mc (22°) "C" band	C21 (osc.)*
8	Follow "Adjustments for Electric Tuning."			

FOR DIAL CALIBRATION  
SEE INDEX

MODELS 98T, 98K2, Chas. RC-386A  
 RCA MFG. CO., INC. Tuner Adjustments, Parts List

**Adjustments for Electric Tuning**

These models have eight push buttons. The left-hand button is a Victrola switch. The right-hand button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

The procedure is as follows:

1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.
3. Push in station button No. 1 (second from left) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

Clockwise adjustment of cores and trimmers tunes the circuits to

insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

lower frequencies.

5. Adjust for each of the remaining five stations in the same manner.
6. Make a final careful adjustment of the oscillator cores and antenna trimmers.

**Precautionary Lead Dress.—**

1. Dress red leads from power transformer to power switch (S8), in corner of chassis and away from volume control terminals.
2. Dress brown lead from push-button switch to gang over end of switch, and away from C27 and bus between S5 and range switch.
3. Leads to C27 must be as short as possible.
4. Blue lead from range switch to oscillator coil must be as short as possible and dressed away from other leads. All leads should be dressed away from antenna coil.
5. Leads across back of chassis must be dressed under electrolytic away from Victrola jack.
6. Parts and leads should be dressed away from R22-R14 as it becomes heated.
7. Leads from oscillator coil to trimmers must be dressed away from coil.
8. Green lead from S4 to range switch must be clear of other leads and away from front edge of chassis.

MODEL R-100

Victrola Attachment

RCA MFG. CO., INC.

Motor Data, Tone Compensation

Parts List

# RCA Victor Model R-100 Victrola Attachment

## Motor Data

Smooth starting and running will be insured by keeping the bearings well cleaned and oiled.

**Hum and Vibration**—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. If excessive vibration occurs, it may be due to:

1. Insufficient lubrication, or any failure that will cause binding.
2. Leather washer not oiled. (Check to make sure that the leather and steel washers are arranged in proper sequence, as shown in the drawings.)
3. Motor not properly fastened in cabinet.
4. Burrs on poles of motor or stator.
5. Slight eccentricity of rotor or spindle.
6. Loose laminations of the stator.
7. Improper horizontal alignment of the rotor and stator (pertaining only to the type motor shown in Figure 1). Correct

horizontal alignment is as shown in the motor assembly drawing. The position of the stator is raised or lowered by adding or removing washers below the leather washer. In the type motor shown in Figure 2, no adjustment is necessary because correct horizontal alignment is provided by the design of the motor.

The damper spring must fit without binding or chattering, in the slot in the stator. The stator must be free to deflect in either direction between the limits of the damper spring. Any binding in the washers or stator bearing which prevents the movement of the stator may cause speed variations in the motor. The damper spring must exert equal force in restoring the stator to its mid-position when the stator is deflected manually in either direction.

## Tone Compensation

Because of the widely varying frequency characteristics of various types of audio amplifiers with which the R-100 may be used, it may be desirable in some cases to make refinements in the pickup circuit of the R-100 to compensate for the characteristics of the amplifier. The following circuits show means of making such refinements.

In Figure 3, R1 controls the low-frequency response; larger values of R1 give increased lows. For maximum low-frequency response, remove R1. R2 controls pickup output, smaller values of R2 increase output. C1 controls high-frequency response; to increase highs, increase C1.

Where a decrease in high-frequency response may be desired (for example, as an aid in reducing "needle scratch" on worn records), the circuit in Figure 4 is applicable. In this circuit, C2 acts as loading on the pickup and is also a controlling factor on the high-frequency response. Smaller values of C2 give more pickup output and also more highs. R3 gives a sharper high-frequency reduction; increasing R3 decreases highs.

The suggested values shown in Figures 3 and 4 should serve as a basis from which slight alterations may be made to suit individual cases.

## Replacement Parts

Insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

Connecting Victrola Attachment to Radio Receivers

Methods of connecting the Victrola Attachment to various types of audio systems are given in the accompanying text and illustrations. Also included are the model numbers of the various RCA receivers to which the particular method applies. The data given requires that an RCA Stock No. 9824 Radio-Phono switch be used for switching from radio to phonograph, as desired. For ease in connecting the "phono" lead to the Stock No. 9824 switch, the male plug on the end of the lead should be removed by unsoldering or by cutting it off.

In general, the Victrola Attachment must be used with radio receivers having at least two stages of high-gain audio amplification. The output of the Victrola Attachment should be connected to the input of the first audio tube, and at the same time the output of radio receiver portion of the chassis should be shorted or opened, to prevent radio signals being heard while the Victrola Attachment is in operation.

1939 RCA RADIOS OF THE "90" SERIES:

RADIO RECEIVERS USING 6C5 OR 6J5, 6C5G OR 6J5G, TUBE FOR FIRST AUDIO AMPLIFIER.

Plug male connector on the end of the "phono" lead into the female connector on the receiver chassis. Push or turn the "Phono" switch to "Phono" position, and operate the Victrola Attachment according to instructions.

RADIO RECEIVERS HAVING "PHONO" TERMINAL BOARDS.

Stock No. 14179 Adaptor opens grid circuit, and inserts 2.700 ohm resistor in cathode of 6C5 or 6J5 tubes, for bias on Phono reproduction.

Stock No. 14180 Adaptor opens grid circuit of 6C5 or 6J5 tube.

Stock No. 14180 Adaptor necessary for RCA: C11-1, C13-2, T10-1, C11-3, C13-3.

Stock No. 14179 Adaptor necessary for RCA: C15-3, C15-4.

RCA Radio Receivers to which the above illustration applies: 5T1, 5T4, 5T5, 5T6, 5T7, 5T8, 6T5, 6T2, 8T11, 8K11, 85T5, 86E, 86K, 86T, 86T1, 86T4, 86K7, 86T44, 87K, 87T, 87K1, 87K2, 87T2, 88K, 810K, 810K1, 810T, 810T4, 811K, 812K, 813K, 816K, 811T.

RADIO RECEIVERS WHOSE FIRST AUDIO AMPLIFIER TUBE IS OF THE GRID CAP TYPE.

For following Receivers, Yellow lead should go on Terminal No. 1, Green lead on Terminal No. 2: 6K2, 6T2, 6K3, 6T10, 7T1, 7K1, 85T8, 86T8, 87T1, 86T2, 86T6, 6K10.

Insulate shield of switch wires from chassis, on following RCA Receivers: 5T, 6T, 6K, 6K1, 7T, 7K, 7X, 8T, 8K, 86X4, 87EY, 87X, 87Y, 8T10, 7X1, 8K1.

NOTE: THIS METHOD FOR USE ONLY WHEN BIAS FOR THE TUBE IS OBTAINED BY MEANS OF CATHODE RESISTOR M8640b

Receivers having a Four Terminal Board: 9K, 9T, 9K1, 9K2, 9K3, 9K10, 10T, 10K, 10K1, 13K, 15K. Reverse Red and Blue leads to Terminal Board of C9-6, T9-9, T8-16, C8-17.

RCA Receivers for which above method applies: 125, 128, 128E, 224E, 225, 226, T6-1, C6-2, T6-9, T7-5, C7-6, T7-12, C7-14, T8-14, C8-15, T8-18, C8-19, C8-20, C9-4, T9-10.

RADIO RECEIVERS WHOSE FIRST AUDIO TUBE IS OF THE GRID CAP TYPE, AND FIXED BIAS FOR TUBE IS OBTAINED THROUGH GRID LEAD.

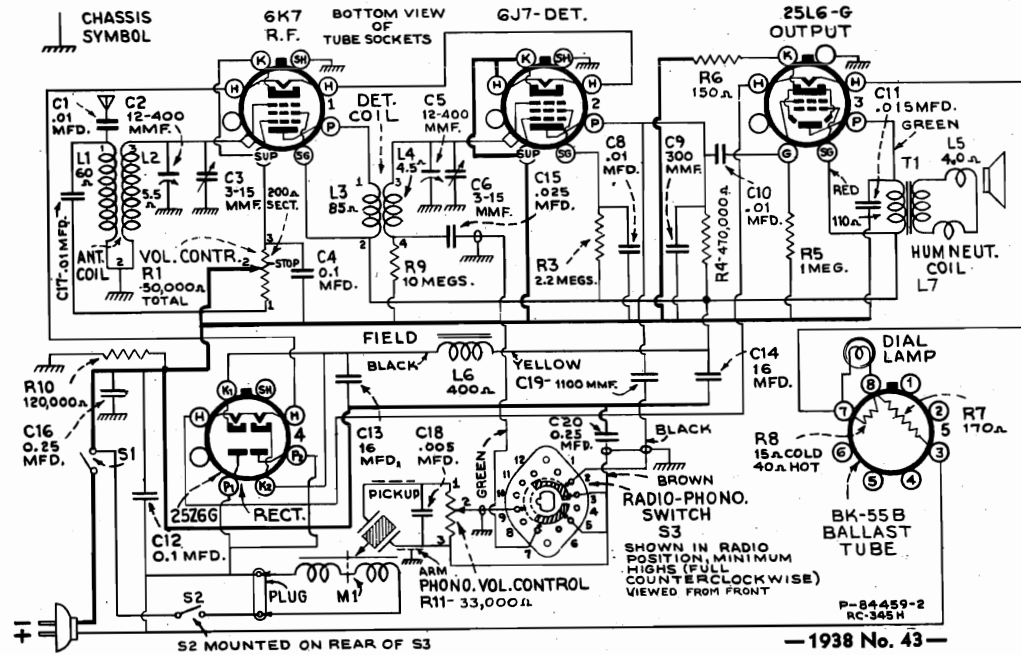

RADIO RECEIVERS WHERE THE VOLUME CONTROL IS IN THE AUDIO INPUT CIRCUIT.

Chassis RC-345H  
Schematic, Voltage  
Chassis Wiring  
Alignment Procedure

RCA MFG. CO., INC.

Five-Tube, Single-Band, AC, Victrola

U-104

R-F Wiring Diagram and Socket Voltages  
Measurements made to common negative line, unless otherwise specified

\* Note: Values with star (\*) are operating voltages.  
 Values not starred are actual measured voltages.

Measurements made with set tuned to quiet point, volume control at minimum, using 1,000-ohm-per-volt meter, having ranges of 10, 50, 250, and 500 volts. (Use nearest range above the specified measured voltage.)

Values should hold within approximately ± 20% for 117 volt 60 cycle supply.

Frequency Range..... 540-1,720 kc  
 Alignment Frequency..... 1,760 kc (ant., det.)

POWER OUTPUT (125-volt, 60-cycle supply)  
 Undistorted ..... 1.0 watt  
 Maximum ..... 1.5 watts

LOUDSPEAKER  
 Type..... 5-inch Electrodynamic  
 Voice-Coil Impedance..... 5 ohms at 400 cycles

PHONOGRAPH..... Synchronous (manual starting)

Records..... 10-inch and 12-inch, 78 r.p.m.  
 Pickup..... Crystal, 100,000 ohms at 1,000 c.p.s.  
 Average Output of Pickup..... 1½ volts at 1,000 c.p.s. across ¼ meg. load

**Alignment Procedure**  
 Adjust the two trimmers (C3 and C6) on side of gang condenser for maximum output, using lowest possible output from test-oscillator.  
 Turn pointer, while holding tuning knob, so that the pointer is horizontal and pointing to low-frequency end when the gang condenser is at maximum. Check pointer adjustment on a station.

**Alignment Procedure**  
 Reel up the antenna wire, and connect the high side of test-oscillator through an 80-mmf. capacitor to the antenna terminal on the antenna transformer. Connect low side of oscillator to receiver chassis through a 0.1-mfd. capacitor. Turn gang condenser to minimum (full out), tune oscillator to 1,760 kc, connect an output meter across the voice coil, and turn volume control to maximum.  
 Keep antenna roll and lead clear of chassis during alignment.

Dial Lamp..... Mazda No. 40, 6.3 volts, .15 amp.  
 POWER SUPPLY RATINGS  
 A-5..... 105-125 volts, 50 cycles, 60 watts  
 A-6..... 105-125 volts, 60 cycles, 60 watts

RCA MFG. CO., INC.

MODEL U-104  
Chassis RC-345H  
Chassis Wiring, Lead Dress  
Pick-up, Phono. Data

**Precautionary Lead Dress**

1. Dress power cord and line bypass C12 away from detector coil.
2. Plate lead from 6K7 to detector coil must be dressed close to chassis and run through center of chassis.
3. Green lead from detector coil to gang must be dressed clear of other leads.
4. Green lead from antenna coil to C17 must be dressed against front apron.
5. Dress all heater leads close to base.
6. Yellow lead from cathode 6K7 to volume control must be dressed against chassis, under gang condenser and against front apron.

**Power Supply.**—Although this model employs an ac-dc chassis, it is not suitable for use on dc, as this would damage the motor.

**Antenna.**—The set is equipped with a 25-foot antenna. Do not connect the antenna to ground. If an outdoor antenna is used, it should not be longer than 100 feet, including lead-in. If it is longer, connect a 100- to 200-mmf. capacitor in series with the lead-in.

**PHONOGRAPH SERVICE DATA**

U-104

*Pickup Connections*

The motor is started by turning the phono-radio tone control to either 3rd or 4th position clockwise and giving the turntable a clockwise spin with the hand. Smooth starting and running will be insured by keeping the bearings well cleaned and oiled.

**Hum and Vibration.**—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. If excessive vibration occurs it may be due to:

1. Insufficient lubrication, or any failure that will cause binding.
2. Leather washer not oiled. (Check to make certain that the leather washer is above the steel washer.)

*Cross Section of Motor Assembly*

This drawing shows the lubrication points

3. Motor not properly supported from motor board.
4. Burrs on poles of rotor or stator. Remove with fine emery cloth.
5. The damper spring must fit without binding or chattering in the slot in the stator. The stator must be free to deflect in either direction between the limits of the damper spring. The damper spring must exert approximately equal force in restoring the stator to its mid-position when the stator is deflected manually in each direction.

**Removing Rotor.**—The rotor and turntable assembly simply rests on the ball bearing at bottom of vertical bearing. Remove by lifting up.

**Rotor Adjustment.**—Loosen the three screws that hold the rotor to the turntable, insert three 16-mil shims at equal distances around the gap between the rotor and stator, and then carefully tighten the three screws. The top of rotor must be flush with top of stator; add additional steel washers beneath the stator if necessary.

**Lubrication.**—Oiling points are indicated in the diagram.

**On Phonograph Operation,** turn the radio volume control to minimum, and tune to a quiet point on the dial.

*Motor Coil Assembly and Connections*

D-C resistance of each coil (for 110 volts, 50 and 60 cycles) is approximately 82 ohms

C-6	105-125, 200-250 volts, 60 cycles, 100 watts
C-5	105-125, 200-250 volts, 50 cycles, 100 watts

OIL HOLE AND PLUG

The crystal pickup is sealed in a metal case as protection against extreme changes of climate. If failure occurs, do not attempt to repair the unit, but install a new crystal unit.

The phonograph motor is a self-starting constant-speed induction type. Two styles of motor are employed: One style (drawing No. 84430) has a cast frame and mounts from below the motorboard. The other style (drawing No. 84484) has a drawn metal case, and mounts from top of motorboard through a cutout. The two types are shown in the accompanying illustrations.

Motor Lubrication.—Apply a few drops of light machine oil to the spindle bearing and oil hole every six months.

The motor spindle is tapered, and a conical rubber piece fits snugly on the spindle. The hole in the turntable bushing is tapered to fit the rubber. This provides an excellent self-centering floating mounting.

A metal washer is placed on the spindle under the rubber piece. The washer has ears on the under side which fit over a pin that projects through the spindle.

The automatic stop should be adjusted so that the lever will snap to the "off" position when the pickup needle is 1 1/4 inches from the center line of the spindle.

Calibration Marks.—The tuning dial is fastened in the cabinet and can not be used for reference during alignment. Therefore calibration marks corresponding to dial readings of 600 kc and 1,500 kc have been stamped in the plate on the front of the chassis, as shown in the accompanying drawing. These marks are used for reference during alignment.

Drum and Dial Indicator Adjustment.—As the first step in r-f alignment, check the position of the drum on the front shaft of the gang condenser. With the gang at maximum (full mesh) the drum set-screw should be pointing directly down as shown in the drawing. With the drum in this position, and the gang at maximum, move the dial indicator

along the drive cord to coincide with the left-hand line as shown. The indicator is held to the drive cord by means of spring clips.

After completion of alignment, and after the chassis has been fastened in the cabinet, turn the gang to maximum and note whether the dial indicator is at the left-hand end mark on the dial; if it is not, loosen the drum set-screw (which is accessible through a slot in the bottom of the cabinet), turn the drum slightly so that the indicator is at this mark, and then tighten the set-screw.

After completion of alignment, seal the i-f core-adjustment screws with household cement.

For additional details, refer to booklet, "RCA Victor Receiver Alignment."

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L8 (2nd I-F Trans.)
2	6A8-G grid cap, in series with .01 mfd.	455 kc		L5 and L6 (1st I-F Trans.)
3	Antenna lead (blue) in series with 200 mmf.	1,500 kc	1,500 kc calibration mark.	C6 (osc.)* C3 (ant.)
4	Follow "Adjustments for Electric Tuning."			

\* The oscillator section of the gang condenser has two trimmers, one on top, accessible through a hole in the chassis, and the other on bottom. It may be necessary to adjust both of these trimmers to secure a peak on 1,500 kc.

Adjustments for Electric Tuning DRUM SHOWN WITH GANG AT MAXIMUM CAPACITY

These models have six push buttons. The right-hand button connects the gang condenser for dial tuning. The other five buttons are for electric tuning of five different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments. Use a regular antenna for the preliminary adjustments.

The procedure is as follows:

1. Make a list of the five desired stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning (right-hand) button, and manually tune in the first station on the list.

3. Push in station-button No. 1 (left-hand) and adjust No. 1 oscillator core (L12) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until the station is received.

4. Adjust No. 1 antenna trimmer (C20) for maximum output on this station.

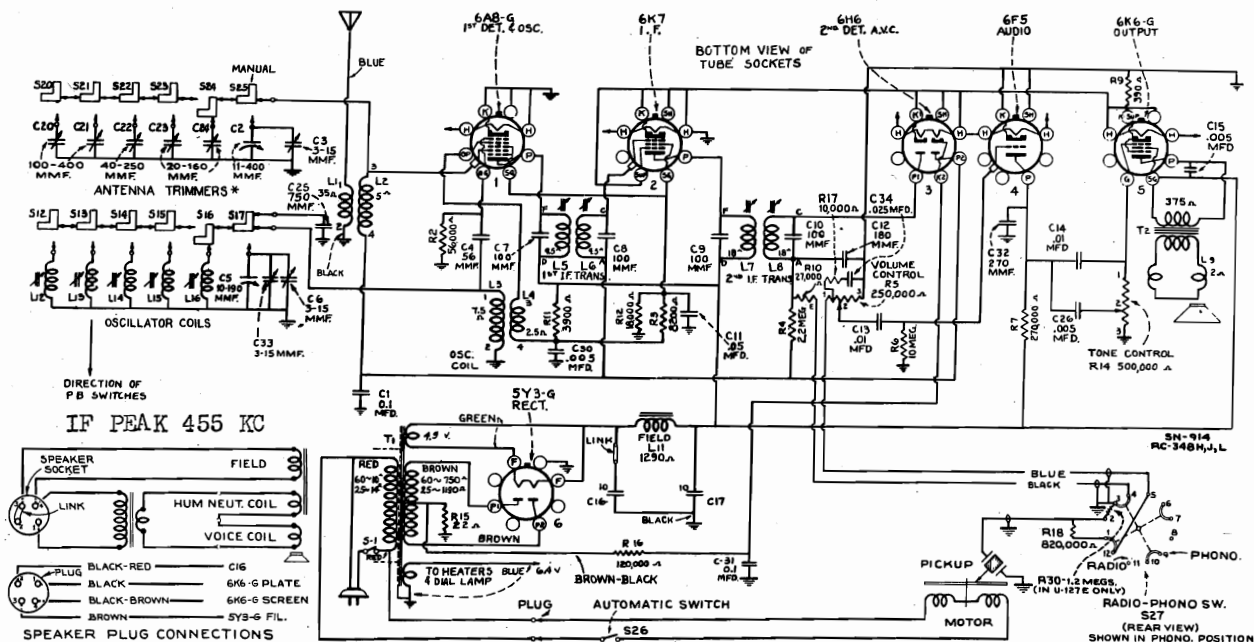

5. Adjust for each of the remaining four stations in the same manner.

(Clockwise adjustment of oscillator cores and antenna trimmers tunes the circuits to lower frequencies.)

6. Make a final careful adjustment of the oscillator cores using one or two feet of wire as an antenna.

Alignment Procedure

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are shown in the chassis drawing. Turn the receiver volume control to maximum.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

**Calibration Marks.**—The tuning dial is fastened in the cabinet and can not be used for reference during alignment. Therefore calibration marks corresponding to dial readings of 600 kc and 1,500 kc have been stamped in the plate on the front of the chassis, as shown in the accompanying drawing. These marks are used for reference during alignment.

**Drum and Dial Indicator Adjustment.**—As the first step in r-f alignment, check the position of the drum on the front shaft of the gang condenser. With the gang at maximum (full mesh) the drum set-screw should be pointing directly down (RC-348 series) and up for RC-421. With the drum in this position, and the gang at maximum, move the dial indicator along the drive cord to coincide with the left-hand line as shown. The indicator is held to the drive cord by means of spring clips.

After completion of alignment, and after the chassis has been fastened in the cabinet, turn the gang to maximum and note whether the dial indicator is at the left-hand end mark on the dial; if it is not, move the pointer the required distance along the cord.

## RCA MFG. CO., INC. Automatic Record Changer

Automatic Record Changer  
Adjustments, Notes

Before servicing the automatic record changer, inspect the assembly to see that all levers, parts, gears, springs, etc. are in good order and are correctly assembled.

A bind or jam in the mechanism can usually be relieved by rotating the turntable in the reverse direction.

The changer can be conveniently rotated through its change cycle by pushing the index lever to "Reject" and revolving the turntable

by hand. Six turntable revolutions are required for one change cycle. If the record changer or cabinet is not perfectly level, normal operation is likely to be affected.

The 10 and 12 inch records must be absolutely flat for smooth operation when using a mixture of the two sizes.

A shorting switch, located in the pickup head, operates due to pressure when the pickup is placed on the pickup rest.

### ADJUSTMENTS

**A. Main Lever.**—This lever is basically important in that it interlinks the various individual mechanisms which control needle landing, tripping, record separation, etc. One adjustment is provided for the main lever. Rotate the turntable until the changer is out-of-cycle; and adjust rubber bumper bracket (A) so that the roller clears the nose of the cam plate by 1/16 inch.

**B. Friction Clutch.**—The motion of the tone arm toward the center of the record is transmitted to the trip pawl "22" by the trip lever "7" through a friction clutch "5." If the motion of the pickup is abruptly accelerated or becomes irregular due to swinging in the eccentric groove, the trip finger "7" moves the trip pawl "22" into engagement with the pawl on the main gear, and the change cycle is started. Proper adjustment of the friction clutch "5" occurs when movement of the tone arm causes positive movement of the trip pawl "22" without tendency of the clutch to slip. The friction should be just enough to prevent slippage, and is adjustable by means of screw "B." If adjustment is too tight, the needle will repeat grooves; if too loose, tripping will not occur at the end of the record.

**C. Pickup Lift Cable Screw.**—During the record change cycle, lever "16" is actuated by the main lever "15" so as to raise the tone arm clear of the record by means of the pickup lift cable. To adjust pickup for proper elevation, stop the changer "in-cycle" at the point where pickup is raised to the maximum height above turntable plate, and has not moved outward; at this point adjust locknuts "C" to obtain 1 inch spacing between needle point and turntable top surface.

**D. & E. Needle Landing on Record.**—The relation of coupling between the tone arm vertical shaft and lever "20" determines the landing position of the needle on a 10 inch record. Position of eccentric stud "E" governs the landing of the needle on a 12 inch record; this, however, is dependent on the proper 10 inch adjustment.

To adjust for needle landing, place 10 inch record on turntable; push index lever to reject position and return to the 10 inch position; see that pickup locating lever "17" is tilted fully toward turntable; rotate mechanism through cycle until needle is just ready to land on the record; then see that pin "V" on lever "14" is in contact with "Step T" on lever "17." The correct point of landing is 4-11/16 inches from the nearest side of the turntable spindle; loosen the two screws "D" and adjust horizontal position of tone arm to proper dimension, being careful not to disturb levers "14" and "17." Leave approximately 1/32 inch end play between hub of lever "20" and pickup base bearing, and tighten the blunt nose screw "D"; run mechanism through several cycles as a check, then tighten cone pointed screw "D."

After adjusting for needle landing on a 10 inch record, place 12 inch record on turntable; push index lever to reject and return to 12 inch position; rotate mechanism through cycle until needle is just ready to land on the record; the correct point of landing is 5-11/16 inches from nearest side of spindle. If the landing is incorrect, turn stud "E" until the eccentric end adjusts lever "14" to give correct needle landing. The eccentric end of the stud must always be toward the rear of the motor board, otherwise incorrect landing may occur with 10 inch records.

### MISCELLANEOUS SERVICE HINTS

Incorrect adjustment of a particular mechanism of the changer is generally exhibited in a specific mode of improper operation. The following relations between effects on operation and the usual misadjustments will enable ready adjustment in most cases.

- For any irregularity of operation, the adjustment of the main lever "15" should be checked first as in "A."
- Needle does not land properly on both 10 and 12 inch records → Make complete adjustments "D" and "E."
- Needle does not land properly on 12 inch record but correct on 10 inch → Effect adjustment "E."
- Failure to trip at end of record → Increase clutch "5" friction by means of screw "B." Also, see that levers "7" and "12" are free to move without touching each other.
- Pickup strikes lower record of stack or drags across top record on turntable → Adjust lift cable per adjustment "C."
- Needle does not track after landing → Friction clutch "5" ad-

**F. & G. Record Separating Knife.**—The upper plate (knife) "25" on each of the record posts serves to separate the lower record from the stack and to support the remaining records during the change cycle. It is essential that the spacing between the knife and the rotating record shelf "27" be accurately maintained. The spacing for the 10 inch record is nominally .058 inch, and for the 12 inch record is .075 inch.

To adjust, rotate the knife to the point of minimum vertical separation from the record shelf and turn screw and locknut "F" to give .055—.061 inch separation. Screw "G" must not be depressed during this adjustment. After setting screw "F" adjust screw "G" so that when its tip is depressed flush with top of record shelf, the vertical spacing between the knife, in its lowest rotational position, and the shelf, is .072—.078 inch.

**H. Record Support Shelf.**—The record shelf revolves during the change cycle to allow the lower record to drop onto the turntable. Both posts are rotated simultaneously by a gear and rack coupled to the main lever "15," and it is necessary that adjustment be such that the record is released from both shelves at the same instant. To adjust, place a 12 inch record on the turntable, rotate mechanism into cycle to the point where tone arm is at maximum distance outward from turntable; lift record upward until it is in contact with both separating knives, then loosen screws "H" and shift record shelves so that the curved inner edges of the shelves are uniformly spaced at least 1/16 inch from record edge. Tighten the blunt nose screw "H," run mechanism through cycle several times to check action, then tighten cone pointed screw "H."

If record shelves or knives are bent, or not perfectly horizontal, improper operation and jamming of mechanism will occur.

**J. Tone Arm Rest Support (not shown).**—When the changer is out-of-cycle, the front lower edge of the pickup head should be 5/16 inch above surface of motor board. This may be adjusted by bending the tone arm support bracket, which is associated with the tone arm mounting base, in the required direction.

**K. Trip Pawl Stop Pin.**—The position of the trip pawl stop pin "K" in relation to the main lever "15" governs the point at which the roller enters the cam. By bending the pin support either toward or away from trip pawl bearing stud, the roller can be made to enter the cam later or earlier, respectively. This adjustment should be made so that the roller definitely clears the cam outer guide as well as the nose of the cam plate.

**Lubrication.**—Petrolatum or petroleum jelly should be applied to cam, main gear, spindle pinion gear, and gears of record posts.

Light machine oil should be used in the tone arm vertical bearing, record post bearings, and all other bearings of various levers on underside of motor board.

Apply a few drops of light machine oil to the motor spindle bearing and oil hole adjacent to the spindle bearing. The oil hole has a screw plug.

Do not allow oil or grease to come in contact with, rubber mounting of tone arm base, rubber bumper, or rubber spindle cap.

adjustment "B" may be too tight; bind in tone arm vertical bearing; levers "7" and "12" fouled; or pickup output cable twisted.

- Cycle commences before record is complete—Record is defective, or adjustment "B" of friction clutch "5" is too tight.
- Wow in record reproduction—Record is defective; or instrument is not being operated at normal room temperature (65° F).
- Record knives strike edge of records—Records warped; record edges are rough; or knife adjustments "F" and "G" are incorrect.
- Record not released properly—Adjust record shelf assemblies in respect to shaft by means of adjustment "H."
- Needle lands in 10 inch position on 12 inch record or misses record when playing both types mixed—Increase tension of pickup locating lever spring "34."

NOTE: Numbers refer to parts—letters refer to adjustments

Details of Record Shelf Posts, and Locating Lever Assemblies

Radio features include: Magnetite-core electric-tuning oscillator coils and magnetite-core i-f transformers; automatic volume control; automatic bass compensation; continuously-variable high-frequency tone control; temperature-stabilized capacitors in oscillator circuit; electro-dynamic loudspeaker; straight-line dial and electric tuning for five stations in the broadcast range.

Turntable Assembly (All Models)

The crystal pickup is sealed in a metal case as protection against extreme changes of climate. If failure occurs, do not attempt to repair the unit, but install a new crystal unit.

The phonograph motor is a self-starting constant-speed induction type.

**Motor Lubrication (Models U-121 and U-127E).**—Apply a few drops of light machine oil to the spindle bearing and oil hole every six months. The oil hole is located in the motor casting, adjacent to the spindle bearing, and has a screw plug.

The automatic stop (Models U-121 and U-127E) should be adjusted so that the lever will snap to the "off" position when the pickup needle is 1 1/2 inches from the center line-of the spindle.

Adjustments for Electric Tuning

**Push-Button Ranges in RC-348J, 348H, and 348L (Single-Band Receivers)**  
No. 1 and 2... Approximately 550- 980 kc  
No. 3..... Approximately 690-1,225 kc  
No. 4 and 5... Approximately 850-1,500 kc

**Push-Button Ranges in RC-421 (Two-Band Model U-123)**  
No. 1..... Approximately 550- 980 kc  
No. 2..... Approximately 590-1,020 kc  
No. 3..... Approximately 690-1,225 kc  
Nos. 4, 5..... Approximately 890-1,500 kc

These models have six push buttons. The right-hand button connects the gang condenser for dial tuning. The other five buttons are for electric tuning of five different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments. Use a regular antenna for the preliminary adjustments.

The procedure is as follows:

1. Make a list of the five desired stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.

3. Push in station-button No. 1 and adjust No. 1 oscillator core to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until the station is received.
4. Adjust No. 1 antenna trimmer for maximum output on this station.
5. Adjust for each of the remaining four stations in the same manner.  
(Clockwise adjustment of oscillator cores and antenna trimmers tunes the circuits to lower frequencies.)
6. Make a final careful adjustment of the oscillator cores using one or two feet of wire as an antenna.

Models U-121 and U-127E have a non-automatic Victrola mechanism, with crystal pickup, automatic stop, and self-starting constant-speed motor.  
Model U-123 has an automatic Victrola mechanism which permits playing seven 12-inch or eight 10-inch records in succession. It has a crystal pickup and constant-speed self-starting motor.

Dial Mechanism

31422	Condenser—2-gang variable tuning condenser (C2, C3, C5, C6, C33).....	2.70	Model U-123		
32355	Control—Volume and tone control and power switch (R5, R14, S1).....	3.00	32956	Coil—Field coil and laminations for 25-cycle motor.....	7.15
32634	Cord—Drive cord.....	.10	32955	Coil—Field coil and laminations for 50-cycle motor.....	5.90
31386	Core—Core and stud assembly for push button oscillator coils.....	.15	32954	Coil—Field coil and laminations for 60-cycle motor.....	5.35
31421	Drum—Tuning drive drum and hub.....	.45	32960	Gear—Motor spindle gear and pin.....	.75
11891	Lamp—Dial lamp.....	.17	32873	Motor—Motor complete, 25-cycle, 110 volts AC.....	15.95
32136	Lead—Phonograph input shielded lead and connector (U-121 and U-123).....	.35	32872	Motor—Motor complete, 50-cycle, 110 volts AC.....	13.75
32908	Lead—Phonograph input shielded lead and socket (U-127E only).....	.40	32871	Motor—Motor complete, 60-cycle, 110 volts, AC.....	13.25
31419	Plate—Dial color plate.....	.12	30870	Plug—2-prong male plug—used on motor leads.....	.35
30868	Plug—2-contact female for motor leads.....	.35	32959	Spindle—Turntable spindle complete with metal pinion and fibre gear for 25-cycle motor.....	2.90
31420	Pointer—Dial indicator pointer.....	.10	32958	Spindle—Turntable spindle complete with metal pinion and fibre gear for 50-cycle motor.....	2.90
31373	Pulley—Tuning indicator drive pulley.....	.08	32957	Spindle—Turntable spindle complete with metal pinion and fibre gear for 60-cycle motor.....	2.90
31388	Resistor—390 ohms, 1 watt (R9).....	.22	32875	Switch—Motor control switch.....	1.30
14559	Resistor—10,000 ohms, 1/2 watt (R17).....	.20	<b>MOTORBOARD ASSEMBLIES</b>		
12738	Resistor—27,000 ohms, 1/2 watt (R10).....	.20	Model U-121 and U-127E		
12286	Resistor—56,000 ohms, 1/2 watt (R2).....	.20	14803	Brake—Automatic brake and switch.....	2.95
13734	Resistor—120,000 ohms, 1/2 watt (R16).....	.20	31464	Damper—Comprising one rubber spindle sleeve, and one metal damper plate.....	.30
12199	Resistor—270,000 ohms, 1/2 watt (R7).....	.20	30870	Plug—2-contact male for motor leads.....	.35
30963	Resistor—820,000 ohms, 1/2 watt (R18).....	.20	32610	Rest—Rubber rest for pickup arm.....	.10
32028	Resistor—1.2 meg., 1/2 watt (R30) (U127E only).....	.20	30100	Springs—One set of springs for automatic brake.....	.08
12679	Resistor—2.2 meg., 1/2 watt (R4).....	.20	32743	Switch—Radio-Record switch (S27).....	.95
13601	Resistor—10 meg., 1/2 watt (R6).....	.20	14804	Switch—Switch only for automatic brake (S26).....	.60
31425	Resistor—Voltage divider resistor tapped at 22 ohms, 18,000 ohms, 8,200 ohms, and 3,900 ohms (R15, R12, R3, R11).....	.90	31463	Turntable—Record turntable.....	1.50
14887	Retainer—Indicator drive pulley retainer.....	.01	<b>MOTORBOARD ASSEMBLIES</b>		
31482	Screw—No. 8 square head set screw for drive drum.....	.03	Model U-123		
5040	Socket—4-contact socket for speaker cable.....	.30	31149	Base—Tone arm mounting base.....	.35
31364	Socket—Dial lamp socket.....	.20	32876	Board—Motorboard complete with all riveted and welded posts and brackets—less operating mechanisms.....	6.50
31251	Socket—Octal base tube socket.....	.25	14209	Bumper—Main lever rubber bumper (1).....	.08
31418	Spring—Drive cord tension spring.....	.05	9848	Cup—Used needle cup, rest, and lid complete.....	.75
31414	Switch—Selector switch for push button switch assembly (S20, S21, S22, S23, S24, S25, S12, S13, S14, S15, S16, S17).....	3.05	32877	Escutcheon—Index escutcheon.....	.40
30902	Transformer—First i.f. transformer (L5, L6, C7, C8).....	1.90	31151	Guide—Pickup lift cable guide (coil spring, 80T 2-in. large) (2).....	.10
30903	Transformer—Second i.f. transformer (L7, L8, C9, C10).....	1.80	31150	Mounting—Pickup arm base rubber mounting complete.....	.45
31445	Transformer—Power transformer, 110 volts, 25-60 cycle (T1).....	7.80	31155	Spring—Needle cup lid tension spring.....	.04
31380	Transformer—Power transformer, 110 volts, 50-60 cycle (T1).....	4.75	<b>OPERATING MECHANISM</b>		
31575	Transformer—Power transformer, 110-220 volts, 50-60 cycle (T1).....	8.35	Model U-123		
<b>PICKUP AND ARM ASSEMBLIES</b>					
Model U-121 and U-127E					
31212	Base—Pickup arm pivot shaft, trip lever, and mounting base assembly.....	.95	31134	Bracket—Pickup locating lever mounting bracket (3).....	.30
32138	Cable—Shielded cable and male plug for pickup arm.....	.20	32878	Cam—Cam and drive gear (42).....	2.80
31050	Crystal—Pickup crystal and needle screw.....	3.75	6808	Clutch—Trip lever friction clutch assembly (5).....	.35
32137	Pickup and arm complete.....	7.00	31129	Cover—Cap for top of record post.....	.45
12539	Screw—Pickup needle screw.....	.15	32883	Damper—Motor spindle rubber drive sleeve and metal damper plate.....	.30
<b>PICKUP AND ARM ASSEMBLIES</b>					
Model U-123 (Single-Band)					
31162	Cable—Pickup arm lift cable and clips.....	.15	31116	Finger—Trip lever friction finger assembly (7).....	.45
32885	Cable—Pickup arm output cable.....	.25	32879	Gear—Rack gear for front left-hand record post (41).....	.60
			32880	Gear—Rack gear for rear right-hand record post (40).....	.55
			31121	Gear—Record post gear (10).....	.90
			31123	Guide—Main lever spring guide (11).....	.40
			31114	Lever—Index lever assembly (12).....	.75
			31137	Lever—Index lever tension spring lever (13).....	.30
			31138	Lever—Locating lever and pawl assembly (14).....	.70
			31113	Lever—Main lever assembly (15).....	1.35

31124	Pin-Record post driver pin (23)	.55	32989	Pulley-Indicator drive cord pulley	.35
14207	Roller-Pickup lift cable roller and bracket assembly (24)	.04	12261	Resistor-390 ohms, 1 watt (R12)	.20
31118	Screw-Cone pointed set screw for trip lever hub or record post shaft	.06	14569	Resistor-10,000 ohms, 1/2 watt (R7)	.20
4563	Screw-Pickup lift cable screw and nuts	.04	33489	Resistor-15,000 ohms, 2.5 watt (R3)	.55
31117	Screw-Special screw to adjust friction clutch tension (B)	.03	14284	Resistor-32,000 ohms, 1/10 watt (R5)	.20
31126	Separator-Record separator knife (25)	.75	12454	Resistor-33,000 ohms, 1/2 watt (R2)	.20
31122	Shaft-Record separator post shaft (26)	1.25	13730	Resistor-470,000 ohms, 1/2 watt (R9)	.20
3576	Spring-Record post shaft assembly (27)	.04	13872	Resistor-1 meg., 1/2 watt (R1)	.20
32882	Spring-Cam pivot tension spring on main gear turns, 180-in. O.D., 4-5/16-in. lg.	.04	13873	Resistor-1.5 meg., 1/2 watt (R8)	.20
14190	Spring-Pickup locating lever spring (28) (18 turns, 8-in. O.D., 3-in. lg.)	.05	13874	Resistor-10 meg., 1/2 watt (R4)	.20
31136	Spring-Index lever tension spring (30) (25 turns, 180-in. O.D., 15/16-in. lg.)	.08	30340	Retainer-Pulling knob retaining ring	.50
3566	Spring-Pickup lift cable tension spring (31) (20 turns, 196-in. O.D., 1-in. lg.)	.04	14343	Retainer-Tuning knob shaft retaining ring, for drum	.03
31127	Spring-Record separator pressure spring (32) (8 turns, 5/8-in. O.D., 3/4-in. lg.)	.02	32702	Screw-No. 8-32 x 1/2 square head set screw for shaft	.20
14191	Spring-Trip detaining lever tension spring (33) (15 turns, 180-in. O.D., 3/4-in. lg.)	.04	32712	Shaft-Tuning knob shaft and pulley	.03
31875	Spring-Trip detaining lever tension spring (34) (15 turns, 220-in. O.D., 27/32-in. lg.)	.04	31319	Socket-Octal base tube socket	.25
32436	Spring-Pickup locating lever tension spring (35) (16 turns, 182-in. O.D., 21/32-in. lg.)	.05	31418	Spring-Drive cord tension spring	.05
32881	Turntable complete	2.00	32703	Switch-Push button switch (#29, #29, #30, #31, #32)	2.25
31128	Washer-"C" washer for top of record post	.04	33113	Switch-Radio record switch (S5)	.65
			32702	Switch-Range switch (SS, S4)	1.15
			14308	Transformer-First i.f. transformer (L7, L8, L10, L11, L12, L13, L14)	2.45
			33112	Transformer-Second i.f. transformer (L9, L10, L11, L12, L13, L14)	2.90
				Transformer-50-60 cycle (T1)	4.50
				PICKUP AND ARM ASSEMBLIES	
			33096	Arm-Pickup arm complete—less crystal cartridge, needle screw, and cable	2.80
			31162	Cable-Pickup arm lift cable and clips	.15
			32885	Cable-Output cable and plug	.25
			31156	Crystal-Pickup crystal cartridge and needle screw	4.25
			33114	Damper-Viscoloid damper for crystal armature	.15
			31160	Screw-Pickup needle screw	.15
			31161	Shaft-Pickup pivot arm and shaft assembly	.45
				SPEAKER ASSEMBLIES (RL-70H6)	
				Model U-123 (Two Band)	
			31825	Cap-Dust cap for cone center	.05
			11469	Coil-Hum neutralizing coil (L12)	.30
			33176	Coil-Hum neutralizing coil (L11)	.20
			33175	Cone-Speaker cone and voice coil (L13)	1.75
			51118	Plug-3-prong male for speaker	.25
			33115	Speaker-Speaker complete	10.55
			14358	Screw-Screw, washer, and lockwasher to hold core in yoke	.04
			31301	Transformer-Output transformer (T2)	1.70
			14357	Washer-Spring washer to hold field coil	.08
			32798	Button-Push button	.10
			31303	Cap-Pilot lamp cap (bulbless)	.15
			31487	Clip-Spring clip to mount dial scale	.12
			31095	Cover-One set protective discs for call letter markers	.10
				Dial-Glass dial scale	.50
				Escutcheon-Dial scale escutcheon	.55
				Escutcheon-Push button escutcheon	.55
				Hinge-Cabinet lid hinge	.95
				Knob-Tuning or radio-record switch knob	.15
				Knob-Tuning or radio-record switch knob	.15
				Knob-Volume control knob	.15
				Marker-One set station call letter markers	1.00
				Marking-Photograph compartment lamp screen	.40
				Spring-Motorboard mounting springs, bolts, and washers (4 required)	.10
				Spring-Retaining spring for push button	.10
				Spring-Retaining spring for tone control knob	.10
				Spring-Retaining spring for tuning, volume control, or switch knob	.10
				Support-Cabinet lid support (For Model U-121 only)	1.85
				Support-Cabinet lid support (For Model U-123 only)	2.20
				Switch-Radio-Record switch (For Model U-123)	.60
				Switch-Escutcheon-Dial scale escutcheon	.95
				Escutcheon-Push button escutcheon	.55
				Hinge-Cabinet lid hinge (For Models U-121 and U-123)	.50
				MISCELLANEOUS ASSEMBLIES	
				Model U-123 (Two Band)	
			32138	Cable-Photo. input cable and socket	.35
			31379	Capacitor-Dual trimmer—comprising one 3-30 mmfd. and one 2-10 mmfd. sections (C10, C11)	.40
			13605	Capacitor-27 mmfd. (C19)	.35
			13795	Capacitor-56 mmfd. (C7)	.35
			14292	Capacitor-109 mmfd. (C13, C14)	.30
			14244	Capacitor-180 mmfd. (C15, C16)	.30
			14712	Capacitor-180 mmfd. (C21)	.30
			30232	Capacitor-300 mmfd. (C2)	.35
			15952	Capacitor-510 mmfd. (C4)	.45
			30608	Capacitor-730 mmfd. (C6)	.70
			32714	Capacitor-5,600 mmfd. (C8)	.45
			13895	Capacitor-.005 mfd. (C23, C25)	.25
			4838	Capacitor-.01 mfd. (C20, C22)	.25
			4937	Capacitor-.025 mfd. (C18)	.20
			4970	Capacitor-.05 mfd. (C12)	.20
			32787	Capacitor-Electrolytic—comprising three 10 mfd. and one 20 mfd. sections (C8, C24, C26, C27)	1.90
			33014	Capacitor-Push button trimmer capacitor bank (C25, C29, C30, C31, C32)	1.20
			32705	Capacitor-Push button coil mounting clip	.04
			31382	Coil-Push button coil (L1, L3, L4)	1.25
			32706	Coil-Oscillator coil (L1, L3, L4)	.95
			31385	Coil-Push button oscillator coil—less core, 650-950 kc (L28)	.30
			32704	Coil-Push button oscillator coil—less core, 590-1,020 kc (L29)	.35
			32340	Coil-Push button oscillator coil—less core, 690-1,225 kc (L30)	.35
			31383	Coil-Push button oscillator coil—less core, 890-1,600 kc (L31, L32)	.30
			32249	Condenser-2-gang variable (C2, C3, C5)	2.70
			32355	Control-Volume control, tone control, and power switch (R6, R11, S1)	3.00
			32684	Core-Drive cord	.10
			31386	Core-Core and stud for coil, Stock Nos. 31388, 31386, and 32704	.15
			45	Dial-Glass dial scale (For Model U-127E only)	.40

MODEL U-125, Ch. RC-386  
Alignment, Tuner Data

RCA MFG. CO., INC.

## ALIGNMENT PROCEDURE

**Cathode-Ray Alignment** is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output Meter Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-Oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

**Calibration Scale on Indicator-Drive-Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be ver-

tical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed  $\frac{3}{8}$  inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6A8-G det. grid cap, in series with .01 mfd.	455 kc		L10 and L11 (1st I-F Trans.)
3	Antenna Terminal, in series with 300 ohms	20 mc	20 mc (23°) "C" band	C21* (osc.) C30** (ant.)
4	Antenna Terminal, in series with 300 ohms	6 mc	6 mc (33°) "B" band	C23 (osc.)†
5	Antenna Terminal, in series with 200 mmf.	1,500 kc	1,500 kc (28½°) "A" band	C25 (osc.)
6	Follow "Adjustments for Electric Tuning"			

\* Use minimum capacity peak if two peaks can be obtained.

\*\* Rock gang slightly and use maximum capacity peak if two peaks can be obtained with C30. Check to determine that C21 has been adjusted to the correct peak by tuning to approximately 28° (19.09 mc), where a weaker signal (image) should be received.

† Use minimum capacity peak if two peaks can be obtained. Check to determine that C23 has been adjusted to the correct peak by tuning to approximately 51° (5.09 mc), at which point a weaker signal (image) should be received.

Note.—Oscillator tracks 455 kc above signal on all bands.

## ADJUSTMENTS FOR ELECTRIC TUNING

This model has eight push-buttons. The front button is the Victrola switch. The rear button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

Use one or two feet of wire as an antenna to ensure sharp peaking.

The procedure is as follows:

1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.
3. Push in station button No. 1 (second from front) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

Clockwise adjustment of cores and trimmers tunes the circuits to lower frequencies.

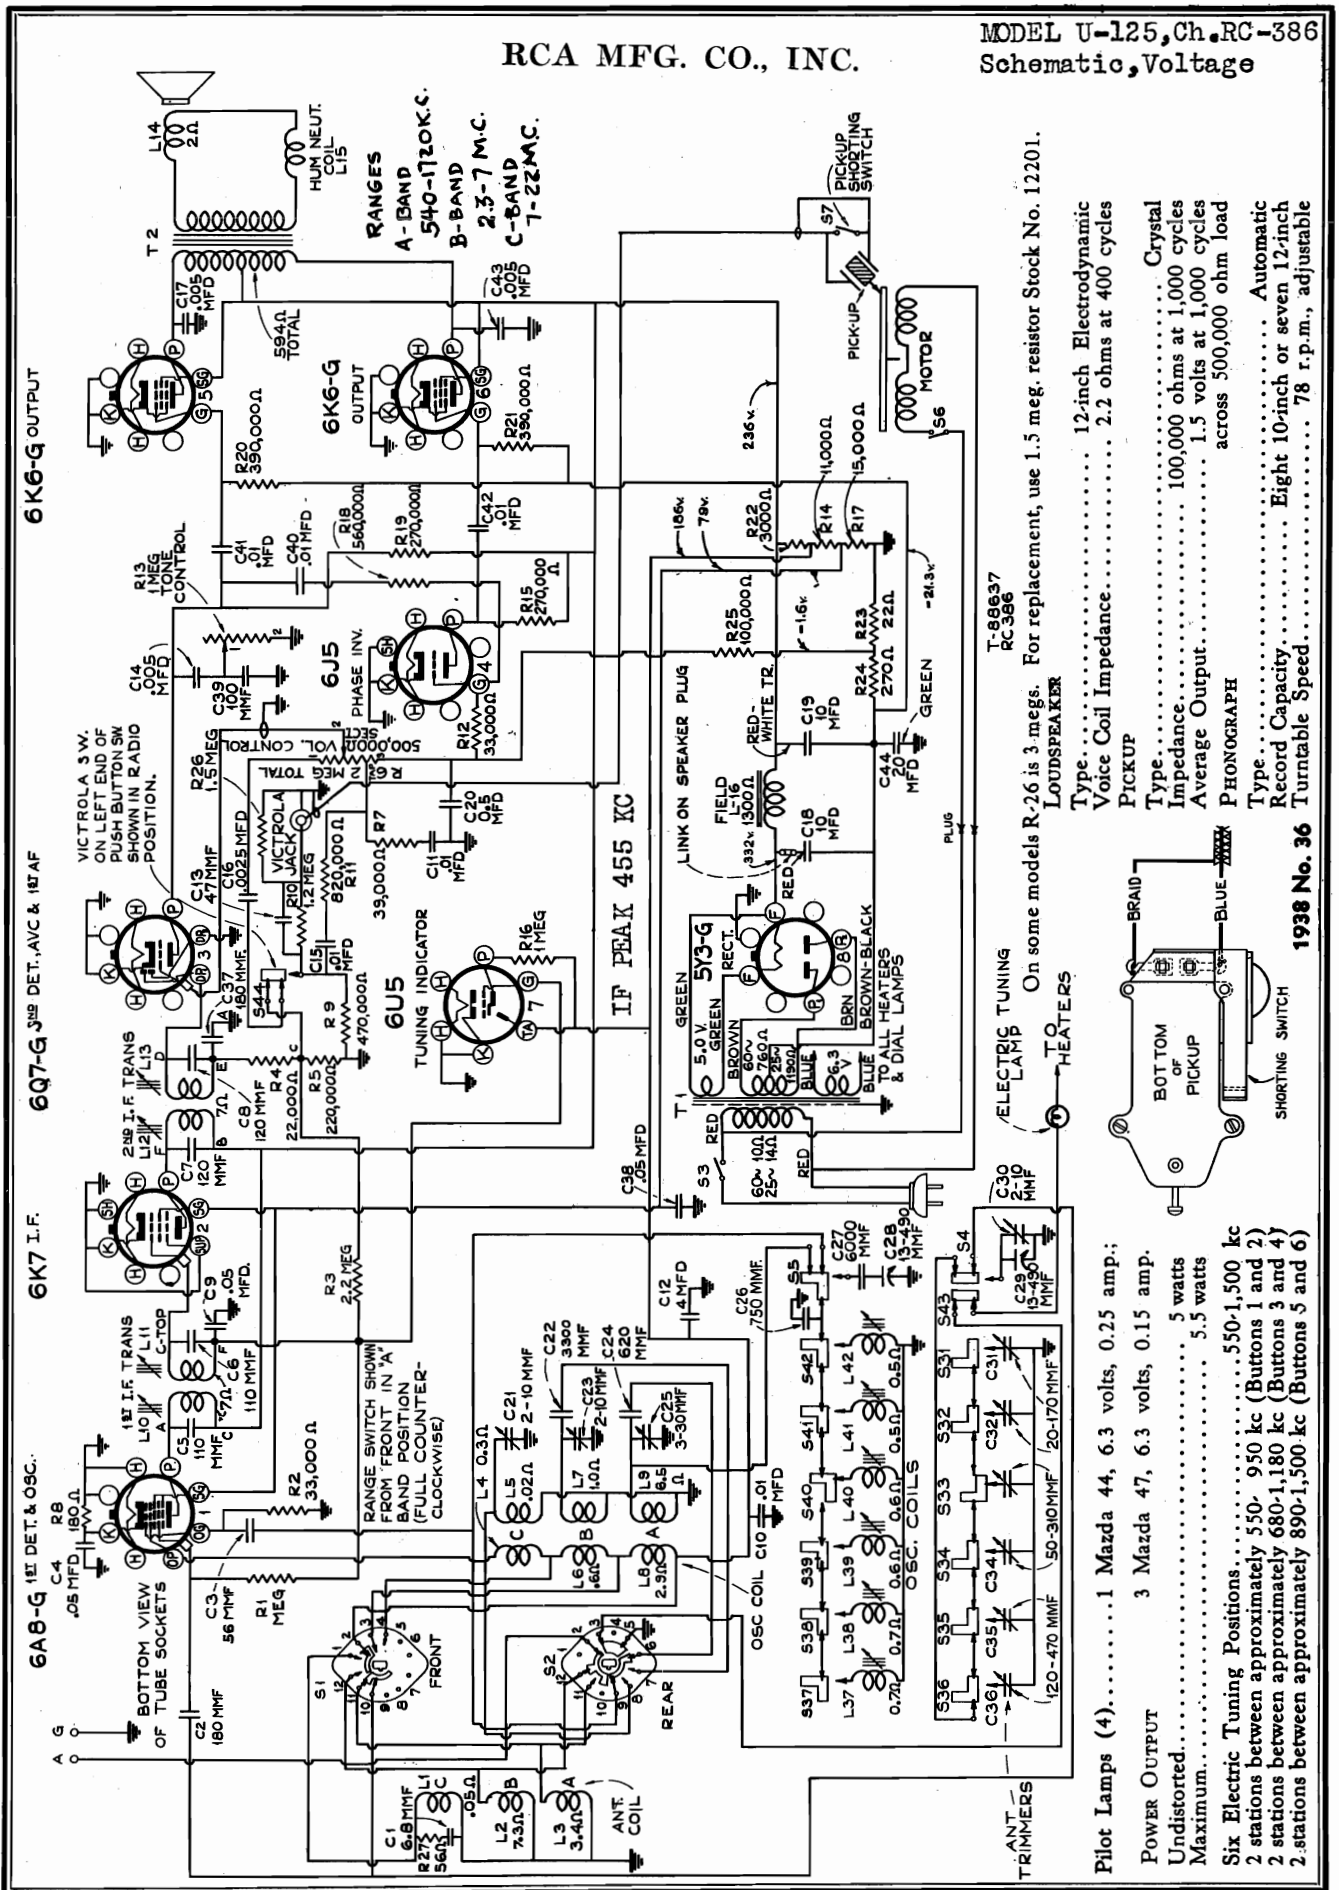

5. Adjust for each of the remaining five stations in the same manner.
6. Make a final careful adjustment of the oscillator cores and antenna trimmers.

### Precautionary Lead Dress.—

1. Dress red leads from power transformer to power switch (S3), in corner of chassis and away from volume control terminals.
2. Dress brown lead from push-button switch to gang over end of switch, and away from C27 and bus between S5 and range switch.
3. Leads to C27 must be as short as possible.
4. Blue lead from range switch to oscillator coil must be as short as possible and dressed away from other leads. All leads should be dressed away from antenna coil.
5. Leads across back of chassis must be dressed under electrolytic away from Victrola jack.
6. Parts and leads should be dressed away from R22-R14 as it becomes heated.
7. Leads from oscillator coil to trimmers must be dressed away from coil.
8. Green lead from S4 to range switch must be clear of other leads and away from front edge of chassis.

\* NOTE.—Values with star (\*) are operating voltages in circuits with high series-resistance, and when measured will read lower, depending on the voltmeter loading.

\* NOTE.—Measurements made to chassis unless otherwise indicated, with set tuned to quiet point, volume control at minimum. Values should hold within approximately ±20% with 117-volt a-c supply.

31383	Coil—Oscillator coil—A band (L41, L42).....	.30	8808	Clutch—Trip lever friction clutch assembly (5).....	.35
31384	Coil—Oscillator coil—A band (L39, L40).....	.30	31146	Coupling—Motor coupling complete with turntable drive gear, rubber strips, motor coupling, and drive arm (6).....	1.80
31385	Coil—Oscillator coil—A band (L37, L38).....	.30	31129	Cover—Cap for top of record post.....	.45
31369	Condenser—2-gang variable tuning condenser (C28, C29, C30).....	2.65	31116	Finger—Trip lever frict on finger assembly (7).....	.45
31366	Control—Volume control, tone control, and on-off switch (R6, R13, S3).....	3.00	31119	Gear—Long arm and rack gear for front left-hand record post (8).....	.60
31375	Cord—Indicator pointer drive cord.....	.30	31120	Gear—Short arm and rack gear for rear right-hand record post (9).....	.55
31374	Cord—Variable condenser drum drive cord.....	.15	31121	Gear—Record post gear (10).....	.90
30905	Core—Adjustable core and stud for i-f transformer	.35	31123	Guide—Main lever spring guide (11).....	.40
31386	Core—Adjustable core and stud for oscillator coil, Stock Nos. 31383, 31384, and 31385.....	.15	31114	Lever—Index lever assembly (12).....	.75
31372	Drum—Variable condenser drive cord drum and calibration dial.....	.65	31137	Lever—Index lever tension spring lever (13).....	.30
11891	Lamp—Phono. compartment lamp.....	.17	31138	Lever—Locating lever and pawl assembly (14).....	.70
31480	Lamp—Dial and "Electric Tuning" lamp.....	.20	31113	Lever—Main lever assembly (15).....	1.35
30868	Plug—2-contact female plug for motor cable.....	.35	31140	Lever—Pickup lift cable lever and spring assembly (16).....	.55
5040	Plug—4-contact female plug for speaker cable.....	.30	31135	Lever—Pickup locating lever assembly (17).....	.85
31373	Pulley—Drive cord pulley.....	.08	31130	Lever—Record separator elevating lever complete with adjustment screws (18).....	.80
32143	Resistor—Voltage divider comprising one 11,000-ohm, one 3,000-ohm, one 22-ohm, and one 270-ohm sections (R14, R22, R23, R24).....	.90	31132	Lever—Trip detaining lever (19).....	.30
13220	Resistor—56 ohms, 1/2-watt (R27).....	.20	31115	Lever—Trip lever assembly (20).....	1.85
30545	Resistor—180 ohms, 1/2-watt (R8).....	.20	31131	Lever—Trip regulator lever (21).....	.25
5114	Resistor—15,000 ohms, 1-watt (R17).....	.22	31133	Pawl—Trip pawl assembly (22).....	.80
14284	Resistor—22,000 ohms, 1/10-watt (R4).....	.15	31124	Pin—Record post drive pin (23).....	.04
12454	Resistor—33,000 ohms, 1/2-watt (R2, R12).....	.20	14207	Roller—Pickup lift cable roller and bracket assembly (24).....	.55
12266	Resistor—39,000 ohms, 1/2-watt (R7).....	.20	31118	Screw—Cone pointed set screw for trip lever hub or record post shelf.....	.06
14560	Resistor—100,000 ohms, 1/2-watt (R25).....	.20	4563	Screw—Pickup lift cable screw and nuts.....	.04
11398	Resistor—220,000 ohms, 1/10-watt (R5).....	.15	14195	Screw—Set screw for flexible coupling.....	.05
12199	Resistor—270,000 ohms, 1/2-watt (R15, R19).....	.20	31117	Screw—Special screw to adjust friction clutch tension.....	.03
13479	Resistor—390,000 ohms, 1/2-watt (R20, R21).....	.20	31126	Separator—Record separator knife (25).....	.75
12285	Resistor—470,000 ohms, 1/2-watt (R9).....	.20	31122	Shaft—Record separator post shaft (26).....	.40
12486	Resistor—560,000 ohms, 1/2-watt (R18).....	.20	31125	Shelf—Record post shelf assembly (27).....	1.25
30963	Resistor—820,000 ohms, 1/2-watt (R11).....	.20	31141	Spindle—Turntable spindle shaft and spring.....	1.40
12013	Resistor—1 meg., 1/10-watt (R16).....	.15	3676	Spring—Cam pawl tension spring on main gear (12 turns, .190-in. O.D., 43/64-in. lg.).....	.04
13730	Resistor—1 meg., 1/2-watt (R1).....	.20	14190	Spring—Pickup locating lever short spring or locating lever pawl tension spring (28) (16 turns, .180-in. O.D., 19/32-in. lg.).....	.08
30208	Resistor—1.2 meg., 1/2-watt (R10).....	.20	31145	Spring—Main lever tension spring (29) (18 turns, 9/16-in. O.D., 3-in. lg.).....	.05
12201	Resistor—1.5 meg., 1/2-watt (R26).....	.20	31136	Spring—Index lever tension spring (30) (25 turns, .190-in. O.D., 15/16-in. lg.).....	.05
12679	Resistor—2.2 meg., 1/2-watt (R3).....	.20	3666	Spring—Pickup lift cable tension spring (31) (20 turns, .195-in. O.D., 1-in. lg.).....	.04
14343	Retainer—Retaining spring for station selector knob shaft.....	.03	31127	Spring—Record separator pressure spring (32) (8 turns, 1/2-in. O.D., 1/2-in. lg.).....	.02
14887	Retainer—Drive cord pulley retainer.....	.01	14191	Spring—Trip detaining lever tension spring (33) (15 turns, .190-in. O.D., 1/2-in. lg.).....	.04
4669	Screw—No. 8-32 square head set screw for drum, Stock No. 31372.....	.03	31875	Spring—Pickup locating lever tension spring (34) (14 turns, .220-in. O.D., 27/32-in. lg.).....	.04
31368	Shaft—Station selector knob shaft and pulley.....	.30			
3682	Shield—Tube shield.....	.22			
30868	Socket—2-contact female socket for motor power cable.....	.35			
12493	Socket—5-contact female socket for speaker cable.....	.30			
13871	Socket—Magic Eye socket.....	.45			
14278	Socket—Pickup input socket.....	.25			
31251	Socket—Tube socket.....	.25			
31418	Spring—Indicator or drum drive cord tension spring.....	.05			
31398	Switch—Range switch (S1, S2).....	1.25			
31370	Switch—Station selector push-button switch (S4, S5, S31, S32, S33, S34, S35, S36, S37, S38, S39, S40, S41, S42, S43, S44).....	3.85

The rear push-button is for dial tuning  
 The front push-button is the Victrola switch

NOTE: INSERT CONNECTOR BETWEEN COMMON CONTACT AND CONTACTS CORRESPONDING TO PREVAILING POWER SUPPLY RATING.

UNIVERSAL TRANS. CONNECTIONS

(110-volt supply for the Victrola motor is obtained by connecting the motor to the red and the red-black leads.)

REPLACEMENT PARTS (Continued)

STOCK No.	DESCRIPTION	Unit List Price
32436	Spring—Locating lever tension spring (35) (16 turns, 192-in. O.D., 21/32-in. lg.)	.05
31142	Spring—Turntable spindle spring	.03
31147	Strip—Complete set of rubber strips for flexible coupling	.40
31139	Turntable Assembly—less spindle	3.35
31128	Washers—"C" washer for top of record post	.04
31143	Washers—Turntable thrust washers (1 steel, 1 bronze, 1 felt)	.15
MOTOR ASSEMBLIES		
11703	Governor—Motor speed governor (M1)	3.05
31448	Motor—105-125 volts, 25 cycles (M1)	23.70
31163	Motor—105-125 volts, 50-60 cycles (M1)	20.50
31157	Motor—105-125 volts, 60 cycles (M1)	17.75
30870	Plug—2-contact male plug for motor power cable	.35
31447	Screw—Complete set of motor mounting screws, washers, and spacers—for 25 cycle models only	.40
31158	Screw—Complete set of motor mounting screws, washers, and spacers—for 50-60 cycle models only	.25
14206	Switch—Motor toggle switch (S8)	.80
PICKUP AND ARM ASSEMBLIES		
31162	Cable—Pickup arm lift cable and clips	.15
31156	Crystal—Pickup crystal cartridge and needle screw	4.25
31159	Pickup and arm complete	7.45
31160	Screw—Pickup needle screw	.12
31161	Shaft—Pickup pivot arm and shaft assembly	.45
MISCELLANEOUS ASSEMBLIES		
12038	Band—Rubber band for Magic Eye	.02
31397	Button—Station selector push-button	.15
13103	Cap—Pilot light jewel	.15
31456	Cover—8-protective covers for push-button markers	.08
31541	Cushion—Motor plate mounting cushions and clamps sufficient for one instrument	.50
31591	Dial—Station selector dial scale	.75
31407	Escutcheon—Magic Eye or Electric Tuning indicator escutcheon	.60
31395	Escutcheon—Tuning dial escutcheon only, less push-buttons and dial scale	1.15
30898	Hinge—Cabinet lid hinge	.95
31543	Indicator—Electric tuning indicator disc	.25
31392	Indicator—Indicator, phono, carriage, and clip	.19
31355	Knob—Range selector knob	.19
14359	Knob—Station selector knob	.15
31591	Knob—Tone control knob	.15
30773	Knob—Volume control knob	.15
31460	Marker—"Dial Tuning" marker for push-button	.04
31459	Marker—"Victrola" marker for push-button	.04
31590	Markers—Station call letter markers	.40
31393	Screen—Dial color screen	.40
31760	Screw—Phono. compartment lamp screen lockwashers	.20
11210	Screw—Chassis mounting screws, washers, and lockwashers	.05
31470	Springs—Motorboard suspension top spring, bottom spring, screw, and lockwasher (4 reqd.)	.10
4982	Spring—Retaining spring for knob Stock No. 14359	.05
14270	Spring—Retaining spring for knob Stock No. 30773 and 31355	.05
30330	Spring—Retaining spring for knob Stock No. 31391	.05
31478	Support—Cabinet lid support	2.20

receiver in which is installed a quartz filter. It is therefore better if no test oscillator is had, since a broadcast station of constant signal strength will furnish adequate test signal for alignment of the intermediate frequency amplifier, using the quartz filter for establishing the proper IF frequency as indicated in the following procedure.

The meter on the RME-69 receiver affords an excellent method of indicating the peak alignment of each of the transformers. The location of the three-intermediate frequency amplifier transformers, T-3, T-4, and T-5 is given on Figure 4 of the illustrated sheet attached. The two padding condensers located in each of these transformers and accessible through apertures in the top of the shields can also be seen.

#### OUTLINE OF PROCEDURE FOR CORRECT ALIGNMENT OF THE INTERMEDIATE FREQUENCY AMPLIFIER TRANSFORMERS OF THE RME-69 RECEIVER.

The intermediate frequency amplifiers in the RME-69 Receiver are designed for a frequency of 465 KC. Since these receivers are always supplied with a quartz crystal filter, it is essential that the intermediate frequency amplifier transformers be accurately aligned with the crystal frequency. Crystals are supplied in frequencies slightly at variance from the above stated value of intermediate frequency by an amount not greater than one kilocycle plus or minus 465 KC. Rather therefore than align the intermediate frequency amplifier stages of the RME-69 to a set frequency of 465, it is essential that the alignment be done in conjunction with the quartz filter so that alignment of the intermediate frequency amplifier is achieved at the frequency of the filter. This is done as follows and when the process as herein outlined is followed accurately, maximum results will be obtained. The use of any other process of a general type will produce inferior results.

The first step in the alignment procedure is to tune in a broadcast station, preferably in the low frequency portion of the broadcast band. The signal should be one of medium signal strength so that the R meter indicates a signal level of R9 or slightly less. If no station of this amplitude is available but a stronger station is available, a reduction in the efficiency of the antenna by the connection of a short wire to the antenna post may help to bring the signal strength as indicated down to R9. Usually between 550 and 800 KC in most any territory a station can be received at most any time for this test and adjustment.

When the station has been chosen, let us assume that its frequency is 700 KC, the next step is to slightly detune the main tuning control so that the frequency reads approximately 715 or 720 KC. This of course will tune the station out. It does not necessarily have to be the frequency mentioned or the exact frequency of detune, but the general procedure is to tune the main tuning control slightly higher than the chosen station so that it may be brought back to resonance by decreasing the scale loading of the band-spread control. This is done merely to provide vernier tuning.

With the station chosen and resonated on the band-spread scale, the crystal filter is switched to the series position which is the middle position of the three available. The band-spread scale is then adjusted with respect to the signal so

#### SERVICE NOTES FOR THE RME-69 RECEIVER

##### ALIGNMENT

One of the first evidences of misalignment in a receiver is low over-all gain of the receiver. In the RME-69 Receiver this is evidenced by low meter readings on signals which were formerly capable of producing higher meter readings. Due to the tremendous gain available in the audio system of the RME-69 Receiver, a misalignment due to loss of gain may not be noticed if the condition of the receiver is judged by audio output, since it may be possible to turn the volume control to the maximum output position and still obtain high values of audio output. Misalignment, however, does not affect the circuits of the audio amplifier and has solely to do with the intermediate frequency amplifier and, to some extent, the radio frequency amplifiers. Principal among the contributions to low gain is the part which the intermediate frequency amplifier plays in providing over-all sensitivity and selectivity of a satisfactory order.

Misalignment of the radio frequency section (principally that part of the section which is made up of the high frequency oscillator) is the control of the receiver calibration. This also is susceptible to certain outside influences which can cause variations to such a degree that the stated calibration of the receiver is changed to other values. However, this effect is not a common effect and usually the calibration of the receiver, unless tampered with by inexperienced hands, will remain very close to its stated value indefinitely.

This loss of gain when occurring in the radio frequency section of the receiver is usually due to the fact that the oscillator has been grossly misaligned so that it is apparent in the frequency calibration of the receiver. In other words, it might well be said that a loss of sensitivity in the receiver occurring simultaneously with a wide-spread condition of off calibration might indicate the fact that the loss of gain is caused by misalignment of the radio frequency section of the receiver.

On the other hand, if the gain of the receiver is low, but the calibration is correct, it might be said without hesitation that the most probable cause for the low gain is the misalignment of the intermediate frequency amplifiers relative to the trimming condensers of the intermediate frequency amplifier transformers.

It is for the purpose of realignment of these intermediate frequency transformers that the following test procedure is outlined. **IMPORTANT NOTE.** It is essential that the 465 KC intermediate signal which is used for realignment of the intermediate frequency amplifier is not set according to any arbitrary calibration on the test oscillator itself since it has been found that commercial test oscillators for service work vary considerably, at least to an extent which will not permit proper alignment of a communication type

## RADIO MFG. ENGINEERS, INC.

station, preferably on the low frequency end of Band 1. Then tune the main tuning control slightly to the high frequency side of it, say 10 KC or more higher in frequency than the selected station.

Then resonate the station again by means of the band-spread control. Next set the crystal switch to the series position as indicated on Figure 2A by the position "S" on control "B". Now vary the band-spread control as may be required to produce peak reading of the signal on the R meter by resonating with the crystal resonance peak.

With this setting achieved, vary the dial Number 1 slightly higher and slightly lower by five kilocycles as can be approximated by the calibration of the dial (one half division each way since one division is representative of 10 kilocycles) and notice the drop in the R meter reading. The drop so achieved by varying the setting of Dial 1 five kilocycles above and below the selected signal should be productive of an R meter drop of 40 db. or greater. In other words, if the signal when resonated produces an R meter reading of 60 db. on the R meter scale, setting the dial Number 1 five kilocycles higher in frequency than the frequency of the signal being used should make the R meter fall to 20 db. or less. Similarly, setting the dial Number 1 five kilocycles lower in frequency than the station being used, the R meter should again fall to 20 db. on the scale to 20 db. or less. Should it fail to do this, the phasing condenser (C-1, figure 4) should be adjusted and a test made as just described by five kilocycle above and below adjustment of Dial 1 until the proper variation in the R meter is achieved.

It will be found that the condenser C-1 will usually run at a very low value of capacity, very close to its minimum capacity adjustment. Therefore only slight turning of this condenser will be productive of changes which materially affect the attenuation of the crystal filter. It is usually found that this condenser is not required to be adjusted since it holds its setting very well over long periods of time. The procedure just outlined gives the proper method for checking the phasing and adjusting when necessary.

## ALIGNMENT OF RADIO FREQUENCY SECTION OF THE RME-69 RECEIVER

Alignment of the radio frequency section of the receiver will affect principally the calibration of the receiver. Within certain limits this of course will also affect the sensitivity. A small variation in frequency (up to 2%) will not materially reduce the sensitivity of the receiver although they of course will show up as variations in the calibration as indicated by the required setting of the main tuning dial in diator. Correction for any variation in calibration can be made by following the suggestions outlined below.

Band 1 includes the frequencies between 550 and 1500 KC. For band one there are two frequency adjustments for adjusting the indicator to proper calibration. One of these is adjusted as indicated on Figure 4 through the top of the shield can just in the rear of the main tuning condenser assembly. Just in front of this aperture and on the main tuning condenser assembly is Ct which is used to adjust the

that a maximum meter reading is obtained. This procedure is one which requires patience and accuracy of adjustment since the receiver is ultra sharp with the crystal filter in and there will be one definitely sharp peak indicating crystal resonance. The receiver should be tuned to this peak and left on it during all adjustments to be made regarding the intermediate frequency amplifier.

When this peak has been tuned to and the meter is at maximum reading, a small standard intermediate frequency trimmer tool of the insulated screw-driver type should be used. Then the control "G" Figure 2A, should be set so that the condenser it adjusts is set at 50% mesh. Then, without particular attention to a course of procedure in tuning, any transformer may be adjusted at any particular time, the important factor being that they all be adjusted so that the R meter is brought to and left at a maximum meter reading. Usually this adjustment will not require very much turning of the adjustment screws. A good procedure to follow is to start with the No. 1 transformer and align in sequence No. 2 and No. 3. All adjustments should be made as before mentioned so that the meter reading is maximum.

It is advisable from time to time to make sure that the signal is still adjusted to peak resonance of the crystal by slightly varying the adjustment of the band-spread control. When this procedure has been completed as outlined and all transformers have been adjusted and left at maximum meter reading, the intermediate frequency amplifier of the receiver is in peak adjustment and the crystal aligned with it for maximum effectiveness in filter action.

## RME-69 RECEIVER INTERMEDIATE FREQUENCY AMPLIFIER ALIGNMENT WITH SILENCER INSTALLED

The general procedure for alignment of the intermediate frequency amplifier as described above also applies to receivers in which the LS-1 silencer has been installed. Preliminary adjustment as above described should be made with the silencer threshold control set at maximum clockwise position, of rotation. When the intermediate frequency transformers have been aligned as outlined, the silencer transformer may be peaked by turning the band switch to No. 6 band on the receiver and tuning in and resonating the frequency band around 50 megacycles so that the receiver is sensitive at that point. Then under conditions of automobile ignition interference the silencer control should be set to maximum counter-clockwise rotation position and the small screw accessible through the hole in the noise rectifier transformer located on the silencer auxiliary chassis should be adjusted for a minimum response, of the interference noise. This insures accurate alignment of the noise amplifying system with that of the intermediate frequency, a condition which must necessarily exist for efficient silencer action.

After the intermediate frequency amplifier has been aligned as per the instructions under the article concerning intermediate frequency transformer alignment, a check of the phasing of the crystal filter should be made. Tune in a broadcast

MODEL RME 69

Alignment, Part 3

- Band 2: 2 megacycles and 3 megacycles.  
 Band 3: 4 megacycles, 5 megacycles, 6 megacycles.  
 Band 4: 7 megacycles, 9 megacycles, 11 megacycles, 13 megacycles.  
 Band 5: 14 megacycles, 15 megacycles, 17 megacycles.  
 Band 6: 30 megacycles.

After the calibration has been made accurately on all of the frequencies, or if the receiver has been found to be accurately set insofar as its calibration is concerned on all frequencies, the trimmers C<sub>b</sub> and C<sub>a</sub> have a distinct effect upon the RF grid circuits for bands 5 and 6 respectively. They are adjusted as follows: With a steady incoming signal on between 14 and 15 megacycles and the most effective setting of the control "D" for signal in that region, and with the antenna connected, the condenser C<sub>b</sub> is adjusted for maximum meter reading. With these same conditions existing on 30 megacycles, with the band switch set on band 6 and the antenna connected, C<sub>a</sub> is adjusted for maximum response on a given steady signal. All other trimming and adjusting is done manually by means of control "D", Figure 2-A, and is a variable RF amplifier and detector grid padder which can be critically adjusted for peak resonance at any frequency it is desired to tune to.

It is of importance to note the setting of the condenser C<sub>c</sub> (Figure 4). This is the antenna coupling condenser used when the receiver is set to Band 1. It as well as condenser "C" (Figure 4) should be set to practically its minimum capacity in order to provide constant alignment and proper coupling to the antenna when using Band 1. Excessive capacity in the condenser C<sub>c</sub> will cause misalignment of the RF amplifier and hence promiscuous beating of harmonically related broadcast frequencies to the effect that a number of whistling tones will be received on the high frequency end of the broadcast band. Excessive capacity on C will somewhat contribute to the same result but will, more than that, reduce the sensitivity on the broadcast band. When the receiver leaves the factory, they are set at a very small capacity and should not be set at any other capacity or material reduction in the efficiency of operation will be produced.

Whenever the receiver is gone over for alignment, it is well to remove the dust cover from the condenser assembly and inspect the permanence of position of the rotor plates of the ganged condenser controlled by the knob "D". This is located between the two main variable condensers and is located underneath the dust cover which is removable by unscrewing the four acorn nuts holding it down on the condenser assembly. Some times the rotors become loosened and misplaced angularly with respect to each other. They should always be adjusted so that the rotors are at full mesh at the same time. Any slight angular displacement of one rotor with respect to the other will materially reduce the sensitivity of the receiver and destroy the preselection, thereby reducing the image frequency rejection and also the sensitivity, especially on the high frequency bands.

The padders C<sub>b</sub> and C<sub>a</sub> (Figure 11-B) materially contribute to the image signal rejection on the bands 5 and 6. Special care should therefore be taken in the adjustment of these condensers when the receiver is aligned.

frequency for the high frequency end of Band 1. The procedure is this: Put the main tuning indicator to a position so that the main tuning condensers are fully meshed. The pointer of the main tuning control should then be set at maximum left end of scale so that the pointer falls just below the line above the numbers indicating the various channels. In this respect it will partially cover the top half of the numerals indicating the different tuning bands on this scale. In other words, the line which borders the semi-circular scale at the extreme counter-clockwise position should rest on the top edge of the pointer as it is turned to maximum counter-clockwise rotation and the condenser plates are at full mesh.

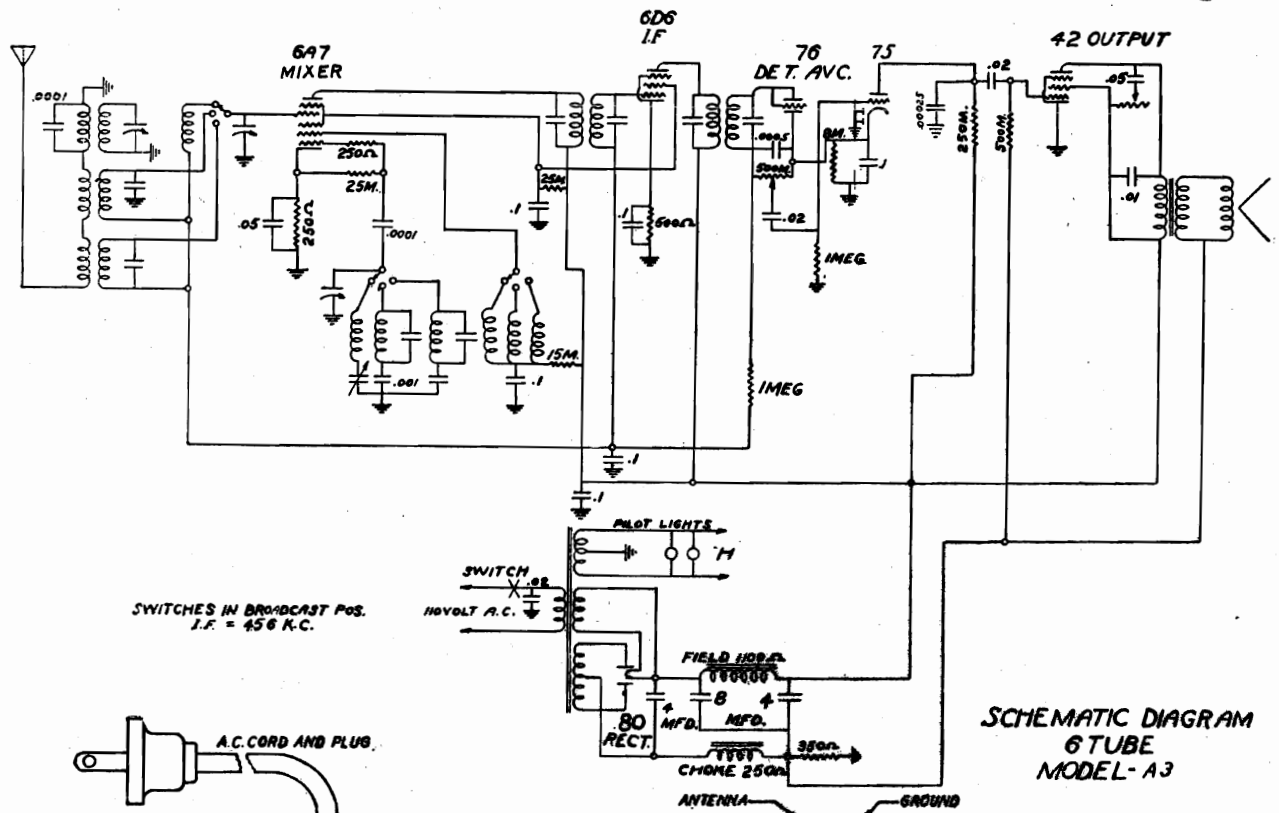

The next step is to choose a station or a signal of accurately known frequency, around 700 KC, and set the main indicator to the frequency of the signal which is going to be used for the test. For example: There is a station available with fairly good signal strength or a test oscillator is available which can ACCURATELY be set at 700 KC. If the receiver indicator on the main tuning dial is set at 700, and the receiver is considerably out of calibration of course the signal will not be received. However, leave the indicator at the correct frequency of the signal being used for the test and set the band-spread control to a reading of 180 on the dial at which position it has no material effect on the tuning circuits of the receiver and permits the calibration of the main tuning dial to indicate accurately the frequency of setting.

Then by means of condenser C<sub>c</sub> (Figure 4) accessible through the trimming hole in the oscillator shield can for Band 1, adjust until the signal is brought in with the pointer set at the proper frequency. Then choose a signal at about 1200 or 1300 kilocycles, and set the main tuning dial indicator to the correct frequency for that signal and bring the signal in on that setting with trimmer C<sub>t</sub>. It will then be necessary to return to the former frequency setting of 700 KC to make sure that the variation of C<sub>t</sub> has not made some slight change in the setting for the lower frequency calibration point and it may be necessary to readjust C<sub>b</sub> slightly again. Then in order to make certain of the accuracy of both settings return to the frequency chosen between 1200 and 1300 KC and if necessary, slightly readjust C<sub>t</sub> again. After several checks on each frequency, it will be found that the calibration can be made satisfactorily.

Calibrations on the higher frequency bands are controlled for Bands 2, 3, 4, 5, and 6 by the trimmers C<sub>r</sub>, C<sub>q</sub>, C<sub>p</sub>, C<sub>o</sub>, C<sub>n</sub>, (Figure 11-B) respectively. High side beat is used on all frequencies in the RME-69 Receiver which means that all of the condensers C<sub>r</sub>, C<sub>q</sub>, C<sub>o</sub>, C<sub>p</sub>, C<sub>n</sub> must be set to the lowest capacity setting which will provide a beat and the proper calibration for the frequencies in the respective bands. Calibration frequencies used are as follows:

adjusted with a small screw driver or knife blade. This control is adjusted at the factory to give normal sensitivity for a set of this type; and in most locations there will be no need for re-adjustment. However, in rural areas where signal strength is low, the gain of the receiver can be increased by three or four times by turning the trimmer in the following manner:

1. Tune in a station.
2. Increase sensitivity by turning trimmer in a clockwise direction until the station signal is distorted by a whistle.
3. Turn trimmer slowly counter-clockwise until whistle ceases. This is the point of maximum sensitivity.
4. Tune in several stations. If some of these signals still whistle, the sensitivity must be again retarded slightly.

**ALIGNMENT DATA AND SERVICING**

Connect the signal generator through a .1 mfd. condenser to the grid of the 6D6 tube. Connect an output meter across the voice coil of the speaker. Set the generator to 456 K.C. and align the I.F. transformer for maximum reading on the output meter. Set the sensitivity control about 1/4 turn counter-clockwise from the point where the whistles start and re-align the I.F.

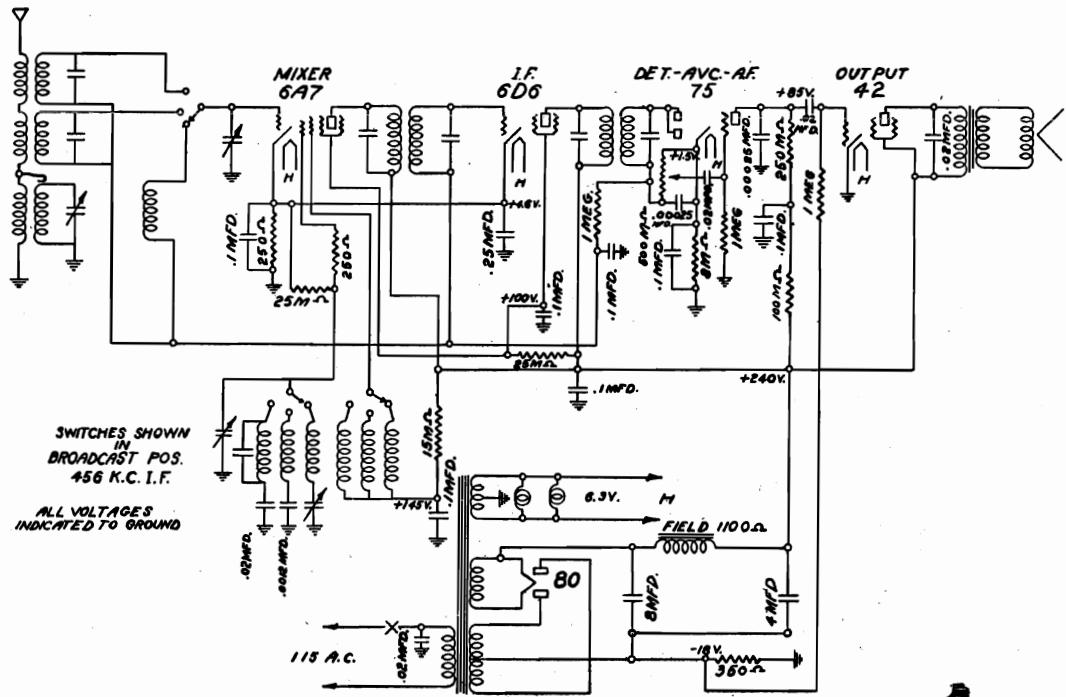

Feed the generator through a 100 mmf. condenser to the antenna lead of the receiver. Set the generator to 1400 K.C. Turn the dial of the radio to 1400 K.C. Align the oscillator and antenna trimmers on the gang condenser for maximum output on the meter.

**ADJUSTMENT OF SENSITIVITY CONTROL**

The sensitivity control is accessible from the rear of the cabinet, (see layout) and takes the form of a trimmer condenser, which may be

R.F. ALIGNMENT. Adjust the test oscillator to 1550 K.C. and connect the output to the antenna through a .00005 mfd. mica condenser to give the equivalent of a low capacity average antenna. When this adjustment is made, the signal must be introduced into the receiver through the shielded lead supplied with the receiver. The plug should be inserted to conform with the "Low Capacity" position. (See Figure 1). Set the gang condenser to minimum and adjust the oscillator trimmer to peak. (Center section of gang condenser). The next step is to set the test oscillator and receiver to 1400 K.C. and adjust the front and rear trimmers of the gang condenser to peak. The rear section of the gang condenser tunes the antenna amplifier stage (6K7 tube), and the front condenser section tunes the detector grid coil of the 6A8G tube.

SETTING UP PUSH BUTTONS:-

The push button set up may be changed as follows:

The selection of stations should be arranged with the location of the lowest frequency station on the extreme left button. A resonance indicator or output meter will aid in making the adjustments. With the band switch on "BC", tune in the desired station with the selector, depress the button and turn the band switch to "A". Now with a screwdriver adjust the trimmer on the top of the chassis nearest the back and adjacent to the speaker. When the desired station is tuned in adjust the trimmer nearest the front panel for maximum volume. Now turn the band switch to "BC" to check the adjustment. Proceed with the next lower frequency station for the next set of trimmers with the band switch on "A".

CONVENTIONAL ALIGNMENT, SEE SPECIAL SECTION VOL.VIII.

The mixer coil is located on the right side of the variable condenser and the oscillator coil on the left side. Trimmers for oscillator and mixer coils are adjustable through holes in the coil supports.

The broadcast trimmers are at the top, the medium wave in the middle and the short wave nearest the bottom of the support.

Trimmers for the I.F. transformers are accessible through openings in the top of the I.F. transformer shields.

VOLTAGE READINGS A.C. voltages:- Line 120 volts; Heaters-6volts; Rectifier filament-5 volts.

D.C. voltages (Taken with no signal from ground to points indicated) 80 Rectifier filament--250 volts; 42 plate--235 volts; 42 Screen--250 volts; 42 bias--20 volts; 6SK7---audio plate 60,---audio screen 10, I.F. plate 250,---I.F. screen 100,---and I.F.bias 2.5 volts; 6K8----plate 250,---oscillator plate 90,---screen 100, and bias supply 2.5 volts.

ALIGNMENT PROCEDURE

**PRELIMINARY:**  
 Output meter connections . . . . . Across load speaker voice coil  
 Output meter reading to indicate 1 watt . . . . . See chart below  
 Average sensitivity microvolts for I watt output . . . . . See chart below  
 Dummy antenna value to be put in series with generator output . . . . . Receiver Chassis  
 Connection of generator output lead . . . . . See chart below  
 Position of volume control . . . . . 30% 400 cycles  
 Cover must be on case when making R. F. adjustments. . . . . Fully clockwise

**ALIGNMENT PROCEDURE:**  
 Output meter connection . . . . . Across speaker voice coil  
 Output meter reading to indicate 50 milliwatts . . . . . See chart below  
 Average sensitivity in microvolts for 50 milliwatts output . . . . . See chart below  
 Dummy antenna value to be in series with generator output . . . . . See chart below  
 Connection of generator output lead . . . . . See chart below  
 Connection of generator ground lead . . . . . Receiver chassis  
 Generator modulation . . . . . 30%, 400 cycles  
 Position of Volume Control . . . . . Fully on  
 Position of Tone Control . . . . . Fully clockwise  
 Position of Dial Pointer . . . . . To fall on end line of scale (low frequency end). Loosen dial drum set screws and rotate drum if necessary. Tighten set screws after pointer is properly set.

WAVE BAND SWITCH POSITION	DIAL FREQUENCY POSITION	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	ADJUSTED POSITION	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
#P	8 mc	465 kc	.1 mfd.	1C7G Grid	X3, X2, X1	IF	20
#A	1400 kc	1400 kc	.0003 mfd.	Ant. Term.	C8, C5, C3	Antenna	7
#A	800 kc (rock)	800 kc	.0002 mfd.	Ant. Term.	C9	Padder	7
#P	5 mc	5 mc	400 ohms	Ant. Term.	C10, C8	Oscillator Translater	10
#P	15 mc	15 mc	400 ohms	Ant. Term.	C7	Translater	15

IMPORTANT ALIGNMENT NOTES

Note that the IF must be adjusted with the Wave Band Switch in the #P position. Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

Always keep the output from the signal generator at its lowest possible value to prevent the AVC action of the receiver from interfering with accurate alignment. As the receiver sensitivity is increased through alignment, the output from the generator should be decreased to compensate.

MECHANICAL SPECIFICATIONS

**OPERATING CONTROLS:**  
 1. Left knob . . . . . On-Off Switch  
 2. Center lower knob . . . . . Volume; Flash-O-Light  
 3. Center upper knob . . . . . Station Selector  
 4. Right knob . . . . . Tone Control

**CONTROL OPERATION:**  
 Turning right: Power on; Volume increase; Flashing down; Flash-O-Light turning right: "A", "P", "M"  
 Tuning Ratio: 30:1  
 Turning right: "LO", "MED", "HI"

SUBJECT: CIRCUIT REVISIONS TO REDUCE BATTERY DRAIN

Later production of chassis number 101.472X described in RL 469 is identified as 101.472X. A change was made from the original design to reduce battery drain. The two 1150 output tubes have been replaced with 4450 output tubes. These changes reduce the "A" battery drain from .5 amperes to .3 amperes, and reduce the "B" drain from 23 ma. to 15 ma.

The Schematics List, Locations of Parts Diagrams, and Wiring Diagram follow. Be sure to mention chassis identification number 101.472X when ordering parts for this chassis.

MODEL 4700. CHASSIS 104.235. ALIGNMENT PROCEDURE

**PRELIMINARY:**  
 Output meter connections . . . . . Across load speaker voice coil  
 Output meter reading to indicate 1 watt . . . . . See chart below  
 Average sensitivity microvolts for I watt output . . . . . See chart below  
 Dummy antenna value to be put in series with generator output . . . . . Receiver Chassis  
 Connection of generator output lead . . . . . See chart below  
 Position of volume control . . . . . 30% 400 cycles  
 Cover must be on case when making R. F. adjustments. . . . . Fully clockwise

**ALIGNMENT PROCEDURE:**  
 Output meter connection . . . . . Across speaker voice coil  
 Output meter reading to indicate 50 milliwatts . . . . . See chart below  
 Average sensitivity in microvolts for 50 milliwatts output . . . . . See chart below  
 Dummy antenna value to be in series with generator output . . . . . See chart below  
 Connection of generator output lead . . . . . See chart below  
 Connection of generator ground lead . . . . . Receiver chassis  
 Generator modulation . . . . . 30%, 400 cycles  
 Position of Volume Control . . . . . Fully on  
 Position of Tone Control . . . . . Fully clockwise  
 Position of Dial Pointer . . . . . To fall on end line of scale (low frequency end). Loosen dial drum set screws and rotate drum if necessary. Tighten set screws after pointer is properly set.

IMPORTANT ALIGNMENT NOTES

Make the generator connection to the receiver through a shielded lead having not more than 50 MMF (.0005) capacity. If a series condenser has been employed as outlined in the first paragraph under "General Information and Service Hints" the dummy antenna should be the same as the antenna itself.

\*\*Readjust C-2 after installation as outlined under "Antenna Matching in Service Hints". Each step of the Alignment Procedure should be repeated in order to afford greater accuracy. Always keep the output from the signal generator at its lowest possible value to prevent any possible AVC action.

Alignment Adjustment screws are shown in Figures 3 and 4.

Only the dummy antenna indicated in the chart for any particular frequency should be used. Grid cap leads should remain in place during alignment.

Oscillator circuit alignment can be made only at high frequencies. A fixed padder is used in series with the return of the oscillator coil secondary. Oscillator coil inductance is preadjusted at factory.

Values shown under "Microvolts" are only approximate.

Dial Adjustments:  
 Rotate dial completely to the right. Then rotate dial completely to the left. Now dial will be set to properly.

CAUSES AND REMEDIES FOR UNUSUAL NOISE CONDITIONS

If controls operate with too much difficulty it indicates that the control cables are bent too sharply. This should be avoided.

If after making proper installation of receiver, you encounter noises you cannot eliminate refer to RL's Nos. 2, 6, 40, 41, 72, 73, 117, for suggestions and remedies.

**ELIMINATING WHISTLE AT 900 TO 920 KC:**  
 In localities where a strong 910 KC station is in operation, a whistle may be experienced at 900 to 920 KC. This whistle is due to a beat between the second harmonic (910 KC) of the 455 KC I. F. and the 910 KC station. Such a condition can be corrected by changing the I. F. frequency to a higher or lower value until the whistle disappears. However, the I. F. amplifier should not be shifted to a frequency higher than 455 KC nor lower than 445 KC but should be as close to 455 KC as possible.

If the I. F. frequency is changed, it will be necessary to realign the rest of the receiver as described under "Alignment Procedure".

**Antenna Matching:**  
 An antenna padder condenser is used to match antenna capacities up to 500 MMF. If, in the installation this padder is not effective, it is because the capacity of the antenna is over 500 MMF. In that case a fixed capacity of .0005 MFD. or less should be connected in series with the antenna. The location of the antenna adjustment is found on Fig. 3.

**ELIMINATING WHISTLE AT 930 KC: MODELS 4632A, 6005, 6016, 6022, 6073, 6125.**

A whistle, due to a beat between the second harmonic (930 kc) of the 485 kc IF, and a 990 kc signal may be experienced in certain stations. In order to eliminate this whistle, the 990 kc signal will be adjusted to shift the whistle frequency to a value which will not be objectionable. This can be done by shifting the IF frequency of the receiver. Determine at what point between 900 kc and 980 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near to 485 kc as possible.

**IMPORTANT ALIGNMENT NOTES**

\* The generator should be adjusted for high output. The trimmer should be adjusted for minimum output meter reading instead of the usual maximum reading. If the frequency of an interfering station around 485 kc is known, the generator should be adjusted to the frequency of that station instead of to 485 kc.

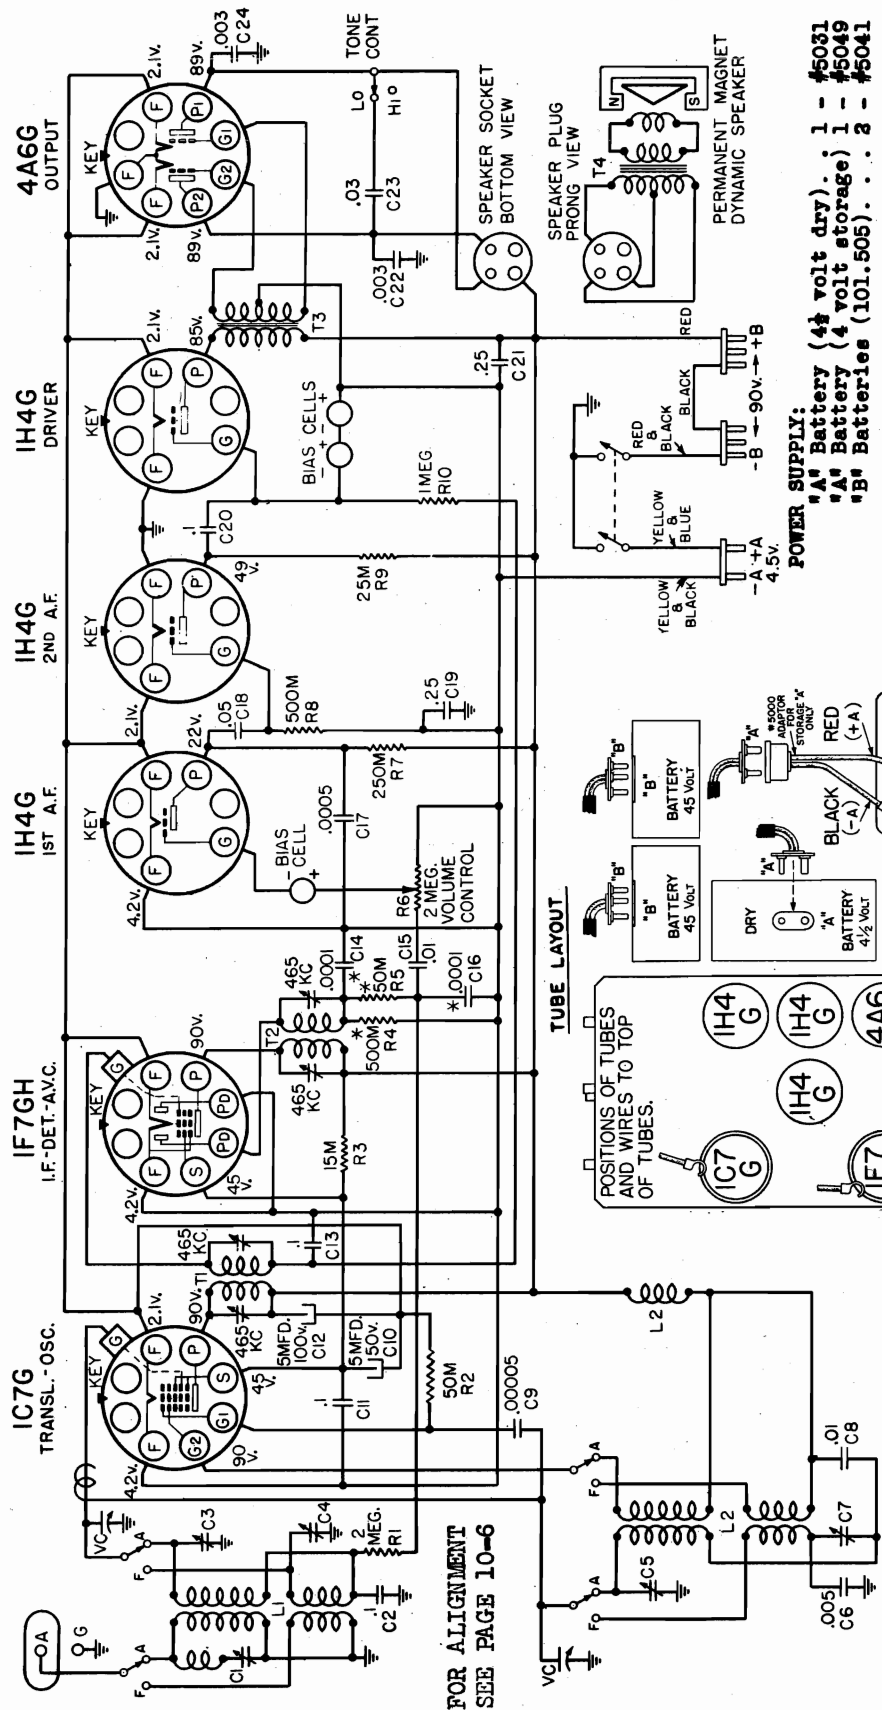

Where indicated by the word "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

600 kc (rook)	600 kc	.0002 mfd.	Antenna Term	C6	C5	C6	C5	Padder	33	70	80	80

\*The generator should be adjusted to give high output. The trimmer should be adjusted for minimum output meter reading instead of usual maximum output meter reading. If the frequency of an interfering code station near 465 kc is known, the generator should be adjusted to that frequency instead of 465 kc.

\*\*Using the dial as a template make a dummy dial of cardboard with only the 1400 kc calibration on it. Slip this dummy dial over the shaft, hold it horizontal so the 1400 mark will come at the same position as the 1400 mark of the actual dial and turn the dial pointer to the 1400 kc mark. (The dial pointer should be horizontal when the condenser is fully open or fully meshed.)

The variable should be rooked back and forth a degree or two while making the 600 kc adjustment. The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

Values shown under "Microvolts" are only approximate.

ELIMINATING WHISTLE AT 930 KC: MODELS 4644A, 6052, 6054-5, 6010.

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near to 465 kc as possible.

Align the IF at the new frequency and then realign the rest of the receiver as described.

"P"	5 mc (rock)	400 ohms	Ant. Term.	C31	Translator	70
"P"	16 mc (rock)	400 ohms	Ant. Term.	C32	Translator	80

IMPORTANT ALIGNMENT NOTES

\* If the frequency of an interfering code station is known, the generator should be adjusted to that frequency instead of 485 kc. The trap should be adjusted to give minimum output meter deflection instead of the usual maximum reading.

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is NECESSARY to repeat the entire alignment procedure step by step in the original order to secure proper alignment. Perfect alignment is not possible with one adjustment of the trimmers.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

Values shown under, "Microvolts", are only approximate.

Tuner Data  
Jack Installation

The trap has two terminals marked "AVT" and "SPT". Disconnect the antenna lead-in from the terminal of the trap to the "AVT" terminal of the trap. Connect the antenna lead-in from the chassis remains as it was. The trap then is in series between the antenna and the receiver. The trap should be tuned to eliminate the interfering station. The sensitivity of the receiver will be reduced in the region of the frequency to which the trap is tuned.

#### INSTALLATION OF A PHONOGRAPH PICKUP JACK OR AN EARPHONE JACK FOR CHASSIS 101.498 ONLY

A kit, part #1013117189, can be ordered from Colonial Radio Corporation, 364 Main Street, Buffalo, N. Y. The kit contains a 41.7 m. pick-up or earphone jack, a 500M ohm resistor, and a 500M ohm electrolytic capacitor. If the customer desires to install either a phonograph pick-up jack or an earphone jack, it will be necessary to use two kits both a phonograph pick-up jack and an earphone jack, it will be necessary to use two kits and to drill an additional hole in the back of the chassis for the additional jack.

**PHONOGRAPH PICK-UP JACK.** A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert and mount the jack in this hole. Insulate the jack socket with the right side of thin brass nuts. Mount one of the terminal boards, supplied in the kit, in this hole.

There is an electrolytic condenser just above the terminal board mentioned in the preceding paragraph. Remove the three leads that are soldered to the mounting nut of this condenser and connect them to the terminal board mentioned in the preceding paragraph.

Solder a lead from the mounting nut of the electrolytic, mentioned in the preceding paragraph, to prong #1 of the speaker socket.

There is a terminal board mounted under one of the nuts that mount the IF output transformer. Mount the terminal board supplied in the kit, between this new terminal board and terminal #1 of the jack.

Run a lead from the new terminal board to the cathode prong of the 6B6G tube.

There is a two-terminal board mounted on the front of the Wave Switch assembly bracket. Run a lead from the terminal of this board that is nearest the Volume Control to lug #2 of the jack.

Run a lead from lug #3 of the jack to prong #1 of the speaker socket.

Connect the 500M ohm resistor between lug #4 of the jack and the coil terminal shown in the illustration.

The radio Volume Control and Tone Control will operate for the phonograph pick-up.

**EARPHONE JACK.** Mount the jack in the hole in the back of the chassis. The jack frame must be reworked to the chassis. Therefore, do not use the insulating washers.

Connect terminal #3 of the jack to terminal #6 of the speaker socket.

Connect terminal #4 of the jack to terminal #5 of the speaker socket.

This is the only wiring necessary. The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.

With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired to have the loud speaker operate at the same time the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

## GENERAL INFORMATION & SERVICE HINTS

### INSTRUCTIONS FOR SETTING UP PUSH BUTTON STATIONS:

1. Remove the two escutcheons that enclose the push buttons. Remove the celluloid call letter holders. A label will be seen telling what frequency (kilocycles) stations can be set up on each button. Each button can be used for only ONE station in its frequency range.
2. Turn the Wave Switch knob to the "American" position and use the tuning knob to tune in the station chosen for #1 button. Then turn the Wave Band switch to the Push Button position, and push button #1 all the way in.

3. It will be seen that there are two adjusting screws for each button, an upper one and a lower one. Turn the lower adjusting screw for #1 button until #1 station is tuned in. Turn the upper adjusting screw for #1 button until the station is tuned in. When the station is tuned in, turn the tuning knob to the upper adjusting screw one or two turns to the right and then proceed with the lower screw adjustment. To check whether you are adjusting to the correct station, turn the Wave Switch knob back to the "American" position momentarily.

4. After the best possible setting of the lower screw has been made, adjust the #1 upper screw right or left to make the slit of the Tuning Eye still narrower.

5. Proceed in the same manner for each button. Be sure the Wave Switch knob is in the "Push Button" position and that you have pushed in the proper button before starting the screw adjustments for that button. The lower screw for each button MUST be adjusted before the upper screw adjustment. The upper screw can be turned back to the "American" position momentarily at any time, to check whether you are adjusting to the correct station.

6. Place the call letters for the chosen stations in the celluloid call letter holders. Be sure to insert the call letters in the proper order so that they will be over the push button for their respective stations. Then replace the celluloid call letter holders and the escutcheons.

### THE A.V.C. CIRCUIT:

The diode current of the 6B6G tube, flowing through the 500M ohm resistor, R11, creates a voltage drop across it. This voltage is applied to the control grids of the RF, Translator, and IF tubes to provide AVC.

### OSCILLATION:

Be sure the tube shields are making good contact to their base clips. Poor contact may cause oscillation.

### ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 485 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently used, this whistle will be desirable. It will be desirable to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to choose the new IF frequency as near to 485 kc as possible.

Align the IF at the new frequency and then realign the rest of the receiver as described under "ALIGNMENT PROCEDURE". It will also be necessary to readjust any stations set up on the Push Button Tuning Mechanism.

### WAVE TRAPS:

A wave-trap, designed to eliminate code interference from ship transmitters, airports or other stations operating in the vicinity of the receiver, is included in the chassis. It is to be used in the alignment procedure. As explained in the alignment procedure, this trap should be tuned to the interfering station in the vicinity of 485 kc.

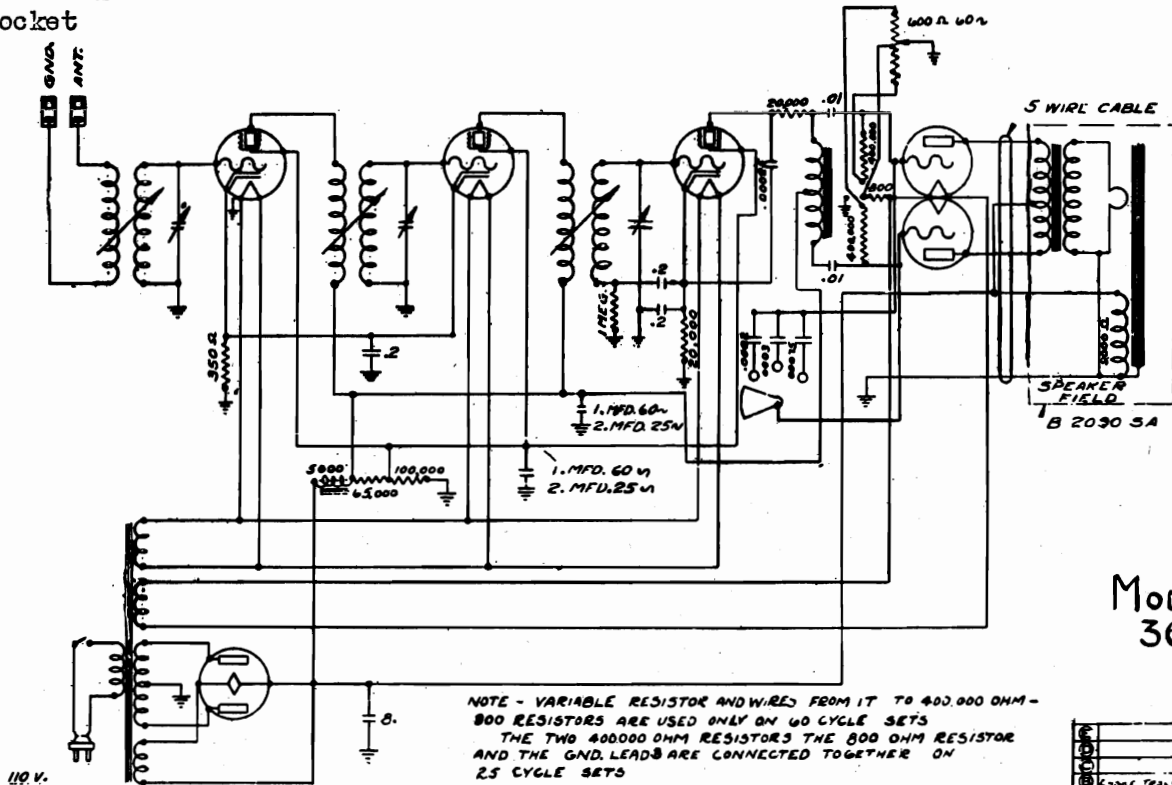

A wave-trap, designed to eliminate whistles and cross modulation troubles on the broadcast band when the receiver is located comparatively near some powerful broadcast station, is available.

This trap can be ordered under part #1013117415 directly from Sears Roebuck and Co. Retail Sure of Mail Order branch, using Purchase Order Blank Form F2384. The retail selling price is \$1.30.

Mount the trap to the chassis mounting shelf or to the inside of the cabinet by means of wood screws through the brackets on the trap. It is important to connect a wire from under the head of one of the wood screws to the chassis so that the wave-trap shield becomes grounded to the chassis.

Phone, Phono, Jacks  
Installation, Schematic

**INSTALLATION OF A PHONOGRAPH PICKUP JACK OR AN EARPHONE JACK:**

A kit, part #1016117189, can be ordered from Colonial Radio Corporation, 354 Rano Street, Buffalo, N. Y. The retail selling price is \$1.11. This kit contains the necessary parts for installing either a phonograph pick-up jack or an earphone jack. If the customer desires both a phonograph pick-up jack and an earphone jack, it will be necessary to use two kits and to drill an additional hole in the back of the chassis for the additional jack.

**PHONOGRAPH PICK-UP JACK:** A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert and mount the jack in this hole. Insulate the jack from the chassis by means of the two insulating washers supplied in the kit. The Schematic Section shows the connections to the jack.

Disconnect the jumper that is between prongs #1 and #4 of the speaker socket and move the lead on prong #1 to prong #4.

Locate the electrolytic condenser mounted alongside of the power transformer. A green lead runs from the anode (center terminal) of this electrolytic to prong #2 of the speaker socket. Transfer the connections of this lead from the anode to the cathode (mounting nut) of the electrolytic and from prong #2 to prong #1 of the speaker socket.

There is a jumper between the cathodes of the two electrolytics. Disconnect this jumper. Run a jumper between the anodes of the two electrolytics.

There is a four-terminal board mounted under the nut that holds the IF output transformer. Run a lead from the terminal nearest the speaker socket on this board to prong #2 of the speaker socket.

Run a lead from lug #1 of the jack to the cathode of the 6Q7G tube.

Connect the .05 mfd. condenser from lug #2 of the jack to the blank prong (3rd one clockwise from the locating pin when viewed from the underside) of the 6K7G tube socket.

Run a lead from lug #3 of the jack to the coil terminal shown in the illustration.

Connect the 500M ohm resistor, supplied in the kit, between lug #4 of the jack and prong #1 of the speaker socket.

The radio Volume Control and Tone Control will operate for the phonograph pick-up.

**EARPHONE JACK:** Mount the jack in the hole in the back of the chassis. The jack frame must be grounded to the chassis. Therefore, do not use the insulating washers.

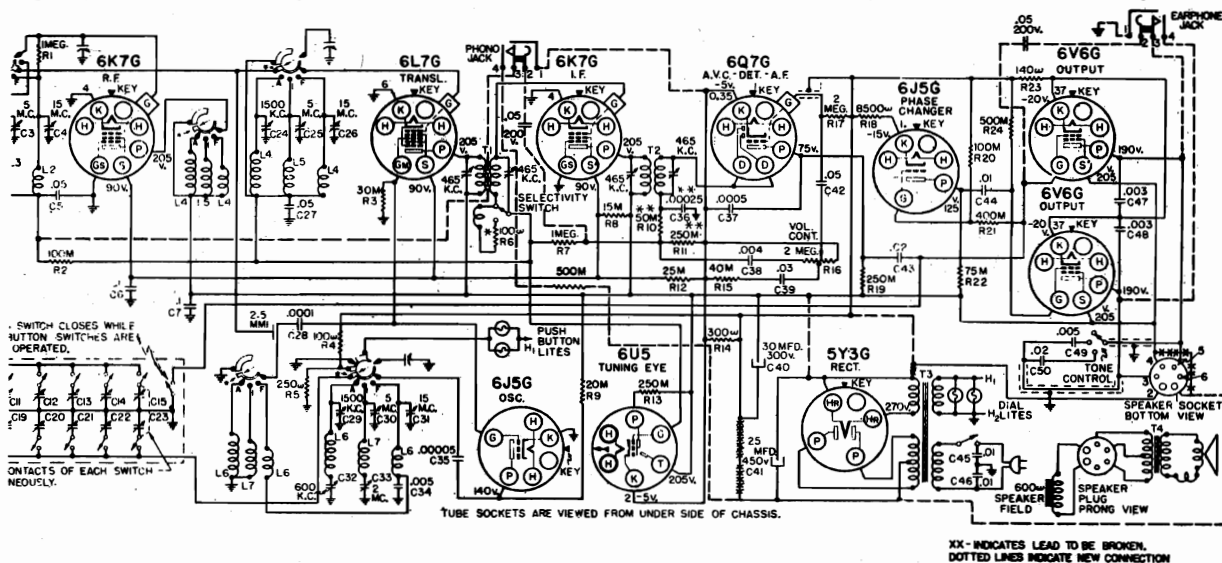

Connect the .05 condenser from terminal #3 of the jack to the grid prong of the 6V6G output tube.

Connect terminal #3 of the jack to terminal #5 of the speaker socket.

Connect terminal #4 of the jack to terminal #3 of the speaker socket.

This is the only wiring necessary. The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.

With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired to have the loud speaker operate at the same time the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

3. Center knob . . . . . Tuning
4. Next to right knob . . . Selectivity
5. Right knob . . . . . Tone Control

DIAL & KNOB FUNCTIONS

The trap has two terminals marked, "ANT" and "SET". If a conventional antenna is being used (not a doublet), the trap will be connected as follows. Disconnect the antenna leadin from the receiver and connect it to the "ANT" terminal of the trap. Connect a wire

from the "SET" terminal of the trap to the "ANT" terminal of the chassis. The ground connection to the chassis remains as it was. The trap then is in series between the antenna and the receiver. The trap should be tuned to eliminate the interfering station. The sensitivity of the receiver will be reduced in the region of the frequency to which the trap is tuned.

If a doublet antenna is installed with the receiver, the trap must be connected between the antenna lug of the broadcast antenna coil primary and the Wave Switch. Remove the lead between the antenna lug of the primary and the wave switch. Connect the "ANT" terminal of the trap to the wave switch lug. Connect the "SET" terminal of the trap to the antenna coil lug. See Illustration below.

- ANTENNA CONNECTIONS:

"FOR"	15 mc (rock)	15 mc	400 ohms	Ant. Term.	C28, C4	Transal., RF	5

IMPORTANT ALIGNMENT NOTES

\* If the frequency of an interfering code station is known, the generator should be adjusted to that frequency instead of to 485 kc. The trap should be adjusted to give minimum output meter deflection instead of the usual maximum reading.

Where indicated by the word "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is necessary to repeat the entire alignment procedure step by step in the original order to secure proper alignment. Perfect alignment is not possible with one adjustment of the trimmers.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

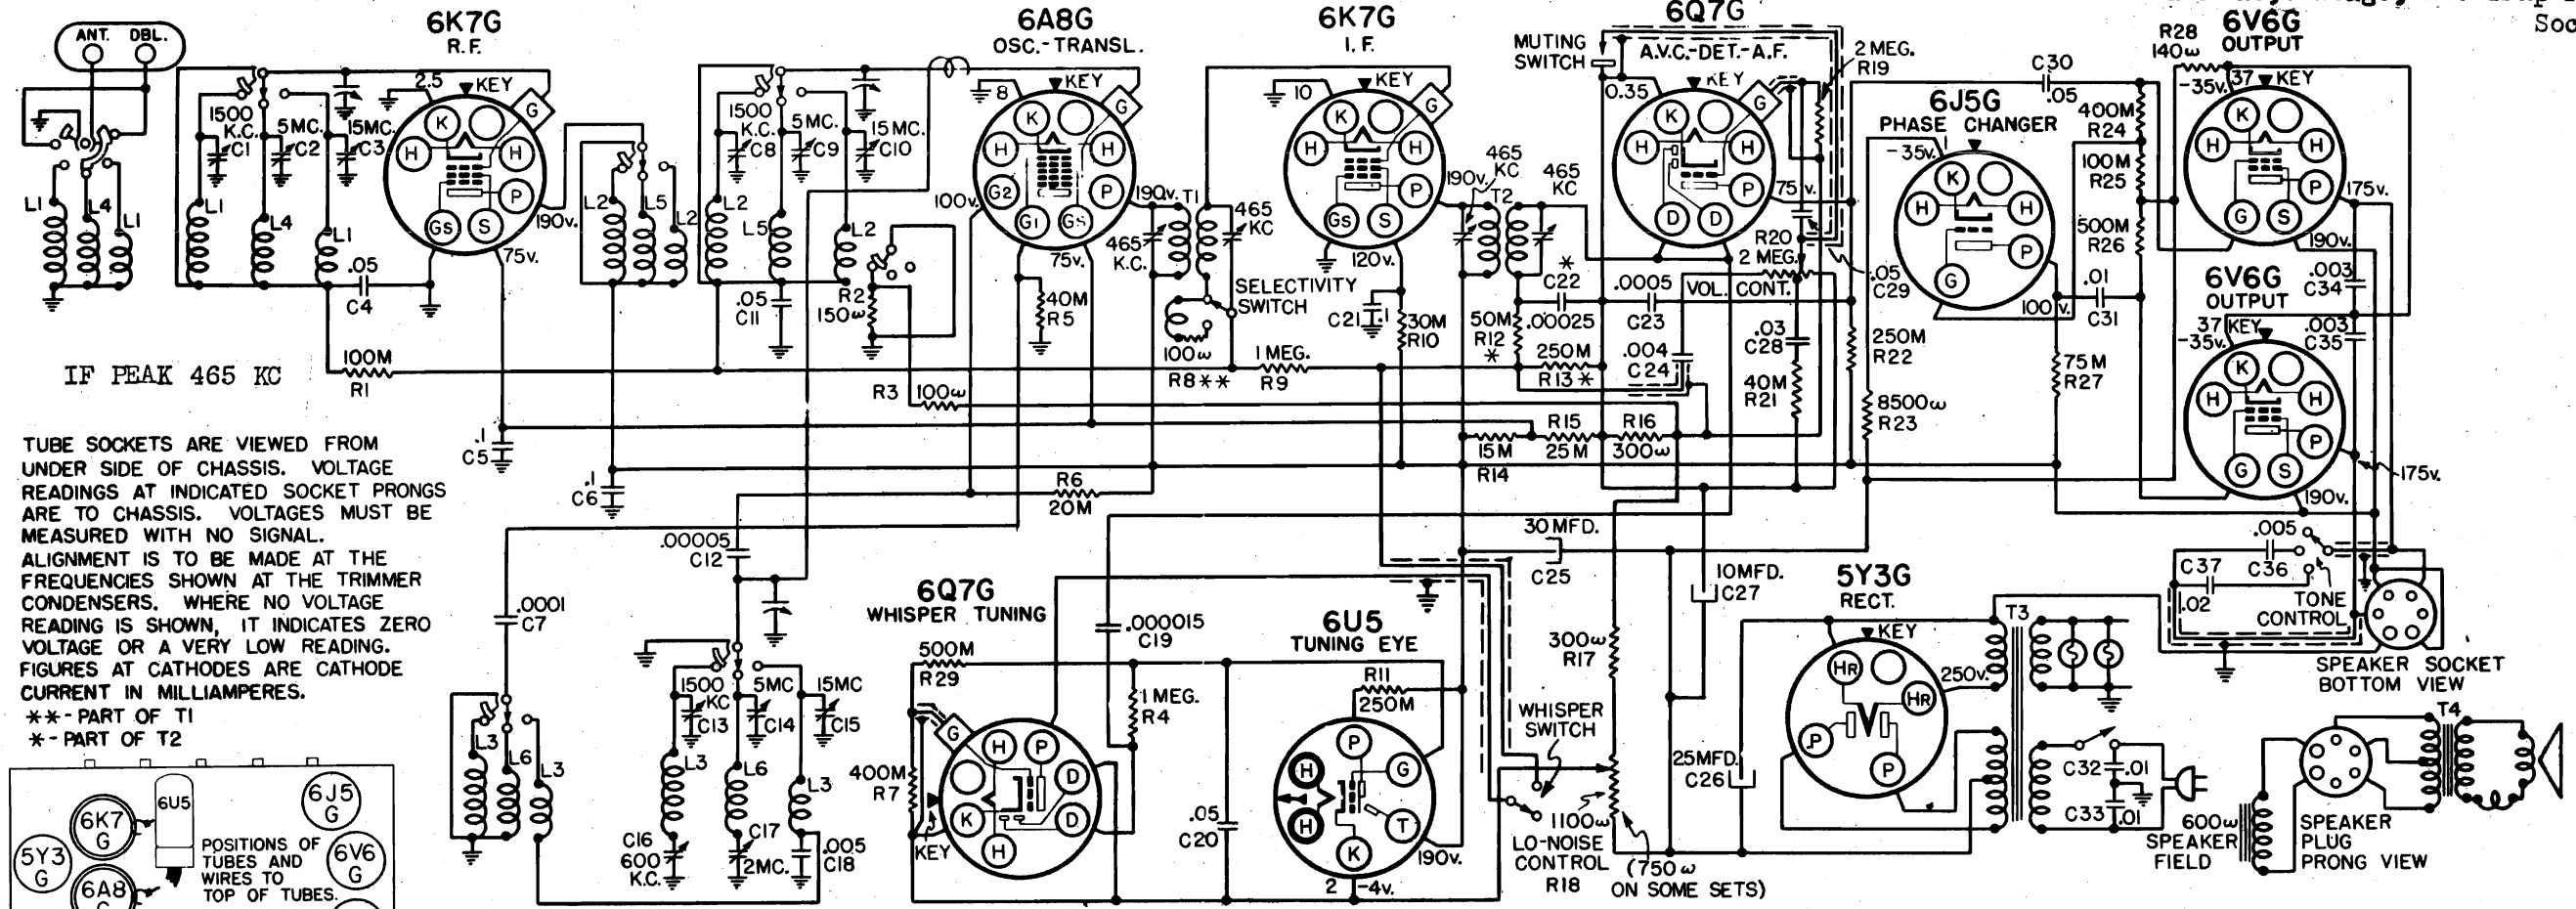

The shield plate that covers the coil assembly should be left in place while making the alignment adjustments. The trimmer screws are accessible through the holes in the shield.

Only the dummy antenna indicated in the chart for any particular band should be used. Remove the dummy antenna used for alignment of any other band.

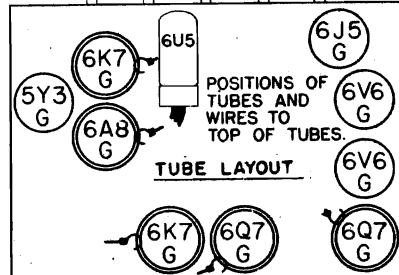

No connection should be made to the doublet terminal on the antenna connection block.

WAVE TRAPS:

Two wave-traps are available and can be ordered directly from source 101, using Purchase Order Blank Form F2284. The retail selling price is \$1.20.  
Part #1013117417 wave-trap is designed to eliminate code interference from ship transmitters, airports or air beacon stations, in locations where the receiver is near such transmitters. This trap operates in the vicinity of 465 kc.  
Part #1013117418 wave-trap is designed to eliminate whistles and noise modulation troubles that occur when the receiver is located comparatively near some powerful broadcast stations.

It is possible to use both traps simultaneously if conditions make this necessary.  
The trap can be mounted within the chassis by drilling the holes shown in the following illustration. It will be necessary to remove the bracket from the trap in order to mount it in the chassis. An alternative method of mounting is to screw the trap to the chassis mounting shelf by means of wood screws through the bracket. If the trap is not mounted on the chassis as shown, the wave-trap shield plate becomes redundant to the chassis.

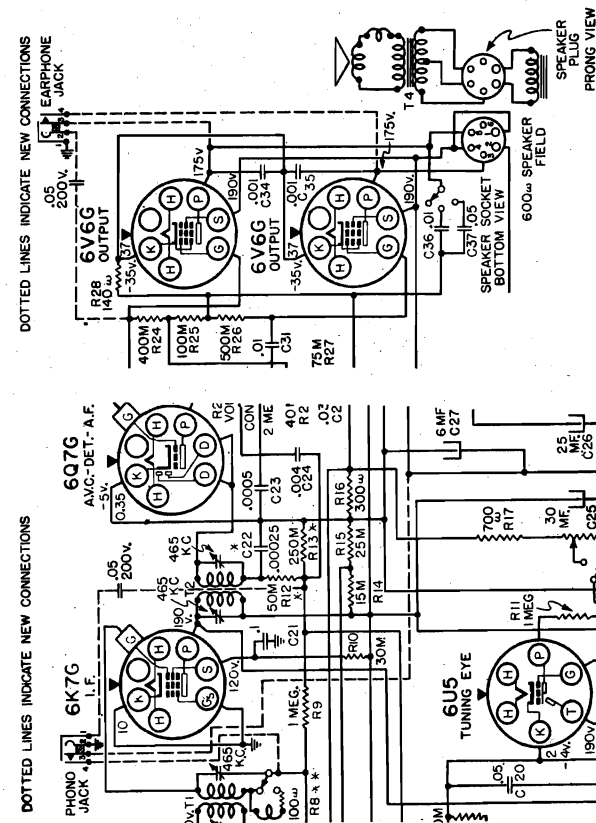

If a conventional antenna is being used with the receiver, the traps are to be connected as described in the next two paragraphs and the illustration that follows them.

The part #1013117417 trap, for broadcast station interference elimination, has two terminals marked "ANT" and "GND". Connect a wire between the "ANT" terminal of the trap and the "ANT" terminal of the chassis. Connect a wire between the "GND" terminal of the trap and the "GND" terminal of the chassis. The antenna and ground connections to the receiver remain as they were, the trap is connected across them. The trap should be adjusted to minimum response from the interfering station.

Part #1013117418 trap, for broadcast station interference elimination, has two terminals marked "ANT" and "SER". Disconnect the antenna lead from the receiver and connect it to the "ANT" terminal of the trap. Connect the "SER" terminal of the trap to the antenna lead of the chassis. The ground connection to the chassis remains as it was. The trap then is in series between the antenna and the receiver. The trap should be tuned to eliminate the interfering station. The sensitivity of the receiver will be reduced in the region of the frequency to which the trap is tuned.

If a doublet antenna is installed with the receiver, the antenna terminal of the #1013117417 trap should be connected to the antenna terminal of the receiver. The antenna lead of the chassis #1013117418 trap must be connected between the antenna lug of the broadcast antenna coil primary and the wave switch. Remove the lead between the antenna lug of the primary and the wave switch. Connect the antenna terminal of the trap to the wave switch lug. Connect the set terminal of the trap to the antenna coil lug. See next illustration.

PHONOGRAPH PICK-UP JACK: A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert and mount the jack in this hole. Insulate the jack terminals with insulating washers supplied in the kit. The schematic section shows the connections to the jack.  
Connect the .05 condenser between lug #1 of the jack and the plate prong of the 6Q7 tube socket that is just above the LO-NOISE control rheostat.  
Connect lug #3 of the jack to ground.  
There is a terminal board mounted under the IF input transformer. Connect the terminal on this board nearest the back of the chassis to lug #3 of the jack.  
Connect lug #4 of the jack to the LO-NOISE control rheostat.  
The radio Volume Control and Tone Control will operate for the phonograph pick-up. The jack frame must be secured to the chassis. Therefore, do not use the insulating washers.  
Connect the .05 condenser from terminal #2 of the jack to the grid prong of the 6V6G output tube.  
Connect terminal #3 of the jack to terminal #5 of the speaker socket.  
Connect terminal #4 of the jack to terminal #3 of the speaker socket.  
This is the only wiring necessary. The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.  
With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired that the loud speaker operate when the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

Automatic Tuner Data

SEARS-ROEBUCK & CO.

MODEL 4786  
Chassis 100.196

Carefully pull out the key allowing the button to snap back into position. If the button sticks, the button must be out before proceeding to the next step. When the button is out, it must not be pushed in again until the mechanism has been looked as described in the following paragraph.

Lock the mechanism by moving the stud to the right as indicated by the forefinger and thumb. If the mechanism has been pushed in accidentally, do not push it back in until you check the accuracy of your settings of your tuning mechanism. Then push the button that you have just adjusted all the way in with your finger and turn the mechanism so that the button is carried toward the bottom point of the AUTOMATIC TUNING dial until it reaches its stop. Then remove your finger from the button and your ear from the speaker. Push the button in until the Tuning Eye to determine exactness of tuning. If you find that you can tune the station in more exactly by means of the center shaft than by means of the AUTOMATIC TUNING dial button, it indicates that you have not adjusted the button carefully enough and the procedure should be repeated more accurately.

FIG. 13  
CAP WITH CALL LETTERS IN PLACE ON BUTTON #1.

THE AUTOMATIC TUNING DIAL.  
The method of setting up the Automatic Tuning Dial follows in detail. In some cases frequency tuning may be necessary to reset the dial. In other cases, particularly the ones for the high frequency end of the broadcast band, the tuning dial buttons have been reset once it is seldom necessary to reset them again although in some cases further aging and drifting does occur, making a second resetting necessary.

THE FIXED BUTTON, IDENTIFIED BY A RED CAP, CANNOT BE ADJUSTED TO ANY STATION. DO NOT TAMPER WITH THE ADJUSTMENT OF THIS BUTTON.

Table with columns for Frequency (Kilocycles), Range, and Button #. It lists various radio stations and their corresponding tuning buttons.

Make a list of the stations you want to set up on the AUTOMATIC TUNING dial. Mark down the frequency of the stations as well as their call letters. Arrange the stations in the order of their frequency. That is, the one of lowest frequency first; next higher frequency second, etc.

IF TWO OR MORE OF YOUR SELECTED STATIONS FALL WITHIN ONE BUTTON ADJUSTMENT, YOU MUST REVISE YOUR LIST OF STATIONS SO THAT ONLY ONE STATION WILL BE ASSIGNED TO A BUTTON. To proceed with the setting up, turn the Selectivity Control knob to the SHARP position. See Fig. 7. The AUTOMATIC TUNING dial should be turned to the position only or setting up station with the knob in either the BROAD or SHARP positions.

If you select fewer than eleven stations so that there is no station in one or more of the frequency sections the button for that section will be left unadjusted. (54) Pull the large knob, marked "TUNE", off of its shaft. See Fig. 7A. The mechanism will then appear as in Fig. 9. Note the numbering of the buttons. Unwind the AUTOMATIC TUNING mechanism by pushing the stud to the left as shown by the forefinger and thumb in Fig. 10. Turn the dial until the tuning eye and the stud make more contact than in Fig. 10. (You will find that the tuning eye will tend to move to the right. This is normal.) It takes quite a bit of pressure to move the stud so that it is necessary to hold the mechanism firmly with one hand, as shown.

Tune in the first station on your selected list. (The first station is the one of lowest frequency.) This can be done by rotating the center tuning shaft as shown in Fig. 11. (Be sure the Wave Band Switch is turned to the AMERICAN position.) Note that the dial pointer in the illustration is turned to the station you have selected. The station as being tuned and that button #1 is in position to be adjusted. Your station for button #1 may be any station between 540 kc and approximately 550 kc since this is the frequency range of this button.

The key (see Fig. 12) fits the handle. Insert the other end of the key into button #1. Push the button all the way in by means of the key and turn the button. You will find that the button can be turned in either direction but that it cannot be turned for more than one-half a circle. See Fig. 13.

If button #1 cannot be pushed in far enough to allow it to turn, it will be necessary to remove the hairpin clip from the red button. Then proceed to adjust button #1 as described in the following paragraph, being very careful not to turn the red button. The red button will go in slightly when adjusting button #1 but will return to its original position when #1 button is released after completing its adjustment. Replace the hairpin clip on the red button. This removal of the hairpin clip is not necessary when adjusting any of the other buttons.

There is a notch in the outer edge of the button that will tell you in what direction to turn the button. The button should be turned so that the notch would fall on an imaginary line drawn straight down from the center of the dial. The notch on the button will cause the AUTOMATIC TUNING mechanism to turn and will also cause the pointer to move on the dial. Carefully turn the key so that your #1 station will be tuned in exactly. The station cannot be heard while the button is pushed in by means of the key, so that the tuning eye must be used for precise tuning as described in the preceding paragraph. The station must be heard for precise tuning as described in the preceding paragraph. The station must be heard for precise tuning as described in the preceding paragraph.

Over dial pointer may not be exactly at 550 kc. See Fig. 14. If the "Log" lists two buttons (#1 or #2) for the station you have selected, you may find that when button #1 is turned as far as possible its notch does not quite come to the imaginary center line of the dial and that the station cannot be tuned in with button #1. If this is the case, turn the key to button #2. If you have no other station for button #2, turn the button so that its notch is about midway in its range as shown by button #2 in Fig. 13. This will keep it from interfering with the adjustment of adjacent buttons. This procedure must be followed for all those stations that have two button numbers listed in the "Log".

MODEL 4786, Ch. 100.196  
MODELS 4610, 4669, 4769  
4789, Ch. 101.482

SEARS-ROEBUCK & CO.

Automatic Tuner Data  
Part 2

When all of the buttons have been adjusted and the caps put on them, the mechanism will appear as in Fig. 28. If you have selected over than 11 stations, not all of the buttons need to be adjusted. In such cases, use one of the discs that has a printed star.

Replace the round AUTOMATIC TUNING dial plate, using the four screws. If there was a paper washer behind the plate, put it back in place before screwing on the plate. Then push the dial into place. The dial must always be turned in such direction that the bottom point of the dial will reach the bottom of the dial before the red button does. In other words, when you place your finger on a button for a desired station, turn the dial so that the red index button follows your finger rather than having your finger follow the dial. This will eliminate noise between stations while tuning with the AUTOMATIC TUNING dial.

To tune in any of the stations that have been set up on the AUTOMATIC TUNING dial, merely push into place the dial plate, all the way to the left. The dial must always be turned into place with your finger on it will reach the bottom point of the dial before the red button does. In other words, when you place your finger on a button for a desired station, turn the dial so that the red index button follows your finger rather than having your finger follow the dial. This will eliminate noise between stations while tuning with the AUTOMATIC TUNING dial.

OPERATION:  
To tune in any of the stations that have been set up on the AUTOMATIC TUNING dial, merely push into place the dial plate, all the way to the left. The dial must always be turned into place with your finger on it will reach the bottom point of the dial before the red button does. In other words, when you place your finger on a button for a desired station, turn the dial so that the red index button follows your finger rather than having your finger follow the dial. This will eliminate noise between stations while tuning with the AUTOMATIC TUNING dial.

UNLOCKING MECHANISM BEFORE TUNING IN #2 STATION NOTE LEFT HAND HOLDING MECHANISM FROM TURNING.

After the AUTOMATIC TUNING dial button has been adjusted properly and the mechanism locked as described, you are ready to insert the cap with the station call letters in it. If you purchased your radio from a Sears Retail Store proceed as follows:

RETAIL STORE MODELS:  
Push out the disc containing the call letters of your selected station. Place one of the clear celluloid discs into one of the metal caps and then place the disc with your station call letters in the cap. Be sure to put the disc in so that the call letters are readable from the front of the cap. See Fig. 17.

Push the cap into place on the button for your station. See Fig. 18. Be sure the cap is put on so that the letters are upright and can be read easily.

Again unlock the dial mechanism by moving the stud to the left as shown by the forefinger and arrow in Fig. 20. As before, the mechanism must be held firmly with one hand, being careful not to push in any of the buttons, while unlocking the mechanism.

MAIL ORDER MODELS:  
Push in the second station on your selected list. This can be done by rotating the center of the dial pointer is at approximately 590 kc on the Roll Over dial, as an example. Note that the station as being tuned and that button #2 is in position to be adjusted. Your station for button #2 may be any station between approximately 590 kc and 580 kc since this is the frequency range for button #2. See Fig. 19.

Adjust the tuning eye to the station you wish to tune in. When the tuning eye is in the correct position, you will find that the button can be turned in either direction but that it cannot be turned for more than one-half a circle. See Fig. 13.

There is a notch in the outer edge of the button that will tell you in what direction to turn the button. The button should be turned so that the notch would fall on an imaginary vertical line through the center of the dial. When the notch reaches this point you will find that further rotation of the button will cause the Roll Over dial. Carefully turn the key so that your #2 station will be tuned in exactly. The station cannot be heard while the button is pushed in by means of the key, so that the tuning eye is in the correct position. When the tuning eye is in the correct position, the Roll Over dial pointer may not be exactly at 590 kc. See Fig. 22.

Carefully pull out the key allowing the button to snap back into position. If the button sticks when you try to pull the key out, shake it slightly and it should snap out. Be sure the button is out, and that the mechanism is in the next step. When the button is out, it must not be pushed in again until the mechanism has been locked as described in the following paragraph.

Lock the mechanism by moving the stud to the right as indicated by the forefinger and arrow in Fig. 24. Note that one hand is holding the mechanism at the outer edge of the buttons so that they are not pushed in accidentally.

You can check the accuracy of your setting of the button by turning the red AUTOMATIC TUNING dial to the station you have indicated all the way in with your finger. The mechanism will reach its stop. Then move your finger from the bottom point of the AUTOMATIC TUNING dial until it is low as it can be turned any more exactly by rotating the center shaft as illustrated in Fig. 25. This is to prevent the station from being turned in again. You can check the accuracy of your setting of the button by turning the red AUTOMATIC TUNING dial to the station you have indicated all the way in with your finger. The mechanism will reach its stop. Then move your finger from the bottom point of the AUTOMATIC TUNING dial until it is low as it can be turned any more exactly by rotating the center shaft as illustrated in Fig. 25. This is to prevent the station from being turned in again. You can check the accuracy of your setting of the button by turning the red AUTOMATIC TUNING dial to the station you have indicated all the way in with your finger. The mechanism will reach its stop. Then move your finger from the bottom point of the AUTOMATIC TUNING dial until it is low as it can be turned any more exactly by rotating the center shaft as illustrated in Fig. 25. This is to prevent the station from being turned in again.

After the AUTOMATIC TUNING dial button has been adjusted properly and the mechanism locked as described, you are ready to insert the cap with the station's call letters. If you purchased your radio from a Sears Retail Store proceed as follows:

RETAIL STORE MODELS:  
Push out the disc containing the call letters of your selected station. Place one of the clear celluloid discs into one of the metal caps and then place the disc with your station call letters in the cap. Be sure to put the disc in so that the call letters are readable from the front of the cap. See Fig. 25.

Push the cap into place on the button for your station. See Fig. 26. Be sure the cap is put on so that the letters are upright and can be read easily.

MAIL ORDER MODELS:  
The same perforated paper sheet with station call letters and the clear celluloid discs are used as described in this is the easiest method. However, if you have purchased your radio from a Sears Retail Store proceed as follows:

Push out the disc containing the call letters of your selected station. Place one of the clear celluloid discs into one of the metal caps and then place the disc with your station call letters in the cap. Be sure to put the disc in so that the call letters are readable from the front of the cap. See Fig. 25.

Push the cap into place on the button for your station. See Fig. 26. Be sure the cap is put on so that the letters are upright and can be read easily.

JULY 15, 1937

**SUBJECT: READJUSTING THE AUTOMATIC TUNING DIAL STOP BUTTON TO MAKE IT POSSIBLE TO SET UP DESIRED STATIONS, THAT ARE CLOSE IN FREQUENCY, ON ADJACENT BUTTONS.**

By referring to ranges it will be seen that WMAQ, 670 kc, would be set up on button #4. WGN, 720 kc, would be set up on button #4 or #5. WBBM, 770 kc, would be set up on button #5. Since these three stations come within the frequency range of only two of the buttons, the customer would ordinarily have to give up one of the three stations for AUTOMATIC TUNING.

It is possible, however, to change the setting of the "fixed" button and make it possible to set up three such stations, close together in frequency, on three separate buttons.

The method of doing this is as follows:

FIG. 2

FIRST:-

Make a full size reproduction of button frequency ranges on a suitable paper or cardboard, - an eleven division scale, one division for each button range as illustrated.

SECOND:-

Likewise make a full size reproduction of the AMERICAN band on suitable paper or cardboard.

Make a light pencil mark on the reproduction of the tuning scale at the frequency of each of the eleven desired stations. Then lay the eleven division scale against the reproduction of the tuning scale and move the eleven division scale to such a position that each of the pencil marked positions for the eleven desired stations will fall within the range of a different button. However, the eleven division scale can only be moved so that its left index mark comes between the dotted lines of the reproduction of the tuning scale, as shown in Fig. 2. In Fig. 2 it will be seen that by moving the eleven division scale to the point shown, WMAQ will be within the range of button #3; WGN will be within the range of button #4; and WBBM will be within the range of button #5.

When a position of the eleven division scale is found that will allow the eleven desired stations to fall within the range of separate buttons, carefully note at what point on the reproduction of the dial scale the left index mark of the eleven division scale comes. In the illustration for stations WMAQ, WGN, and WBBM, the index mark is just about opposite 550 kc on the dial scale. (Fig. 2).

Remove the chassis from its cabinet. Leave the AUTOMATIC TUNING dial escutcheon off.

Turn the AUTOMATIC TUNING dial to its stop so that the variable is fully meshed. Now move the pointer along its drive cable to the point on the dial that corresponds exactly to the position of the left index mark of the eleven division scale, as described in the preceding paragraph. As can be seen by inspection, the pointer is pinched onto the drive cable and it will be necessary to pry this pinching open slightly so that the pointer can be moved along the cable. The AUTOMATIC TUNING dial must be kept turned all the way to the left to its stop during the operation of moving the pointer. After the pointer has been moved to its new position it should be pinched onto the cable again so that it cannot slip.

Loosen the set screw that holds the variable condenser drive drum to the variable condenser shaft.

Unlock the AUTOMATIC TUNING dial mechanism by moving the studs counter-clockwise. Pull out the "hair pin" clip that will be found on the unnumbered stop button. This button can then be pushed in and turned the same as the other eleven numbered buttons. Push in the unnumbered button and turn it to such position that when the AUTOMATIC TUNING dial mechanism is turned to its limit the pointer will be at its original stop at the left end of the dial. Then lock the mechanism by rotating the studs clockwise. (Be careful not to push in button #1 while the unnumbered button is pushed in as this may jam the mechanism. If this should happen the mechanism can be freed by pushing in the stop latch, as will be seen by inspection.) Replace the "hair pin" clip on the unnumbered button.

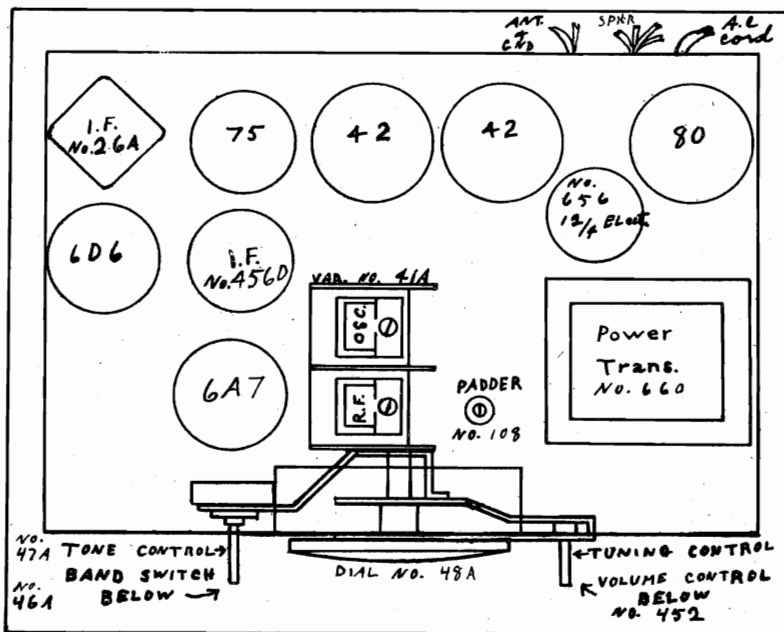

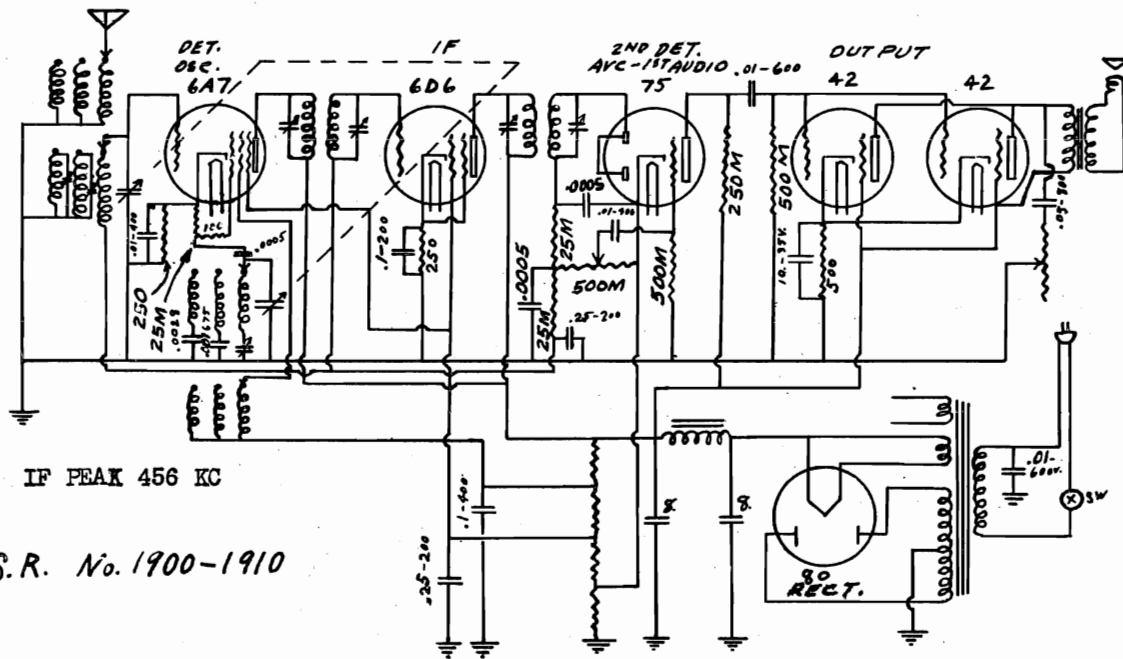

With the mechanism turned all the way to the left to its stop and with the dial pointer at its left limit on the dial, fully mesh the variable condenser by turning the movable plates with the fingers. Then re-tighten the set screw that holds the condenser drive drum to the variable condenser shaft.

The eleven desired stations can then be set up on the eleven adjustable buttons in accordance with the instructions. (SEE PRECEDING PAGES). The new frequency ranges for the buttons will be determined by holding the eleven division scale against the reproduction of the tuning scale, with the left index mark of the eleven division scale at the proper point between the dotted lines on the reproduction of the Tuning dial scale.

MODELS 1900,1910  
Schematic, Socket

SEARS-ROEBUCK & CO.

Trimmers, Alignment

**ALIGNMENT**

- 1- Apply 456 KC note to control grid of 6A7 and peak IF trans. for max. gain.
- 2- Apply 4000 KC note to antenna wire; set band switch to 2nd band and align trimmer on oscillator section of variable condenser to track with 4000 KC on dial.
- 3- Turn Band switch to Broadcast band; apply 1500 KC note to antenna wire, adjust trimmer on RF section of variable condenser for maximum gain.
- 4- Apply 600 KC note to antenna, adjust padder condenser for maximum gain, swinging condenser back and forth across 600 KC signal.
- 5- Check 1400 KC signal for alignment.
- 6-Turn band switch to 2nd band; check 4000 KC signal for alignment and adjust trimmer on antenna coil for greatest gain at 4000 KC.
- 7-Turn band switch to last band and adjust trimmer on antenna coil for greatest noise on 12 megacycles.

**RECEIVER RANGE - THREE WAVE BANDS**

540 - 1720 kilocycles; 1720 - 5000 kilocycles; 5.5 - 16 megacycles

MODEL 4796, Ch. 126.201  
Schematic, Voltage

**OPERATING FEATURES:**  
Phonograph-Radio operation  
Automatic Phonograph Mechanism with self-starting, governor-type motor  
Two-point Tone Control  
Automatic Volume Control

**PHONOGRAPH:**  
Type . . . . . Automatic-Manual  
Record Capacity . . . . . Eight 10-inch  
Turntable Speed . . . . . 78 R.P.M.  
Type of Pickup . . . . . Crystal  
Pickup Impedance . . . . . 75,000 ohms at 1,000 cycles

**Radio Only**      **Total**  
Power Supply Rating . . . . . 105-125 volts, 60 cycles . . . 75 watts . . . 105 watts

**ALIGNMENT FREQUENCIES:**  
Band "F" . . . . . 540-1720 kc  
Band "A" . . . . . 600 kc(osc.), 1500 kc(osc.)

**LOUDSPEAKER:**  
Type . . . . . Pentode  
Size . . . . . Electrodynamic  
V.C. Impedance . . . . . 2.25 ohms at 400 cycles  
Field Coil Resistance . . . . . 1.290 ohms  
App. Field Coil Voltage Drop . . . . . 80 volts

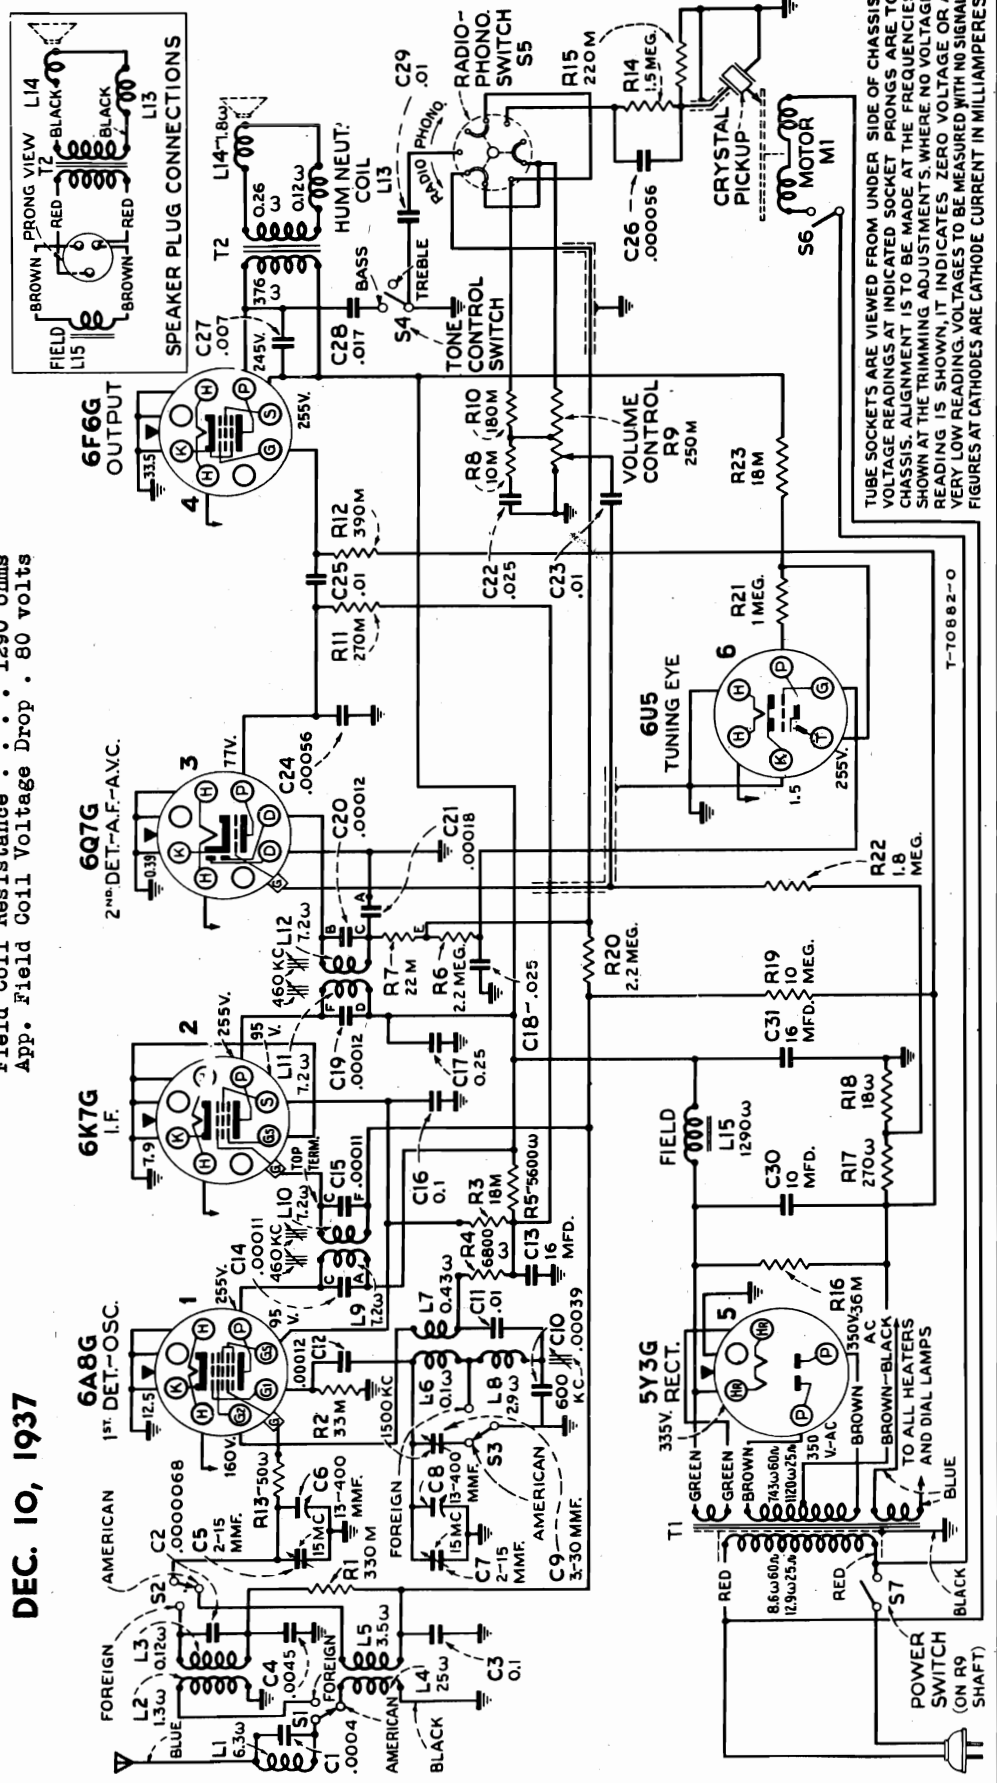

**POWER SUPPLY RATING** . . . . . 105-125 volts, 60 cycles . . . 75 watts . . . 105 watts

**FREQUENCY RANGES:**  
American Band . . . . . 540-1720 kc  
Foreign Band . . . . . 5.8-18 mc

**INTERMEDIATE FREQUENCY** . . . . . 460 kc

**POWER OUTPUT:**  
Type . . . . . Pentode  
Undistorted . . . . . 2.5 watts  
Maximum . . . . . 4.5 watts

DEC. 10, 1937

TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS. VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO CHASSIS. ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMING ADJUSTMENTS, WHERE NO VOLTAGE READING IS SHOWN, IT INDICATES ZERO VOLTAGE OR A VERY LOW READING. VOLTAGES TO BE MEASURED WITH NO SIGNAL. FIGURES AT CATHODES ARE CATHODE CURRENT IN MILLIAMPERES.

GENERAL INFORMATION AND SERVICE HINTS

ELIMINATING WHISTLE AT 920 KC.

A whistle due to a beat between the second harmonic (920 kc) of the 460 kc I.F. and a 920 kc signal may be experienced. In localities where the 920 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the I-F frequency of the receiver.

Determine at what point between 890 kc and 950 kc the whistle will be least objectionable. Dividing this frequency by two will give the new I-F frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 905 kc would not be objectionable, the I.F. should be re-aligned at 905/2 or 452.5 kc. Try to select the new I-F frequency as close as possible to 460 kc.

An interfering whistle may also be caused by two stations having a frequency difference equal to the I-F frequency (460 kc) of the receiver and will be evidenced by a whistle appearing when the receiver is tuned to either of the stations. It may be further localized by tuning the receiver to each of these stations and then stopping the oscillator in each case by grounding the oscillator stator section of the variable tuning condenser C8 to chassis. If the whistle, in each case, still persists, it is being caused by the beat between these two stations and may be corrected by shifting the I-F frequency of the receiver, to a frequency other than the difference frequency of the two local or strong signals (stations).

The I-F amplifier should not be shifted to a frequency higher than 475 kc, nor lower than 445 kc, but should be as close to 460 kc as possible.

Align the I.F. at the new frequency and then re-align the rest of the receiver as described under "ALIGNMENT PROCEDURE."

AUTOMATIC RECORD MECHANISM:

The record changing mechanism is designed to be simple and fool-proof. Certain adjustments may be required occasionally. The adjustments are illustrated in this booklet.

It is important, when servicing the automatic mechanism, to have it placed on a level support. It is also important to refer in recording the mechanism if there is a tendency to bind or jam, since beat levers and broken parts may result. Application of oil to the felt pad which rubs against the motor governor disc will insure smooth operation.

**CAUTION**--Do not leave records stacked on record-holder posts, when not in use, as they are liable to warp, particularly so in warm climates.

LOUDSPEAKER:

Centering of the loudspeaker is made in the usual manner with three, narrow-paper feelers, set with the receiver at a frequency that must be determined by sorting the cement with a light application of sections, using care not to allow the cement to enter the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

DIAL POINTER AND CONDENSER DRIVE HOOK-UP:

The drive hook-up for the dial pointer and the variable condenser is illustrated.

CONNECTIONS FOR 110 VOLT, 60 CYCLE  
REPLACEMENT POWER TRANSFORMER  
(1261030607)

DIAL DRIVE HOOKUP

ALIGNMENT PROCEDURE

PRELIMINARY:

- Output meter connections . . . . . Across speaker voice coil
- Output meter reading to indicate 1.0 watt output . . . . . 1.5 volts
- Approximate average sensitivity in microvolts for 1.0 watt output . . . . . See chart below
- Dummy antenna value to be inserted in series with generator output . . . . . See chart below
- Connection of generator output lead . . . . . See chart below
- Connection of generator ground lead . . . . . To chassis
- Generator modulation . . . . . 30%, 400 cycles
- Position of Radio-Phono. switch . . . . . Countar-clockwise
- Position of Volume Control . . . . . Fully clockwise
- Position of Tone Control . . . . . Fully clockwise
- Position of Dial Pointer with variable tuning condenser fully closed . . . . . To fall on last calibration mark at 540 kc end of "American" band.

WAVE-BAND SWITCH POSITION	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
"AM"	No signal 550-750 kc	.001 mfd.	6K7-G Grid.	L11, L12	End I-F Trans.	15,000
"AM"	No signal 550-750 kc	.001 mfd.	6AB-G Grid	L9, L10	1st I-F Trans.	200
"FOR"	15 mc	300 ohms	Ant. Lead (blue)	C7**	"FOR" Osc.	-
"FOR"	15 mc	300 ohms	Ant. Lead (blue)	C5*	"FOR" Det.	60

"AM"	600 kc (rock)	.0002 mfd.	Ant. Lead (blue)	L8	"AM" Osc.	29
"AM"	1500 kc (rock)	.0002 mfd.	Ant. Lead (blue)	C9	"AM" Osc.	97

IMPORTANT ALIGNMENT NOTES:

- \*\*Use maximum capacity peak if two peaks can be obtained.
- \*Use minimum capacity peak if two peaks can be obtained.
- Where indicated by the word "Rock," the variable tuning condenser should be rocked back and forth a degree or two while making this adjustment.
- Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the a-v-c action of the set from interfering with accurate alignment.
- Adjustment locations are shown on the top and bottom parts location views of chassis.
- Only the dummy antenna indicated in the chart for any particular band should be used. Remove the dummy antenna used for alignment in any other band. Grid cap leads should remain in place during alignment.
- Values shown under, "Microvolts," are only approximate.

- CHASSIS FEATURES:
- No. I-F stages . . . . . One
  - Antenna . . . . . Doublet or Conventional
  - Tuning Eye . . . . . Adjusted IF Transformers
  - Line Noise Electrostatic Transformer Shield . . . . . "American" Band Low-Frequency Oscillator Tracking
  - Aural-Compensated Radio and Phonoograph Volume Control
  - Fixed Wave-Trap
  - Magnetic Core

 No current used while at rest Returning current . . . 5 amps. for 2 seconds

**GENERAL INFORMATION AND SERVICE HINTS**

FIG. 1

Fasten mounting brackets A and B to receiver with four #8-32 machine screws and lockwashers.

Determine the angular position of key in variable condenser drive fitting that is located directly under the tuning cable opening in the radio case. Lower Moto-matic tuner into place between mounting brackets and rotate shaft on Moto-matic tuner so that slot has the same angular position as the key on variable condenser drive fitting. When lowered all the way into place no play should exist between key on variable condenser drive fitting and the slot on Moto-matic shaft. This is very important, and if there is play it should be corrected by lightly pinching together the slot on Moto-matic shaft.

Fasten tuner with four #8-32 machine screws and lockwashers. Remove plug button C as shown in Fig. 1 and plug in power lead.

**NOTE:** Check worm gear on the gang condenser for slippage of the clutch which is provided, as this will cause the tuner to tune inaccurately. This gear should not slip except when the condenser plates are all the way open of all the way closed when the worm is rotated in the direction to open or close the plates.

**SUBJECT: ADDITION OF A DRIFT COMPENSATING CONDENSER TO MAINTAIN ACCURACY OF STATION TUNING.**

A drift compensating condenser, to eliminate frequency drift of the receiver as it warms up, is available from source 101. This condenser is connected across the oscillator trimmer as shown by the Schematic sections in this Supplement.

## SEARS-ROEBUCK &amp; CO.

MODEL 5731  
Moto-Matic Tuner  
Part 128.15600  
Adjustments, Part 1

**ACCURACY ADJUSTMENT OF CONTROL BAR ADJUSTING SCREWS FULLY MOUNTED IN CAR OR ON BENCH**

Improvement of accuracy is sometimes necessary after installation due to additional springy torque load added by the control lead cables, which are sometimes laid in an "S" bend to make a satisfactory fit in the car. The following procedure should be used to make the necessary adjustments for good accuracy. A complete kit of adjusting tools is provided for this work and consists of the following:

- 1 - Double end socket wrench in combination with screw driver.
- 1 - Dummy cover with opening for access to accuracy adjusting screws.
- 1 - .004 x 3/8 x 6 shim for adjusting armature and selector coil clearance gap. See parts list for ordering this material.

It is suggested that a complete assembly and accuracy check be made on the bench approximating the conditions that will be in the car. The check should not be made until the set has warmed up for about 20 to 30 minutes.

- (1) Remove cover of Moto-matic unit, the side which is away from the radio. Two small screws at each end are to be removed and the cover will pry off easily.
- (2) Replace with dummy cover and connect control lead to bushing and lay cables as they would be in the car installation.

Before making any accuracy adjustments determine by trial whether or not the inaccuracy is being caused by the tuning control cables. If there are severe bends in the cables there will be a certain amount of spring that will tend to detune the station after an automatic selection has been made. Make the necessary adjustments in the station in the car when it is possible to do so. As far as possible, if necessary shorten the tuning cables rather than having them kinked or placed in small clearances.

After you have eliminated the possibility of inaccuracy due to the above, the following procedure should be followed closely:

- (3) Set up a station at 1000 KC or higher, using one distantly located, or use your oscillator with low input. Hold down the station button which is set up and use the double-ended adjusting wrench with screw driver insert. Place over adjusting screw and locknut on the control bar. (The proper screw can be found by pressing the selector switch button several times and noting which armature moves. (See Fig. 3 for location with respect to switch.) DO NOT APPLY ANY PRESSURE TO CONTROL BAR ADJUSTING SCREW WHILE MAKING THE FOLLOWING ADJUSTMENTS. Back off the adjusting screw very slowly until the armature arm falls into the slot. The adjusting screw should be held down until the armature arm falls into the slot. (See Fig. 1.) Now turn back or to the right until clutch drops back or open. Turn further to the right about 1/8 turn.

Look up locknut; holding screw steady to prevent further turning. Remove rubber band. Make tuning check by changing station and button setup for adjustment and check for accuracy by listening to signal. In each case push the button setup for adjustment and check for accuracy by listening to quality of signal received, or use an output meter if signal generator is used.

Repeat for the rest of the buttons, using the same frequency setting.

If unit rocks back and forth while making the above adjustments it is due to one or two reasons. First - it is necessary that the control switch operates as outlined in the paragraphs under "Adjustment of Control Switch". Second - the armature arm must not strike the pole pieces of the control magnet before it falls entirely into the "W" of the selector disc. The correction for this difficulty is also outlined in the paragraphs under "Adjustment of Control Switch".

Inaccuracy in station selection or inability to make accuracy adjustments due to rocking while making these adjustments will exist if the armature arm will not allow the "W" end to seat properly in the selector disc slot. This is caused by the armature pad striking against the coil core. For the correction of this use the following method:

You will find a small rectangular slot directly in line with the selector coil pole tops at the end of the frame. (See Fig. 5.) This opening is used for slotting air gap clearance to the armature pad and pole face. The armature pad is made of brass or bronze 3/8" wide x 8" long furnished in the kit. Any greater gap than .0075" will cause setting up troubles at a low voltage of 5 volts at the battery.

If the armature does not fall entirely into the "W" slot of the selector disc when the .004 shim is inserted between armature pads and pole pieces, bend the armature at the point marked "Y" (Fig. 4) until armature "W" seats properly all the way into "W" slot of selector disc.

The 5 volt check for setting up stations checks the ability of the armature arm to hold into the slot. To make this check connect a 5 volt battery charger with an output of 10 amperes or more that is adjustable up to 10 amperes. Connect two cells (4 pairs) and allow charger to raise the voltage to 5 volts. Connect motor button held down. The armature arm should not slip out during this test while setting up a station. This also checks that you have the proper gap between armature pad and core face of selector coil.

**ALIGNING MOTO-MATIC WITH RECEIVER:**

Gear box and flexible drive shaft and dial drive shaft can be placed into the tuner temporarily so that the receiver and tuner can be aligned on the bench. Turn the fine end of the flexible drive shaft until it is in line with the dial drive shaft. The dial drive shaft is on the gear condenser clockwise again so that the stop is again felt. This will cause the worst gear on the gear condenser to slip at the end which is short on travel and automatically correct after rotating as specified above. It is best to have the top cover off the receiver while doing this to ascertain that the condenser goes through 180 degrees when the shaft is rotated eight complete turns.

**HOW TO SET UP STATIONS:**

To set button for a certain station, have the receiver in operation and hold down button until tuner stops running. Now tune in the desired station manually, continuing to hold button down until station comes in accurately. Release button and this station is set to this particular button. After station is once set up it is not necessary to hold bar down to tune automatically; merely depress the button and the station will be set up automatically. Repeat this procedure once started. To set the other five buttons repeat for each button as outlined above.

**HOW THE TUNER OPERATES:**

The Moto-Matic tuner is a mechanical electro device actuated by an electric motor to speedily and accurately tune an automobile radio receiver. This device functions in the following manner:

**ADJUSTMENT OF CONTROL SWITCH:**

CAUTION: Do not adjust control switch unless accuracy adjustment of control bar (see instructions above) has failed to produce correct operation of the unit.

The purpose of the control switch is to open the circuit to the motor magnetic clutch and selector coils when the armature arm falls into the slot of the selector disc. Opening of this circuit is used when setting up a selector disc to a station by the fact that the armature arm is down in the "W" slot. This holds the selector disc stationary while the shaft slips when tuning manually for a station setting.

The timing of the control switch is adjusted individually for each armature arm by screwing in or out the control bar adjustment screw as outlined under "Accuracy Adjustment of Control Bar". With the unit connected to 5 volts depress the selector switch button and hold down until motor stops running with selector switch button held down. The armature arm should be at rest at the bottom of the "W" groove on the selector disc. If contacts do not open when the armature arm falls into slot it will be necessary to screw in the control bar adjustment screw. When adjusted properly the control switch will open when armature arm falls in slot and will not open when armature arm comes down on the edge of selector disc. If this adjustment is made improperly so that there is a gap between the selector disc and the armature arm, the control switch will not open. It is extremely due to the fact that the armature arm will not hold down enough. It is important that the armature arm falls practically all the way into the "W" slot of the selector disc before the control switch opens in order to obtain maximum accuracy.

To check switch operation disconnect power source. By hand press down the armature arm against the edge of the selector disc. (Be sure you have rotated each selector disc to a position away from the slot). Check each armature arm. The switch should not open nor should the fibre contact be broken. When the switch is closed, the control bar adjustment screw with the fibre contact opens and that particular control bar adjustment screw with the fibre contact. The armature arm is riding on the edge of the selector disc. Now rotate selector disc until armature arm drops into the slot without play in the selector disc slot when rotated slightly. Now both switch contacts should open with about .025" clearance between points.

If you are troubled with rocking or bucking when making the initial accuracy adjustment, check for the parallel movement or opening of the control switch. By moving the fibre control arm (see Fig. 5) hand so the control switch contacts open, make certain that they open and close simultaneously.

By referring to Fig. 2 it may be seen that the #2 blade controls the selector coil, the #4 blade the motor and magnetic clutch. It is desirable to give the #2 blade a very slight lead in opening the motor and magnetic clutch. This adjustment can be made with a #2 or #3 blade, as the #2 blade has only the #2 blade. Never adjust the #4 or #5 blades, as these must always move parallel to each other.

When a selector switch button is depressed the contact finger opens the common circuit to the other buttons and closes the circuit to the selector coil, which pulls down the armature arm and closes the contact to the terminal strip. (See Fig. 2.) The contact blade the selector coil circuit closed the selector switch button. The selector switch button is on the common circuit to the selector coil. The armature being held down on the selector disc which completes the circuit to one of the fields of the motor and through the clutch coil. The half of selector disc that is common to the shaft causes the motor to rotate in a clockwise direction, viewing the motor from the pinion end. The other half of the selector disc will give counter clockwise rotation. Through the reduction gear the selector disc shaft is driven in the direction of whichever half of the selector disc is selected. The selector disc shaft is driven in the direction of whichever half of the selector disc is selected. This moves the control bar and control arm which opens the control switch. The control switch opens the motor and clutch coil circuits, and immediately resets for the next selection. The Moto-Matic drive shaft has revolved to the proper point which rotated the gang condenser to the angular position of the station setting. When setting a selector disc to a station the formed end of the armature arm is held down into the "W" slot of the selector disc. The selector disc is held down into the "W" slot of the selector disc, although the control switch is open. This keeps the armature down from running and the clutch from closing while manually tuning to set up a station on any button.

Adjustments, Part 2  
Parts List

HOW TO ORDER PARTS FOR THIS MOTO-MATIC TUNER - IDENTIFICATION NUMBER 128.15600

- Use Purchase Order Form 5264.
- On the Purchase Order always give the following information:  
(1) PART NUMBER and DESCRIPTION for each part ordered, as given in this parts list, regardless of number printed on part itself. When no part number is assigned, order by description and rating. Also give PRICE of part (indicate if no selling).  
(2) THE IDENTIFICATION NUMBER, which is 128.15600. This number is found inside the top cover of the unit.

Authorized Replacement Parts for this model may be obtained from any Sears, Roebuck and Co. Retail Store or Mail Order branch. Always give part numbers and the chassis identification number.

MOTO-MATIC TUNER ADJUSTING KIT (NO SELLING) - 85¢ each Cost.  
PRICES SUBJECT TO CHANGE WITHOUT NOTICE

TENSION ADJUSTMENT OF SELECTOR DISC:

On one side of the selector disc one shaft will be found two 5/8" nuts that determine the tension of the selector disc. These are permanently adjusted at the factory and should not require any adjustment. The other side of the disc has two 5/8" nuts that determine the tension of the selector disc. The adjustment nut until the armature arm will hold and turn the selector disc when necessary. The selector coil is energized by 5 volts. Tighten the lock nut. The purpose of this adjustment is to keep the selector disc as tight as possible and still loose enough so that the armature arm will not be forced out of the wv slot when setting up a station.

Angular Adjustment of the Armature Arm "wv":

The angular position of the sides of the "wv" of the armature arm is correct when the angle of each side is the same with respect to the radius of the selector disc. (See Fig. 5). Too much angle on one side will cause the armature arm to stick. The correct angle is determined by the conditions not enough angle will cause the armature arm to stick. Any adjustments to the angle of the armature arm "wv" should be made carefully with a pair of long nose pliers. Sticking armature arms may be caused by a burr on the face of the armature arm "wv" that is cut into the metal by the edge of the groove of the selector disc slot. This burr may be removed by carefully filing this surface with a fine file.

IMPROVE ALIGNMENT OF CONDENSER DRIVE SHAFT WITH WORM DRIVE FITTING ON VARIABLE CONDENSER:

On earlier production the mounting bracket holes were too small to allow for production variations. If trouble is experienced with the mounting of the unit to the receiver case or if it is necessary to correct the alignment of the worm drive fitting, the mounting holes should be drilled the mounting holes of the brackets with a 3/16" drill.

Remove the cover of the receiver and mount the Motomatic tuner making sure the condenser drive shaft is centered in the worm drive fitting on the variable condenser.

MAGNETIC CLUTCH ARM ADJUSTMENT:

There may be an occasional complaint or observation of a chattering or skipping of the Motomatic tuner clutch when under full load. This is caused by the engaging pins not being engaged deep enough into the main driving gear. Press the clutch down by hand over the top of the coil and note if the clutch engages properly. If not, the clutch is not engaged properly. This may be due to the worn or remove clutch arm and bend it to the correct position. The clutch arm is made of soft annealed steel and bends easily. Replace and check; several trials may be necessary.

After making magnetic clutch adjustments it may be necessary to readjust the stop located above the clutch to the correct position. The stop is made of brass and is held in place by a screw. When the clutch is disengaged it is important that the clutch pins do not drag when tuning manually.

Sticking open of clutch when a button is depressed may be caused by many misadjustments. First - the clutch arm may be warped during the process of bending the clutch arm. Second - it is the operative that both embossed bumps on the underside of the clutch arm apply an equal pressure to the clutch arm when the button is depressed. Check this by depressing the clutch arm and measuring the embossed bumps from the clutch face. Correct any differences by bending slightly the forked section of the clutch arm.

SELECTOR SWITCH:

Failure of tuner to operate may lie in the selector switch. Remove back plate and place jumper wire from the first terminal on the end worm lead selector switch case to the red to blue wire terminals. Each one of these should operate an armature arm. Doing this will give a check as to whether the selector switch is operating properly. If the selector switch is not operating, the selector switch contact fingers from the preceding button is making contact when button is out. See schematic wiring diagram for details. The selector switch contact fingers are not making contact when button is depressed. Remedies for the above are as follows:

First - it may be necessary to bend contact fingers so that good connection is made. Second - The selector switch case may be bulged in the center. This can be corrected by placing a strap across both sides.

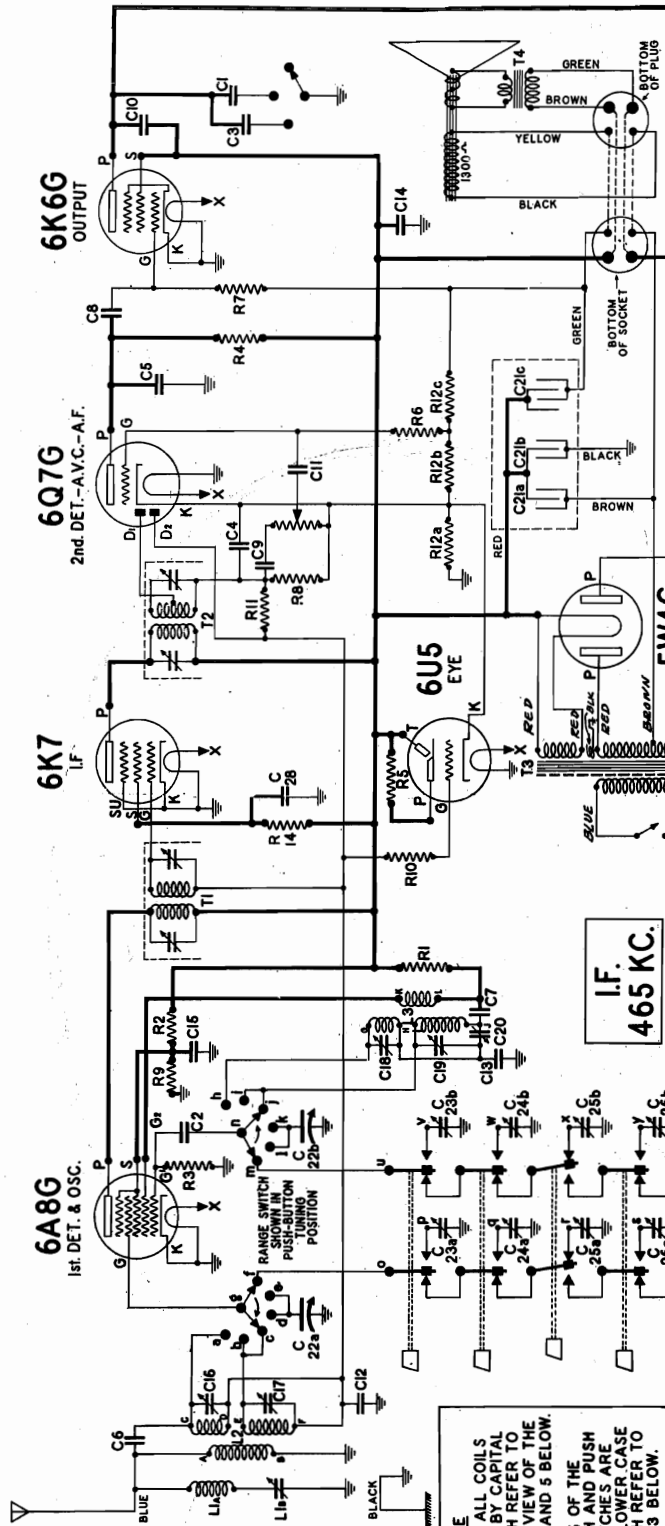

The selector switch plunger back up plate may become loosened, in which case it will be necessary to push back in place and put a wood wedge between this plate and switch case.

CONDENSER DRIVE SHAFT END PLATE:

The condenser drive shaft (Fig. 4) should not have any lateral or axial play. If some does exist, the shaft should be removed and packed adjusting nut lockwasher tabs and taking up on the nut until no play is felt and no additional torque required to turn shaft.

Jacks Installation  
Schematic  
Alignment

SUBJECT: CONNECTION OF EARPHONE AND PHONOGRAPH PICKUP JACKS:

Part number 1015119531 Jack, for connection of earphones or phono-graph pick-up, can be ordered directly from source 101. Retail selling price is 79¢.

The schematic section on the back of this sheet shows the connections.

If a crystal pick-up is used, a filter composed of a .01 mfd. condenser and a 100M ohm resistor connected in series, should be connected across the pick-up to prevent excessive bass response. This filter will also act as a partial scratch filter.

\* - PART OF T2  
TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS. VOLTAGE READINGS SHOWN AT SOCKET PRONGS ARE TO CHASSIS, AND ARE TAKEN WITH NO SIGNAL. LINE VOLTAGE AT 115 VOLTS. WHERE NO READING IS GIVEN, THE VOLTAGE IS ZERO OR TOO LOW TO READ.  
X X INDICATES LEAD TO BE BROKEN.  
DOTTED LINES INDICATE NEW CONNECTIONS.

RAVE BAND SWITCH POSITION	POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS

"AM"	500 kc (rock)	500 kc	.0002 mfd.	Ant. Term.	Padder	80

IMPORTANT ALIGNMENT NOTES

The alignment must be done in the order given.  
Two peaks can be had, one with the trimmer screwed further out than the other. The correct adjustment is with the trimmer screwed further out. The other peak is the image. Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.  
The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

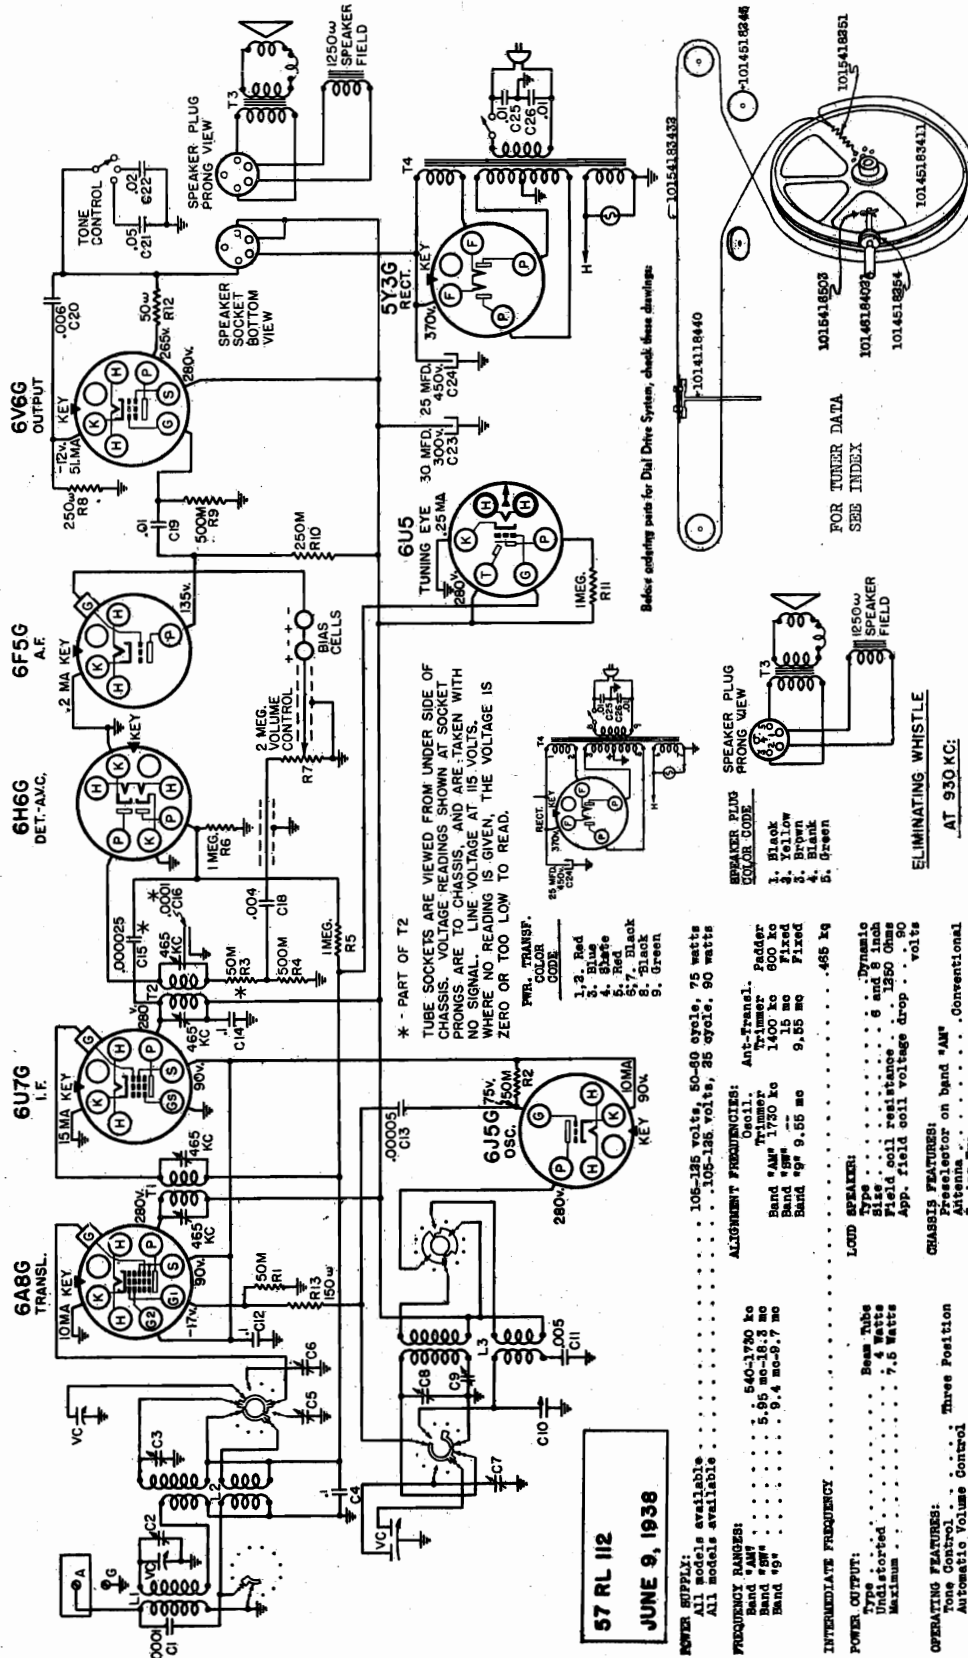

ALIGNMENT PROCEDURE

- Output meter connection . . . . . Across loud speaker voice coil
- Output meter reading to indicate 500 milliwatts . . . . . 0.85 volts
- Average sensitivity in microvolts for 500 milliwatts output . . . . . See chart below
- Generator ground lead connection . . . . . Receiver chassis
- Dummy antenna value to be in series with generator output . . . . . See chart below
- Connection of generator output lead . . . . . See chart below
- Generator modulation . . . . . 30%, 400 cycles
- Position of Volume Control . . . . . Fully clockwise
- Position of Tone Control . . . . . HI
- Position of Dial Pointer with variable fully closed . . . . . Center of block to left of 550 kc calibration mark.

2. Lower left knob . . . . . On-off switch & tone  
3. Lower right knob . . . . . Band switch  
4. Upper right knob . . . . . Station Selector

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver. Determine at what point between 900 kc and 930 kc the whistle will be least objectionable. Shift the IF accordingly. If necessary, the IF should be realigned at 915/3 or 457.5 kc. Try to select the new IF frequency as close as possible to 465 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under "Maintenance Adjustments".

**SILVERTONE BATTERY CHARGERS AVAILABLE:**

The customer should be told about the SILVERTONE GAS-O-POWER and the SILVERTONE SUPER AIR-CHARGER. Either of these units provides an economical means of keeping the storage battery charged. The customer should be informed of the advisability of frequent hydrometer testing of the storage battery to prevent it from becoming too low in charge. A battery that is allowed to run too low before re-charging will not have as long a life as one that is re-charged more frequently.

**LOUD SPEAKER:**

Type . . . . . PM Dynamic  
Size . . . . . 6"

**POWER OUTPUT:**

Type . . . . . Pentode

**IMPORTANT ALIGNMENT NOTES**  
The alignment must be done in the sequence given.  
The generator should be adjusted for high output. The trimmer should be adjusted for minimum meter reading. The dial should be set to the frequency of the station. The interfering station around 465 kc is known, the generator should be adjusted to the frequency of that station instead of to 465 kc.  
Where indicated by the word, "Rook", the variable should be rooked back and forth a degree or two while making the adjustment.  
The alignment procedure should be repeated stage by stage. In the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

WAVE BAND SWITCH POSITION	POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMERS ADJUSTED (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
'AM'	Closed	465 kc	.1 mfd.	8488 Grid	T3, T1	IF Output IF Input	--

'SW'	14.9 mc	14.9 mc	400 ohms	Ant. Term.	C14	Translator	10
'AM'	1400 kc	1400 kc	.0003 mfd.	Ant. Term.	C20	Oscillator Translator	15
'AM'	600 kc (rook)	800 kc	.0003 mfd.	Ant. Term.	C21	Padder	40

**IMPORTANT ALIGNMENT NOTES**  
The alignment must be done in the order given.  
Two peaks can be had, one with the trimmer screwed further out than the other. The correct adjustment is with the trimmer screwed further out. The other peak is the image.  
Where indicated by the word, "Rook", the variable should be rooked back and forth a degree or two while making the adjustment.  
The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

Notes

**BATTERY REPLACEMENT:**

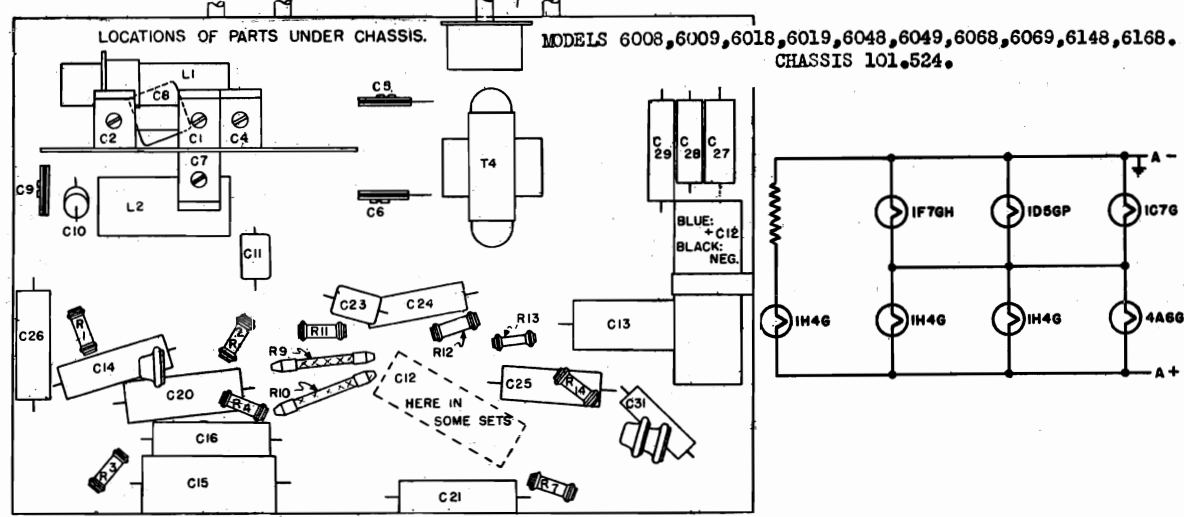

The dry 4 1/2 volt "A" battery should be replaced when its voltage drops to 3.4 volts, under load. The 6 1/2 volt "B" battery should be replaced when the voltage of the battery has dropped to 4 1/2 volts, under load. The life rating of the various size batteries, given on the next page, are for an average use of three hours a day.

**THE "A" SUPPLY:**  
These models may be used with either a 4 1/2 volt dry "A" battery or a 4 volt storage "A" battery. Catalog #5000 adaptor is necessary to make the connection between the "A" plug and the terminals of the storage battery.

**THE FILAMENT CIRCUIT:**  
Since the tubes have two volt filaments and the "A" supply is four volts, a series parallel 1:1 arrangement is used for the filament circuit. Accordingly, if any tube burns out its companion will not light either. The full "A" voltage will appear across the filament terminals of the burnt out tube.

**THE AVC CIRCUIT:**  
Diode current of the IF7GH tube, flowing through the 500M ohm resistor, R6, creates a voltage drop across it. This voltage is applied to the control grid of the IC7G tube to provide AVC.

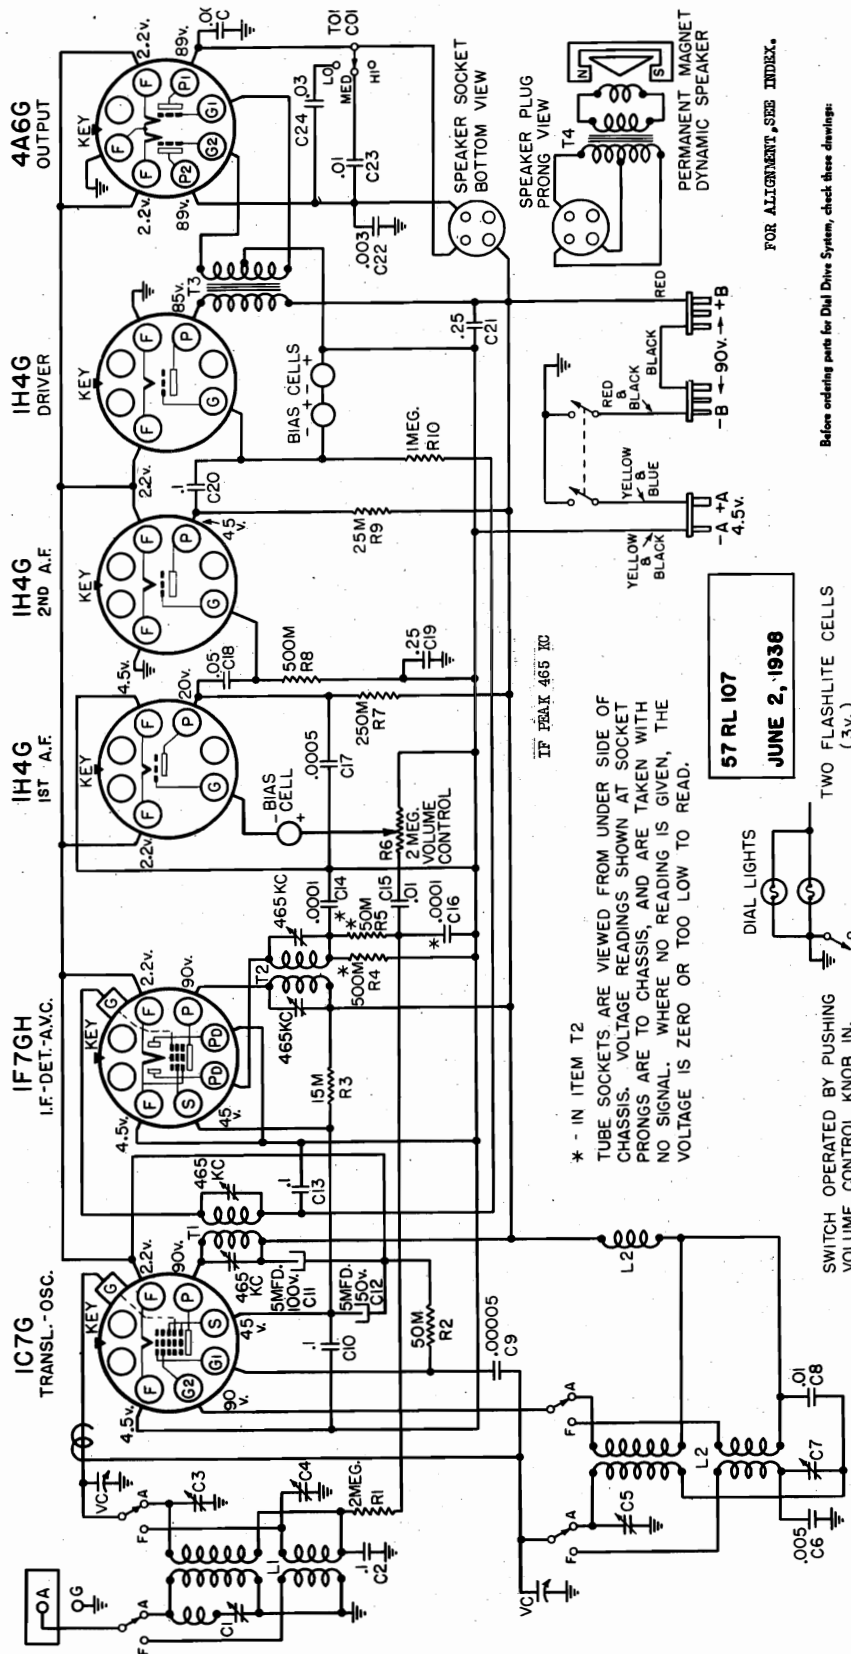

**THE FILAMENT CIRCUIT:**  
Since the "A" supply is four volts and the tube filaments are rated at two volts, a series parallel arrangement is used for the filament circuit. A simplified diagram is shown below. If any one tube burns out (except the 1H4G first AF), the filament voltage and current of the other tubes will be affected.

A Catalog #5000 adaptor must be used on the "A" cable plug when a storage "A" battery is used. The owner should be warned not to attempt the use of a six volt automobile storage battery. Only a four volt storage "A" battery should be used.

**Loudspeaker:**  
Centering of the loudspeaker voice-coil is made in the usual manner with three, narrow paper feelers, after first removing the front dust-cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The dust cover should be cemented back in place with ambroid after adjustment has been completed.

**ELIMINATING WHISTLE AT 930 KC:**

A whistle, due to a beat between the second harmonic (930 kc) of the 455 kc I.F. and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the I.F. frequency of the receiver.

Determine at what point between 900 kc and 930 kc the whistle will be least objectionable. Dividing this frequency by two will give the new I.F. frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the I.F. should be realigned at 915/2 or 457.5 kc. Try to select the new I.F. frequency as close to 455 kc as possible.

Align the I.F. at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

**ALIGNMENT PROCEDURE**

MODEL 6038, 6138 CHASSIS 101.517.

- Output meter connections.....Across speaker voice coil
- Output meter reading to indicate 1.0 watt output.....2.25 volts
- Approximate average sensitivity in microvolts for 1.0 watt output.....See chart below
- Dummy antenna value to be inserted in series with generator output.....See chart below
- Connection of generator output lead.....See chart below
- Connection of generator ground lead.....To chassis
- Generator modulation.....30%, 400 cycles
- Position of Volume Control.....Fully clockwise
- Position of Radio-Phono Switch.....Second position from left
- Position of Dial Pointer with variable tuning condenser fully closed.....To coincide with horizontal lines on dial

Position of Dial Pointer	Generator Frequency	Dummy Antenna	Generator Connection	Trimmer Adjusted (In order shown)	Trimmer Function	Approximate Microvolts
Low End	455 kc	.001 mfd.	6K7 Grid	L7, L8	2nd LP Trans.	15,000
Low End	455 kc	.001 mfd.	6A8 Grid	L5, L6	1st LP Trans.	270
1,500 kc	1,500 kc	.0002 mfd.	Ant. Lead (Blue)	C18*, C3	Osc., Ant.	25

**IMPORTANT ALIGNMENT NOTES**

\* Trimmer C17, on opposite side of gong condenser from C18, should be screwed clockwise for maximum capacity before adjusting C18.

Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value to prevent the a-v-c action of the set from interfering with accurate alignment.

Adjustment locations are shown on the top and bottom parts location views of chassis.

Only the dummy antenna indicated in the chart for any particular frequency should be used. Remove the dummy antenna used for alignment at any other frequency. Grid cap leads should remain in place during alignment.

Values shown under "Microvolts" are only approximate.

**Eliminating Whistle at 910 KC:**

A whistle, due to a beat between the second harmonic (910 kc) of the 455 kc I.F. and a 910 kc signal may be experienced. In localities where the 910 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the I.F. frequency of the receiver.

Determine at what point between 880 kc and 940 kc the whistle will be least objectionable. Dividing this frequency by two will give the new I.F. frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the I.F. should be realigned at 915/2 or 457.5 kc. Try to select the new I.F. frequency as near to 455 kc as possible.

Align the I.F. at the new frequency and then realign the rest of the receiver as described under "ALIGNMENT PROCEDURE".

**Phonograph Motor:**

Starting—The phonograph motor switch (S3) is turned "on" in the two phonograph positions of the Radio-Phono switch; and it is turned "off" in the two radio positions. To start the phonograph motor, turn the Radio-Phono switch to one of the two phonograph positions, which applies power to the motor, and then **give the motor a clockwise whirl** with the hand.

Hum and Vibration—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. If excessive vibration occurs it may be due to:

1. Insufficient lubrication, or any failure that will cause binding.
2. Leather washer not oiled. (Check to make certain that the leather washer is above the steel washer.)
3. Motor not properly supported from motor board.
4. Burrs on poles of rotor or stator. Remove with fine emery cloth.

**Removing Rotor.**—The rotor and turntable assembly simply rests on the ball bearing at bottom of vertical bearing. Remove by lifting up.

**Rotor Adjustment.**—Loosen the three screws that hold the rotor to the turntable, insert three 16-mil shims at equal distances around the gap between the rotor and stator, and then carefully tighten the three screws. The top of the rotor must washers beneath the stator, if necessary.

Lubrication.—Oiling points are indicated on "Details of Motor".

**OPERATING FEATURES:**

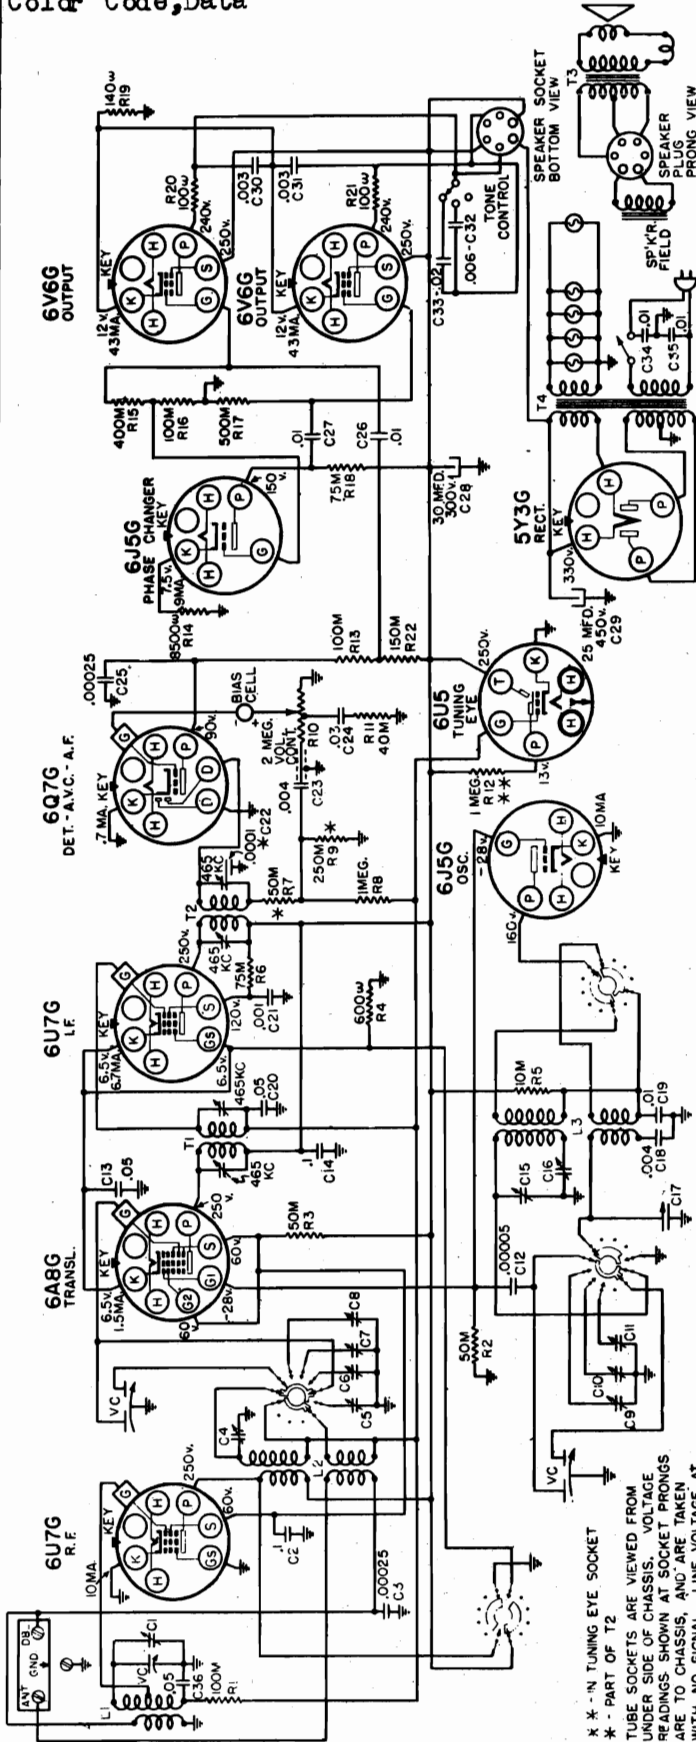

- Monograph-Radio operation
- Monograph, synchronous-type motor
- Two-speed Turntable Control
- Automatic Volume Control

**CHASSIS FEATURES:**

- No. I.F. Stages.....Double
- One Motor.....Conventional
- Line Noise Electrostatic Transformer Shield
- Magnet Core Adjusted I.F. Transformers

Phone, Phono. Jacks  
Drive Data, Notes

SUBJECT: CONNECTION OF EARPHONE AND PHONOGRAPH PICKUP JACKS:

Part number 1015119531 Jack, for connection of earphones or phonograph pick-up, can be ordered directly from source 101.

If a crystal pick-up is used, a filter composed of a .01 mfd. condenser and a 100M ohm resistor connected in series, should be connected across the pick-up to prevent excessive bass response. This filter will also act as a partial scratch filter.

X INDICATES LEAD TO BE BROKEN.  
DOTTED LINES INDICATE NEW CONNECTIONS.

CHASSIS FEATURES:

- Number RF stages . . . One (on Band "AM")
- Number IF stages . . . . . One
- Tuning Eye
- Number condensers in gang . . . Three
- Antenna . . . . . Doublet

CONTROL OPERATION:

- Turning right: . . . . . Volume increase
- Turning right: . "ON", "HI", "MED", "LO"
- Turning right: "AM", "SW", "9", "11", "15"
- Tuning ratio: . . . . . 13:1

OPERATING FEATURES:

- Tone Control . . . . . Three position
- Automatic Volume Control
- Three Spread Bands
- Push Button Tuning (8 button)
- Band Indicator

OPERATING CONTROLS:

1. Upper left knob . . . . . Volume
2. Lower left knob . . "On-Off" Switch and Tone
3. Lower right knob. . Wave Band Switch
4. Upper right knob. . Station Selector

THE AVC CIRCUIT:

The diode current of one of the 6Q7G diode plates, flowing through the 250M ohm resistor R9, creates a voltage drop across it. This voltage is applied to the control grids of the RF, translator, and IF tubes, to provide AVC.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as near as possible to 465 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

**PUSH BUTTON TUNING**  
 SETTINGS UP.

Leave the radio turned on for about 15 minutes before adjusting the push buttons. This "warming up" period will insure permanent and accurate settings.

1. Make a list of the stations that you want to set up for push button tuning. It is advisable, but not necessary, to arrange the stations in the order of their frequency (kilocycles) that is, the stations of lowest frequency will be at the top of the list. Leave one station for the next upper one for station #6, etc. If you wish, short wave stations that can be tuned in on the 11', 11', or 11' bands can be set up for push button tuning. The stations selected must give strong and reliable reception. The Band Switch knob must be turned to the proper position for the stations selected.
  2. Pull the volume control and tuning knobs off of their shafts. Remove the snap-in buttons that were covered by the knobs. Be careful not to lose the snap-in buttons. The buttons protrude) can then be removed. Be careful not to lose the snap-in buttons.
  3. Replace the tuning knob on its shaft. Push the knob in and turn it so that the dial pointer comes to the left end of the dial. A key will be found in the Instruction Leaflet envelope. Engage this key with the slotted chart that is between the tuning knob and the push buttons. Unlock the mechanism by pushing the chart in and unscrewing it (turn counter-clockwise as far as it will go. Do not force it. About 6 turns is sufficient to loosen it completely. (A screw driver can be used for unlocking the mechanism instead of the key supplied.) Then remove the key.
  4. Push the button that you wish to use for your #1 station, all the way in and hold it in firmly. Push the tuning knob in and turn it until your #1 station is tuned in exactly as indicated by the tuning eye. Be as exact as possible in tuning your station since this will determine how accurately your station will be tuned whenever you use the push button. Then let go of the push button, making sure not to turn the tuning knob until you have let go the button. (Turning the knob while the button is pushed in would spoil the accuracy of the adjustment.)
  5. Push in your #2 button. Hold it in firmly and tune in your #2 station accurately. Then let go of the push button and then the tuning knob. Proceed in the same manner for the other stations on your list.
  6. When all of the stations have been set up, push the tuning knob in and turn it so that the dial pointer is at the right end of the dial. Then turn the key supplied or a screw driver, by tightening (turning clockwise) the slotted shaft, using the key supplied or a screw driver.
  7. Punch out the call letters of your desired stations from the call letter sheets supplied. Insert the call letters in the celluloid holders at the back of the esoutechon. Be sure to insert the call letters so that they are opposite their respective push buttons. Then replace the esoutechon.
  8. You may change your choice of stations at any time by unlocking the mechanism as described in Step 3 and adjusting the button to the new station, as described in Step 4. Then relock the mechanism as described in Step 6. The call letters of the new station should be inserted in the call letter holder in their proper position.
- OPERATION:**  
 Push the button, indicated for your desired station, all the way in. Your station then will be tuned in. If you have selected short wave stations for push button tuning, be sure the band switch is turned to the proper band. The button will remain part way in, indicating that station is tuned in, until you push another button or the tuning knob.

ALIGNMENT PROCEDURE:

FOR CONVENTIONAL ALIGNMENT - SEE SPECIAL SECTION VOL. VIII INDEX

Either a broadcast station of about 1400 kc or a signal generator can be used for alignment. The chassis must be taken out of the cabinet for alignment of the trimmer, C8. The volume control setting should be reduced so that the signal is just audible in order to facilitate accuracy of adjustment. This set has no AVC so that a strong input signal may be used.

Use a high resistance voltmeter of 1,000 ohms per volt.

NOTE A: The bias for the control grid of the 877-G tube is -1.0 volt supplied by a bias cell. Due to the high resistance of the cell the voltmeter will indicate only a fraction of a volt.

IMPORTANT: The bias for the control grid of the ID5-GP tube is -2.0 volts measured across the filament of the 6T7-G tube. The bias for the control grid of the IC7-G tube is 15 volts measured from the low side of the IF5-G tube filament to ground.

**ALIGNMENT PROCEDURE**

Before attempting to align the receiver check to see that the dial pointer is opposite the last scale division of the low frequency end of the dial scale when the gang condenser is in full mesh. If the pointer is not exactly in this position it is merely necessary to move the pointer to the correct position by hand, while holding the gang condenser in the full-mesh position.

**IMPORTANT ALIGNMENT NOTES**

Where indicated by the word, "Book", the variable should be rotated back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

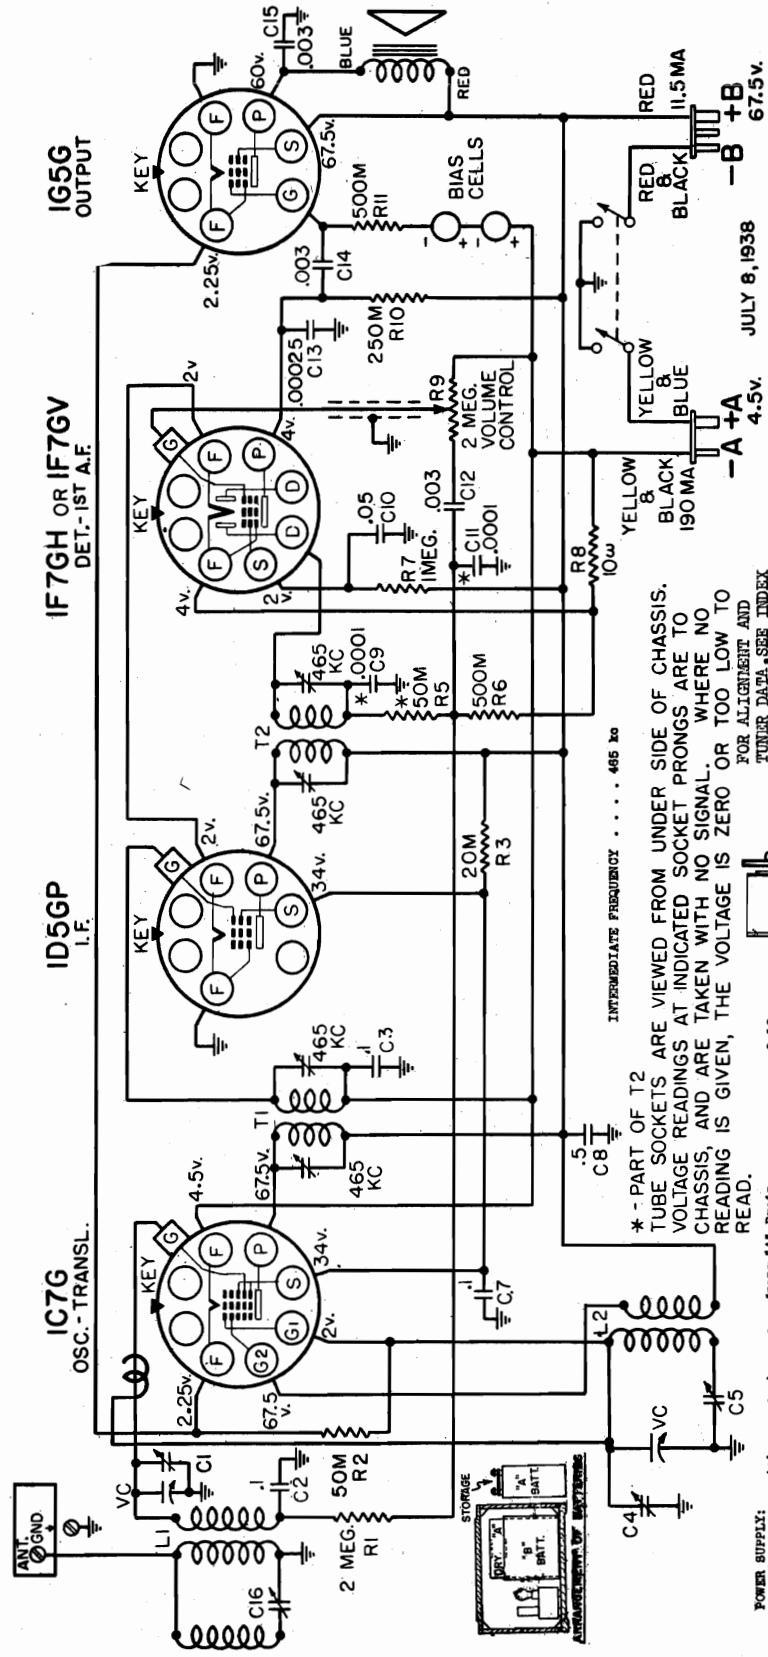

Values shown under "Microvolts" are only approximate.

\*\*Short oscillator section of variable condenser.  
See chart below for details to see that top tuning  
alignment must be done with maximum signal input.  
\*\*Adjust trimmer for minimum signal response with maximum signal input.  
\*First time it is misaligned about one turn by loosening center screw.

MODEL 6101. CHASSIS 101.496.

**ANTENNA MATCHING:**

Two separate adjustments are provided for matching the receiver to the particular ear antenna. One adjustment consists of two taps on the antenna coil. The second adjustment is a trimmer, C1, on the variable condenser. It is accessible through a hole in the bottom cover of the receiver case. These adjustments are to be made as follows:

**THE TAPPED ANTENNA COIL:**

The adjustment of the tapped antenna coil should be made before installing the receiver on the set. Remove the bottom cover of the receiver and locate the antenna coil. The bottom cover of the variable condenser plate should be closed for the adjustment. This terminal board has four jack holes, only two of which are used. These two are marked with the numerals #1, #2. The sets are shipped with the plug in hole #2.

**THE ANTENNA TRIMMER ADJUSTMENT.**

With the set tuned to a weak station at about 1500 kilocycles, turn the adjusting screw (accessible through the hole in the bottom cover) to the point affording maximum volume. A weak station must be used to prevent the AVC action of the receiver from interfering with accurate peaking. If a peak cannot be reached with the trimmer, the capacity of the ear's antenna may be such that the other antenna tap adjustment should be used.

The plug position should be changed to hole #1 if a WHIP type aerial, such as Catalog #582, or any other aerial of less than 125 mm. capacity is used.

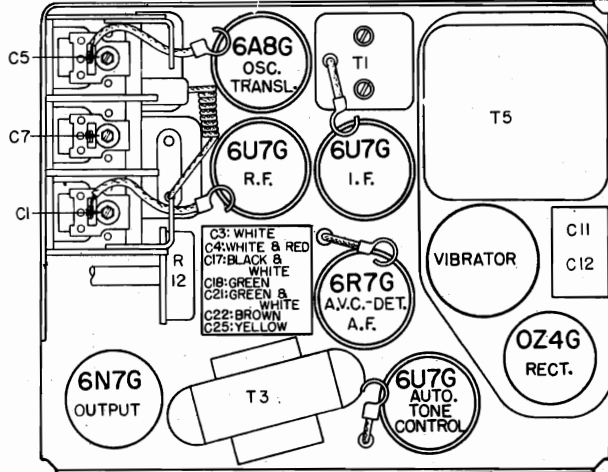

**CHASSIS FEATURES:**

- Automatic Tone Control . . . . . One
- Number RF stages . . . . . One
- Number IF stages . . . . . One
- Number condensers in gang . . . . . Three
- Antenna filter . . . . . Three
- Antenna coil for matching tapped antenna capacity.

- Variable antenna trimmer
- Non-synchronous vibrator
- Provision for combined Tone and Sensitivity control unit accessory.
- Provision for Push Button Automatic Motor Tuner Accessory.
- Provision for Auxiliary Speaker.

600 kc (rock)	600 kc	.0003 mfd.	Antenna Conn.	C8	Padder	2.8 2.0

IMPORTANT ALIGNMENT NOTES

\*MODEL 6101 - C1, C5  
 The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.  
 The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.  
 Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

 Provision for Auxiliary Speaker.

OPERATING FEATURES:  
 Automatic Volume Control

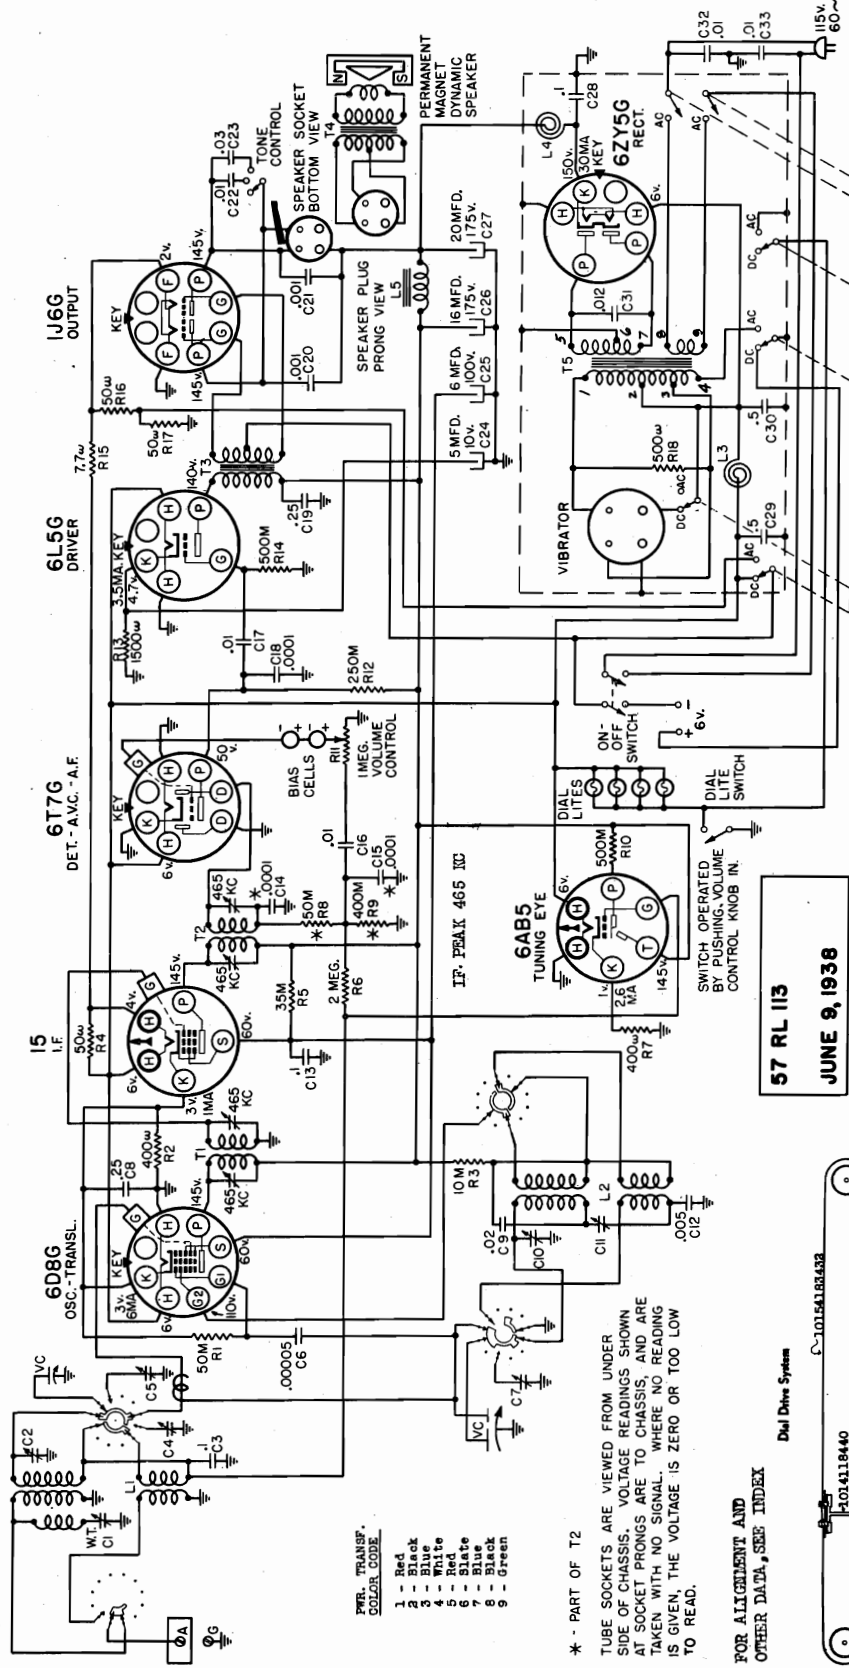

LOCATIONS OF PARTS UNDER CHASSIS USE INSULATED TYPE RESISTORS FOR REPLACEMENT WHERE USED ORIGINALLY

THE ANTENNA TRIMMER ADJUSTMENT:

With the set tuned to a weak station at about 1500 kilocycles, turn the adjusting screw (accessible through the hole in the bottom cover) to the point affording maximum volume. A weak station must be used to prevent the AVC action of the receiver from interfering with accurate peaking. If a peak cannot be reached with the trimmer, the capacity of the car's antenna may be such that the other antenna tap adjustment should be used.

- 1013919508 Knob - Volume, brown
- 1013919609 Knob - Tuning, brown

**JUNE 15, 1938**

**ALIGNMENT PROCEDURE**

The receiver need not be taken out of the cabinet for alignment.

Either a broadcast signal of about 1500 kc should be tuned in or else a signal generator, connected through a .0003 mfd. condenser to the set's antenna, should be used.

Tune in the signal and adjust the trimmer (accessible through the hole in the bottom of the cabinet) for maximum loud speaker response. This can be done most accurately, if the volume control setting is reduced to give low volume level. (This set has no AVC.) The variable should be rocked a degree or two during the adjustment. An insulated screw driver should be used, since the chassis may be above ground potential as explained previously.

**SUBJECT: CHANGES IN PUSH BUTTON MECHANISM.**

Chassis embodying these changes have the identification number 101.526-1. The suffix letter "A" also has been added to the catalog number.

The design of the push button tuning mechanism has been changed somewhat. Stations are set up as follows:

Pull the push buttons off of their levers. Using the small screw driver supplied, unscrew the push button screw two or three turns. With screw and lever pushed in firmly, tune in the desired station. Then securely tighten the screw. Check the accuracy of the setting by pushing the lever to get the station and then seeing if the station can be still more accurately tuned with the tuning knob. If necessary, repeat the adjustment to obtain a more accurate setting. Punch out the station's call letters from the sheet, insert them in the recess in the front of the button, cover them with the clear celluloid disc, and replace the button. Proceed in the same manner for the remaining buttons.

**FREQUENCY RANGE:**

Broadcast . . . . . 540-1730 kc

 Notes

**THE ANTENNA:** MODEL 6125, CHASSIS 101.527.

An attached antenna wire is supplied with the receiver. It should be uncoiled and extended as far from the radio as possible. If interference between stations is encountered, insert a ferrite bead in the antenna wire. Station identification is made by inverting the antenna. Locations remote from broadcasting stations additional pick-up can be had by connecting the end of the antenna to a conventional outdoor antenna lead-in.

**THE FILAMENT CIRCUIT:**

All of the tubes are connected in series. Accordingly, if any one tube burns out, the others will not light. The full line voltage will appear across the heater prongs of the burnt out tube. The power cord contains a resistor, in series with the tube heaters, and it is normal for the cord to become warm during operation.

MODEL 6104, Ch. 126.203  
Tuner Assembly, Data

SEARS-ROEBUCK & CO.

FIGURE 1—PUSH BUTTON AND MANUAL TUNING ASSEMBLY

FIGURE 2—BOTTOM VIEW OF PUSH BUTTON MECHANISM

**Push Button Tuning Mechanism:**

The push button tuning mechanism used in this receiver is of the mechanical type, wherein the movement of the button actually turns the tuning condenser to any pre-determined setting. The movement is actuated thru a Push-Arm, Cam, Rocker Plate and Sector Gear, which meshes with a Scissors Gear directly fastened to the tuning condenser shaft — (See Figures 1 and 2.) The scissors gear prevents backlash between the sector gear and the tuning condenser. Since the sector gear is mounted directly on the rocker plate shaft, the position of the rocker plate will accurately determine the position of the tuning condenser.

The cams (Figure 2) which determine the stop points for each button are mounted on the push arms and are locked in place by the locking screws and lock-shoes, which press firmly against the cams when the locking screws are tightened. Care should be used when locking screws are tightened not to use excessive force as the threads may become damaged or stripped.

Adjustments for Push Button Tuning are very easily made. To adjust a push button for any station proceed as follows:

- (1) Pull the push button off the push arm.
- (2) Loosen the cam locking screw one-half turn.
- (3) Using the Dial Tuning Control tune in the station.
- (4) Press the push arm in as far as it will go and accurately retune station.
- (5) With the push button still held down, tighten cam locking screw.
- (6) Replace the push button.

With the locking screw tight, the cam is locked in position and when the button is pushed in, the cam pressure causes the rocker plate to assume the position that tunes in the desired station (See Figure 2.)

**Manual Tuning Dial:**

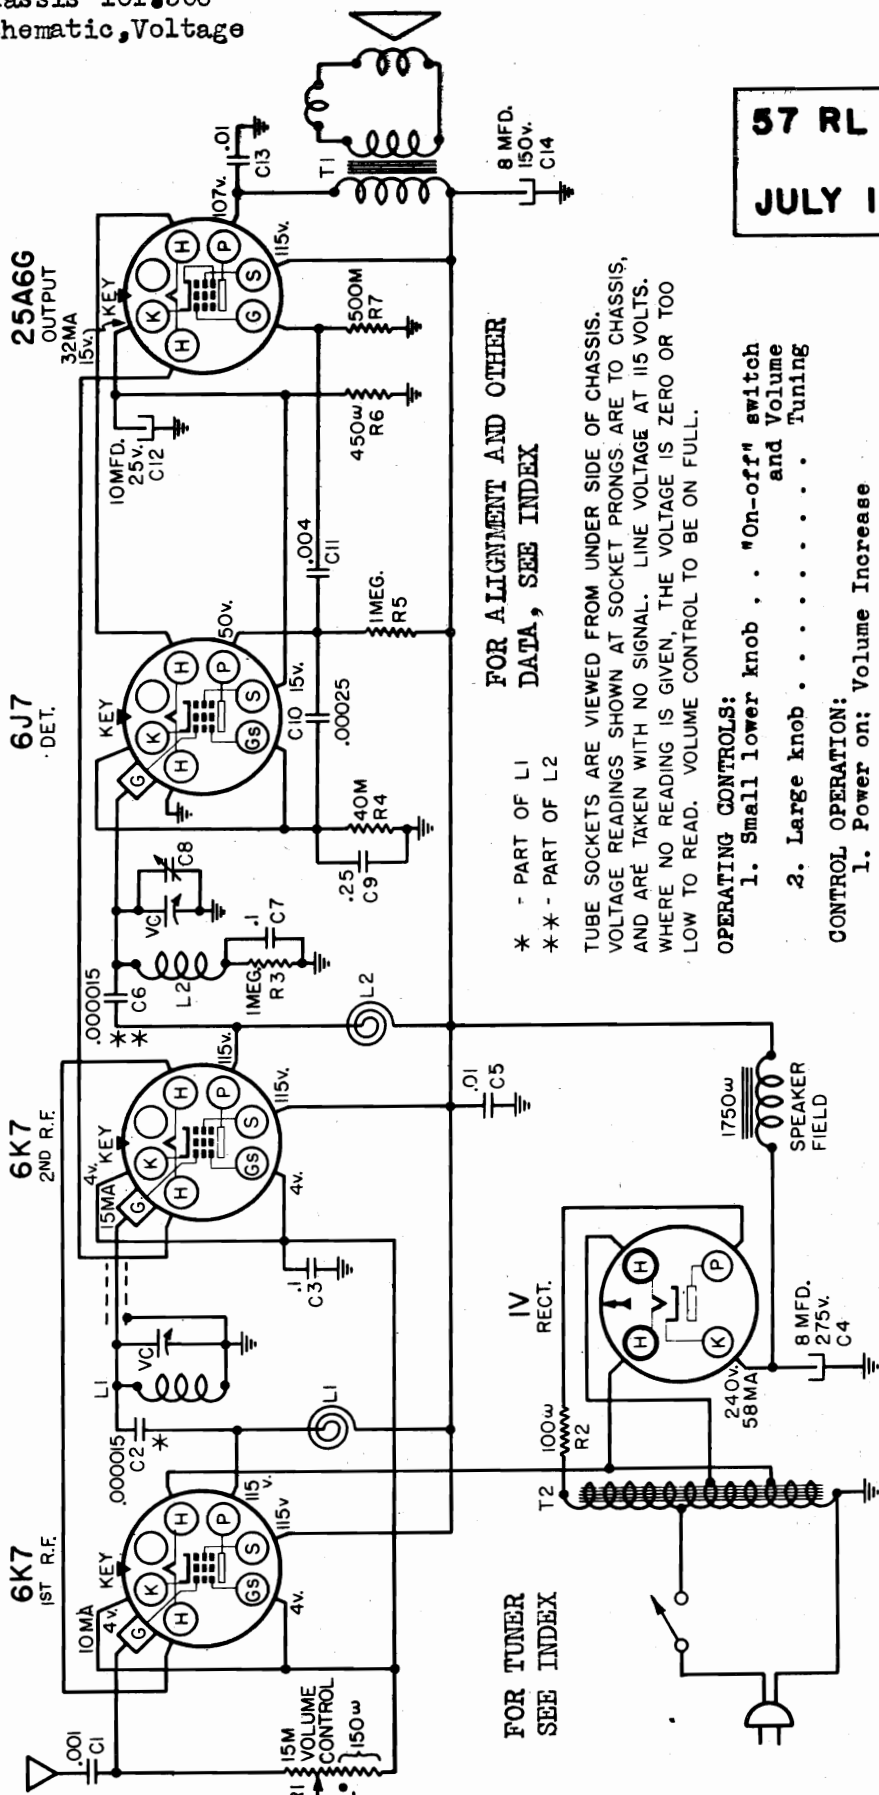

A manual tuning knob is provided so that additional stations may be tuned in as desired. The manual tuning shaft is connected thru a cord drive to a drum on the rocker plate shaft. This same cord drives the dial drum by passing over a pulley on the drum shaft. Figure 6 shows the complete cord drive assembly and the correct number of turns which the cord should be wrapped around the drive shaft and dial drum pulley. Stops are provided on the dial drum so that dial scale adjustment is made by tuning the set to the extreme ends of the band.

 TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS. VOLTAGE READINGS SHOWN AT SOCKET PRONGS ARE TO CHASSIS, AND ARE TAKEN WITH NO SIGNAL; WAVE SWITCH IN BROADCAST POSITION. LINE VOLTAGE AT 115 VOLTS WHERE NO READING IS GIVEN, THE VOLTAGE IS ZERO OR TOO LOW TO READ.

X X INDICATES LEAD TO BE BROKEN.  
 DOTTED LINES INDICATE NEW CONNECTIONS.

**DIAL LIGHT REPLACEMENT:**

The lamps that illuminate the push button call letters are made accessible for replacement by removing the push button escutcheon.

**SUBJECT: CONNECTION OF EARPHONE AND PHONOGRAPH PICKUP JACKS:**

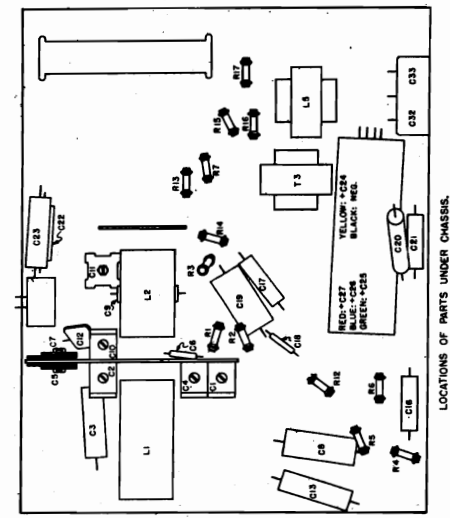

Part number 1016119531 jack, for connection of earphones or phonograph pick-up, can be ordered directly from source 101.

If a crystal pick-up is used, a filter composed of a .01 mfd. condenser and a 100M ohm resistor connected in series, should be connected across the pick-up to prevent excessive bass response. This filter will also act as a partial scratch filter.

INTERMEDIATE FREQUENCY.....465 KC.  
POWER OUTPUT  
Type.....Push-Pull Pentodes  
Undistorted.....6 watts  
Maximum.....10 watts

Use high resistance voltmeter of at least 1000 ohms per volt. The bias on the control grids of the 6A8-G, 6U5 and 6K7-G and the delay voltage on the diode plate (D1) of the 6H6-G is -4.3 volts, measured across resistor R24

SEARS-ROEBUCK & CO. MODEL 6157, Ch. 100.198  
Alignment, Trimmers

**ALIGNMENT PROCEDURE**

Before attempting to align the receiver, see that the dial pointer is correctly set. With the gang condenser in full mesh, set the pointer to the last mark on the left end of the dial scale. If the pointer is incorrectly set, it is only necessary to loosen the set screw on the dial cord drive drum and push the gang condenser in full mesh with the pointer properly set, then retighten the set screw.

Output meter connections-----	Across voice coil leads	1.325 volts

**HOW TO SET UP AND USE YOUR PUSH BUTTON TUNER.**

- SET-UP PRELIMINARY**
- Be sure that your set is connected to a good antenna system.
  - Turn on the set and allow it to operate at least one quarter hour before setting-up the push buttons.
  - Make a list of station call letters for six nearby powerful broadcast stations for which you wish to set up the buttons. Arrange the stations in your list in the order of their frequency. The station of lowest frequency will be first; the next higher frequency, second, and so on. Refer to the chart on the back of the receiver and you will be able to determine the correct frequency for the station call letters. After you have marked down the frequencies on your chart, alongside of the station call letters and arranged them in their proper order, number them 1, 2, 3, 4, 5, 6, 7 and 8 respectively. Check each frequency using Figs. 1 & 2. If each frequency falls within the range of its button, proceed as outlined in the following paragraphs.

A typical list of stations and the buttons that would be used to set them up is shown below:-

Station Call Letters	Frequency	Button No.
WMAQ	670 KC.	3
WLM	700 KC.	4
WGN	720 KC.	5
WENR-WLS	870 KC.	6
WFO	1000 KC.	7
Police(State)	1640 KC.	8

- Notice in Fig. 1 that buttons 1 and 2 are for use as tone control buttons. Buttons 3 to 8 inclusive are set-up for the automatic station selector. The automatic station selector has a frequency between 540 KC and 920 KC can be set-up on buttons 3, 4 and 5. Stations with a frequency assignment between 630 and 1490 KC may be up on button 6 and 7. Button No. 8 may be used for setting up a station between 720 KC and 1700 KC. There can be only one station on your list that has a frequency rating between 1490 KC and 1700 KC. However, on the same button it is possible to set-up a station whose frequency is as low as 720 KC.
  - Remove the escutcheon around the push buttons by taking out the six screws holding it to the cabinet. This will bring into view the six pairs of adjustment screws, each pair of which is used to tune in a station that you wish to set-up on a particular button.
- SET-UP PROCEDURE**
- Turn the band switch (right hand knob) to the right (clockwise) until the word "BROADCAST" appears in the lower opening in the dial. Then using the tuning knob (center) tune in the station.

- Now turn the band switch to the extreme clockwise position until the word "AUTOMATIC" appears in the dial opening.
- Push in the button to which you wish to set up the station (See Fig. 1).
- Use a small screw driver and insert it in the "a" screw for that button (see Fig. 1).
- Rotate the screw back and forth slowly until the program previously heard is heard again. If trouble is experienced in getting the station, turn the volume control to the right. NOTE: Be sure that you adjust this particular screw until the sides of the tuning eye "shadow" are closest together.
- If you are not successful in tuning in the station by turning the "a" screw back and forth, carefully re-read paragraphs "C" and "D", and repeat procedure 1, 2, 3, 4 and 5.
- Check to see if you have the proper station by changing the band switch from "Automatic" to "Broadcast" and vice versa.
- Now insert the screw driver in the "b" screw for that button (see Fig. 1) and turn it to the left or right until the program is received with maximum volume. The correct setting for this screw is when the sides of the tuning eye "shadow" are closest together.
- Re-adjust the "a" and "b" screws slightly while the band switch is in the "Automatic" position until the sides of the tuning eye "shadow" are closest together.
- Set-up buttons 4, 5, 6, 7 and 8 following steps 1 to 7 inclusive.
- Call letter tabs and celluloid windows are supplied with your receiver. The tabs are supplied as a perforated sheet which is to be broken into eight sections. Select the proper call letter tabs from station call letter sheets supplied.
- Place the call letter tabs in back of the celluloid window and insert them in their respective slots in the push button escutcheon.
- Replace the escutcheon with its six retaining screws.

**REPLACING THE POINTER DRIVE CORD**

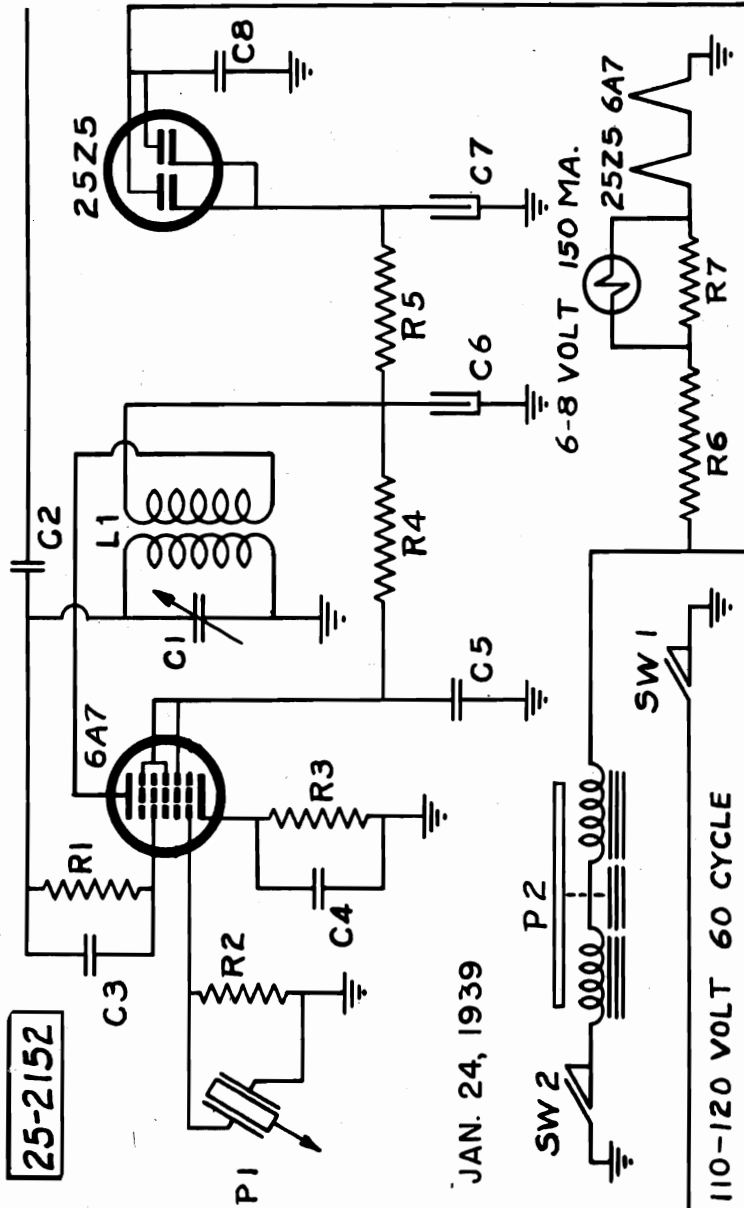

- Tie one end of 51' of special dial cord to the number 11 post to which the spring is attached to lug H.
- Thread the free end of the cord through hole A in drum C. (threading from the inside of the drum out) See Fig. 3.
- After pulling the cord through hole A, make one half turn around the drum C in a clockwise direction (viewed from the front) using the front groove in the drum.
- Continuing draw the cord up around the back of pulley E and around to pulley F.
- Go over pulley E and down to the bottom of the front groove on drum C. Continue up around the drum to hole B.
- Draw the cord through hole B and tie it to the end of the tension spring in such a manner that when the spring is clipped on to lug H it will be extended to about 1 1/8" long.

CHASSIS TUBE LAYOUT

FRONT

SUBJECT: ADDITION OF VOLUME CONTROL WITH A "MASTER" SWITCH.

There has been effected a change to further promote the satisfaction to be derived from this equipment by the incorporation of a volume control with the "Master" switch control.

To place the volume control in a position for easier operation, the "Master" switch has been placed on the right hand side of the equipment, the "Motor" switch taking up its position on the left hand side of the equipment.

To place the equipment in operation, the right hand switch marked "Master" should be turned on and advanced to the limit of its clockwise turn, which will place the volume control "Full-on". Slightly to the left of the right hand control will be noticed a small metal cap. This should be pried up with the screw driver furnished to gain entrance to the tuning control, instead of making this adjustment from the bottom as directed through as indicated under "Set Up Procedure".

The volume control can now be set at a level indicated by the satisfaction of the user. Turning the control to the right increases volume, turning it to the left decreases volume.

MODELS 6195, 6196, 6197  
 Chassis 109.216  
 Schematic, Voltage  
 Socket, Trimmers  
 Alignment

ALIGNMENT PROCEDURE

Either a broadcast signal between 1400 and 1500 KC may be used.

The antenna of the receiver should be extended as in normal use. Tune in a station between 1400 and 1500 KC. and adjust the trimmers on top of the variable condenser for maximum signal.

If a signal generator is used, extend the antenna as described above, run a wire from the generator parallel to, but insulated from the antenna. Set the generator at 1720 KC. Turn the variable condenser all the way to the right (minimum capacity). Tune in the signal from the generator with the trimmer on the front section of the variable condenser. Set the generator at about 1400 KC. Tune in the signal and adjust the trimmer on the rear section of the variable condenser for maximum signal.

The signal generator method is most satisfactory and should always be used when available.

CAUTION:

Under no condition should a ground be attached to this receiver, also no grounded object should be allowed to come in contact with the chassis.

POWER SUPPLY:

105-125 volts, 50-60 cycle or D. C. 43 Watts on 117 volt line.

FREQUENCY RANGE:

Broadcast and other services 540 to 1720 KC.

ALIGNMENT FREQUENCIES:

1720 and 1500 KC.

POWER OUTPUT:

Type.....Beam Power

Alignment

## SEARS-ROEBUCK &amp; CO.

Peak oscillator trimmer C-10 to 5 M.C. from test oscillator. And Ant. coil trimmer C-6 to same frequency.

**NOTE:** After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

**EXAMPLE:** The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 M.C.

Increase oscillator signal by "opening up" the alternator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

## IV THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400 KC (the top scale).

2. Peak oscillator trimmer C-9 to 1400 KC., the Antenna presselector C-12 (variable condenser trimmer) to 1400 KC, and trimmer C-5 to 1400 KC.

3. Set dial hand to 550 KC and adjust oscillator padding condenser C-8 to 550 KC.

4. Recheck dial at 1400 KC as in number (1) and (2).

5. Points in the middle of the dial may be checked and if necessary the plates of the front section of variable condenser may be bent for alignment.

## V NOTES.

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the schematic for the voltages at the tube sockets.

## THE ALIGNMENT PROCEDURE

The following alignment instructions are given with the assumption that the service station has an oscillator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be 0 to 3 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the 42 power tube in series with an 8 MFD paper condenser.

## I THE I. F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers number C1, C2, C3, C4. (See pictorial diagram).

The sensitivity of the I.F. stages will be 40 microvolts or better.

Always use as low an output as possible from the test oscillator in making the various adjustments.

## II ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the condenser shaft to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can be easily lined up by loosening the set screw behind the dial card in the drive hub.

1. Set the test oscillator to 17 megacycles.

2. Turn wave band switch all the way to right for highest S.W. band, and set dial hand to 17 M.C.

3. Peak trimmer condenser C-11 of the oscillator coil (See pictorial 6-2) to resonance with 17 M.C. fed into antenna.

4. Peak Ant. coil trimmer C-7 at same setting to 17 M.C.

## III SHORT WAVE BAND 1.7 TO 5.5 M.C.

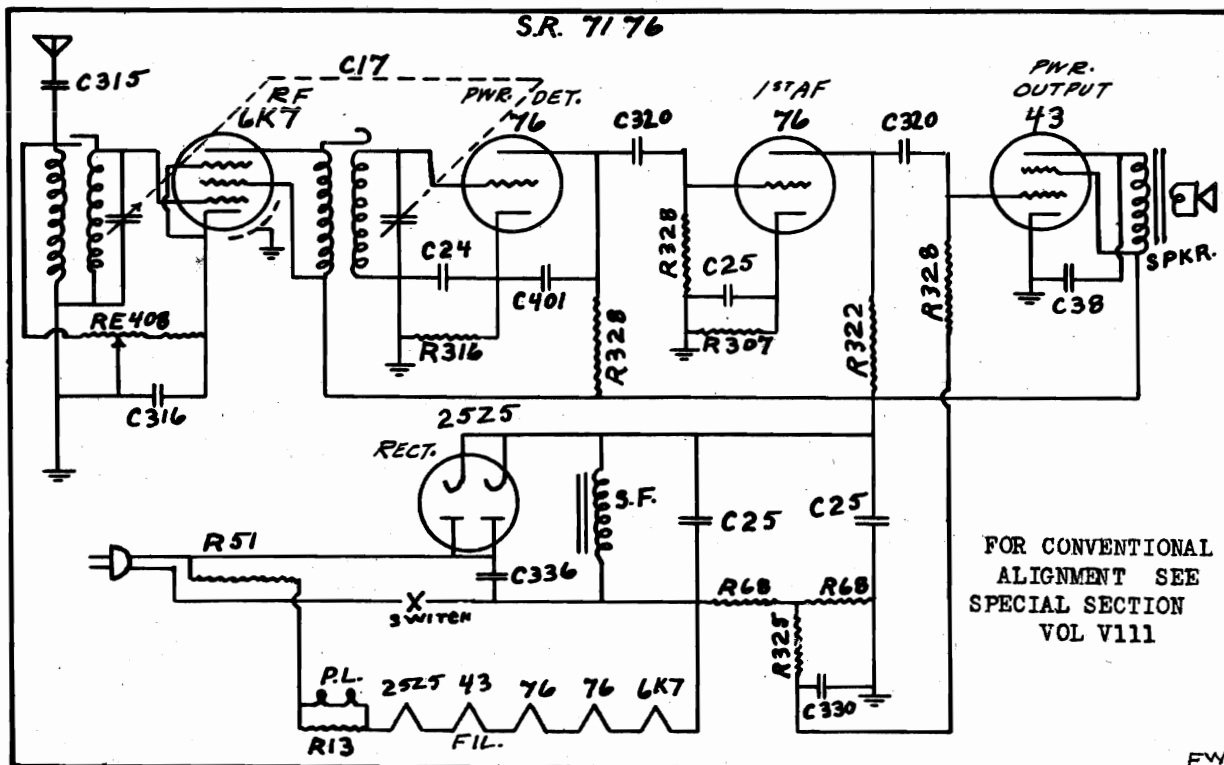

1. Turn wave switch to middle position.

2. Set dial hand to 5 megacycles on the 1.7 to 5.5 M.C. inner scale.

MODEL 7215  
 FACTORY IDENTIFICATION NO. 110.7215  
AUTOMATIC TUNING CONTROL ADJUSTMENT

This radio leaves the factory with the push button unset, and the user will have to make the necessary adjustments for setting the buttons.  
 The following is the procedure to be followed in making the adjustments for each station.  
 Note: Before attempting to set buttons read through the ENTIRE PROCEDURE VERY CAREFULLY.

1. Decide on station you wish to receive.
2. From the radio section of your daily newspaper find the transmitting frequency in kilocycles of the station.
3. Refer to the diagram underneath cabinet and see which set of adjustment screws will have a tuning range that includes the frequency of the station desired. This is the pair of screws to be adjusted for this particular station. The ranges are listed under each pair of adjustment screws.
4. From the same diagram, after finding where the proper pair of adjustment screws are located, trace the dotted line connecting these screws to one of the push buttons. This is the button which, after the adjustments are completed, will tune in the station.
5. Push button located by paragraph 4 "IN".
6. Turn volume control knob on full (to the extreme right) and adjust screw marked "OV" until desired station is heard. If when making this adjustment, a number of stations can be brought in as the screw is turned and it is doubtful which station is the correct one, press button No. 6 (Manual Tuning) "IN" and move dial pointer by turning station selector knob to the number on the dial that corresponds to the frequency of the station. (The number on the dial must be multiplied by ten to require adjusting screw "OV". Listening to the program being broadcast will identify the station when adjusting screw "OV".
7. Adjust screw marked "A" for maximum volume, retarding the volume control and readjusting if necessary. This completes the adjustments for this particular station.
8. Cut out name of station from list supplied and insert in button.
9. Insert celluloid disc.
10. In a like manner select a station for each of the other buttons and make necessary adjustments for each station.

"5C"	600 (Rock)	600 KC	Ant. lead	T1	Osc.	30
"50"	1500	1500 KC	Ant. lead	T1	Osc.	45

**IMPORTANT ALIGNMENT NOTES**  
 Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.  
 It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.  
 Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.  
 Values shown under "Microvolts" are only approximate.

CONTROL OPERATION:

Turning right; power on; volume increase  
Left Foreign; right Broadcast.

Under certain conditions, the chassis may be above ground potential. Do not allow any grounded object to come into contact with the chassis while the line cord is plugged in. Also, be careful when working on the chassis out of its cabinet, to avoid shocks.

If the power supply is DC, the power cord plug must be in its receptacle in the proper way. If the receiver does not operate after being turned on for a minute, reverse the polarity by removing the power cord plug from its receptacle and turning it half way around before re-inserting it in the receptacle.

OUTPUT

TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS. VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO CHASSIS. ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMING ADJUSTMENTS. WHERE NO VOLTAGE READING IS SHOWN IT INDICATES ZERO VOLTAGE OR A VERY LOW READING. VOLTAGES TO BE MEASURED WITH NO SIGNAL. FIGURES AT CATHODES ARE CATHODE CURRENT IN MILLIAMPERES.

DIAL DRIVE SYSTEM AND POINTER DRIVE HOOKUP

57 RL 106  
MAY 27, 1938

In cases where the customer objects to "boominess," the following circuit change may be made to minimize low-frequency response.

Change condenser C43 to .001 mfd., or in the most stubborn cases to .0001 mfd.  
Add a 2 megohm resistor across the crystal pickup connecting it from junction of pickup cable, C44, and R7 to chassis. This will reduce low-frequency response.

Mount the speaker away from the baffle by about 1/4" to 3/8".

POWER SUPPLY RATINGS AVAILABLE.....	Radio Only	Total

Automatic Record Changer Mechanism

Under normal operating conditions, service requirements on this mechanism should be negligible. Occasionally, however, it may be necessary to adjust the mechanism if there is a tendency to bind or jam, when operating or adjusting, since bent levers and possibly broken parts may result.

Record Changer Adjustments—Mount motor-board on a level support. Remove turntable and cover at right of turntable. Adjustment locations are designated on motor-board illustrations as A, B, C, etc. The adjustments are explained in the following order:

A—Trip rod "A" should be engaged in "Switch Lever" slot. Adjust "A" to obtain about 1/8 of an inch clearance from motor-board.

B—Adjust "B" to the position shown.

C—With "Index Lever" in "Manual" position, "Pickup Arm" should be to extreme left, and switch slipped to open position. Adjust "C" until contact is made. Tighten set screw. Contact arm, until points are opened 10 to 30 thousandths of an inch.

D—With "Index Lever" in "Manual" position, release set screw "D" and force "Manual Index Finger" as far as it will go towards "Trip Pawl Stop Pin." Tighten set screw.

E—Adjust at "E" to provide approximately 1/32 of an inch between outer end of "Link Stop" and screw when rubber "Bumper" is in contact with stop bracket.

F and G—Remove rubber aligner at "F" and adjust "F" and "G" so ejector tip "F" is in line with "Spindle." Longitudinal movement, with respect to "Ejector Arm," may be effected by loosening hex. head at "F." Lateral movement of "Ejector Arm" may be effected by adjustment "G."

H—Adjust "H" so under side of pickup head can be raised 3/8 inches above motor-board.

I—Adjust screw "I" until friction will just force "Trip Finger" to move "Trip Pawl" when "Index Lever" is in "12" inch position.

N—Adjust needle pressure by turning screw under center of "Pickup Arm" so that a force of 75 grams (2.5 ounces) will lift the needle. Tighten record. Hook set screw under needle screw to measure force.

O—Adjustment "O" must be performed prior to this adjustment. With a 12-inch record on turntable, turn on "Motor Switch," place "Index Lever" to "12" position and adjust "K" so that "Cable" tension will allow needle to lower slowly on start of record at completion of eject cycle. Turn motor switch "Off" after eject cycle is completed and check motor switch "Cable" after eject cycle is completed and check it against "Spindle." Replace turntable and put a needle in "Pickup."

L—Adjust "L" so needle will drop into center of smooth portion at the start of a 12-inch record when "Index Lever" is in "12" inch position and "Pickup Arm" is to extreme right.

M—Loosen three screws "M" and rotate "Spacer" until pointer on "Spacer" is in line with screw to right of "Pickup Arm."

P—Adjust turntable height by insertion or removal of three washers at "P" so ejector tip "F" will not eject bottom 12-inch record but will eject second from bottom record.

Q—Adjust position of shorting switch at "Q" so switch closes when needle is just outside a 12-inch record.

R—Adjust screw "R" upward just enough so that with one record on turntable and ejector tip "F" resting on record surface, there is 1/32 of an inch clearance between screw "R" and Ejector Arm.

Loudspeaker: Centering of the loudspeaker voicecoil is made in the usual manner with three, narrow-paper feelers, after first re-sofening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The voicecoil should be pushed back in place with ambroid upon completion of adjustment.

ALIGNMENT PROCEDURE

**PRELIMINARY:**  
Output meter connections..... Across speaker voice coil  
Output meter reading to indicate 1.0 watt output..... 1.3 volts  
Approximate average sensitivity in microvolts for 1.0 watt output..... See chart below  
Dummy antenna value to be inserted in series with generator output..... See chart below  
Connection of generator output lead..... To chassis  
Connection of generator ground lead..... To chassis  
Generator modulation..... 30%, 400 cycles  
Position of Volume Control..... Fully clockwise  
Position of Tone Control..... Fully clockwise  
Position of Dial Pointer with variable tuning condenser fully closed..... To fall on last calibration mark at 540 kc end of "Standard Broadcast" band

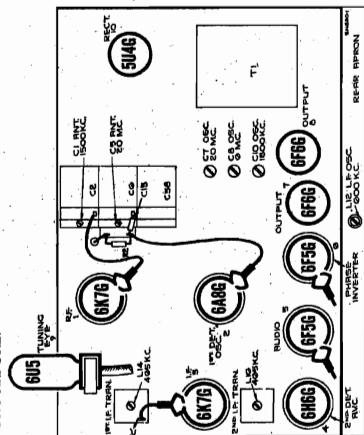

Wave Band	Position	Generator Frequency	Dummy Antenna	Trimmer Function	Approximate Microvolts

"S.B."	1,500 kc	1,500 kc	.0002 mfd.	Osc. Ant.	3

IMPORTANT ALIGNMENT NOTES

\*\* Use maximum capacity peak if two peaks can be obtained.  
\* Use minimum capacity peak if two peaks can be obtained.  
Where indicated by the word "Rock," the variable tuning condenser should be rocked back and forth a degree or two while making this adjustment.  
Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the a-c action of the set from interfering with accurate alignment.  
Adjustment locations are shown on the top and bottom parts location views of chassis.  
Only the dummy antenna indicated in the chart for any particular band should be used. Remove the dummy antenna used for alignment in any other band. Grid cap leads should remain in place during alignment.  
Values shown under, "Microvolts," are only approximate.

Eliminating Whistle at 930 KC.

A whistle due to a beat between the second harmonic (930 kc) of the 465 kc I.F. and a 930 kc signal may be eliminated by adjusting the I.F. frequency of the receiver. This is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the I.F. frequency of the receiver.  
Determine at what point between 900 and 960 kc the whistle is loudest. Dividing this frequency by two will give the new I.F. frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 910 kc would not be objectionable, the I.F. should be realigned at 910/2 or 455 kc. Try to select the new I.F. frequency as close as possible to 465 kc.  
Having frequency difference equal to the I.F. frequency (465 kc) of the receiver will be evidenced by a whistle appearing when the receiver is tuned to either of the stations. It may be further localized by tuning the receiver to each of these stations and then stopping the oscillator, in each case, by grounding the oscillator astor section of the variable tuning condenser. Whistle is to be caused by the beat between these two stations and may be corrected by shifting the I.F. frequency of the receiver to a frequency other than the difference frequency of the two local or strong signals (stations).

The I.F. amplifier should not be shifted to a frequency higher than 480 kc, nor lower than 450 kc, but should be as close to 465 kc as possible.  
Align the I.F. at the new frequency and then realign the rest of the receiver as described under "ALIGNMENT PROCEDURE."

POWER SUPPLY:

All models available . . . . . 105-125 volts, 25-60 cycle or DC, 45 watts

FREQUENCY RANGE:

Broadcast . . . . . 540-1700 KC

ALIGNMENT FREQUENCIES:

Broadcast . . . . . 1500 KC  
Oscil. Trimmer 600 KC  
Oscil. Padder 600 KC

POWER OUTPUT:

Type	Beam Power
Undistorted	1.2
Maximum	1.6

LOUD SPEAKER.

Type	Dynamic
Size	5"
Field resistance	450 ohms

AUTOMATIC TUNING CONTROL:

There are six buttons on the front panel. Five of them can be set so that by simply pushing the button marked with the station's call letters, any of five different broadcast stations can be received.

The sixth button is used to cut out the automatic tuning and convert the set for use with the regular dial and manual tuning.

**THE GROUND:**

In noisy locations, it may be desirable to connect the black lead in rear of chassis to a water pipe or radiator. This may eliminate much of the interference.

**CAUTION:** Do not connect a ground wire directly to the chassis; otherwise harm will result.

**POWER SUPPLY:** All models available . . . . . 105-125 volts, 25-60 cycle or DC, 45 watts

**FREQUENCY RANGE:** Broadcast . . . . . 540-1740 KC

**POWER OUTPUT:**  
Type . . . . . Beam Power  
Undistorted . . . . . 1.7 Watts  
Maximum . . . . . 2.7 Watts

**MECHANICAL SPECIFICATIONS**

**OPERATING CONTROLS:**

MODEL "Automatic Tune"  
Wheel Dial  
Assembly, Details, Notes  
For MODELS 78B, 78BE, 82A  
82AE, 86AE, 91B, 95B

SERVICE NOTES for "AUTOMATIC-TUNE" WHEEL DIAL

USED WITH MODELS 78B, 78BE, 82A, 82AE, 86AE, 91B AND 95B

DIAL MECHANISM

FIG. 3

FIG. 1

4. INSERT CELLULOID ENVELOPE INTO A METAL TAB FRAME BY:
  - (a) Hold curved end of celluloid envelope to... of metal tab holder, and insert celluloid into metal frame.
  - (b) Gently push celluloid inward until curved end of envelope touches edge of celluloid envelope tab frame.
  - (c) Arrange tabs in numerical order according to station frequency.
5. SET THE METAL TAB HOLDERS ON DIAL BY: (See Fig. 3)
  - (a) Set the first metal tab holder for the station that broadcasts on the lowest frequency—next number on frequency scale. The next station tab for the selected station operating on in this way until a tab has been set for all of the selected stations.
  - (b) Carefully tune in the station which broadcasts on the lowest frequency—least number of kilocycles.
  - (c) Insert celluloid envelope between edge of dial and metal tab holder, and turn one end of knurled tab into square notch in slotted dial rail—then slide tab holder along rail until the knurled tab is underneath the indicator stop on the dial at which point station call letter strip will appear directly below the indicator line on the face of the dial.
  - (d) Tighten tab holders, as much as possible without moving dial by turning knurled tab to the right—then swing dial so knurled tab is away from indicator stop on the dial and firmly tighten so that it cannot move on the dial rail. DO NOT USE PLIERS TO TIGHTEN.
6. REPLACING No. 4000 DIAL GLASS SCALE ASSEMBLY
 

As it requires special tools to properly set part No. 4005 shaft assembly on part No. 4000 glass scale—we will ship all orders for No. 4000 glass scales with the No. 4005 shaft assembled on the glass scale.

- (c) Insert No. 4005 shaft into main bushing attached to the cadmium plated bracket on back of dial face.
  - b) Place steel spacer washer and brass tension spring in order named over end of No. 4005 shaft.
  - (c) Place the small die cast primary pulley No. 4009 on shaft—do not tighten No. 2754 set screws.
  - (d) Loosen the two set screws in brass spacer collar on the No. 4005 shaft.
  - (e) Adjust brass spacer collar—by sliding collar on shaft—so that there will be approximately 1/8" clearance between the bottom of metal tab holder and the face plate. Firmly retighten brass collar and No. 2754 die cast pulley set screws. Failure to provide proper clearance will result in scratches on dial face and the dial mechanism will not operate freely.
- TO INSTALL No. 3814 PRIMARY DRIVE CORD:**
- (a) Looking at back of dial, wrap dial cord twice around No. 4355 drive shaft in CLOCKWISE direction.
  - (b) Hook No. 3462 tension spring into loops at end of dial cord.
- NEVER LOOSEN THE FOUR SCREWS THAT HOLD THE CADMIUM PLATED BRACKET TO DIAL FACE—OTHERWISE THE MAIN BUSHING WILL BE THROWN OUT OF CENTER.

MODEL "Automatic Tune"  
Wheel Dial

4352	Spring Tension For Secondary Cord.....	.07
3462	Spring Tension For Primary Cord.....	.07

Prices are subject to change without notice.

TO INSTALL No. 4013 SECONDARY DRIVE CORD:

The dial mechanism picture shows and refers to eye terminals on drive cord—these were used in early production. Loops made by knots in the cords are now used to attach cord to lugs in the No. 4009 die cast pulley and to the No. 4352 & 3462 tension springs.

(a) Looking at the front of the dial rotate dial scale COUNTER-CLOCKWISE until dial stop is reached.

(b) Loosen the two No. 2754 set screws in small die cast pulley No. 4009.

(c) Looking at front of dial turn the small die cast pulley so that the cut out in pulley will be towards the left and approximately in line with the upper edge of the dial light bracket. This bracket which is only used in six volt battery and 110 volt AC models is shown mounted on the cadmium plated dial face plate bracket in dial mechanism picture.

(d) Hook No. 4352 tension spring in dial cord loop.

(e) Turn No. 4011 drum so that the hole in the No. 4012 large die cast pulley—through which the secondary drive cord is pulled—is towards the top of face plate. This will bring the hole approximately in line with the left hand edge (looking at back of dial) of face plate.

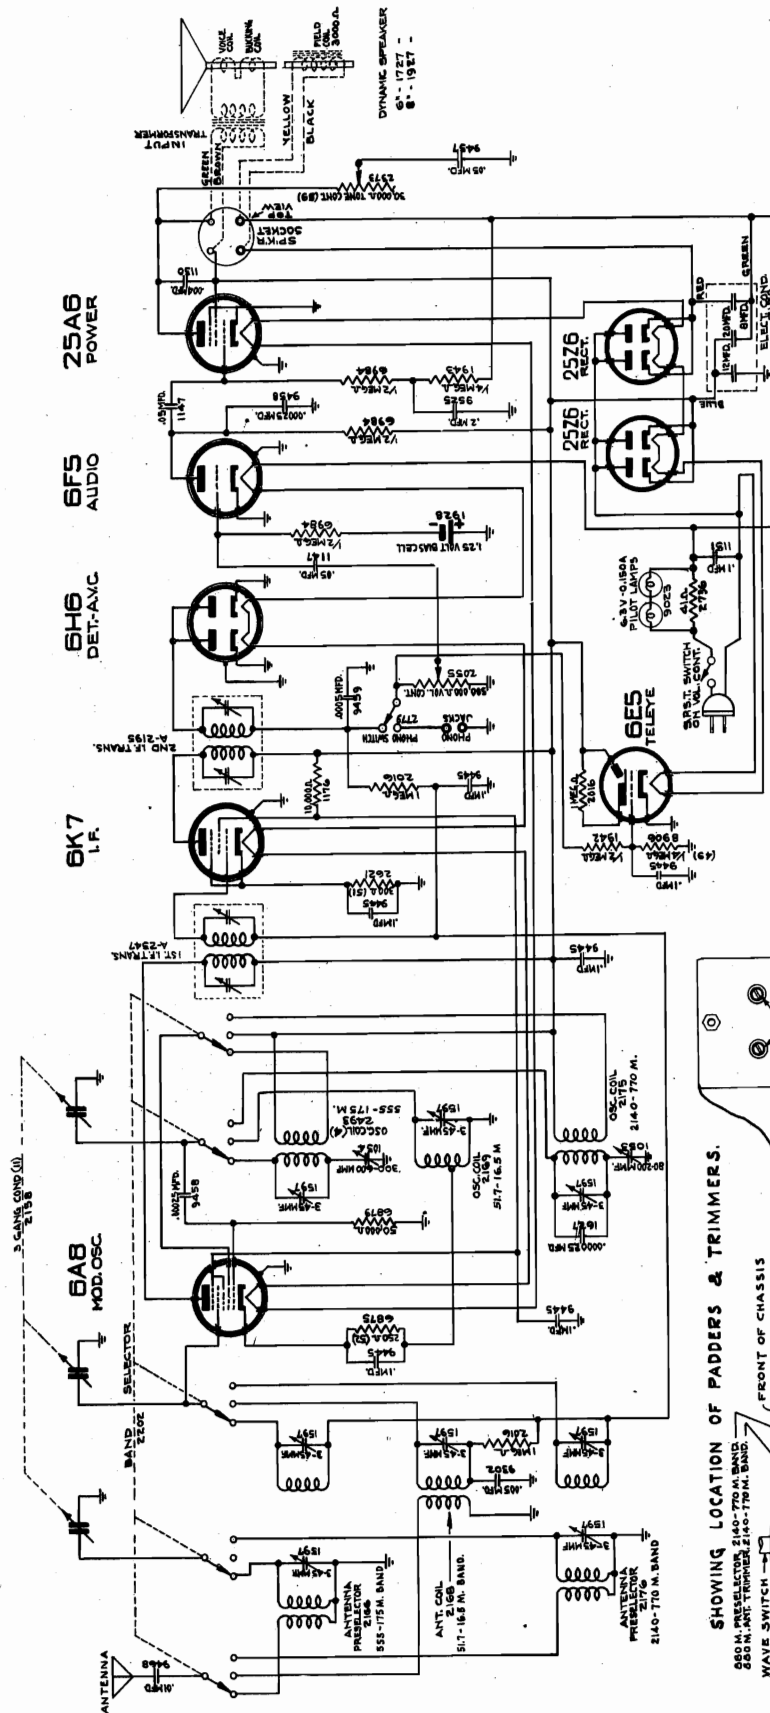

(f) Take long end of No. 4013 secondary drive cord—measured from knot at spring to end of cord—then looking at the front of dial, wrap cord one complete turn CLOCKWISE around the No. 4009 small die cast pulley. The other end of the cord (short end) is placed on bottom half of secondary and primary die cast pulleys.

(g) Firmly tighten No. 2754 set screws in small die cast pulley.

MODEL 56U  
 MODEL 67L  
 MODELS 68B, 68BE  
 Alignment

SENTINEL RADIO CORP.

Model 56U Eight Tube AC-DC Superheterodyne Receiver

ALIGNING I. F. STAGE AT 645 METERS:

- (a) Connect the high side of the test oscillator output to the control grid of the 6A8 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver base through a .2 Mfd. condenser.
  - (b) Set test oscillator frequency to 645 meters (this must be accurate).
  - (c) Peak each of the second I. F. transformer trimmers.
  - (d) Peak each of the first I. F. transformer trimmers.
- To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

ALIGNING 16.5-51.7 METER BAND:

- (a) Connect the high output side of the test oscillator through a 400 ohm resistor to receiver antenna lead and the low side to the set ground through a .02 Mfd. condenser.
- (b) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop, (complete in mesh), at which point the dial needle must be exactly even with the last line at the high wave length end of the dial calibration. If the dial needle does not point exactly to the last line, move needle to correct position.
- (c) Place the band selector switch for operation on the 16.5-51.7 meter band, tune receiver dial and set test oscillator frequency to EXACTLY 16.5 meters. Then tune in the 16.5 METER SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 16.5 METER OSCILLATOR TRIMMER.

**NOTE:** When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE RIGHT PEAK IS USED FOR ALIGNING THE RECEIVER AT 16.5 METERS. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the SECOND PEAK which is the proper one to use is tuned in. If the trimmer is screwed down only to the point where the first peak is received, the incorrect peak will be tuned in.

- (d) Tune the receiver dial and set test oscillator frequency to EXACTLY 20 METERS. Adjust 20 meter antenna trimmer for maximum 20 meter test signal sensitivity.

ALIGNING 175-555 METER BAND:

- (a) Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mfd. condenser, place the band selector switch for operation on the 175-555 meter band, tune receiver dial and set test oscillator frequency to EXACTLY 175 METERS. BRING IN THE 175 METER TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 175 METER OSCILLATOR TRIMMER.
- (b) Set test oscillator frequency and receiver dial to EXACTLY 215 METERS. Adjust 215 meter pre-selector and antenna trimmers for maximum 215 test oscillator signal sensitivity.
- (c) Tune receiver dial and set test oscillator frequency to approximately 500 meters. While rocking gang condenser slightly to right and left adjust 500 meter oscillator padder for maximum sensitivity.

ALIGNING 770-2140 METER BAND:

- (a) Place band selector switch for operation on the 770 to 2140 meter band, and set test oscillator frequency and receiver dial to EXACTLY 770 METERS. BRING IN 770 METER TEST SIGNAL TO MAXIMUM OUTPUT WITH 770 METER OSCILLATOR TRIMMER.
- (b) Tune receiver dial and set test oscillator frequency to EXACTLY 880 METERS. Adjust 880 meter antenna and pre-selector trimmers for maximum 880 meter test signal response.
- (c) Set receiver dial and set test oscillator frequency to approximately 1875 meters. Then while rocking gang condenser slightly to right and left adjust 1875 meter padding condenser for maximum sensitivity.

Model 67L  
 Six Tube Superheterodyne Receiver

ALIGNING I.F. STAGE AT 465 KILOCYCLES:

- (a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead to the grid cap of the 6A7 tube through a .02 Mfd. condenser DO NOT REMOVE GRID CLIP.
- (b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.
- (c) Peak each of the second I.F. transformer trimmers.
- (d) Peak each of the first I.F. transformer trimmers.

ADJUSTING 465 KILOCYCLE WAVE TRAP:

- (a) Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the receiver antenna lead and the low side to the set ground.
- (b) Set test oscillator frequency to EXACTLY 465 kilocycles and adjust the 465 K.C. wave trap trimmer condenser mounted on and accessible through hole in rear of chassis for MINIMUM 465 kilocycle signal response.

ALIGNING 1720-540 KILOCYCLE BAND:

- (a) Adjust band selector switch for operation on 1720-540 kilocycle band and leave test oscillator lead connected to receiver antenna lead through the .00025 Mfd. series condenser.
- (b) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles.
- (c) Adjust 1720 K. C. oscillator trimmer to bring in 1720 kilocycle test oscillator signal to maximum output.
- (d) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles.
- (e) Adjust 1400 K.C. antenna trimmer for maximum sensitivity.
- (f) Set receiver dial and test oscillator frequency to approximately 600 kilocycles.
- (g) While rocking gang condenser slightly to right and left adjust 600 K.C. padder for maximum sensitivity.

ALIGNING 2.3-6.3 MEGACYCLE BAND:

- (a) Replace .00025 Mfd. test oscillator lead series condenser with a 400 ohm resistor. Adjust band selector switch for operation on 6.3 to 2.3 megacycle band, and tune receiver dial and set test oscillator frequency to EXACTLY 6.3 megacycles.
  - (b) Adjust 6.3 M.C. oscillator trimmer to bring in 6.3 megacycle test oscillator signal to maximum output.
  - (c) Tune receiver dial and set test oscillator frequency to 5.8 megacycles, and while rocking gang condenser slightly to right and left adjust 5.8 M.C. antenna trimmer for maximum sensitivity.
  - (d) No adjustment is required at low frequency end of this band as a fixed oscillator pad is used.
- To assure more accurate trimmer setting repeat all above adjustments several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

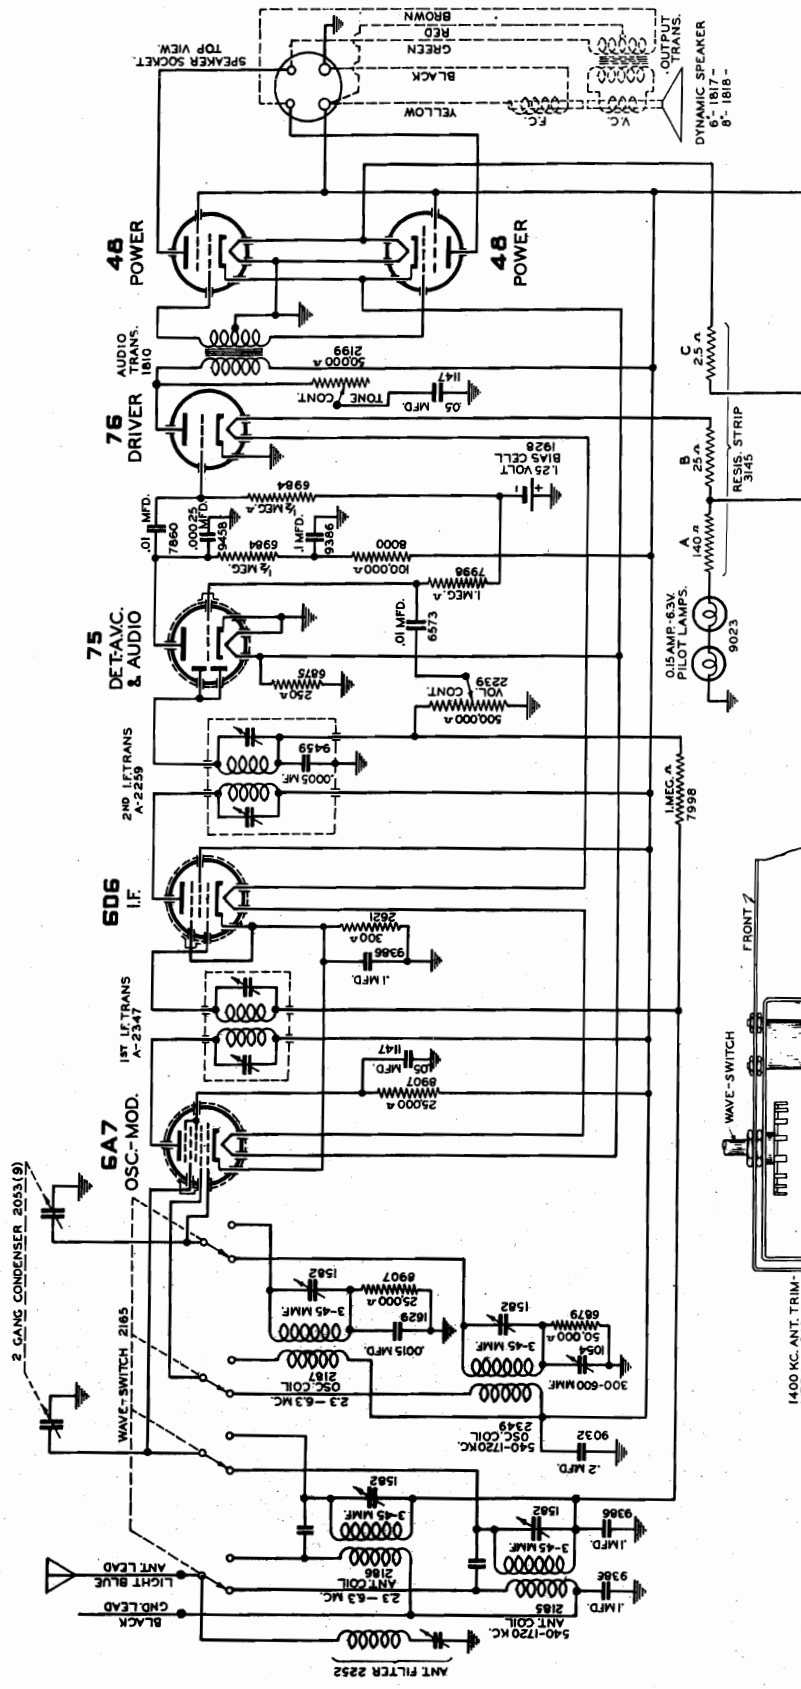

**ALIGNING 1.8-5.8 MEGACYCLE BAND:**  
 (a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor.  
 (b) Adjust band selector switch to 1.8-5.8 megacycles, tune receiver dial and set test oscillator frequency to EXACTLY 5.8 megacycles. Bring in 5.8 megacycle test signal to maximum output by adjusting 5.8 M.C. oscillator trimmer.  
 (c) Tune receiver dial and set test oscillator frequency to EXACTLY 5 megacycles, and adjust 5 M.C. antenna trimmer for maximum sensitivity.  
**ALIGNING 5.8-18.3 MEGACYCLE BAND:**  
 (a) Leave 400 ohm resistor in series with test oscillator lead and place band selector switch for operation on 5.8-18.3 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 18 megacycles.  
 (b) Adjust 18 M.C. oscillator trimmer to bring in 18 megacycle test signal to maximum output.  
 (c) Tune receiver dial and set test oscillator frequency to 17 megacycles, and while rocking gang condenser slightly to right and left adjust 17 M.C. antenna trimmer for maximum sensitivity.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**  
 (a) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid cap of the 6A7 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.  
 (b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.  
 (c) Peak each of the second I.F. transformer trimmers.  
 (d) Peak each of the first I.F. transformer trimmers.  
**ALIGNING 1720-540 KILOCYCLE BAND:**  
 (a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.  
 (b) Remove test oscillator lead from grid of 6A7 tube and connect to receiver antenna lead through a .00025 Mfd. series condenser.  
 (c) Adjust band selector switch for operation on the 1720-540 kilocycle band.  
 (d) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles, and BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.  
 (e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 K.C. antenna trimmer for maximum sensitivity.  
 (f) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K.C. oscillator padder for maximum signal response.

**Model 68B-68BE—Three Band Superheterodyne Receiver**  
**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**  
 (a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead to the grid cap of the 6A7 tube through a .02 Mfd. condenser DO NOT REMOVE GRID CLIP.  
 (b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.  
 (c) Peak each of the second I.F. transformer trimmers.  
 (d) Peak each of the first I.F. transformer trimmers.  
**ALIGNING 1720-540 KILOCYCLE BAND:**  
 (a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.  
 (b) Remove test oscillator lead from grid of 6A7 tube and connect to receiver antenna lead through a .00025 Mfd. series condenser.  
 (c) Adjust band selector switch for operation on the 1720-540 kilocycle band.  
 (d) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles, and BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.  
 (e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 K.C. antenna trimmer for maximum sensitivity.  
 (f) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K.C. oscillator padder for maximum signal response.

**FROM ONE TO TEN STATIONS OPERATING ON FREQUENCIES SEPARATED BY FORTY KILOCYCLES OR MORE MAY BE AUTOMATICALLY TUNED BY PROPERLY SETTING PUSH BUTTONS.**

IT IS A SIMPLE MATTER TO "AUTOMATIC TUNE" AFTER THE STATION PUSH BUTTONS HAVE BEEN PROPERLY SET. ALL THAT IS REQUIRED IS TO PUSH BUTTON HAVING CALL LETTERS OF THE DESIRED STATION PUSHING INWARD—THEN SWING DIAL UNTIL DIAL STOPS AT WHICH POINT THE DESIRED STATION IS TUNED. THIS METHOD OF TUNING SHOULD POINT TO THE INDICATOR LINE ON FACE OF DIAL. If reception is slightly distorted—which may be particularly noticeable when tuning weak stations—tune for maximum clarity by using conventional tuning knob.

WHILE A PUSH BUTTON MAY BE SET FOR DISTANT WEAK STATIONS, IT IS BEST TO SET FOR LOCAL STATIONS IF THE STATIONS SELECTED FOR AUTOMATIC PUSH BUTTON TUNING ARE STRONG NEARBY OR LOCAL STATIONS.

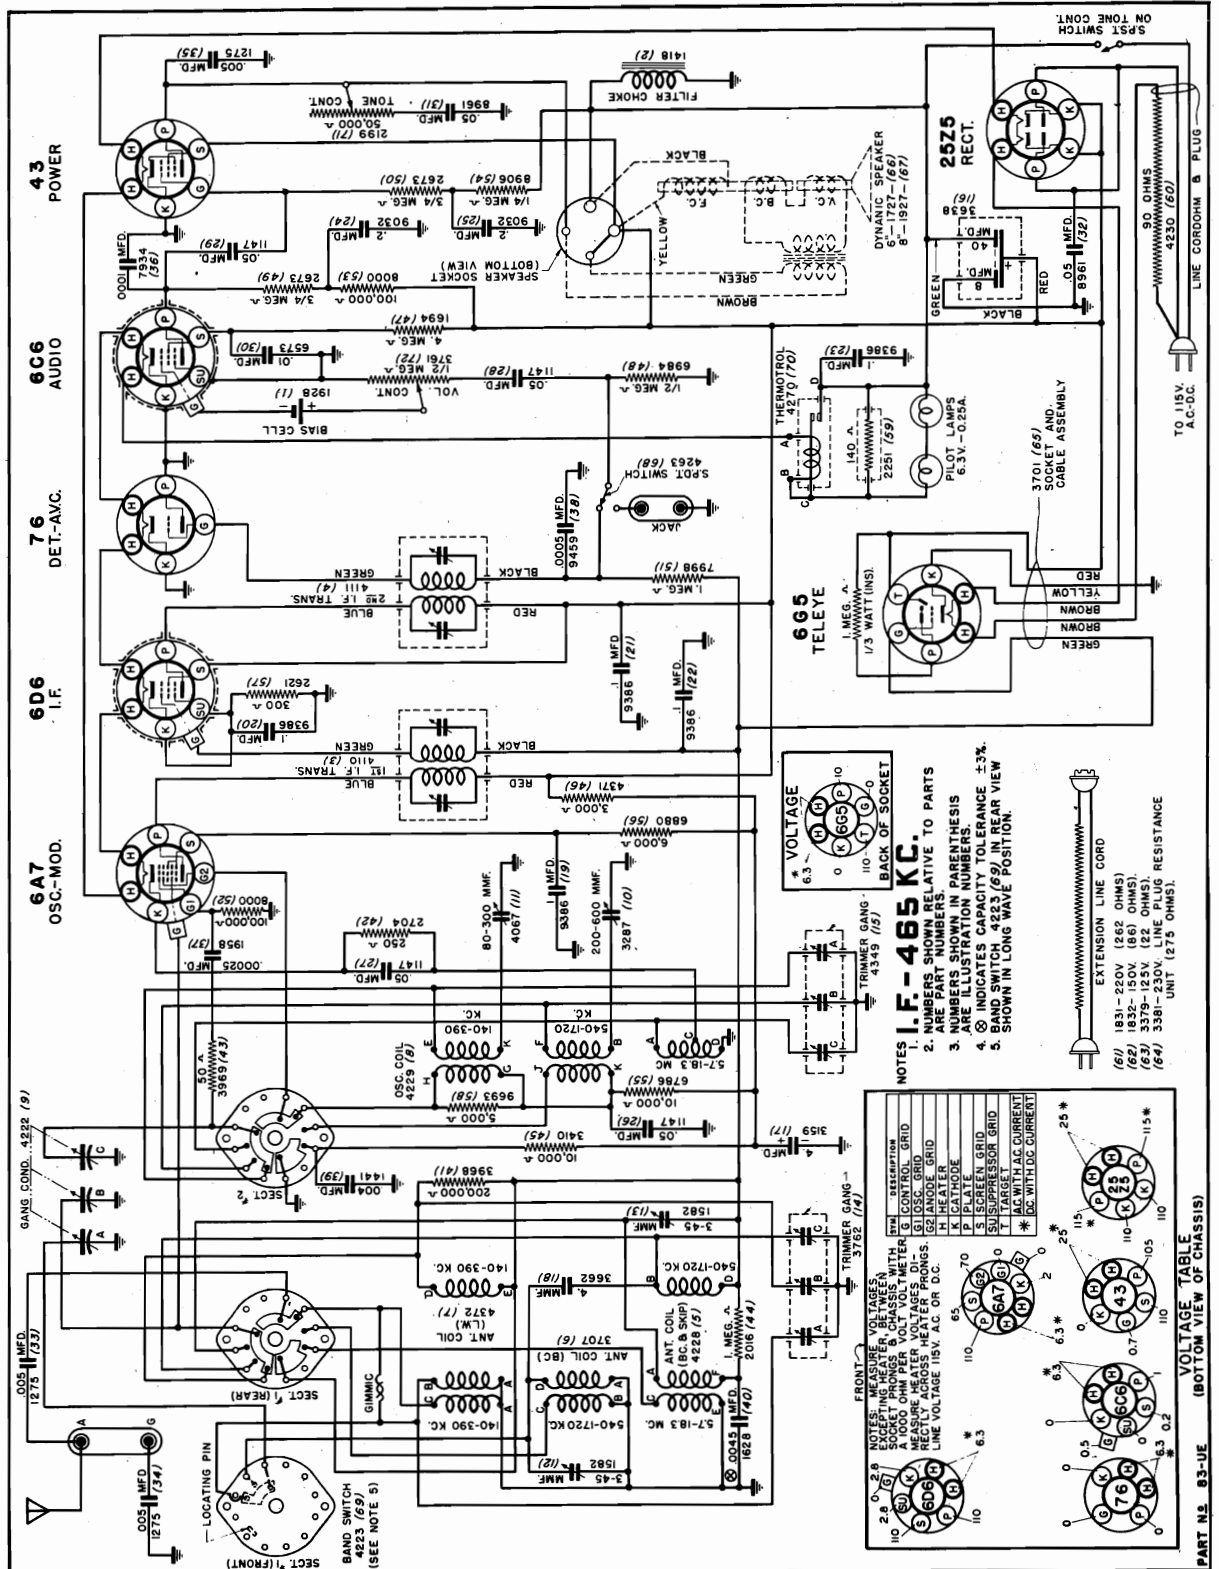

AFTER IT IS DETERMINED WHAT STATIONS YOU WISH TO "AUTOMATIC PUSH BUTTON TUNE" OBTAIN THE STATIONS AND SET PUSH BUTTONS BY:

- SET STATION PUSH BUTTON BY:**
- Gently press desired round paper station call letter tabs out of station tab sets.
  - Always set the first push button for the desired station that broadcasts on the lowest frequency—the least number of kilocycles—and then set the next push button for the next highest frequency on that frequency, continuing on in this manner until a Push Button has been set for all of the desired stations.
  - Loosen Push Button locking screw and remove caps on all Push Buttons by grasping cap between fingers and gently pulling outward—then remove celluloid discs.
  - Carefully tune in the station which broadcasts on the lowest frequency—least number of kilocycles.
  - Slide the Push Button nearest to the low frequency end of dial scale—without moving dial—until metal indicator attached to Push Button is exactly even with the indicator line on the face of the dial—then with a small screw driver, place celluloid protective disc on top of this Push Button locking screw.
  - Place printed paper station call letter tab, having call letters of station tuned in—on top of Push Button cap—then place celluloid protective disc on top of this and gently press Push Button cap firmly down over Push Button.
  - Repeat Push Button for the desired station operating on the next lowest frequency in the same manner as above and continue on in this way until all the Push Buttons have been properly set.

**AFTER THE TEN PUSH BUTTONS HAVE BEEN PROPERLY SET THEY WILL NOT REQUIRE FURTHER ATTENTION EXCEPT WHEN MOVED FROM THEIR POSITION OR WHEN AN ADDITIONAL TAB IS INCLUDED WHICH WOULD DISTURB THE POSITION OF THE OTHER TABS.**

MODEL 98AE  
Trimmers, Chassis  
Alignment

SENTINEL RADIO CORP.

**ALIGNMENT PROCEDURE:**

Lack of sensitivity, selectivity or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, etc. Never attempt to realign set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE: BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING, OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT.**

IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

- Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead of the test oscillator to the grid cap of the 6A7 tube through a .02 Mfd. series condenser. **DO NOT REMOVE GRID CLIP.**
- Set test oscillator to **EXACTLY 465 kilocycles** and turn receiver volume control on full.
- Peak each of the second I.F. transformer trimmers.
- Peak each of the first I.F. transformer trimmers.  
To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**ALIGNING 1720-540 KILOCYCLE BAND:**

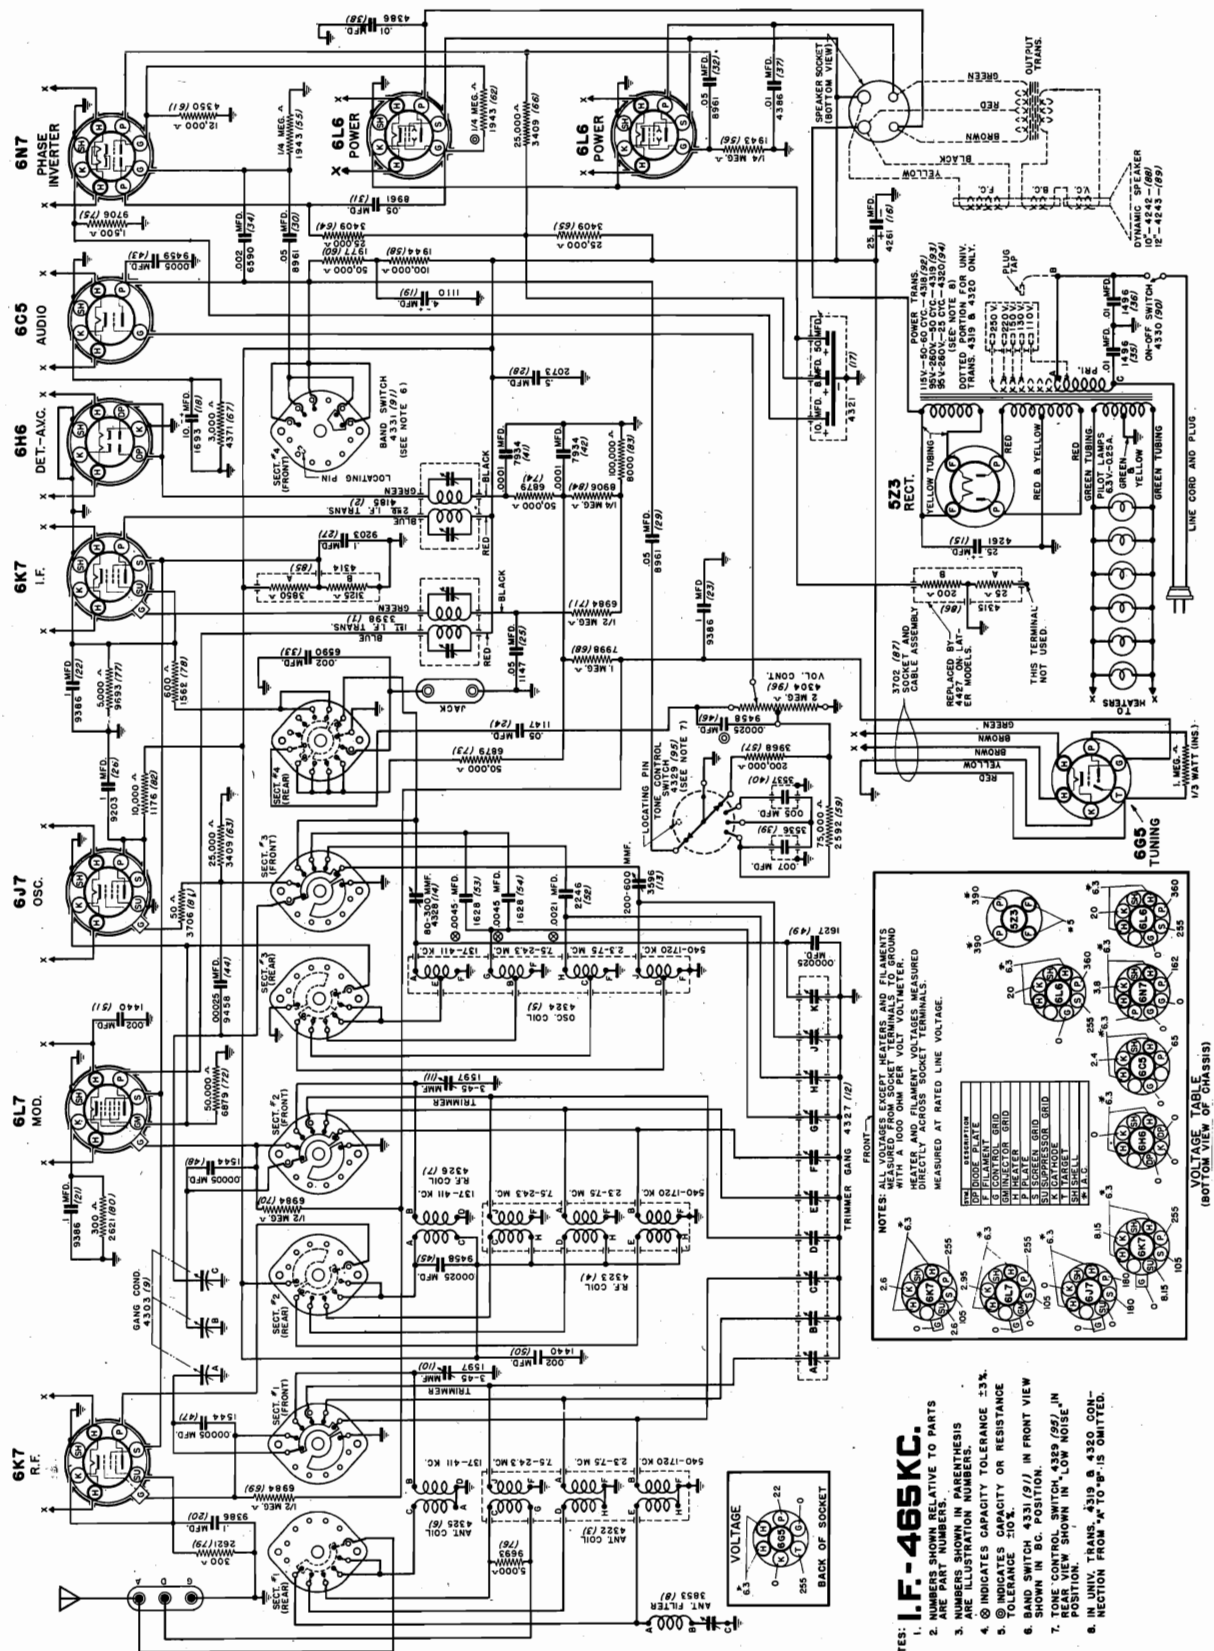

- Remove test oscillator lead from grid of the 6A7 tube and attach it to the receiver antenna lead through a .00025 Mfd. series condenser.
- Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.
- Set receiver dial and test oscillator frequency to **EXACTLY 1720 kilocycles.**
- Bring in 1720 KC test oscillator signal to maximum output by adjusting the trimmer condenser mounted on top of the oscillator section of the gang condenser. Looking at the front of the receiver the rear section of the gang condenser is the oscillator section.
- Tune receiver dial and set test oscillator frequency to **EXACTLY 1400 kilocycles:**
- Adjust trimmer on top of the front section gang condenser (antenna section) for maximum 1400 kilocycle test signal response.
- Tune receiver dial and set test oscillator frequency to approximately 600 kilocycles.
- While rocking the tuning condenser back and forth adjust 600 KC oscillator padder condenser which is accessible through the hole in the top of the chassis adjacent to the gang condenser for maximum 600 kilocycle signal response.

**ALIGNING 2.3-6.3 MEGACYCLE BAND:**

- Replace .00025 Mfd. Test oscillator antenna lead series condenser with a 400 ohm resistor.
- Adjust band selector switch for 2.3-6.3 megacycles band operation, tune receiver dial and set test oscillator frequency to **EXACTLY 6.3 megacycles.**
- Bring in 6.3 megacycle test oscillator signal to maximum output by adjusting 6.3 M.C. oscillator trimmer on top of coil located underneath chassis.
- Tune receiver dial and test oscillator frequency to **EXACTLY 6 megacycles**, and adjust 6 M.C. antenna trimmer which is mounted on coil located on top of chassis for maximum sensitivity.

Chassis

SENTINEL RADIO CORP.

SENTINEL RADIO CORP.

MODEL 99AE  
 MODELS 144X, 144XE  
 MODELS 149A, 149AE, 159AE  
 Alignment

**SENTINEL-ERLA MODEL 99AE ALIGNMENT PROCEDURE:**

Lack of sensitivity, selectivity or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, etc. Never attempt to readjust set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE:** BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING. OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT. THE TRIMMER AND PADDING CONDENSERS WILL BE REFERRED TO BY THEIR FUNCTION AS INDICATED ON PARTS DIAGRAM. IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

- (a) Connect the ground lead of the test oscillator to the chassis or set ground post. Connect the other lead of the test oscillator to the grid cap of the 6L7 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.
  - (b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.
  - (c) Peak each of the second I.F. transformer trimmers.
  - (d) Peak each of the first I.F. transformer trimmers.
- To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**ADJUSTING 465 KILOCYCLE WAVE TRAP:**

- (a) Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the receiver antenna "A" post and the low side to the set ground.
- (b) Set test oscillator frequency to EXACTLY 465 kilocycles and adjust 465 kilocycle wave trap trimmer condenser for MINIMUM 465 kilocycle signal response.

**ALIGNING 137-411 KILOCYCLE BAND:**

- (a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.
- (b) Leave test oscillator lead connected to receiver antenna "A" post through a .00025 Mfd. series condenser.
- (c) Adjust band selector switch for operation on 137-411 kilocycle band, tune receiver dial and set test oscillator frequency to EXACTLY 411 kilocycles.
- (d) Bring in 411 kilocycle test signal to maximum output by adjusting 411 K.C. (K) oscillator trimmer.
- (e) Tune receiver dial and set test oscillator frequency to EXACTLY 350 kilocycles. Adjust 350 K.C. antenna and R.F. trimmers for maximum sensitivity.
- (f) Tune receiver dial and set test oscillator frequency to approximately 180 kilocycles—then while rocking gang condenser slightly to right and left adjust 150 kilocycle oscillator paddler for maximum sensitivity.

**ALIGNING 1720-540 KILOCYCLE BAND:**

- (a) Leave .00025 Mfd. condenser in series with test oscillator lead. Adjust band selector switch for operation on the 1720-540 kilocycle band.
- (b) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles. ADJUST 1720 KILOCYCLE OSCILLATOR TRIMMER (I) TO BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT.
- (c) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles. Adjust 1400 K.C. antenna (C) and R.F. (F) trimmers for maximum sensitivity.
- (d) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K.C. oscillator paddler for maximum signal response.

**ALIGNING 2-3.75 MEGACYCLE BAND:**

- (a) Replace .00025 Mfd. test oscillator lead series condenser with a 400 ohm carbon resistor.

- (b) Adjust band selector switch to 2-3.75 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 7.5 megacycles—then adjust 7.5 megacycle oscillator (H) trimmer for maximum 7.5 megacycle test signal output.
- (c) Tune receiver dial and set test oscillator frequency to EXACTLY 6 megacycles—adjust 6 M.C. antenna (B) and R.F. (E) trimmers for maximum sensitivity.

**ALIGNING 7.5-24.3 MEGACYCLE BAND:**

- (a) Leave 400 ohm resistor in series with test oscillator lead and place band selector switch for operation on 7.5-24.3 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 24.3 megacycles.
  - (b) Adjust 24.3 M.C. oscillator trimmer (G) to bring in 24.3 megacycle test signal to maximum output.
- NOTE:** When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 24.3 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the FIRST PEAK which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 24.3 megacycles, always check to see if the proper peak has been used. To do this leave test oscillator frequency at 24.3 megacycles, increase the output of the test oscillator and tune receiver dial to approximately 23.3 megacycles. Then vary the receiver dial slightly to the right and left of 23.3 megacycles and if the fundamental peak was used in aligning at 24.3 megacycles the test oscillator signal will be heard at approximately 23.3 megacycles on the receiver dial.
- (c) Tune receiver dial and set test oscillator frequency to EXACTLY 20 megacycles.
  - (d) Adjust 20 M.C. antenna (A) and R.F. (D) trimmers for maximum 20 megacycle test signal response.
- To assure most accurate trimmer setting, repeat all above adjustments several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**MODELS 144X, 144XE, 149A, 149AE, and 159AE.**

**ALIGNMENT PROCEDURE IN TABULATED FORM**

Be sure to follow procedure carefully and in the order there-shown. In the case of the dial calibration, however, the alignment procedure read instructions from left to right. If more than one adjustment is required on any one band, make the adjustment marked (1) first, then next, etc. In final adjustment, check tuning dial adjustment by: Turn gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial indicator must be exactly even with the last line at the low frequency end of the dial calibration. If dial needle does not point exactly to the last line move needle to correct position. Use an accurately calibrated test oscillator with some type of output measuring device. Have ground lead of test oscillator attached to chassis.

Place band switch for operation on:	Set receiver dial to:	Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below each:
I.F. alignment use any band position	Any point where no interfering signal is received	Exactly 455 K.C.	.02 Mfd. condenser	High side of 6B8G tube. Do not remove cap.	
1720 K.C.	Exactly 1720 K.C.	Exactly 1720 K.C.	.00025 Mfd. condenser	Receiver blue antenna lead	Adjust 1720 K.C. oscillator trimmer for maximum output.
1400 K.C.	Exactly 1400 K.C.	Exactly 1400 K.C.	.00025 Mfd. condenser	Receiver blue antenna lead	Adjust 1400 K.C. antenna trimmer for maximum output.
540 K.C.	Approximately 600 K.C. mainly	Approximately 600 K.C.	.00025 Mfd. condenser	Receiver blue antenna lead	While rocking gang condenser adjust 600 K.C. oscillator paddler for maximum output.
58 to 18.1 M.C. BAND	Exactly 18.1 M.C.	Exactly 18.1 M.C.	400 Ohm carbon resistor	Receiver blue antenna lead	Adjust 18.1 M.C. oscillator trimmer for maximum output. If more than one peak is noticed, back off trimmer to minimum capacity, then screw down which is the proper one to use is tuned in.
2	Exactly 15 M.C.	Exactly 15 M.C.	400 Ohm carbon resistor	Receiver blue antenna lead	Adjust 15 M.C. antenna trimmer for maximum output.

## SENTINEL RADIO CORP.

MODEL 106A  
MODEL 107AE  
Alignment

(b) Carefully tune in the selected station that broadcasts on the lowest frequency—the least number of kilocycles.

(c) Place a little mullage or celluloid on back of paper tab. Press the paper call letter tab—so that the printed call letters of the station tuned in are at the same angle as the printing on the dial—into the round depression on the cabinet front that is nearest to the dial pointer. By placing call letter tab on angle the call letter can easily be read with cabinet in either a horizontal or upright position.

(d) Tune in the next selected station having the next lowest station frequency, pressing the call letter for this station into the round cabinet depression nearest to the dial pointer needle—continuing on in this way until station call letters have been placed into all nine cabinet depressions.

After the station call letters are set it will be a simple matter to determine the approximate dial position of any of these stations—just rotate tuning knob until dial pointer needle points to station call letter of desired station. It must be remembered that only the approximate tuning location will be indicated by the dial pointer needle—each station must be correctly tuned in by **ROTATING THE TUNING CONTROL KNOB UNTIL A STATION IS TUNED IN WITH GREATEST CLARITY.**

**ALIGNMENT PROCEDURE:**

Lack of sensitivity, selectivity, or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, etc. Never attempt to re-tune set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE: BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING, OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT. THE TRIMMERS AND PADDING CONDENSERS WILL BE REFERRED TO BY THEIR FUNCTION AS INDICATED ON THE PARTS DIAGRAM.**

**IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.**

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

(a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead of the test oscillator to the grid cap of the 6A8G tube through a .02 Mfd. series condenser. **DO NOT REMOVE GRID CLIP.**

(b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.

(c) Peak each of the second I.F. transformer trimmers.

(d) Peak each of the first I.F. transformer trimmers.

To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**ALIGNING 1720-540 KILOCYCLE BAND:**

(a) Remove test oscillator lead from grid of 6A8G tube and attach it to the receiver antenna lead through a .00025 Mfd. series condenser.

(b) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.

(c) Set receiver dial and test oscillator frequency to EXACTLY 1720 kilocycles.

(d) Bring in 1720 KC test oscillator signal to maximum output by adjusting the trimmer condenser mounted on top of the oscillator section of the gang condenser. Looking at the front of the receiver the rear section of the gang condenser is the oscillator section.

(e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles.

(f) Adjust trimmer on top of the front section gang condenser (antenna section) for maximum 1400 kilocycle test signal response.

**SENTINEL-ERLA MODEL 107AE****ALIGNMENT PROCEDURE:**

Lack of sensitivity, selectivity, or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, etc. Never attempt to re-tune set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE: BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING, OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT. THE TRIMMERS AND PADDING CONDENSERS WILL BE REFERRED TO BY THEIR FUNCTION AS INDICATED ON THE PARTS DIAGRAM. IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.**

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

(a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead of the test oscillator to the grid cap of the 6A7 tube through a .02 Mfd. series condenser. **DO NOT REMOVE GRID CLIP.**

(b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.

(c) Peak each of the second I.F. transformer trimmers.

(d) To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**ALIGNING 1720-540 KILOCYCLE BAND:**

(a) Remove test oscillator lead from grid of the 6A7 tube and attach it to the receiver antenna lead through a .00025 Mfd. series condenser.

(b) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.

(c) **PLACE BAND SELECTOR SWITCH FOR 1720-540 K.C. OPERATION. PRESS IN MANUAL PUSH-BUTTON AND SET RECEIVER DIAL AND TEST OSCILLATOR FREQUENCY TO EXACTLY 1720 KILOCYCLES.**

(d) Bring in 1720 KC test oscillator signal to maximum output by adjusting the trimmer condenser mounted on top of the oscillator section of the gang condenser. Looking at the front of the receiver the rear section of the gang condenser is the oscillator section.

(e) Adjust trimmer on top of the front section gang condenser (antenna section) for maximum 1400 kilocycle test signal response.

(f) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles.

(g) Tune receiver dial and set test oscillator frequency to approximately 600 kilocycles.

(h) While rocking the tuning condenser back and forth adjust 600 KC oscillator padder condenser which is accessible through the hole in the top of chassis adjacent to the gang condenser for maximum 600 kilocycle signal response.

**ALIGNING 2.5-3.3 MEGACYCLE BAND:**

(a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor.

(b) Adjust band selector switch for 2.5-3.3 megacycle band operation, tune receiver dial and set test oscillator frequency to EXACTLY 633 megacycles.

(c) Bring in 6.3 megacycle test signal to maximum output by adjusting 6.3 M.C. oscillator trimmer.

(d) Tune receiver dial and set test oscillator frequency to EXACTLY 6 megacycles, and adjust 6 M.C. antenna trimmer for maximum sensitivity.

**MODEL 106A FOR TRIMMER LOCATIONS AND CHASSIS, SEE INDEX**

**THIS RADIO IS DESIGNED SO THAT IT MAY BE PLACED IN A HORIZONTAL OR UPRIGHT POSITION. AS THE OPERATION AND PERFORMANCE OF THE RECEIVER IS THE SAME IN EITHER POSITION, IT IS A MATTER OF PERSONAL PREFERENCE AS TO WHICH POSITION TO USE.**

The approximate position on the dial that any nine stations will be tuned in may be quickly determined—by pressing a paper tab having the station call letters into the round depressions on the front of the cabinet.

**THE STATIONS SELECTED MUST OPERATE ON A FREQUENCY 40 KILOCYCLES OR MORE APART. OTHERWISE IT WILL BE IMPOSSIBLE TO PLACE THE CALL LETTER TABS IN THEIR PROPER POSITION IN CABINET DEPRESSIONS.**

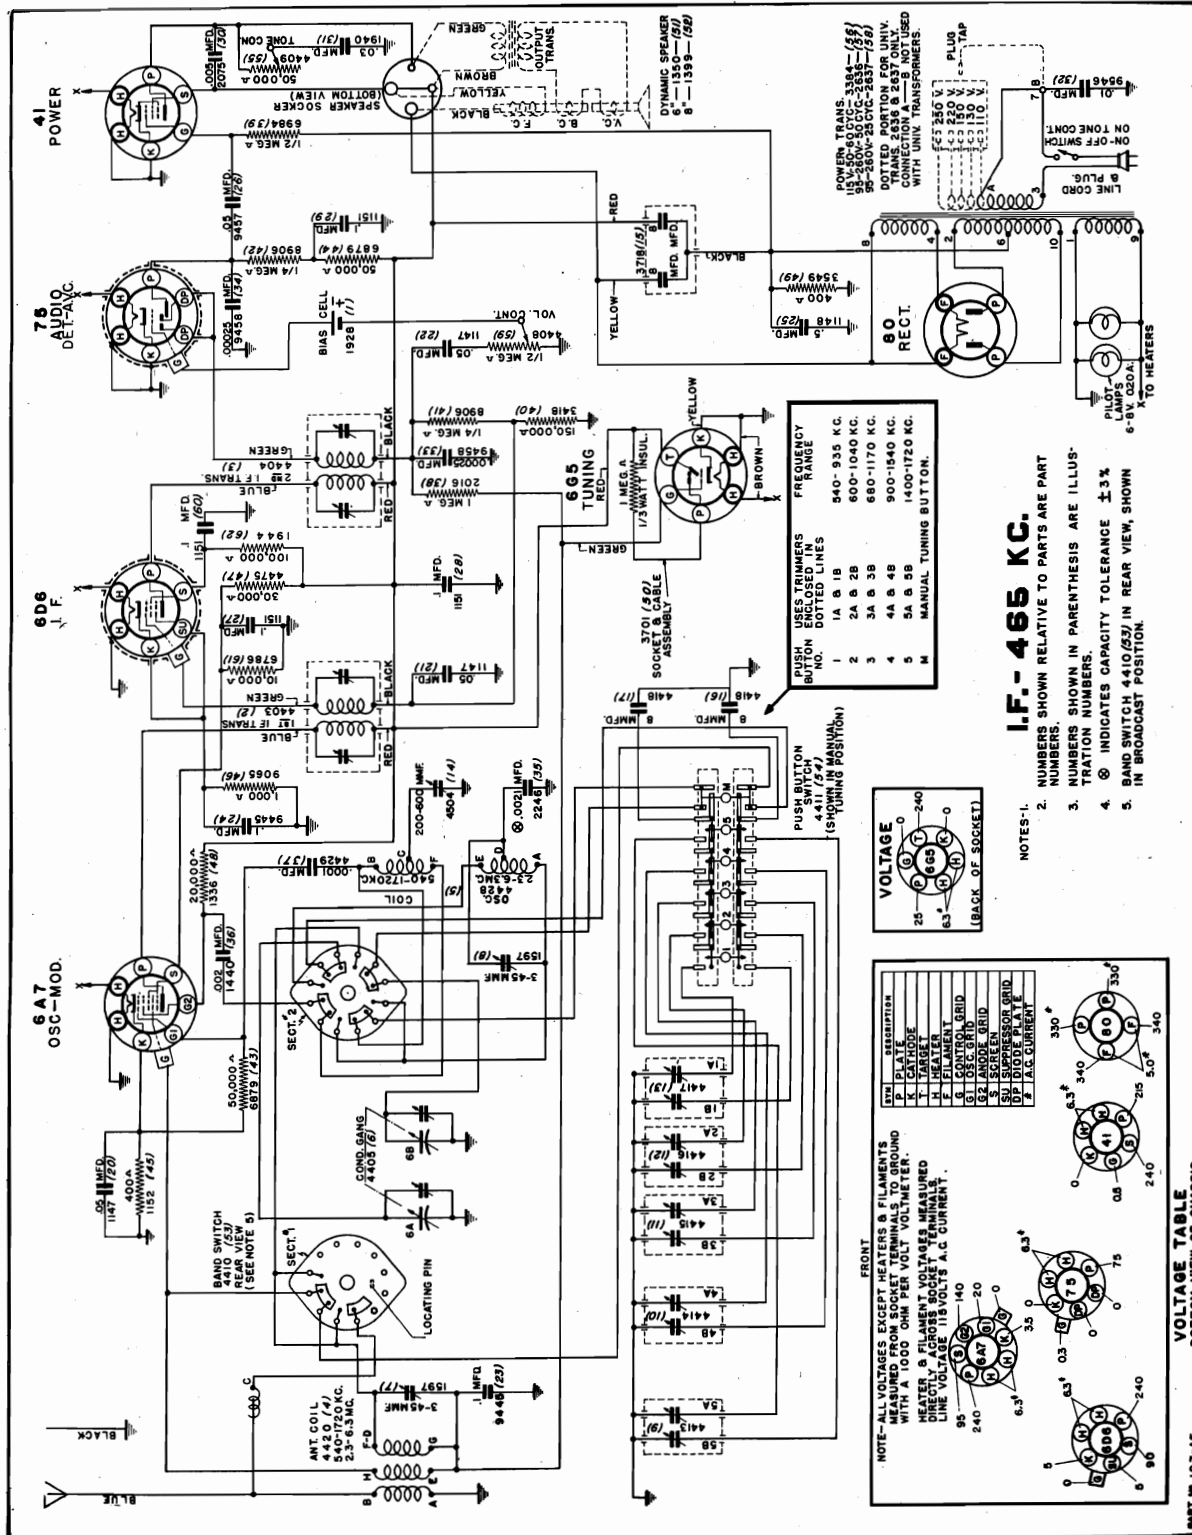

While it will be found that only the approximate location will be indicated, the station call tabs properly located will be an extremely helpful tuning aid.

To set the proper station call letter tabs into the cabinet depressions proceed as follows:

(a) Determine which nine stations call letters you wish to have on the cabinet—press call letter tabs out of the call letter sheets provided.

Sentinel Model 107AE

**INSTRUCTIONS FOR INSTALLING AND OPERATING "AUTOMATIC PUSH BUTTON"**

Five stations operating in the 1720-540 kilocycle broadcast band may be "AUTOMATIC PUSH-BUTTON" tuned by properly setting the ten trimmer screws accessible through holes in the back of the chassis.

AS THE PUSH BUTTONS ARE NOT PRE-SET AT THE FACTORY FOR ANY DEFINITE STATION BE SURE TO SET THEM BY:

- (a) It is important to have the serial, which is used with the set, attached to the radio when adjusting the trimmers.

(b) BE SURE TO OPERATE THE SET AT LEAST ONE-HALF HOUR BEFORE ADJUSTING TRIMMERS. If set is not thoroughly warmed up when trimmers are adjusted, the tuning eye will not show the maximum signal and excessive background noise.

(c) FOR BEST RESULTS SET PUSH-BUTTONS FOR LOCAL OR STRONG, NEARBY STATIONS ONLY. Obtain the transmitter frequency—number of kilocycles—and call letters of each station.

(d) Place band selector switch for operation on 1720-540 kilocycle band.

(e) Press in "MANUAL" tuning button—see diagram.

(f) It is advisable that if a station is selected whose transmitter frequency is between 540-835 K.C., on paper label attached to back of chassis be adjusted first.

(g) Using "MANUAL" tuning knob carefully tune in selected station whose transmitter frequency is between 540-985 kilocycles.

(h) Press in push-button marked "540-985 K.C."—see diagram. STATION SIGNAL WILL DISAPPEAR, OR MAY BE DISTORTED, AND IN SOME INSTANCES ANOTHER STATION MAY BE HEARD.

NOTE: STATION SIGNAL WILL NEVER BE TOO LOOSELY OR TOO TIGHTLY ADJUSTED IT IS IMPORTANT THAT THE PROPER TRIMMERS BE USED.

It may be noticed that the transmitter frequency—number of kilocycles—of a selected station falls within the range of more than one group of trimmers. Generally the transmitter frequency of the selected station will fall well within the minimum and maximum range of one set of trimmers—this is the right group of the other set of trimmers. For example, if a selected station transmitter frequency is 600 kilocycles it would be possible to use

In some instances it may be necessary after the set is operated for a period of time to reset the trimmers as they may drift due to heat, humidity, etc.

This diagram, which is similar to the one attached to the back of chassis over trimmer holes, shows the minimum-maximum range of the five groups of trimmers.

IMPORTANT: WHEN LISTENING TO STATIONS ON BROADCAST BAND, THE "MANUAL PUSH BUTTON" OR ONE OF THE OTHER "PUSH BUTTONS" MUST BE PUSHED IN OTHERWISE NO STATION WILL BE HEARD. DO NOT PRESS IN MORE THAN ONE "PUSH BUTTON" AT ONE TIME—IF MORE THAN ONE "PUSH BUTTON" IS PRESSED INWARD ONLY THE HIGHEST FREQUENCY STATION WILL BE HEARD.

Sentinel Model 145AE

**PUSH-BUTTON ADJUSTMENT**

Nine stations operating in the 1500-540 kilocycle band may be automatically push button tuned by properly setting each station selector push button. AS THE PUSH BUTTONS ARE NOT PRE-SET AT THE FACTORY FOR ANY DEFINITE STATIONS BE SURE TO SET EACH ONE.

**Before Attempting to Set Push Buttons Be Sure to:**

- (a) Have aerial which will be used with the radio attached to the receiver when setting push buttons.
- (b) Operate radio at least 15 minutes before adjusting push buttons.
- (c) Obtain transmitter frequency—number of kilocycles—and call letters of the nine stations you wish to push button tune from radio log or newspaper radio station list.

**Adjust Push Buttons for Selected Stations by:**

- (a) Rotate band switch knob to the NEXT TO MAXIMUM RIGHT HAND POSITION—540-1730 KILOCYCLE BAND MANUAL TUNING POSITION.
- (b) Using regular manual tuning knob carefully tune in one of the selected stations whose transmitter frequency is somewhere between 535-880 kilocycles. Make a mental note of the kind of program on this station, so that when push button is adjusted for this particular station (as instructed in paragraph (e)) it will be easy to recognize the station by the type of program being transmitted.
- (c) Rotate band switch knob to maximum right hand position.
- (d) Press in one of the three push buttons marked 535-880 kilocycles on diagram. NOTE: STATION MAY DISAPPEAR, BE DISTORTED OR IN SOME INSTANCES ANOTHER STATION MAY BE HEARD.
- (e) GRASP END OF PUSH BUTTON JUST PRESSED IN AND BY SLOWLY TURNING THIS BUTTON CAREFULLY TUNE IN THE SELECTED 535-880 KILOCYCLE STATION THAT WAS PREVIOUSLY TUNED IN WITH MANUAL CONTROL.
- (f) Watch tuning eye and listen for the wanted station in opposite direction. WATCH TUNING EYE AND LISTEN FOR THE TWO OPEN ENDS OF THE GREEN INVERTED "W" ON THE TUNING EYE ARE CLOSEST TOGETHER—ON WHICH POINT THE SIGNAL WILL BE HEARD WITH GREATEST VOLUME AND CLEAREST TONE.
- (g) Press station call letter of the station just tuned in out of call letter sheet supplied and insert into depression adjacent to push button just adjusted.
- (h) After the first 535-880 kilocycle push button has been properly set, the other eight push buttons should be adjusted in the same manner preferably in the following order:
  1. Set remaining two push buttons marked 535-880 kilocycles on diagram for any two stations operating between 535-880 kilocycles.
  2. The three push buttons marked 680-1170 kilocycles on diagram should be adjusted for any three selected stations operating between 680 and 1170 kilocycles.
  3. Adjust the three push buttons marked 880-1520 kilocycles on diagram for any three selected stations operating between 880 and 1520 kilocycles.

**IMPORTANT**

For Manual Tuning the Band Switch must be in next to maximum right hand position. When adjusting Push Buttons or when Push Button tuning after Push Buttons have been set, Band Switch must be in maximum right hand position.

Alignment

SENTINEL RADIO CORP.

- (e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles. Adjust 1400 K.C. R.F. and antenna trimmers for maximum sensitivity.
- (f) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rooking gang condenser slightly to right and left, adjust 600 K.C. oscillator padder for maximum signal response.

**ALIGNING 1.68-5.6 MEGACYCLE BAND:**

- (a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor.
- (b) Adjust band selector switch to 1.68-5.6 megacycles, tune receiver dial and set test oscillator frequency to EXACTLY 5.6 megacycles. Bring in 5.6 megacycle test signal to maximum output by adjusting 5.6 M.C. oscillator trimmer.
- (c) Tune receiver dial and test oscillator frequency to EXACTLY 5 Megacycles and adjust 5 M.C. antenna trimmer for maximum sensitivity.

**ALIGNING 5.55-18.5 MEGACYCLE BAND:**

- (a) Leave 400 ohm resistor in series with test oscillator lead and place band selector switch for operation on 5.55-18.5 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 18.5 megacycles.
- (b) Adjust 18.5 M.C. oscillator trimmer to bring in 18.5 megacycle test signal to maximum output.

**NOTE:** When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.5 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the FIRST peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.5 megacycles, always check to see if the proper peak has been used. To do this leave test oscillator frequency at 18.5 megacycles, increase the output of the test oscillator and tune receiver dial to approximately 17.5 megacycles. Then vary the receiver dial slightly to the right and left of 17.5 megacycles, and if the fundamental peak was used in aligning at 18.5 megacycles the test oscillator signal will be heard at approximately 17.5 megacycles on the receiver dial.

- (c) Tune receiver dial and set test oscillator frequency to EXACTLY 15 megacycles. Rock gang condenser alighly to right and left and adjust 15 M.C. antenna trimmer for maximum 15 megacycle test signal response.

To assure more accurate trimmer setting, repeat all above adjustments several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

- (c) Turn receiver on, place A.F.C. switch knob in left position and if meter needle jumps off scale adjust output of test oscillator until an approximate 2 M.A. deflection is obtained on the 0 to 5 milliammeter scale.
- (d) Place band selector switch for operation on 1720-540 K.C. broadcast band—and set receiver dial somewhere near 1000 kilocycles at a point where no station is heard.

- (e) Rotate A.F.C. switch knob from maximum left hand to middle position and note whether the milliammeter reading changes as the position of the A.F.C. switch is changed. No change in reading indicates probable proper discriminator trimmer adjustment, while a noticeable change indicates improper discriminator trimmer adjustment.
- (f) **IMPORTANT: DO NOT ADJUST DISCRIMINATOR TRIMMER UNLESS IT IS ABSOLUTELY NECESSARY.** Place A.F.C. switch in middle position and note milliammeter reading. Then place A.F.C. switch in maximum left hand position. With A.F.C. switch in maximum left hand position, CAREFULLY ADJUST DISCRIMINATOR TRIMMER UNTIL MILLIAMMETER READING IS EXACTLY THE SAME IN BOTH POSITIONS.

**NOTE:** As the discriminator trimmer screw is screwed in (increasing capacity) the milliammeter reading should decrease and as the discriminator trimmer is unscrewed (decreasing capacity) the milliammeter reading should increase. IF WHEN ADJUSTING THE DISCRIMINATOR TRIMMER THE MILLIAMMETER READING DOES NOT SHARPLY INCREASE OR DECREASE AS THE TRIMMER IS ADJUSTED EVEN AFTER SEVERAL TURNS OF THE TRIMMER SCREW, THIS DOES NOT INDICATE PROPER BALANCING BUT DOES INDICATE INCORRECT ADJUSTMENT AND THE DISCRIMINATOR TRIMMER SHOULD BE SET TO ABOUT 1/2 CAPACITY AND THE ADJUSTMENT OF THE DISCRIMINATOR TRIMMER MADE ALL OVER AGAIN.

**ALIGNING 1720-540 KILOCYCLE BAND:**

- (a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line, move needle to correct position.
- (b) Remove test oscillator lead from grid of 6A8 tube and connect to receiver "A" antenna post through a .00025 Mfd. condenser.
- (c) Place A.F.C. control knob in middle A.F.C. "off" position. Adjust band selector switch for operation on the 1720-540 kilocycle band.

- (d) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles, and BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.

**VOLTAGE-TABLE**

**BOTTOM VIEW OF CHASSIS**

**ALIGNMENT PROCEDURE:**

SHOULD REALIGNMENT BE NECESSARY, THERE ARE SEVERAL PRECAUTIONS THAT MUST BE CAREFULLY OBSERVED, THESE ARE:

1. Do not align set until it has reached normal operating temperature. Place the receiver in operation at least 15 minutes before attempting to realign the set.
2. The importance of using the proper type of test equipment and FOLLOWING THE ALIGNMENT PROCEDURE EXACTLY AS GIVEN CANNOT BE TOO STRONGLY EMPHASIZED—failure to do so will result in low sensitivity, poor selectivity, incorrect dial calibration, distortion and unsatisfactory operation of the automatic frequency control.
3. It is absolutely necessary that an accurately calibrated test oscillator with some type of output measuring device and a double scale milliammeter—0 to 1 M. A. and 0 to 5 M.A. be used.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

- (a) Place automatic frequency control knob in the middle A.F.C. "off" position.
- (b) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid cap of the 6A8 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.
- (c) Set test oscillator to EXACTLY 465 kilocycles and turn volume control on full.

- (d) Remove shields held in position by snap fasteners over A.F.C. test jack and over trimmer screw holes in the first and second I.F. transformer shield cans.
- (e) Peak second I.F. transformer trimmers for maximum 465 kilocycle output by adjusting the two trimmers accessible through the two top holes in the second I.F. transformer shield can. DO NOT TOUCH DISCRIMINATOR (BOTTOM) SCREW.
- (f) Peak each of the first I.F. transformer trimmers for maximum 465 kilocycle signal output.

**ALIGNING DISCRIMINATOR CIRCUIT:**

- (a) Place switch underneath push button plate assembly (above gang condenser) in A.F.C. "on" position. Leave test oscillator set to EXACTLY 465 KILOCYCLES and connect to grid of 6A8 tube through a .02 Mfd. Condenser—insert lead of double scale 0 to 1 and 0 to 5 milliammeter into A.F.C. test jack located on top of chassis adjacent to the one of the milliammeter leads short to the metal chassis. ALWAYS TURN OFF RECEIVER WHEN INSERTING OR REMOVING MILLIAMMETER LEADS FROM A.F.C. TEST JACK.

- (b) Short out A.F.C. mute switch by grounding the second from the left (looking at the front of the chassis) of the four lugs mounted on top of the dial assembly. The proper lug to ground is indicated in the "Note X" on chassis top parts view.

ALIGNMENT PROCEDURE IN TABULATED FORM

Be sure to follow procedure carefully and in the order given—otherwise the receiver will be insensitive and the dial calibration incorrect. For alignment procedure read tabulations from left to right. If more than one adjustment is required on any one band, make the adjustment marked (1) first, (2) next, (3) third.  
Before starting alignment:  
(a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If dial needle does not point exactly to last line move needle to correct position.  
(b) Use an accurately calibrated test oscillator with some type of output measuring device.  
(c) Use a ground lead of test oscillator attached to chassis.  
(d) Press in manual tuning button.

Refer to parts layout diagram for location of trimmers mentioned below.

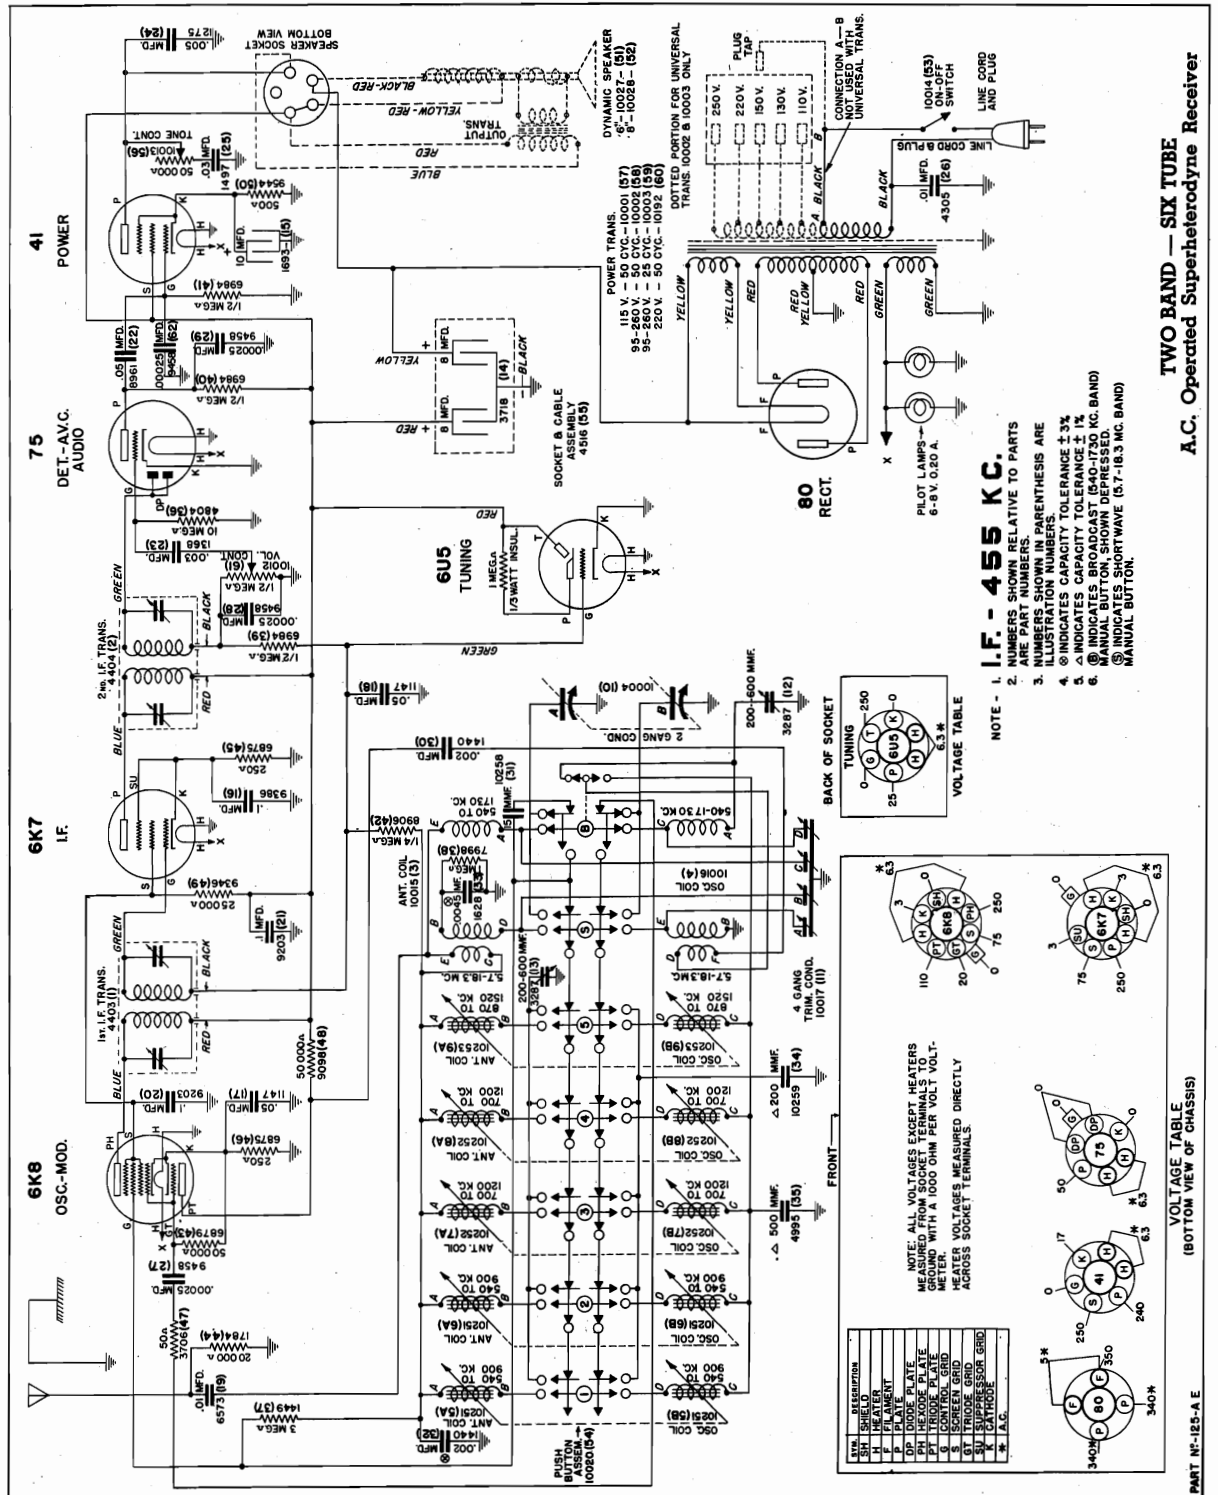

Set receiver dial to:	Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below:
Any point where no interfering signal is received	455 K. C.	.02 MFD. Condenser	High side to grid terminal of 6A8G tube. DO NOT REMOVE CAP.	Adjust each of the second I. F. transformer trimmers for maximum output—then adjust each of the first I. F. trimmers for maximum output.
(1) Exactly 1730 K. C.	Exactly 1730 K. C.	.00025 MFD. condenser	Receiver blue antenna lead	Adjust 1730 K. C. oscillator trimmer for maximum output.
(2) Exactly 1400 K. C.	Approx. 1400 K. C.	.00025 MFD. condenser	Receiver blue antenna lead	Adjust 1400 K. C. antenna trimmer for maximum output.
(3) Approx. 600 K. C.	Approx. 600 K. C.	.00025 Mfd. condenser	Receiver blue antenna lead	While rocking gang condenser adjust 600 K.C. oscillator padder for maximum response.

**NOTE:** 870 K.C. oscillator trimmer need be adjusted only if 870-1520 K.C. Push Button does not tune from 870 to 1520 K.C. If necessary to adjust, proceed by set antenna and ground leads.  
(a) Attach test oscillator to set antenna and ground leads.  
(b) Set test oscillator to exactly 850 K.C.—with attenuator adjusted for maximum signal output.  
(c) Press in 870-1520 K.C. push button.  
(d) Adjust 870-1520 K.C. oscillator push button to bring in 850 K.C. test signal to maximum output & leave in this position.  
(e) Reset test oscillator frequency to exactly 870 K.C.  
(f) Adjust 870 K.C. oscillator trimmer to bring in 870 K.C. test oscillator signal to maximum output.

Place band switch for operation on:	Set receiver dial to:	Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below:
I.F. alignment use any band position	Any point where no interfering signal is received	Exactly 455 K.C.	.02 Mfd. condenser	High side to grid cap of 6K5 tube. Do not remove cap.	Adjust each of the second I.F. transformer trimmers for maximum output—then adjust each of the first I.F. transformer trimmers for maximum output.
1750 to 540 K.C. Band	(1) Exactly 1730 K.C. (2) Exactly 1400 K.C. (3) Approx. 600 K.C.	Exactly 1730 K.C. Exactly 1400 K.C. Approx. 600 K.C.	.00025 Mfd. condenser .00025 Mfd. condenser .00025 Mfd. condenser	Receiver blue antenna lead Receiver blue antenna lead Receiver blue antenna lead	Adjust 1730 K.C. oscillator trimmer for maximum output. While rocking gang condenser adjust 1400 K.C. antenna trimmer for maximum output. While rocking gang condenser adjust 600 K.C. oscillator padder for maximum output.
5.7 to .18.3 M.C. Band	(1) Exactly 18.3 M.C. (2) Exactly 15 M.C.	Exactly 18.3 M.C. Exactly 15 M.C.	400 Ohm carbon resistor 400 Ohm carbon resistor	Receiver blue antenna lead Receiver blue antenna lead	Adjust 18.3 M.C. oscillator trimmer for maximum output—be sure to use proper peak. If more than one peak is noticed, back off trimmer to minimum capacity, then screw down trimmer (add capacity) until the second peak—which is the proper one to use—is tuned in. While rocking gang condenser adjust 15 M.C. antenna trimmer for maximum output.

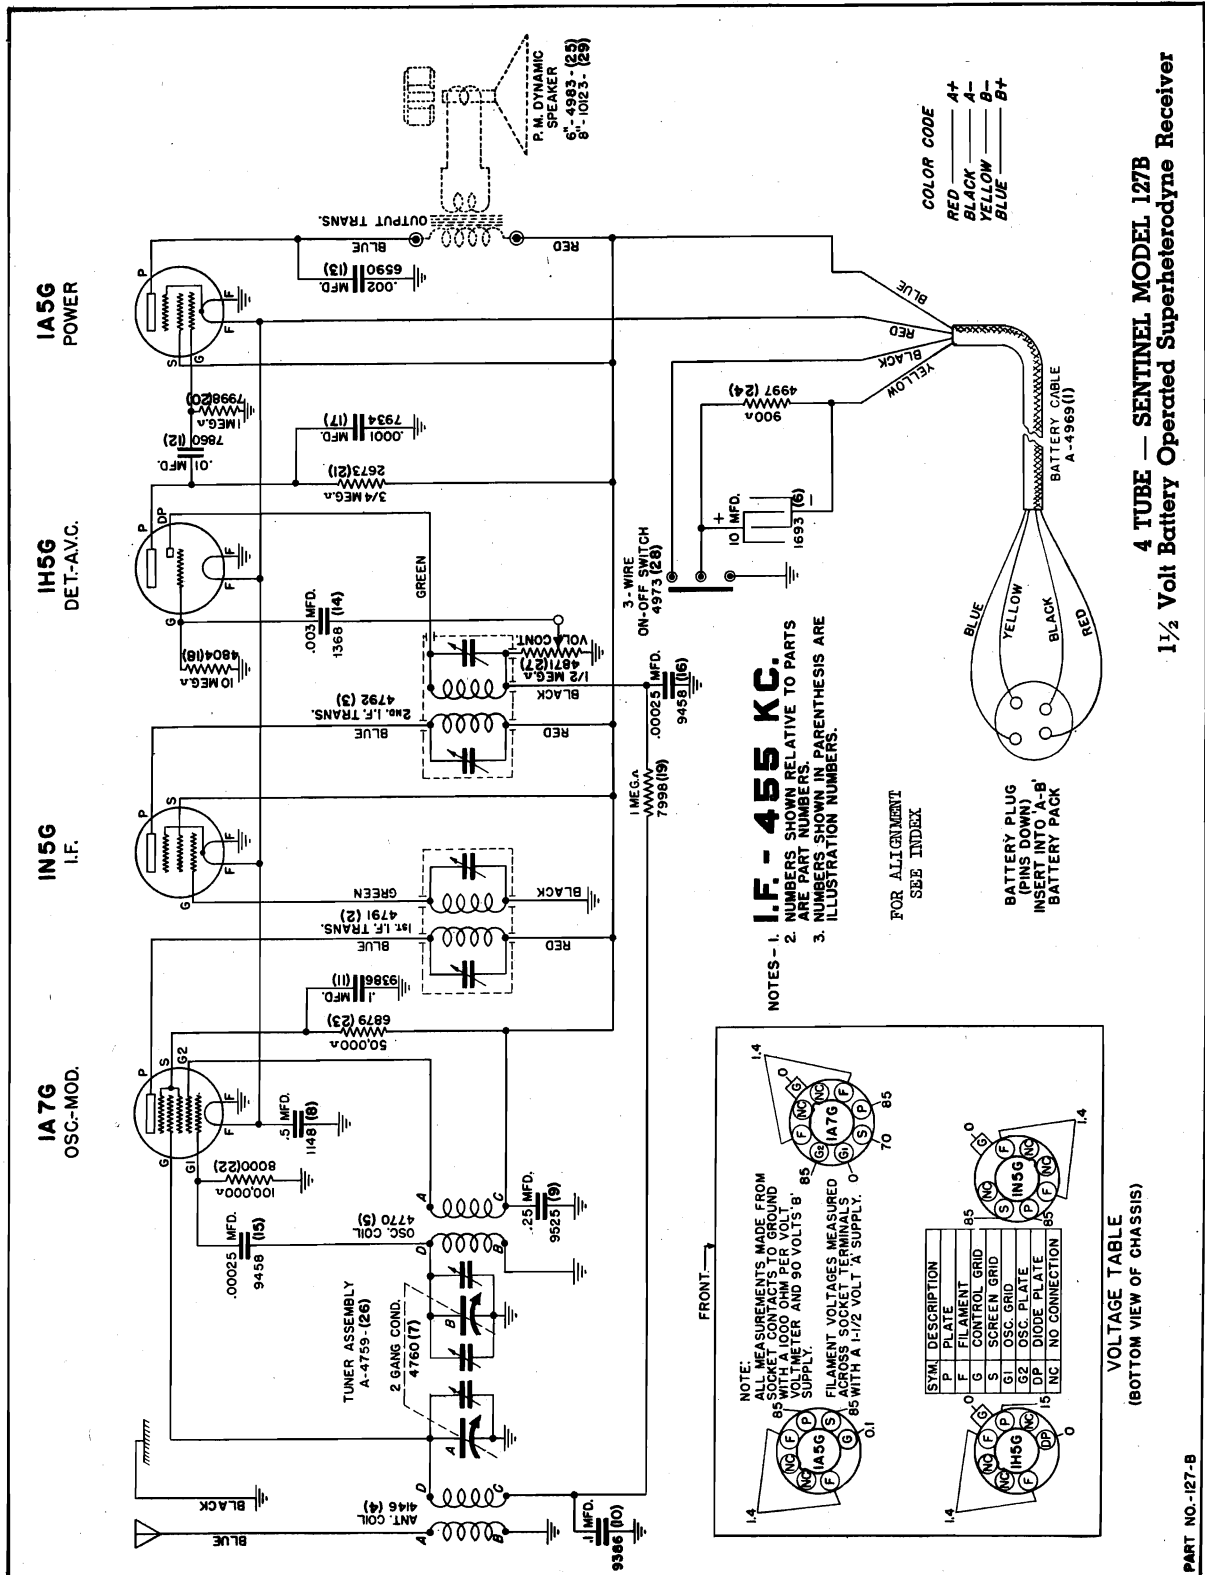

**NOTE: (125AE ONLY)**  
1100 K.C. antenna padder for 870-1520 K.C. (No. 5) pushbutton need be adjusted only if there is an appreciable change in volume when same station is push button and manual tuned. Should there be a great difference adjust 1100 K.C. antenna padder by:  
(a) Attach test oscillator to set antenna and ground leads with .00025 dummy ant. load.  
(b) Screw any two push buttons—except 870-1520 K.C. (No. 5) push button—all the way in—and the other two push buttons all the way out.  
(c) Set test oscillator to exactly 1100 K.C.  
(d) Press in 870-1520 K.C. push button and adjust this button for maximum test signal response.  
(e) Next adjust 1100 K.C. antenna padder for maximum 1100 K.C. test oscillator signal response.

Alignment

**ALIGNMENT PROCEDURE IN TABULATED FORM**

Be sure to follow procedure carefully and in the order given—otherwise the receiver will be insensitive and the dial calibration incorrect. For alignment procedure read tabulations from left to right. If more than one adjustment is required on any one band, make the adjustment marked (1) first, (2) next, (3) third.

Before starting alignment:

(a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If dial needle does not point exactly to last line move to correct position.

(b) Use an accurately calibrated test oscillator with some type of output measuring device.

(c) Have ground lead of test oscillator attached to chassis.

TEST OSCILLATOR		Refer to parts layout diagram for location of trimmers mentioned below:
Set receiver dial to:	Adjust test oscillator frequency to:	
I.F. Any point where no interfering signal is received	455 K. C.	Adjust each of the second I. F. transformer trimmers for maximum output—then adjust each of the first I. F. trimmers for maximum output.
1 Exactly 1730 K. C. 2 Exactly 1400 K. C.	Exactly 1730 K. C.	Adjust 1730 K. C. oscillator trimmer for maximum output.
	Exactly 1400 K. C.	While rocking gang condenser adjust 1400 K. C. antenna trimmer for maximum output.
	.02 MFD condenser	High side to * grid terminal of 6A7 tube DO NOT REMOVE CAP.

ALIGNMENT PROCEDURE  
SEE INDEX.

**ALIGNMENT PROCEDURE IN TABULATED FORM**

Before starting alignment, check tuning dial adjustment by: turn gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial indicator must be exactly even with the last line at the low frequency end of the dial calibration. If dial needle does not point exactly to last line move needle to correct position.  
Use an accurately calibrated test oscillator with some type of output measuring device.

**MODEL 163UL**

BEFORE ALIGNING, PLACE LOOP ANTENNA AND THE "A" AND "B" BATTERIES IN THE SAME APPROXIMATE POSITION IN THE BACK OF CHASSIS THAT THEY WILL BE IN WHEN THE SET IS IN THE CABINET AND THE CABINET BACK CLOSED. When adjusting 1650 kilocycle oscillator trimmer and 1400 kilocycle antenna trimmer, place test oscillator in series with set loop by:

1. Remove the black with white tracer wire used to connect loop antenna to Fohensstock clip on chassis.
2. Attach test oscillator to terminals marked "A" and "B" on points layout diagram.

**IMPORTANT**—No condenser should be in series with generator leads.

TEST OSCILLATOR		Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below—and:
Set receiver dial to:	I. F. Any point where no interfering signal is received	.02 MFD condenser	High side to grid terminal of 1A7G tube Low side to chassis DO NOT REMOVE CAP.	Adjust each of the second I. F. transformer trimmers for maximum output—then adjust each of the first I. F. trimmers for maximum output.
(1) Exactly 1650 K. C.	Exactly 1650 K. C.	None	Attach in series with "A" and "B" Loop terminals	Adjust 1650 K. C. oscillator trimmer for maximum output.
(2) Approx. 1400 K. C.	Exactly 1400 K. C.	None	Attach in series with "A" and "B" Loop terminals	Adjust 1400 K. C. antenna trimmer for maximum output.

**MODEL 178BL**

**IMPORTANT**, BEFORE ALIGNING, PLACE LOOP ANTENNA IN THE SAME APPROXIMATE POSITION IN THE BACK OF CHASSIS IT WILL BE IN WHEN THE SET IS IN THE CABINET AND THE BACK ATTACHED.

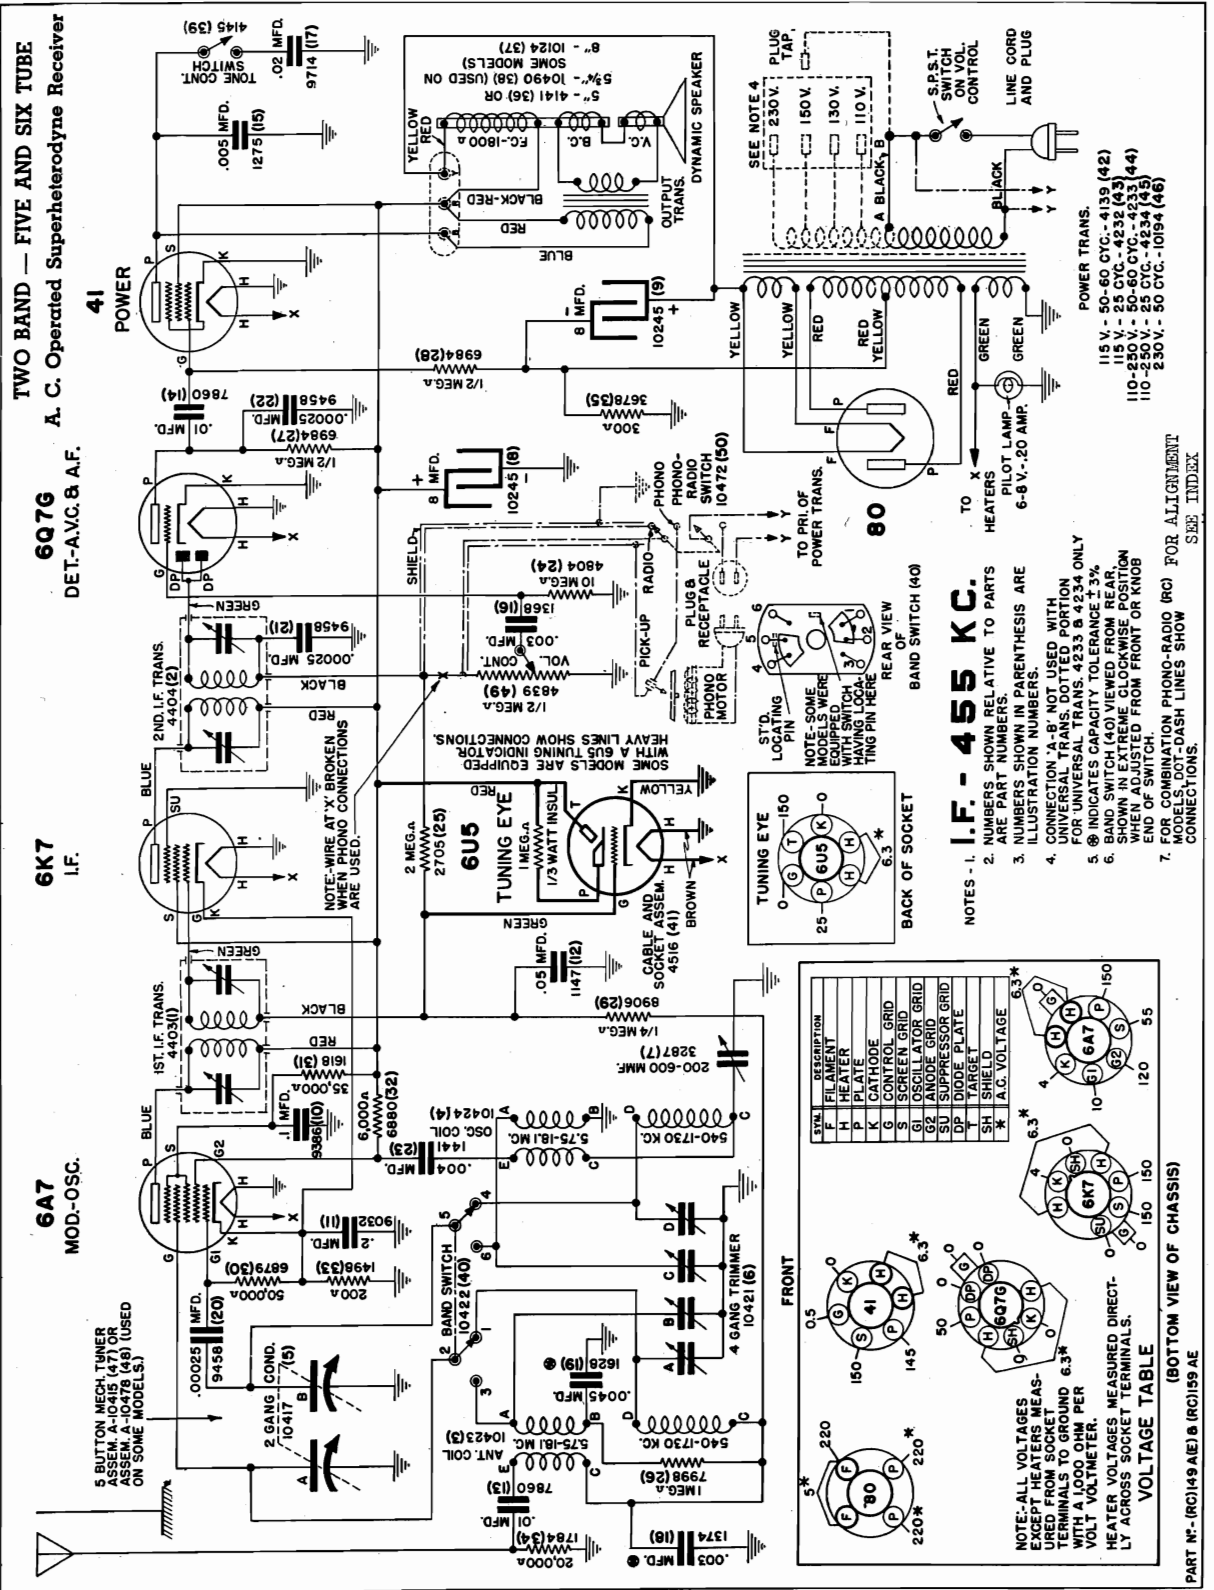

When adjusting 1650 K.C. oscillator trimmer and 1400 K.C. antenna trimmer, couple test oscillator to set loop by placing lead from high side of test oscillator on top of or near set loop. Be sure that neither the loop or test oscillator lead moves during alignment.

**DO NOT ATTACH LOW SIDE OF TEST OSCILLATOR TO RECEIVER—LEAVE UNCONNECTED.**

TEST OSCILLATOR		Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below—and:
Set receiver dial to:	I. F. Any point where no interfering signal is received	.02 MFD condenser	High side to grid terminal of 6A7 tube DO NOT REMOVE CAP. Lay lead on top of or close to loop	Adjust each of the second I. F. transformer trimmers for maximum output—then adjust each of the first I. F. trimmers for maximum output.
(1) Exactly 1650 K. C.	Exactly 1650 K. C.	None	Lay lead on top of or close to loop	Adjust .1650 K. C. oscillator trimmer for maximum output.
(2) Approx. 1400 K. C.	Exactly 1400 K. C.	None	Lay lead on top of or close to loop	Adjust 1400 K. C. antenna trimmer for maximum output.

Sentinel Model 128B

Be sure to follow procedure carefully and in the order given—otherwise the receiver will be insensitive and the dial calibration incorrect. For alignment procedure read tabulations from left to right. If more than one adjustment is required on any one band, make the adjustment marked (1) first, (2) next, (3) third.  
Before starting alignment:  
(a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh) at which point the dial indicator must be exactly even with the line at the low frequency end of the dial calibration. If dial needle does not point exactly to last line move needle to correct position.  
(b) Use an accurately calibrated test oscillator with some type of output measuring device.  
(c) Have ground lead of test oscillator attached to chassis.

Place band switch for operation on:	Set receiver dial to:	Adjust test oscillator frequency to:	Use dummy antenna in series with output of test oscillator consisting of:	Attach output of test oscillator to:	Refer to parts layout diagram for location of trimmers mentioned below add:
I. F. ALIGNMENT use any band position	Any point where no interfering signal is received	Exactly 455 K.C.	.02 Mfd. condenser	High side to grid cap of 6K7 tube Do not remove cap.	Adjust each of the second I.F. transformer trimmers for maximum output—then adjust each of the first I.F. transformer trimmers for maximum output.
	1730 TO 540 K.C. BAND	Exactly 1400 K.C. Approx. 1400 K.C. Approximately 600 K.C.	.00025 Mfd. condenser .00025 Mfd. condenser .00025 Mfd. condenser	Receiver blue antenna lead Receiver blue antenna lead Receiver blue antenna lead	Adjust 1730 K.C. oscillator trimmer for maximum output. Adjust 1400 K.C. antenna trimmer for maximum output. While rocking gang condenser adjust 600 K.C. oscillator pad for maximum output.
	5.7 TO 18.1 M.C. BAND	Exactly 18.1 M.C. Approx. 15 M.C.	400 Ohm carbon resistor 400 Ohm carbon resistor	Receiver blue antenna lead Receiver blue antenna lead	Adjust 18.1 M.C. oscillator trimmer for maximum output—be sure to use proper peak. If more than one peak is noticed, then screw down trimmer (add capacity) until the second peak—which is the proper one—is the highest. Adjust 15 M.C. antenna trimmer for maximum output.

Adjustments, Changes

SPARTON PHONO-SET MODEL 219-P AND 219-PD.

TOP VIEWS OF ALL SOCKET CONNECTIONS

NOTE: Original production models did not have resistor R6 and condenser C10 included in the circuit as shown above. In these first run production sets resistor R1 connected across the microphone tip jacks in the same position as shown for resistor R6. The above change can be made easily, when servicing any of the first run Models 219-P Wireless Phonographs.

The SPARTON Wireless Phonograph Models 219-P and 219-PD are shipped from the factory for operation at approximately 1550 kilocycles.

This frequency may be changed by adjusting a trimmer condenser which is reached through the hole in the bottom of the chassis. An insulated shaft screwdriver should be used. Turning the screw clockwise lowers the frequency and turning the screw counter-clockwise increases the frequency. The normal range of adjustment is from approximately 1200 kilocycles to approximately 1700 kilocycles.

MODELS 527-2, 587-2

Alignment

MODELS 637-6, 687-6

Alignment, Socket, Trimmers

for 15,000 kilocycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore, a signal of this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

Note: There are no other trimmers for the short-wave or foreign band.

Important: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

\* MODELS 637-6 & 687-6  
\*\* MODELS 527-2 & 587-2

Note: This condenser is the adjustment for the code rejector circuit and must be very carefully adjusted if best performance of the receiver is to be expected.

**B. Alignment of Broadcast Band**

1. Connect 150 mmf. dummy antenna in series with the antenna lead, tune test oscillator and receiver to a frequency of 1500 kilocycles and adjust condensers C4 (broadcast band oscillator trimmer) and C3\* (broadcast antenna trimmer) reached from the bottom of the chassis. \*C2 in Models 527-2, 587-2
2. Tune test oscillator and receiver to 600 kilocycles and adjust condenser C5 (broadcast oscillator padder) reached from the front of the chassis.
3. Retune test oscillator and receiver to 1500 kilocycles and check adjustments of condenser C4 and condenser C3\*. Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles. \*C2 in Models 527-2, 587-2

**C. Alignment of Short-Wave Band**

1. Turn the band selector switch to the short wave or "foreign" band.
2. Remove the 150 mmf. condenser from the test oscillator "antenna" lead and replace with a 400 ohm non-inductive resistor dummy antenna.
3. Tune test oscillator and receiver to a frequency of 15,000 kilocycles (15 megacycles) and adjust condenser C2\* (short-wave antenna trimmer) reached from the bottom of the chassis. \*C3 in Models 527-2, 587-2.

Caution: On this band care must be taken to adjust this condenser to the fundamental of the 15 megacycle signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver.

A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condenser for that band has probably been adjusted to the image instead of to the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector of the receiver to approximately 15,900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency

Note: For proper alignment of these chasses, the procedure should be followed in the same order as given.

The dial pointer should be exactly parallel with the horizontal line of the dial scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the two small set screws directly back of the diffusion disc and dial drum, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screws.

IMPORTANT: Alignment of these models should not be attempted unless the voltage is maintained by a fully charged 6-volt storage battery.

**A. Alignment of Intermediate-Frequency Stages**

1. Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.
2. Turn the band selector switch to the broadcast position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.
3. Connect "antenna" of test oscillator to grid cap of Type 1C7G converter tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 1E7G tube to ground.

Note: It is advisable to read carefully the operating instructions included with the test oscillator being used in the alignment procedure.

4. Tune test oscillator to obtain a signal of 456 kilocycles.
5. Turn the volume control of receiver on full and adjust I-F condensers which are reached from the top of the chassis.

Note: Care should be taken when adjusting the I-F stages in order to insure proper and accurate adjustment.

6. Disconnect "antenna" lead of test oscillator from grid cap of converter tube Type 1E7G and connect to the antenna terminal of the chassis.
7. Tune test oscillator to a frequency of 456 kilocycles and adjust condenser C34\* (reached from back of the chassis) to a point where the output of the receiver is at an absolute minimum. \*C7 in Models 527-2, 587-2

MODEL 1568 MODEL 8618  
Selectronne Tuner  
Trimmers, Adjustments

7. When all trimmers have been properly adjusted, replace socket tube and sockets in clamp, replace type 6BG6 Discriminator tube in clamp, Selectronne escutcheon plate to front of cabinet.

8. Any of the six stations to which the SPARTON Selectronne has been adjusted, may not be instantly received simply by pushing the Selectronne button for the desired station with the Band Switch knob pushed in that is, in the automatic position.

NOTE: In case all six of the stations should be received, simply reach into the Selectronne box (from the back of the cabinet) through the side next to the Visc-Glo, and apply a slight pressure of the fingers under the latching bar which runs across the frame work in front of the trimmer box. This will immediately release all buttons.

NOTE: In case all six of the stations should be received, simply reach into the Selectronne box (from the back of the cabinet) through the side next to the Visc-Glo, and apply a slight pressure of the fingers under the latching bar which runs across the frame work in front of the trimmer box. This will immediately release all buttons.

Unless the 6BG6 Discriminator tube is removed when the Selectronne is adjusted, automatic frequency control will prevent correct trimmer adjustment of stations may occur. With the 6BG6 Discriminator tube left in the socket, automatic frequency control action will bring in the station and close the Visc-Glo before the trimmers have been completely adjusted.

Always check the discriminator circuit to see if it is in proper adjustment and adjust it if necessary before adjusting the Selectronne.

TO ADJUST THE DISCRIMINATOR CIRCUIT, it is necessary to remove the 6BG6 Discriminator tube from its socket. Turn the automatic frequency control (A.F.C.) knob to the "OFF" position. Tune in manually a strong station which will nearly close the Visc-Glo. Turn the A.F.C. knob to the "ON" position. Adjust the A.F.C. screw driver (back of cabinet) until the Visc-Glo closes. The Visc-Glo should show the same position. If there is any variation in the Visc-Glo, it is an indication that the Discriminator circuit is out of adjustment and must be adjusted before any attempt is made to adjust any station on the Selectronne.

IMPORTANT: The Type 6BG6 Discriminator tube must be in its socket when adjusting the discriminator circuit, and out of its socket when adjusting the Selectronne trimmers.

TO ADJUST THE DISCRIMINATOR CIRCUIT, it is necessary to remove the 6BG6 Discriminator tube from its socket. Turn the automatic frequency control (A.F.C.) knob to the "OFF" position. Tune in manually a strong station which will nearly close the Visc-Glo. Turn the A.F.C. knob to the "ON" position. Adjust the A.F.C. screw driver (back of cabinet) until the Visc-Glo closes. The Visc-Glo should show the same position. If it does not, adjust more accurately.

CAUTION - The blade of the screw driver positively must be an insulated (bakelite) one.

WARNING - Do not attempt to adjust the other trimmers. Only adjust the one shown in the diagram as "Discriminator Trimmer".

JUNE 1958

(A) Three trimmers are provided for each one of the six stations. They are reached through the three holes arranged in rows one above the other in the back cover of the Selectronne.

(B) Tune in the station in the usual way using the band switch knob, watching the Visc-Glo so that the station will be perfectly "tuned in".

(C) Push in the band selector switch knob. This will extinguish the dial lights and illuminate the Selectronne Indicator, showing that the Selectronne is now connected.

(D) Turn the band selector switch knob to the extreme left (counter-clockwise) to the automatic (Selectronne) position.

(E) Push in the Selectronne button which corresponds to the station just tuned in.

(F) Now from the back of the cabinet, with an ordinary screw-driver adjust the oscillator trimmer (center hole) in the row corresponding to the proper station, until the same station that was tuned in manually is heard. This station may be heard faintly until the remaining trimmers have been adjusted.

It is important that the same station is heard with this adjustment and not some other nearby station. Turn the trimmer to the right or left until the station is loudest.

Care should be taken in turning the adjusting screws so that they will not become disengaged from the trimmers by being turned out too far.

(G) In the same manner adjust first the R.F. trimmer (bottom hole) and then the antenna trimmer (top hole) to this same station.

NOTE: Perfect adjustment of these trimmers is easily obtained by removing the Visc-Glo tube and socket from its clamp and turning the tube toward the back of the cabinet so that every adjustment of the trimmers may be watched in the Visc-Glo. Perfect adjustment is obtained when further turning of the trimmers will not result in any smaller shaded area between the green light sections of the Visc-Glo.

(H) In the same manner adjust to this same station.

NOTE: No Visc-Glo tube is supplied with this model. However, the chassis is wired for, and furnished with, a Visc-Glo at the back of the chassis. For tuning the station, the Visc-Glo will be more easily observed if an extension cable socket (or right-angle adapter) is used when making tuning adjustments.

(I) Re-adjust the oscillator trimmer (bottom hole) while watching the Visc-Glo to see if the shaded area can be made smaller.

(J) Re-adjust the antenna trimmer (top hole) while watching the Visc-Glo to see if the shaded area can be made smaller.

(K) Check the above adjustments by pulling the band switch knob out and without touching the manual tuning controls, observe if the Visc-Glo shows any difference in the amount of shaded area in the tubes compared to the shaded area with the band switch pushed in. If the shaded area is larger with the band switch pushed in, readjust the Selectronne trimmers until the shaded area is equal to that obtained with the Band Switch knob pulled out.

6. Repeat the procedure in paragraph 5 for each of the six stations.

For example: A station having a frequency of 610 kc. should be placed in the 540 to 800 kc. group; a station at 950 should be placed in the 700 to 1500 kc. group, etc.

The six buttons of the Selectronne are arranged in three groups according to frequency limits - 540 to 750 kc., 700 to 1250 kc. and 1100 to 1500 kc. (See illustration also back cover of Selectronne box). The six tabs corresponding to the six broadcast stations which have been chosen must be placed in the proper slots so that the frequency (kilocycle) of each station will be included in the frequency limits of the proper group.

NOTE: For example a station having a frequency of 610 kc. should be placed in the 540 to 750 kc. group; a station at 950 should be placed in the 700 to 1500 kc. group, etc.

Note: Each group has considerable overlap to allow for the selection of six stations which may have frequency allocations comparatively close together.

4. Remove type 6BG6 tube (Discriminator) from chassis (see illustration).

5. Adjust Selectronne trimmers for each one of the six stations as follows:

HOW TO ADJUST THE SPARTON SELECTRONNE  
MODELS 1068, 1268, 1568 ETC. AND 8618.  
NOTE: Each paragraph refers to all Models unless otherwise indicated.

Unless the 6BG6 Discriminator tube is removed when the Selectronne is adjusted, automatic frequency control will prevent correct trimmer adjustments, with the result that unsatisfactory reception of stations may occur. With the 6BG6 Discriminator tube left in the socket, automatic frequency control action will bring in the station and close the Visc-Glo before the trimmers have been completely adjusted.

2. Remove the Selectronne escutcheon plate from the front of the cabinet by means of the two screws. This exposes the steel plate with the slots for holding the station call letter tabs.

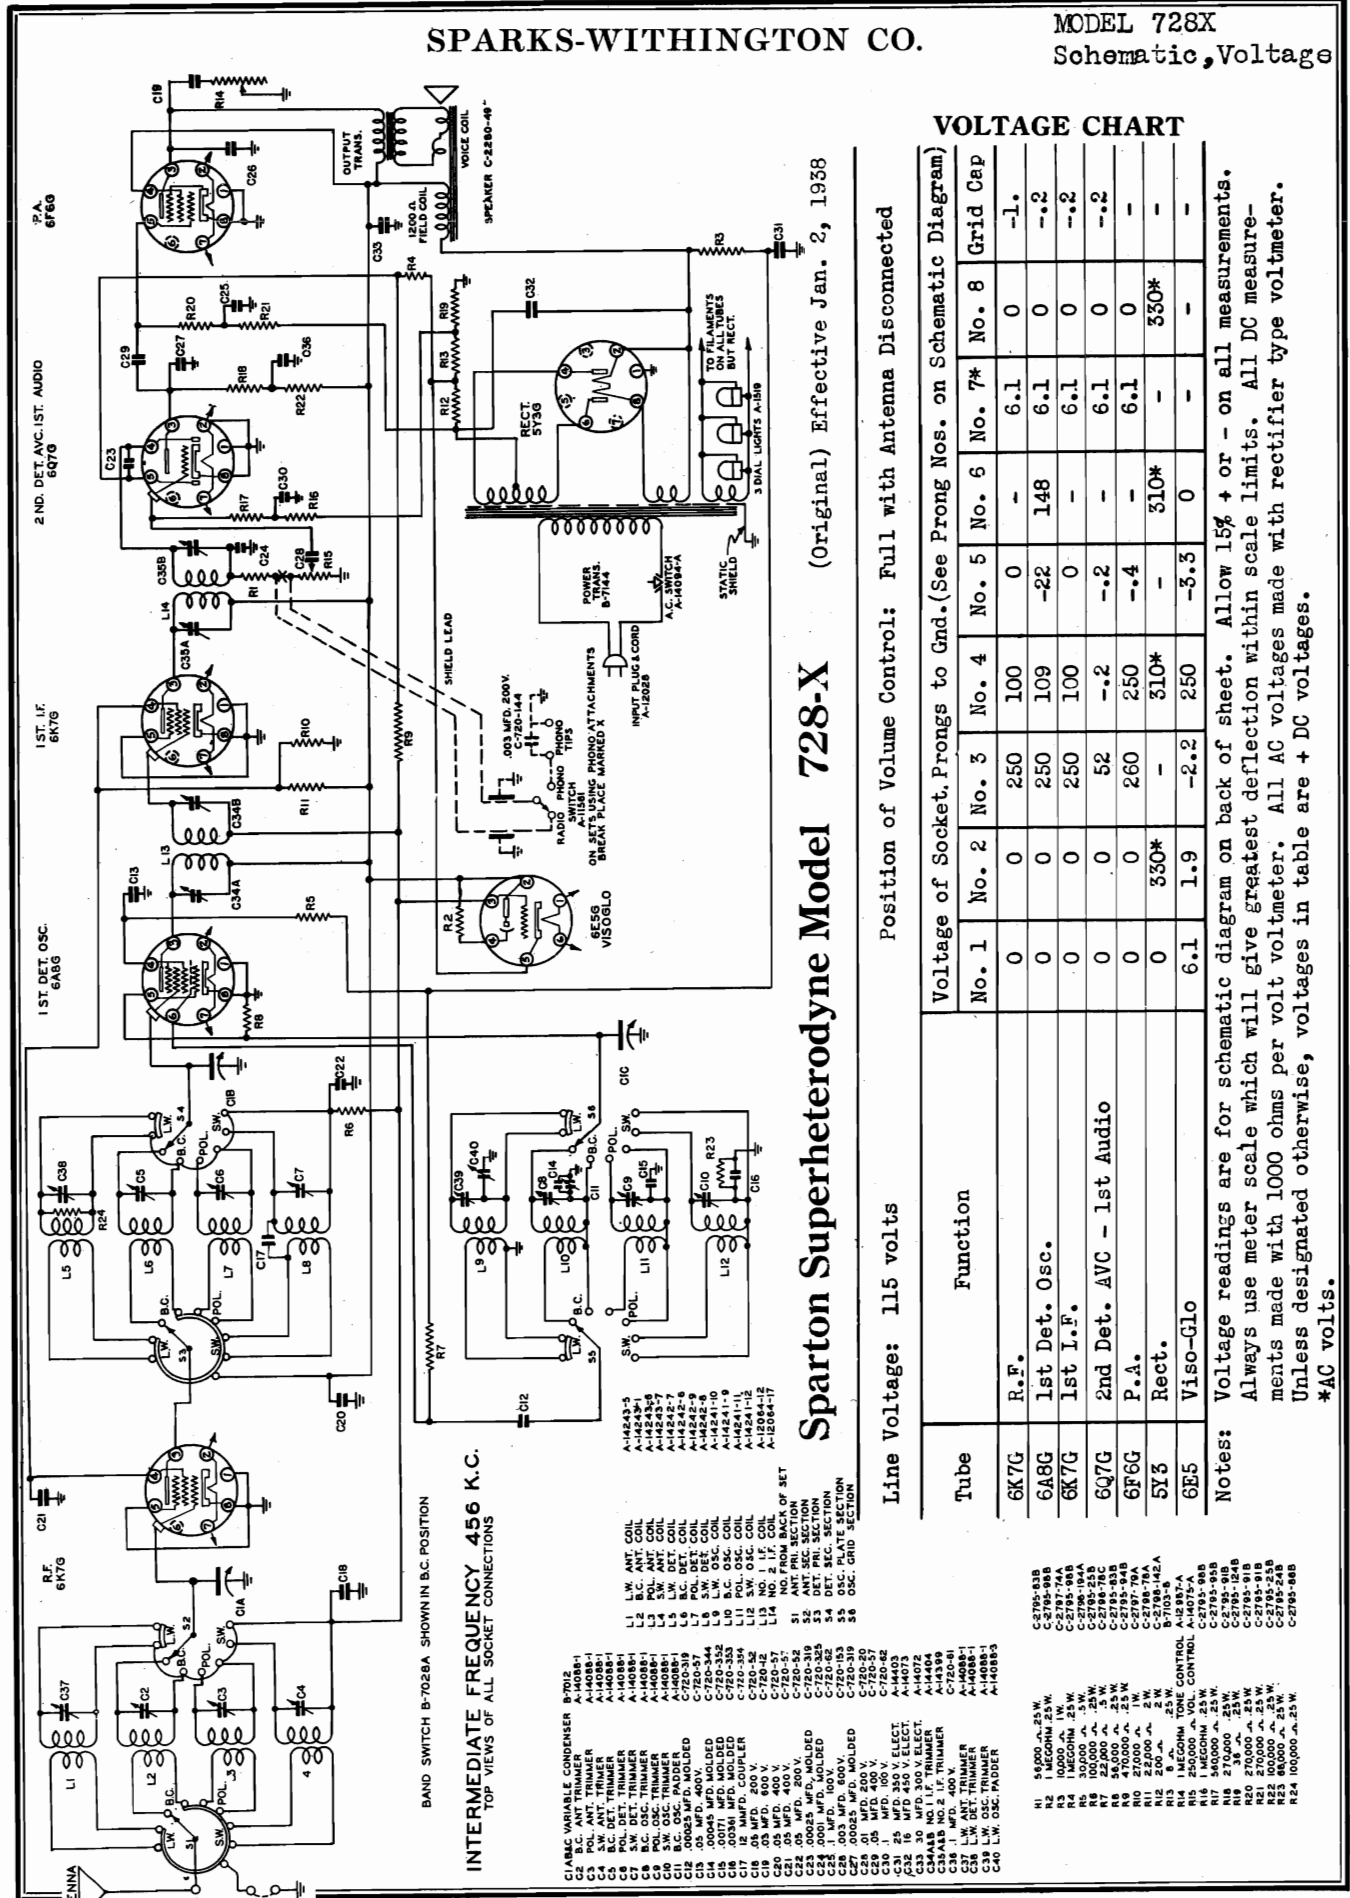

3. The six buttons of the Selectronne are arranged in three groups according to frequency limits - 540 to 800 kc., 700 to 1500 kc. and 1000 to 1500 kc. (See illustration also back cover of Selectronne box). The six tabs corresponding to the six broadcast stations which have been chosen must be placed in the proper slots so that the frequency (kilocycle) of each station will be included in the frequency limits of the proper group.

9	(Repeat operation 7)								
10	(Check calibration and sensitivity at 6 MC. and 1.95 MC.)								
11	2nd Short-Wave Band	Ant.	100 ohm	18 MC.	2nd S.W.	18 MC.	C10 Osc.	Rock dial slightly while adjusting	
			200 mmf. series				C7 R.F.		
							C4 Ant.		
12		Ant.		6 MC.	2nd S.W.	6 MC.	C13 Pad		
13	(Repeat operation 11)								
14	(Check calibration and sensitivity at 18 MC. and 6 MC.)								
15	(Check operations 1 to 14 inclusive)								

\* Check AFC by connecting generator to converter grid cap and tuning generator and receiver to 1500 KC. Note output meter reading with AFC switch "off". Switch AFC "on" and if output changes appreciably, touch up discriminator trimmer until there is no change in sensitivity.

NOTE: Check to see that dial pointer is parallel to horizontal lines on dial when variable condenser rotor plates are fully meshed with stator plates.

TRIMMER LOCATIONS (under chassis)

VOLTAGE CHART

Line Voltage: 115 volts

Position of Volume Control: Full with Antenna Disconnected

6E5	Viso-Glo	6.3	50	-3	280	-4	0	-	-	-

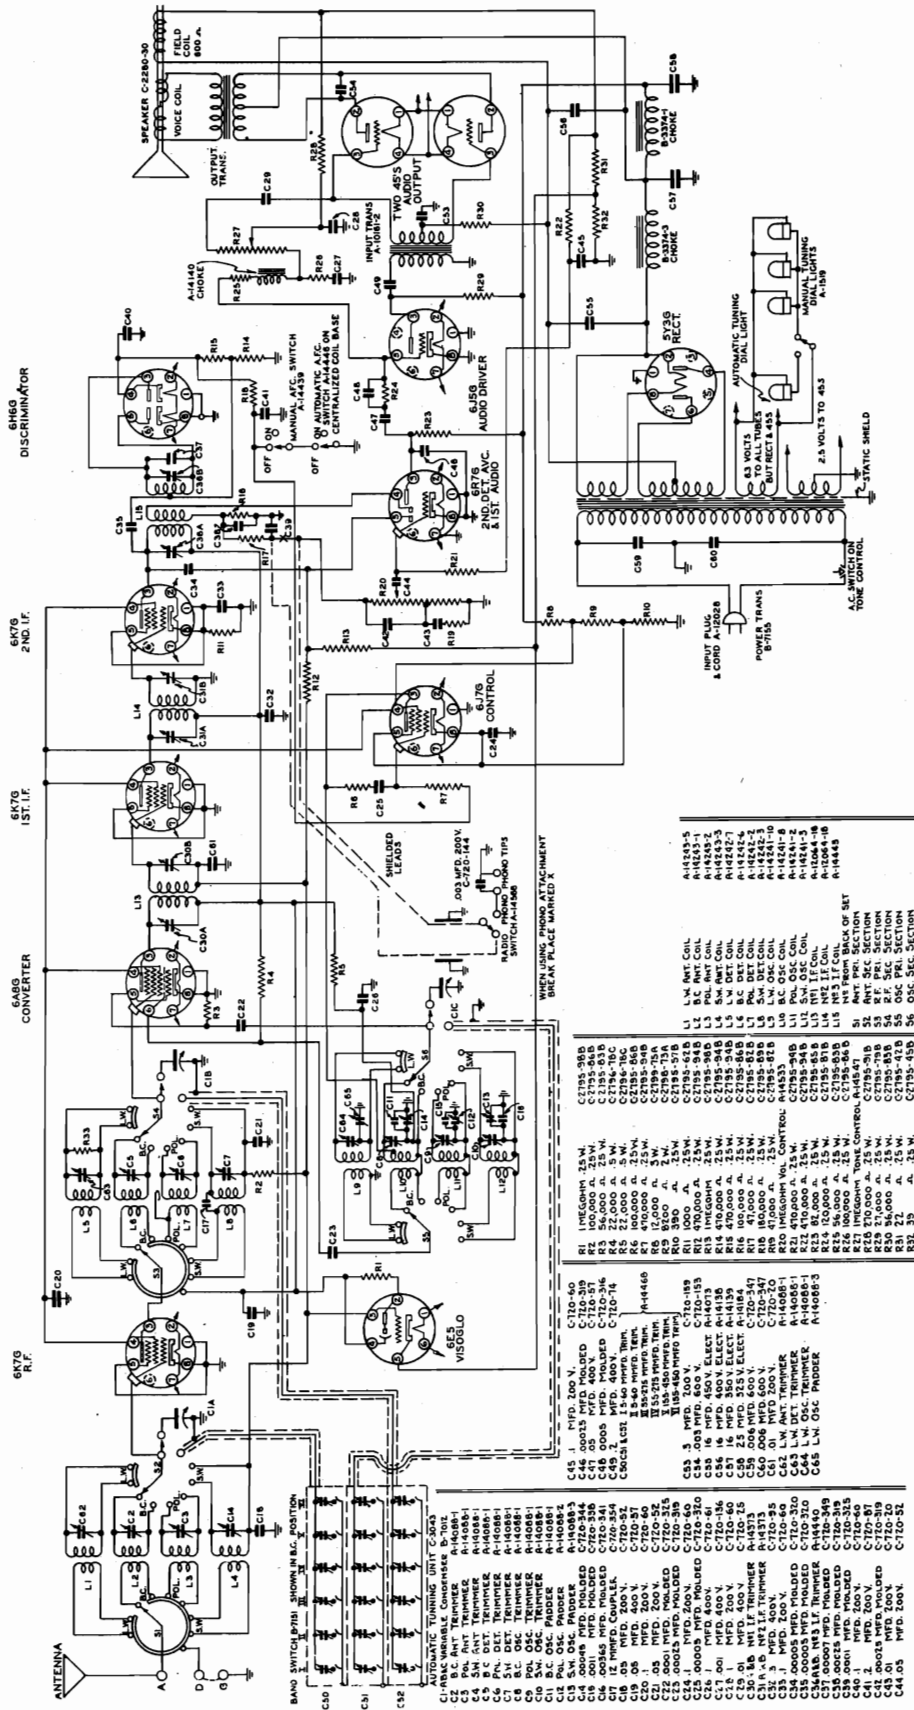

Notes: Voltage readings are for schematic diagram on back of sheet. Allow 15% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits. All DC measurements made with 1000 ohms per volt voltmeter. All AC voltages made with rectifier type voltmeter. Unless designated otherwise, voltages in table are + DC voltages.

\*AC volts.

16		(Repeat operation 14)						
17		(Check calibration and sensitivity at 18 MC, and 6 MC.)						
18		(Check operations 1 to 18 inclusive)						

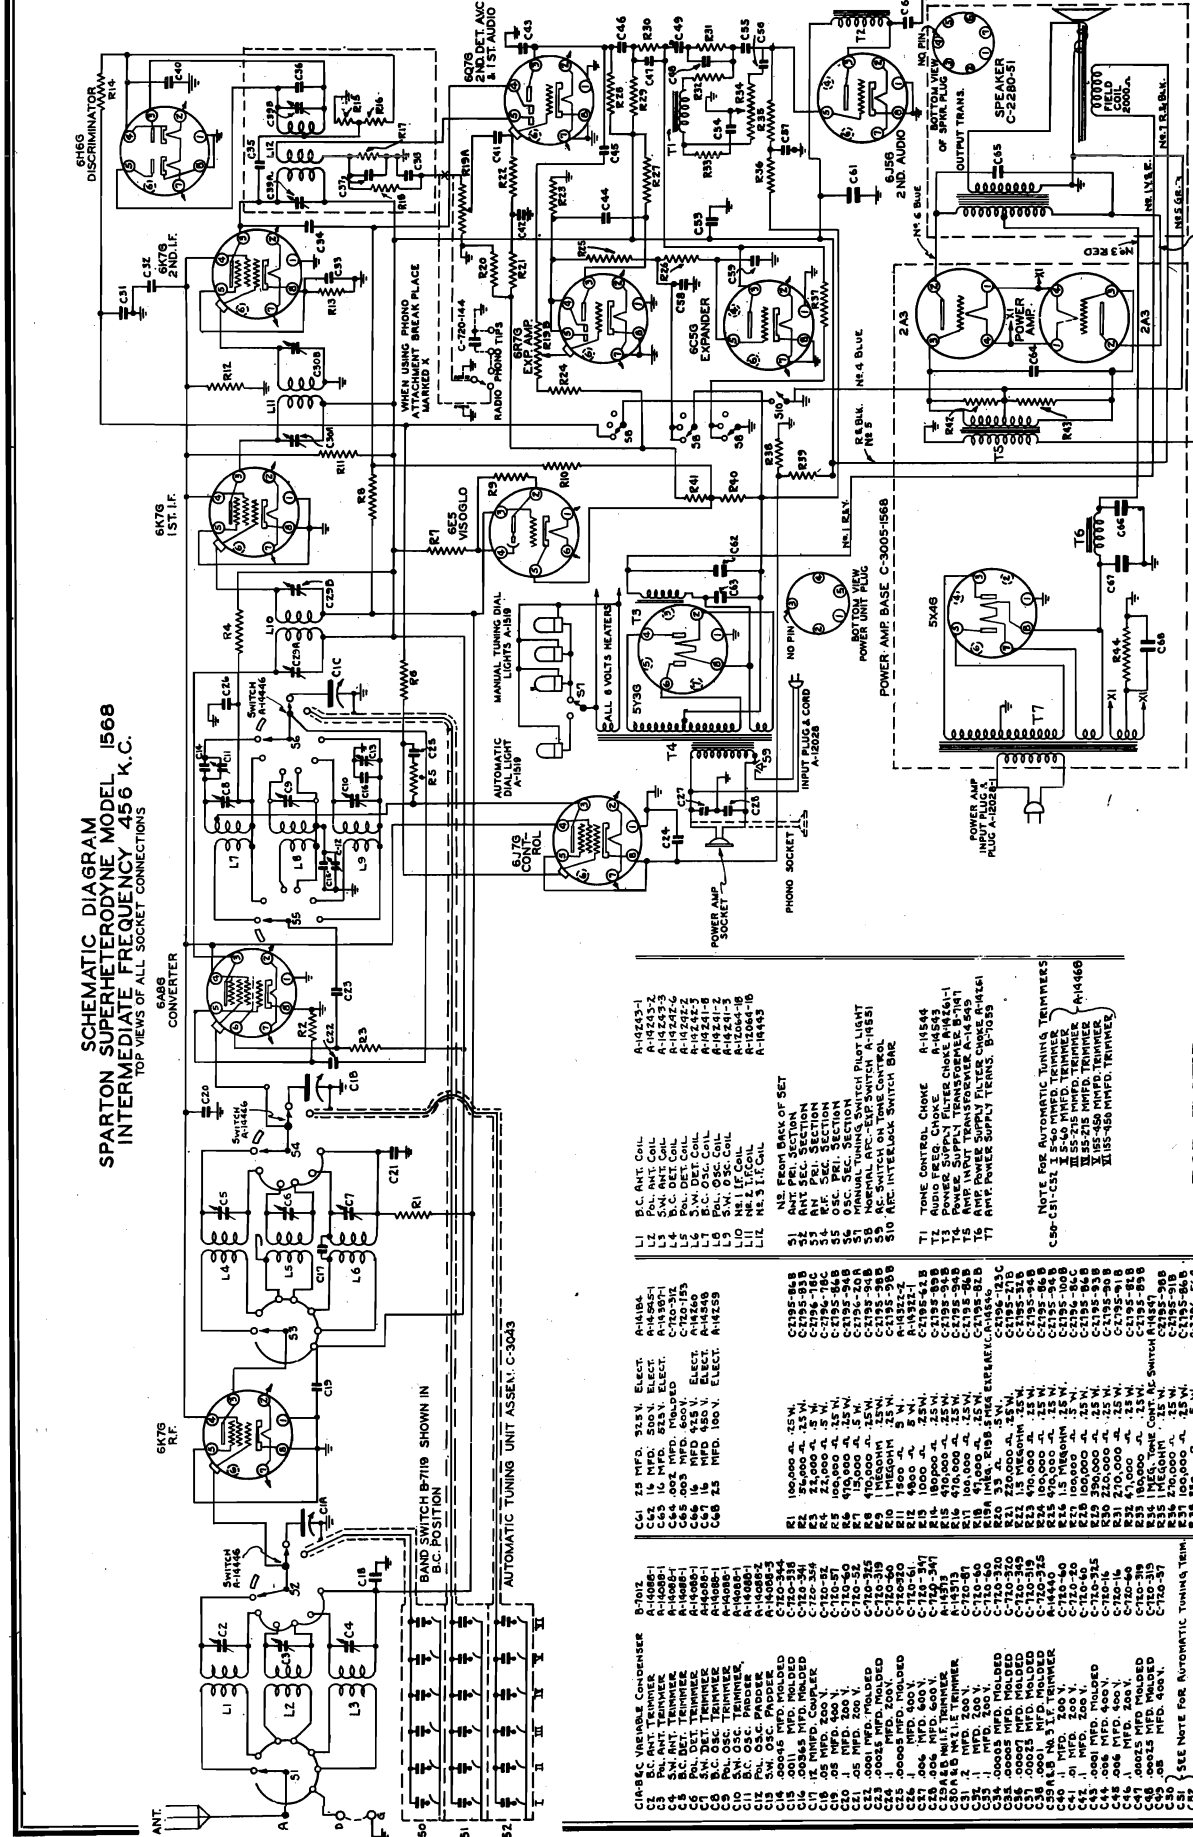

\* Check AFC by connecting generator to converter grid cap and tuning generator and receiver to 1500 KC. Note output meter reading with AFC switch "off". Switch AFC "on" and if output changes appreciably, touch up discriminator trimmer until there is no change in sensitivity.  
\*\* Rock variable condenser slightly while adjusting for maximum output.  
NOTE: Check to see that dial pointer is parallel to horizontal lines on dial when variable condenser rotor plates are fully meshed with stator plates.

(Original) Effective Jan. 2, 1938

MODEL 1867 Above Serial 000751

Schematic Changes

(ORIGINAL) EFFECTIVE NOV 28, 1936

SCHEMATIC DIAGRAM CHANGES

(SERIAL NO'S. 000751 AND UP)

The following changes, which should be made in the Model 1867 schematic diagram are effective Nov. 30, 1936, and are included in all SPARTON Model 1867 chassis with serial numbers above 000750.

1. Replace condenser C49 Part No. C-720-152 (.005 mf. 200v.), by Part No. C-720-144 (.003 mf. 200v.). This condenser connects from ground to the mid-point between the tone control (R14) and resistor R65.

2. Add resistor R67 Part No. C-2795-82B (47000 ohms 1/4 W.) This resistor connects across condenser C49.

3. Replace resistor R56 Part No. C-2795-63C (1200 ohms 1/4 W.) by resistor Part No. C-2795-74C (10000 ohms 1/4 W.). This resistor is in the cathode circuit of the Type 6K7G 1st. I-F Amplifier tube.

Early, Late Productions Voltage

SPARKS WITHINGTON CO.

MODEL 1867  
Below Ser. 000751  
Schematic Changes

(SERIAL NO. 000001 to 000750 INCLUSIVE)

The Schematic Diagram for the SPARTON Models 1867 (Serial Numbers 000001 to 000750 inclusive) is the same as shown except for the three general circuit changes as noted below:

(1) Change in Tone Control circuit as in Fig. 1.

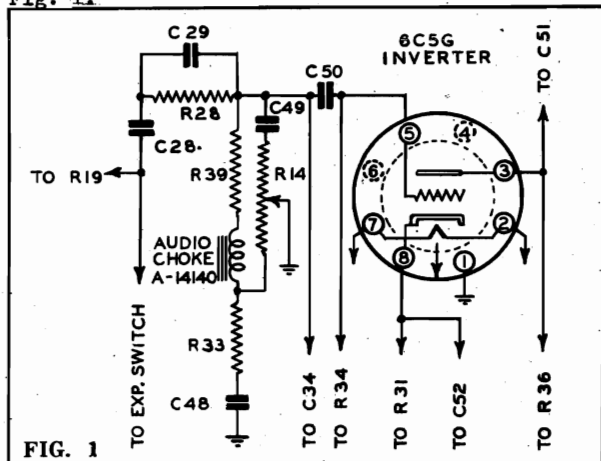

FIG. 1

(1) DETAILS OF TONE CONTROL to conform to schematic

Resistor R39 (27000 ohms .25 w.) removed  
Resistor R33 (100000 ohms .25 w.) removed  
Audio choke (A-14140) removed

Resistor R65 (180000 ohms .25 w.) added  
Resistor R66 (470000 ohms .25 w.) added  
Condenser C85 (.02 mf. 200 v.) added

(Change in circuit as in Fig. 1) VOLTAGE TABLE

Line Voltage: 110 volts  
Symphonic Expander Control: Off

FOR EARLY AND LATE MODELS

Position of Volume Control: Full with Antenna Disconnected  
Position of Band Selector Switch: Broadcast

5X4G	Rectifier (Lower Chassis)	0	0	380	0	380	0	5.2	.1	-

Notes: Voltage readings are for schematic diagram. Allow 15% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits except as noted below. All measurements made with Weston Selective Analyzer No. 665, Type 2.

1 10 volts A-C      2 250 volts D-C      3 5 volts D-C      4 25 volts D-C

(2) Change in Cathode Resistor Network of Type 6F6G High Frequency Power Amplifier as in Fig. 2.

(3) Change in Bias Resistor of Type 6K7G 1st. I-F Amplifier.

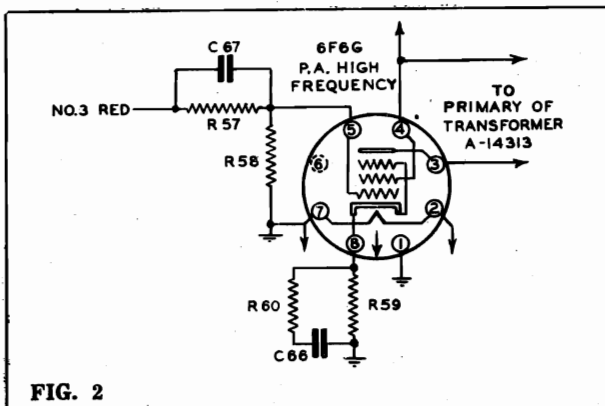

FIG. 2

(2) DETAILS OF RESISTOR NETWORK change in Cathode of Type 6F6G High Frequency Power Amplifier:

Resistor R60 (180 ohms .25 w.) removed.

(3) DETAILS OF BIAS RESISTOR change in Type 6K7G 1st. I-F Amplifier:

Substitute R56 1200 ohm .5 w. resistor (C-2796-63C) in place of 10000 ohm .5 w. resistor (C-2796-74C).

MODEL 1867  
Alignment Trimmers

SPARKS WITHINGTON CO.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15 megacycles or 15,000 kilocycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15 megacycle signal.

G. Alignment of Ultra High-Frequency Band

- Turn the band selector switch to the ultra high frequency band (tan diamond illuminated).
- Tune test oscillator and receiver to 50 megacycles and adjust condenser C76 (R-F trimmer).
- Check operation of receiver at 20 megacycles.

(Condenser C76 is the only adjustment in the ultra high frequency band).

CAUTION: All adjustments should be re-checked to assure accuracy and stability of adjustment and calibration.

TRIMMER LOCATIONS SPARTON MODEL 1867

(4) Return test oscillator and receiver to 345 kilocycles and check the adjustments of condensers C41, C40 and C38.

E. Alignment of 1st. Short-Wave Band

Let short-wave band (red diamond illuminated).

- Turn band selector switch to the 1st. short-wave band (red diamond illuminated).
- Tune test oscillator and receiver to 6 megacycles and adjust the following condensers in the order given: C9 - Oscillator trimmer; C6 - R-F trimmer; C5 - Ant. trimmer.
- Tune test oscillator and receiver to 1.95 megacycles and adjust condenser C12 (oscillator padder).
- Return test oscillator and receiver to 6 megacycles and check the adjustments of condensers C9, C6 and C5.

F. Alignment of 2nd Short-Wave Band

(1) Connect the 100 ohm non-inductive dummy antenna resistor in series with the 200 mf. condenser connected between the test oscillator "antenna" lead and the grid cap of the 6L7 converter tube.

- Turn the band selector switch to the 2nd short-wave band (blue diamond illuminated).
- Tune test oscillator and receiver to 18 megacycles and adjust the following condensers in the order given: C10 - Oscillator trimmer; C7 - R-F trimmer; C4 - Ant. trimmer.
- Tune test oscillator and receiver to 6 megacycles and adjust condenser C15 (oscillator padder).
- Return test oscillator and receiver to 18 megacycles and check adjustments of condensers C10, C7, and C4.

CAUTION: On this band care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

(4) Return test oscillator and receiver to 1500 kilocycles and check the adjustments of condensers C5, C6 and C2.

D. Alignment of 10 KC. Filter

The purpose of this filter circuit is to eliminate the 10,000 cycle note caused by the beating of any two stations operating simultaneously on adjacent channels. It is very important that this filter circuit be adjusted to exactly 10,000 cycles, otherwise the very purpose of the filter is defeated.

- Connect output meter from plate of Type 6F6G high-frequency power output tube to ground.
- Connect lead from audio oscillator to grid cap of Type 6J7G 2nd det. tube.
- Turn receiver volume control to the off position and set tone control to give a convenient deflection on the output meter.
- Adjust condenser C79 (mounted directly in back of the Antenna Coil Section shield) so that minimum deflection of the output meter is obtained.

D. Alignment of Long-Wave Band

(1) Turn the band selector switch to the long wave position (yellow diamond illuminated).

- Tune test oscillator and receiver to 345 kilocycles and adjust the following condensers in the order given: C41 - Oscillator trimmer; C40 - R-F trimmer; C38 - Ant. trimmer.
- Tune test oscillator and receiver to 150 kilocycles and adjust condenser C42 (oscillator padder).

STEP BY STEP PROCEDURE

NOTE: For proper alignment of these chassis, the procedure should be followed in the same order as given. The dial pointer should be exactly parallel with the horizontal line of the kilocycle scale when the condenser plates are fully meshed. If the pointer does not read correctly, loosen the set screw holding the pointer, hold the rotor plates fully meshed with the stator plates and set the pointer so that it is parallel with the horizontal lines on the kilocycle scale, then tighten the set screw.

A. Alignment of Intermediate-Frequency Stages

- Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.
- Turn the band selector switch to the Broadcast position (with white diamond illuminated) and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.
- Connect "antenna" of test oscillator to the grid cap of Type 6L7 converter tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "high tap" from plate of Type 6J5G Low-Frequency power output tube to ground. NOTE: It is advisable to read carefully the operating instructions included with the test oscillator.
- Tune test oscillator to obtain a signal of 456 kilocycles.
- Turn tone control to low note position.
- Turn expander control to "off" position.
- Turn volume control of receiver on full and adjust I-F trimmers C81, C82 and C85 which are reached from the top of the chassis. NOTE: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

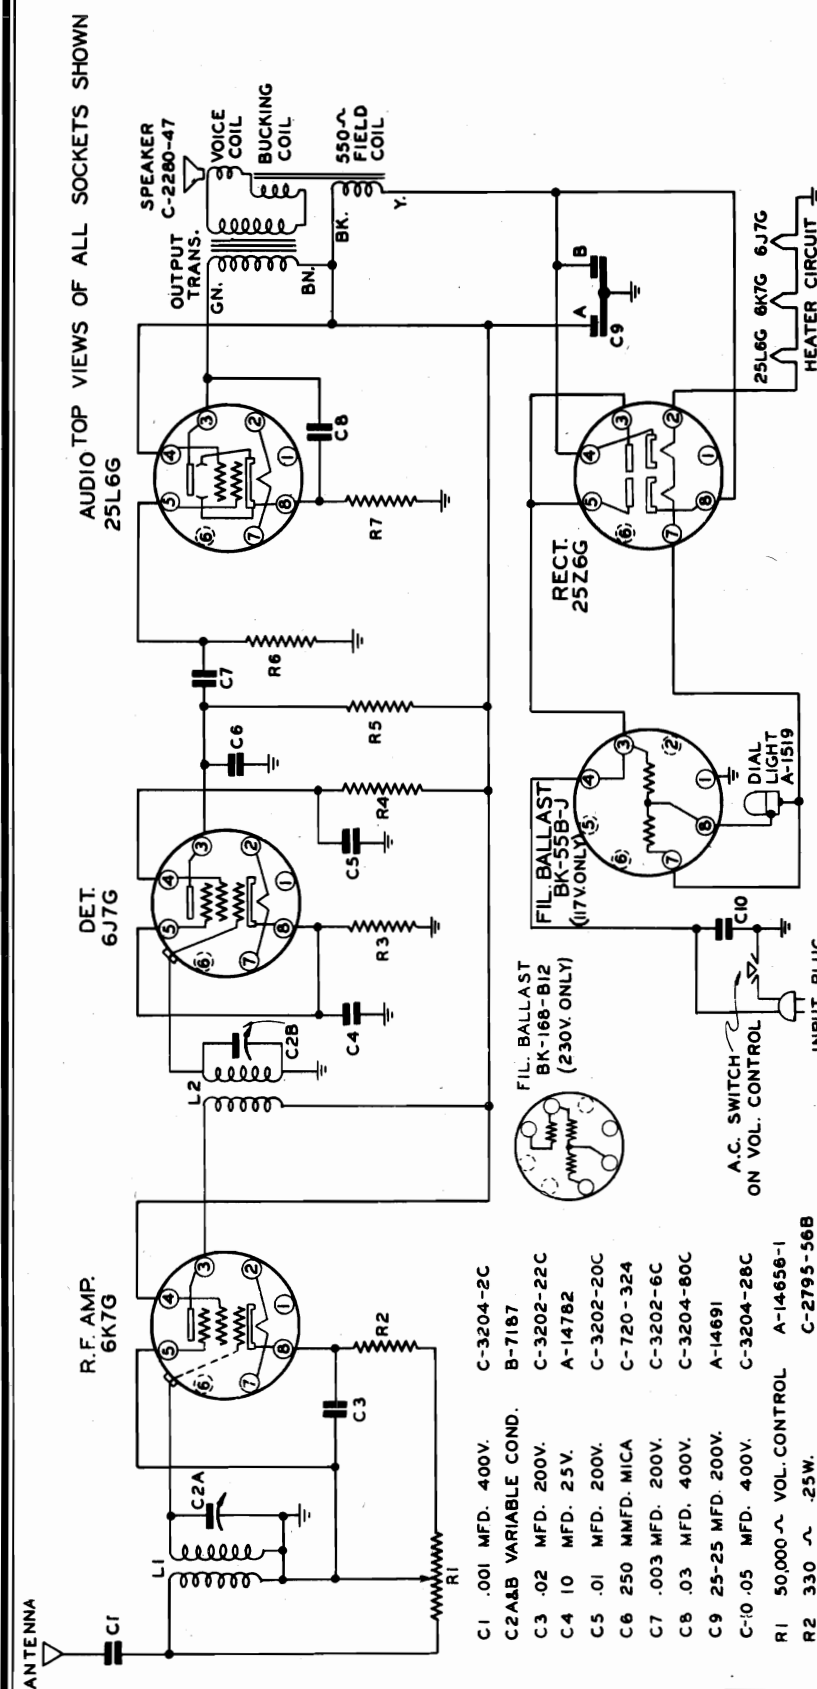

B. Alignment of Broadcast Band

(1) Disconnect "antenna" lead of test oscillator from grid cap of converter tube and connect in series with a 200 mf. condenser dummy antenna to the antenna terminal of the chassis.

- Tune receiver and test oscillator to a frequency of 1500 kilocycles and adjust the following condensers in the order given: C8 - Oscillator trimmer; C5 - R-F trimmer; C2 - Ant. trimmer.
- Tune test oscillator and receiver to 600 kilocycles and adjust condenser C11 (oscillator padder).

HOW TO ADJUST THE SPARTON SELECTRONNE IN THE MODELS

5218                  6218                  7618

1. Select six favorite nearby broadcast stations and detach the corresponding call letter tabs from the station call letter tab sheets.
2. Remove the Selectronne escutcheon plate from the front of the cabinet by means of the two screws and insert the station call letter tabs. Any tab may be used for any button, but it is usually more convenient for the operator if the tabs are arranged in sequence so that the tab for the lowest frequency station (station having lowest number of kilocycles (K.C.)) will be at the extreme left.
3. Using a small screwdriver or other tool that will fit the slot in the end of the button, push the button in as far as it will go and turn to the right or left until the dial pointer has moved to the desired station frequency. Be sure the button is pushed all the way in and the station is tuned in accurately.
4. Repeat the procedure in paragraph 3 for each of the remaining five buttons.
5. Check all buttons by pushing them in, one at a time, to determine whether desired stations are tuned properly.
6. Replace Selectronne escutcheon.
7. Any of the six stations to which the SPARTON Selectronne has been adjusted may now be received simply by pushing the Selectronne button for the desired station.

						C2 B Osc.	
5	(Check for dial reading and sensitivity at 600 kc., 1000 kc.)						
6	(Check operations 1 to 5 inclusive)						

1. Select four favorite nearby broadcast stations and detach the corresponding call letter tabs from the station call letter tab sheets.

2. The tabs should be inserted in the ends of the knobs. For convenience it is recommended that the call letter tabs be arranged in sequence so that the tab for the station having the highest frequency (greatest number of kilocycles (k.c.)) will be at the extreme left. This, however, is not vital, since the Selectronne will operate with any arrangement of the tabs.

3. TO ADJUST SELECTRONNE BUTTONS, loosen selected button by turning one-half turn to left (counter-clockwise). Push this loosened button in as far as it will go, and while in this position, tune in manually the station desired or indicated by tab in end of this loosened button.

Then, with the button still pushed in as far as it will go, tighten by turning button to the right (clockwise) until it can be tightened no more.

Be sure the station is tuned in accurately when pushed in button is tightened.

4. Repeat the procedure in paragraph 3 for each of the remaining three buttons and stations.

5. Be sure the Selectronne buttons have been tightened firmly.

6. Check all buttons by pushing them in, one at a time, to determine whether desired stations are tuned in properly.

7. Any of the four stations to which the SPARTON Selectronne has been adjusted may now be instantly received simply by pushing the Selectronne Button for the desired station.

MODEL 134, Chassis 46A  
Alignment, Voltage, Socket  
Tuning Eye Notes

SPIEGEL INC.

**ALIGNMENT PROCEDURE:**

Realignment of this receiver should never be necessary unless one of the oscillator, antenna, or I. F. coils has been replaced. Lack of sensitivity, selectivity, and poor tone quality may be due to any one or a combination of causes, such as weak or defective tubes or speaker, inadequate or excessively long antenna, open or grounded bias resistor, bypass condenser, etc. Under no circumstances should realignment be attempted until all other possible sources have been first thoroughly investigated and have been definitely proven not to be the cause.

If an I. F. tube is replaced it is advisable to realign the I. F. Amplifier particularly if the replacement tube is one of a different manufacture than the one in the receiver. It is important when aligning to carefully follow the procedure in the order given, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

**IT IS IMPERATIVE THAT AN ACCURATELY CALIBRATED OSCILLATOR BE USED WITH SOME TYPE OF OUTPUT MEASURING DEVICE.**

**INTERMEDIATE ALIGNMENT:**

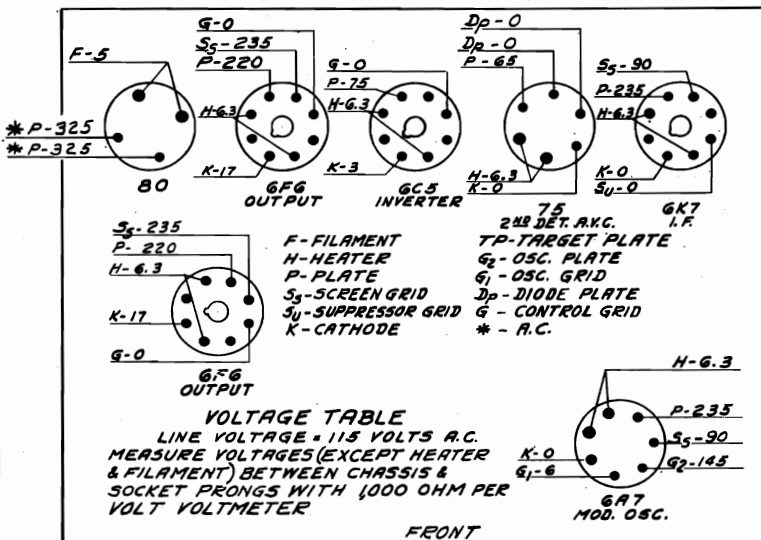

1. Connect the high side of the test oscillator output to the control grid of the 6D6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

**TO ALIGN THE VARIABLE CONDENSER:**

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18.1 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.1 MEGACYCLES. Tune in the 18.1 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.1 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER at 18.1 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.1 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.1 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.1 megacycles, and if the fundamental peak was used in aligning at 18.1 megacycles the test oscillator signal will be heard at approximately 17.1 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.1 megacycle oscillator trimmer must be properly re-adjusted.
3. With band selector switch set for operation on 5.8 to 18.1 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 16 MEGACYCLES. Adjust 16 megacycle antenna trimmer for maximum 16 megacycle signal sensitivity.
4. Place band selector switch for operation on 1.7 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES. BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 5.8 MEGACYCLE OSCILLATOR TRIMMER.
5. With the band selector switch set for operation on the 1.7 to 5.8 megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna trimmer for maximum 5 megacycle signal sensitivity.
6. Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band, tune receiver dial, and set test oscillator frequency to EXACTLY 1720 KILOCYCLES. NEXT BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.
7. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.
8. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

Some of these model receivers were equipped with "Teleye" the cathode ray visual tuning indicator. A 6E5 tube was used in early production models, which was replaced by a 6G5 tube in later production. The parts and connections shown in the dotted lines on the complete circuit diagram are used only when a 6G5 "Teleye" tube is incorporated in the receiver. The diagram below shows 6E5 tube connections.

MODEL 603, (1936)

In case of faulty operation of the receiver, first make sure that the antenna and ground are in good condition and properly attached to the receiver. Then determine if any of the tubes are faulty. In case of trouble within the receiver itself, the circuit diagram shown on the opposite page will be useful to the service man in locating and correcting the trouble.

**I. F. Alignment:**

Connect a test oscillator or signal generator through a .1 mfd. condenser to the grid of the 6D6 tube and set the oscillator to 456 KC. Use an output meter connected to the speaker if possible, to obtain the most accurate adjustments. Peak each I. F. stage to maximum response, reducing the output of the oscillator as far as possible for final adjustments.

**R. F. Alignment:**

With test oscillator set at 1400 KC, feed this signal into the antenna lead of the receiver through a .00025 condenser. With band switch in broadcast position, set the dial pointer to 1400 KC.

Adjust the broadcast oscillator trimmer (the small trimmer attached to the coil located approximately in front of the range switch) to peak at 1400 KC. Next adjust the trimmer on the preselector (this coil is mounted in the center at the front of the chassis). Then adjust the one trimmer on top of the gang condenser.

Now set the test oscillator to 800 KC. Adjust the broadcast paddler condenser (the ceramic-base condenser adjustable through the right hand end of the chassis) in this manner: Move the dial slowly and repeatedly back and forth across the signal while adjusting the paddler. Adjust for maximum gain.

Now set the range switch to middle wave band. Adjust the test oscillator to 4000 KC, and set the dial to 4000 KC. Adjust the two trimmers located on the tops of the two short wave coils, on top of the chassis, for maximum gain.

Now set the range switch to the short wave position, adjust the test oscillator to 15 megacycles. Turn the dial to read 15 megacycles. Adjust for maximum gain the two trimmers located at the bases of the short wave coils.

MODELS 178, 6708, 6754 (1936) Chassis M5  
**ALIGNMENT DATA AND SERVICING**

**FOREIGN BAND ALIGNMENT**

The Foreign Band of 18 to 49 meters can be adjusted by the two trimmers marked and illustrated in the drawing on this band. Connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. Set the receiver pointer to 14,000 KC (also test oscillator).

Then proceed to adjust these two trimmers for peak at 14,000 KC. The fully adjusted trimmer (and) on the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: Always start this procedure by having the oscillator coil trimmer set to the full clockwise adjustment. It is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be the loudest. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

**POLICE BAND**

In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator to align the Police Band oscillator circuit trimmer to peak.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the Police Band oscillator circuit trimmer to peak.

After this has been carefully done, the next step is to adjust the trimmer on the top of the chassis. Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band paddler condenser. Slowly increase or decrease the oscillator paddler condenser at the same time continuously tune back and forth across the signal on the output meter. This adjustment may seem a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section. Return to 4000 KC and again go over the adjustments of this frequency to be certain that they are 1800 KC. If it is found that in returning to 4000 KC the pointer is occasionally on scale, no further adjustment should be necessary (in this respect). If the pointer is found off scale, it may be corrected and put on scale by readjustment of the police band oscillator trimmer. Important: The adjustment, the Police Band Oscillator Trimmer, Police Band Antenna Trimmer and Police Band Paddler Trimmers are the only three adjustments required in aligning this band.

**SERVICE DATA FOR ALL BANDS**

ICS (short actor and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

**GENERAL DATA**

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 800, 1400, 1800, 4000, 8000, and 14,000 KC and an output meter which is to be connected to the speaker. If possible, all components should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

**CORRECT ALIGNMENT PROCEDURE**

The intermediate frequency (I.F.) stages should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the broadcast oscillator should be aligned. Wave bands may be aligned.

**I.F. ALIGNMENT**

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C8) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the oscillator on the output meter. As there are two stages of I.F. in this receiver, there will be consequently three I.F. transformers to align. The I.F. transformer nearest the type 8D diode detector has only one trimmer, (single tuned) and should be the first adjustment. (Double tuned) for maximum output then adjust the two trimmers on the input I.F. transformer (double tuned) for peak.

**BROADCAST BAND ALIGNMENT**

Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 50 feet long. The test oscillator should be set to 1400 KC. After this has been correctly done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the pre-selector circuit. Then adjust the Broadcast Band I.F. trimmer (See drawing for position of Broadcast R. F. trimmer). Next, reset the dial pointer on the receiver and the test oscillator to 800 KC. Slowly increase or decrease the R.C. oscillator paddler condenser at the same time continuously tune back and forth across the signal on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. For location of R.C. paddler condenser see drawing.) Return to 1400 KC and again go over the adjustments of this frequency adjustment was made at 800 KC. This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band.

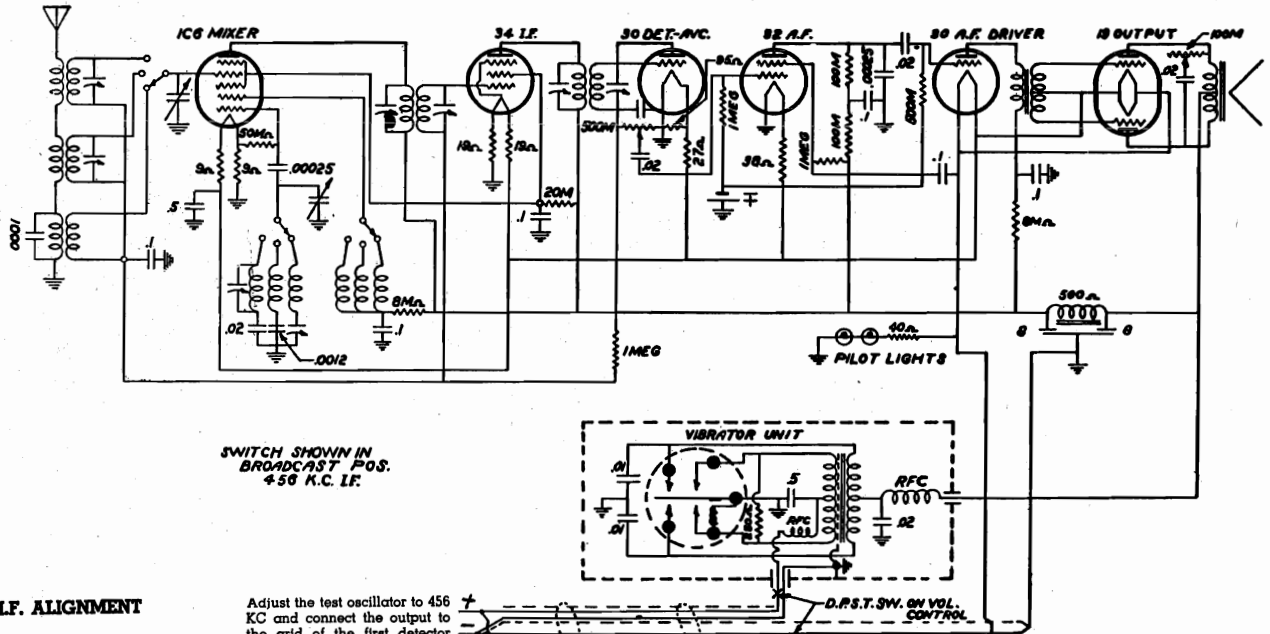

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate trimmer be grounded the oscillator grid of the tube in oscillating, around the oscillator grid of the

LF. ALIGNMENT

Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (1C6) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the front trimmer of the gang condenser to peak. The front condenser section tunes the RF or grid circuit of the 1C6 tube. Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the R.F. section. The padding condenser is located on the left hand side of the chassis, directly to the left of the 1C6 tube and in front of the first I.F. transformer. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC. This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and must always be done before attempting to align the Short Wave Bands.

FOREIGN BAND ALIGNMENT

The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coils located on the top of the chassis. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and alongside the front section of the gang condenser. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly developed for simplicity in servicing, no other adjustments are necessary for aligning this band. Note: Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency. In order to prevent alignment on the image frequency, it is suggested that the following check be made: Readjust the pointer to 13,100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13,100 KC is found to be stronger than the signal at 14,000 KC, it signifies that alignment was incorrectly made on the image frequency.

**IMPORTANT:** Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND ALIGNMENT

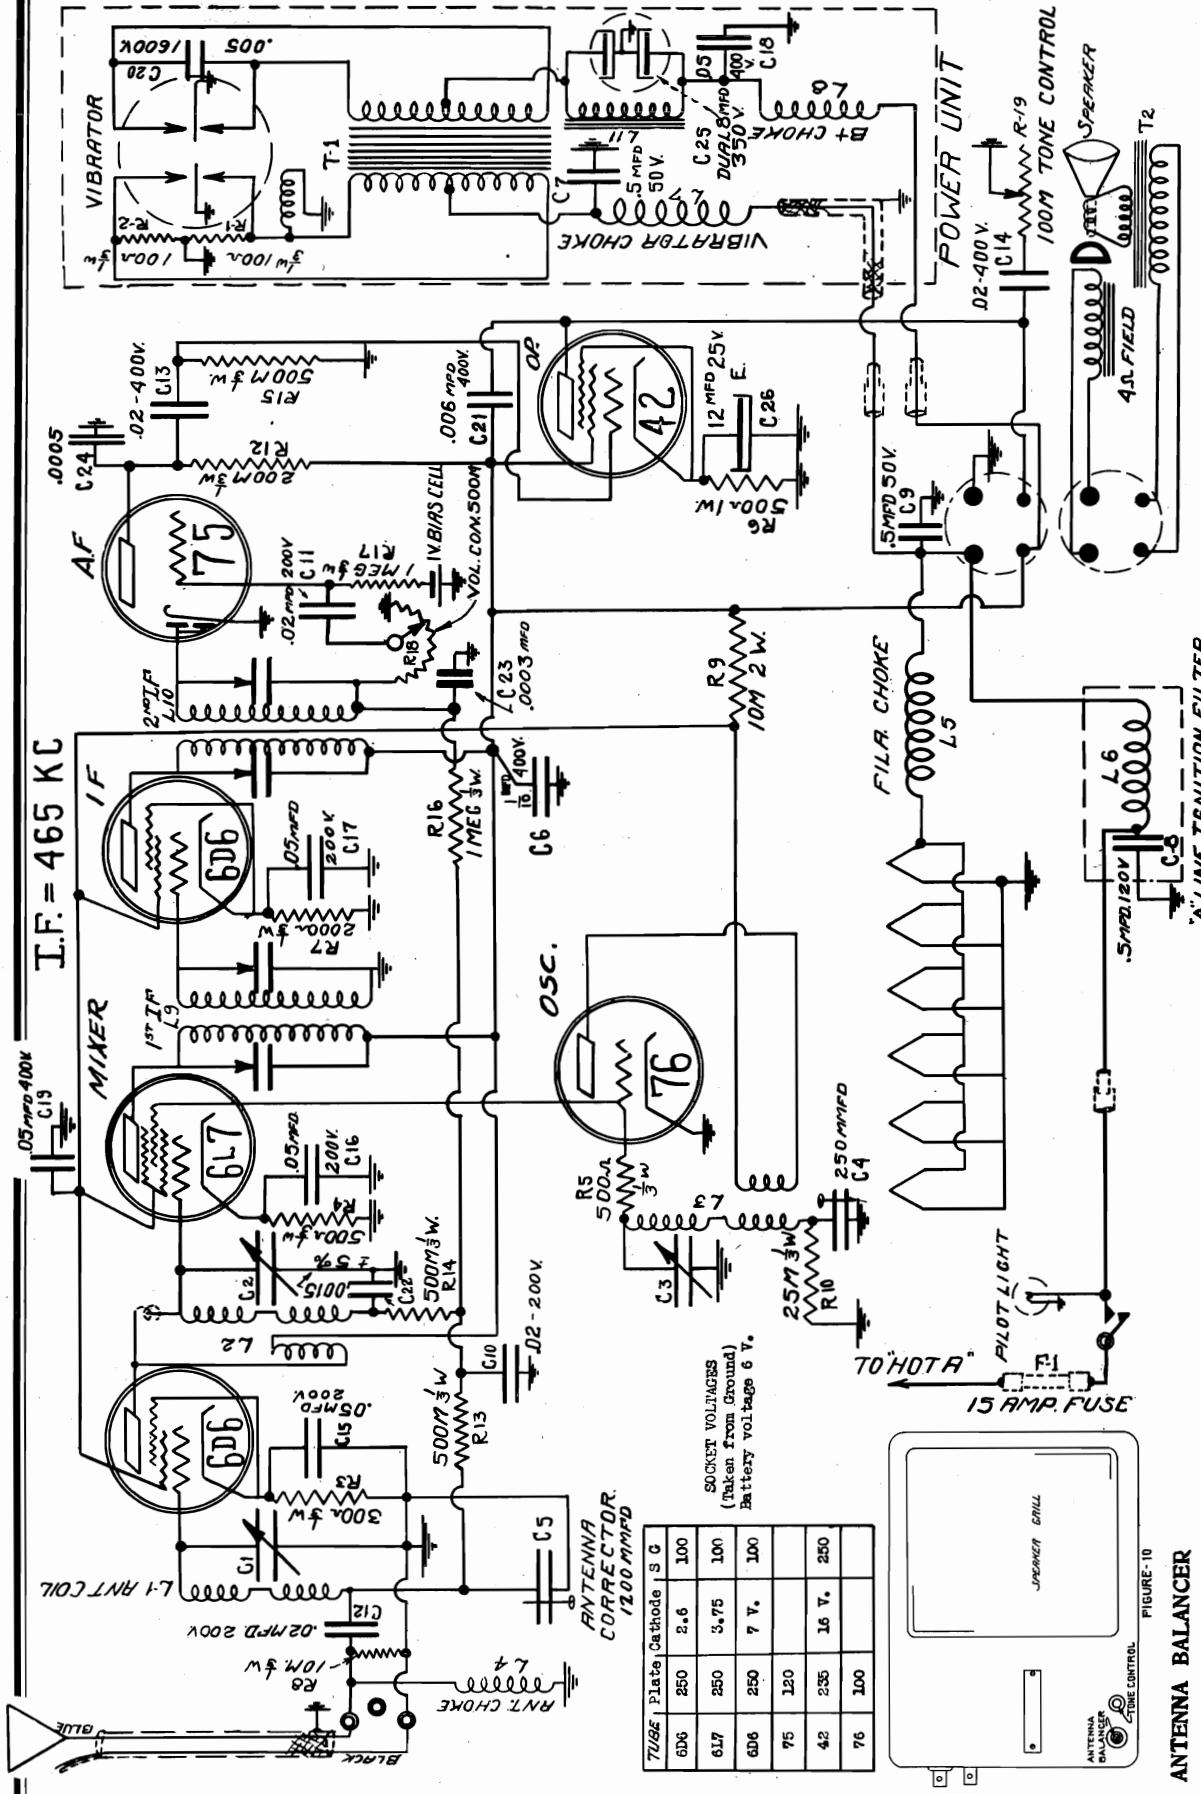

There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary. Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The two police band coils are under the chassis and the antenna coil trimmer is mounted on the end of the antenna coil. **Important:** This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

**IMPORTANT NOTE:** The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharger from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

**DO NOT ATTEMPT TO OPERATE THIS RECEIVER ON DIRECT CURRENT (D.C.) OR ANY OTHER VOLTAGE OR CYCLE AS PERMANENT INJURY TO THE SET WILL RESULT.**

This receiver is designed to operate over two tuning ranges. The broadcast range which extends from 540 K.C. to 1730 and the foreign short wave band which extends from 5800 K.C. to 18000 K.C. The short wave range includes the five important short wave channels 19, 25, 31, 39 and 49 meter bands.

**ALIGNMENT DATA**

The alignment of this receiver requires the use of a test oscillator that will cover the following frequencies, 465, 600, 1400, 6000, and 15000 K.C. and an output meter which is to be connected across the output transformer on the speaker. All alignments should be made with the volume control set at maximum and the output of the test oscillator set as low as possible to prevent the automatic volume control from operating and thus giving incorrect readings during alignment.

**INTERMEDIATE FREQUENCY:** Set oscillator to 465 KC. Feed this to the grid of the pentagrid (6A7) converter tube. Adjust trimmers on the intermediate frequency transformers for peak readings as indicated on the output meter which is to be placed across the output transformer.

**BROADCAST BAND:** Set the band switch for broadcast reception. Adjust oscillator to 1400 KC and connect the output of the generator to the antenna connection at the rear of the chassis through a .0002 mfd. mica condenser. Set the pointer on the dial to 1400 KC making sure that the volume control is set at its maximum position. Adjust the broadcast antenna and broadcast oscillator trimmers for maximum signal (as indicated on the output meter). Re-set the dial pointer on the receiver and on the test oscillator to 600 KC. Slowly increase or decrease the broadcast padding condenser while tuning back and forth across the signal with the station selector knob until the maximum reading is obtained on the output meter. Re-check the 1400 KC alignment as the adjustment at 600 KC may have slightly disturbed the original 1400 KC setting.

**SHORT WAVE:** Set band switch on short wave position. Connect the antenna of the radio receiver to the output of the test oscillator through a 400 ohm carbon resistor. Set oscillator and receiver dial at 15 megacycles. Adjust the short wave antenna and short wave oscillator trimming condensers for maximum output as indicated by readings on the output meter. No other adjustments are necessary for aligning this band.

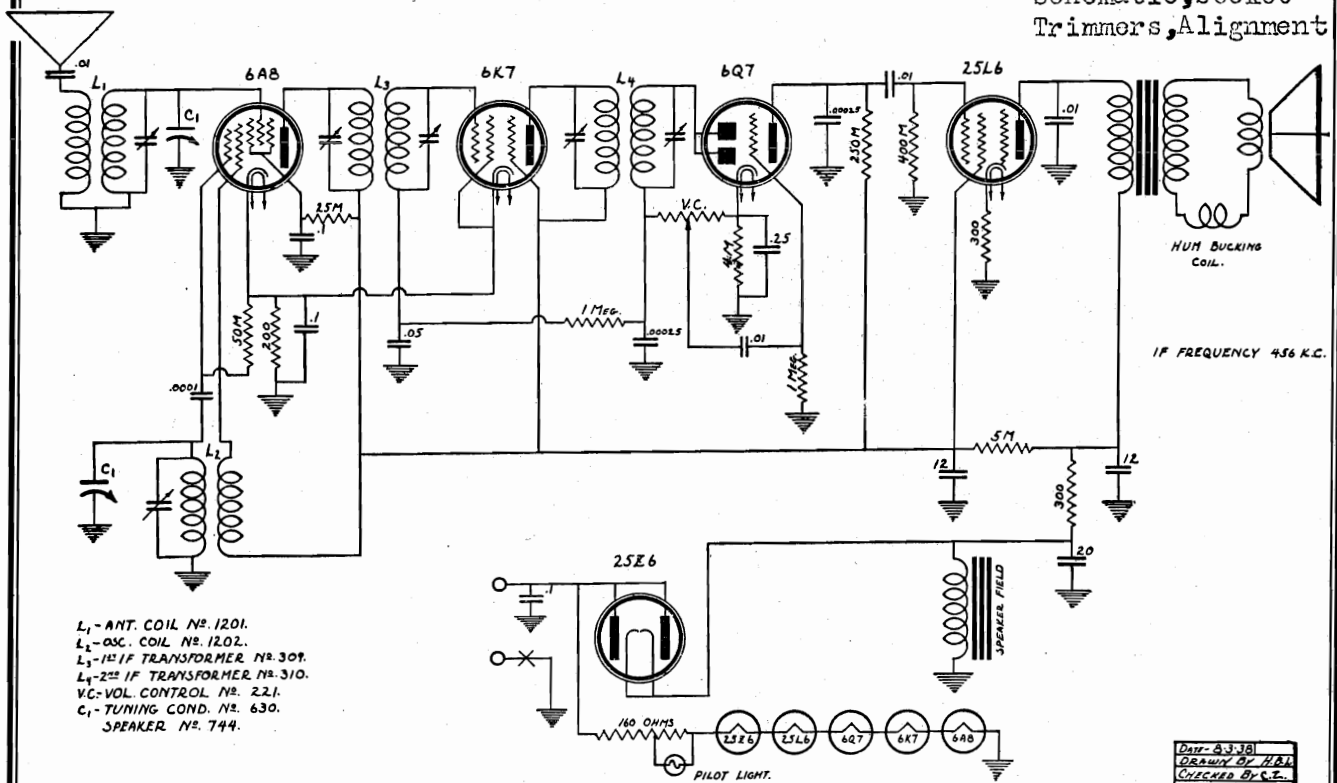

It is advisable to check the sensitivity at 6000 KC to determine whether the circuits are properly aligned. Should the receiver lack sensitivity at this frequency check the .0035 mica condenser for short circuit.

**ALIGNMENT:** The alignment of this receiver (Chassis 43, 218, 220) should be made with the volume control set at maximum and the output of the test oscillator set as low as possible to prevent the automatic volume control from operating and thus giving incorrect readings during alignment.

**INTERMEDIATE FREQUENCY:** Set oscillator to 465 KC. Feed this to the grid of the (6A7) tube. Adjust trimmers on the intermediate frequency transformers for peak readings as indicated on the output meter which is to be placed across the output transformer.

**BROADCAST BAND:** Set the band switch for broadcast reception. Adjust oscillator to 1400 KC and connect the output of the generator to the antenna connection at the rear of the chassis through a .0002 mfd. mica condenser. Set the pointer on the dial to 1400 KC making sure that the volume control is set at its maximum position. Adjust the broadcast antenna and broadcast oscillator trimmers for maximum signal (as indicated on the output meter). Re-set the dial pointer on the receiver and on the test oscillator to 600 KC. Slowly increase or decrease the broadcast padding condenser while tuning back and forth across the signal with the station selector knob until the maximum reading is obtained on the output meter. Re-check the 1400 KC alignment as the adjustment at 600 KC may have slightly disturbed the original 1400 KC setting.

**INTERMEDIATE BAND:** For a dummy antenna use a .0002 mfd. mica condenser in series with a 400 ohm carbon resistor. Set band switch to the intermediate band position and feed a 5100 KC signal from the oscillator. Set dial pointer at 5100 KC. Adjust intermediate antenna and intermediate oscillator trimmers for maximum output. Re-set oscillator and set dial to approximately 1800 KC. Slowly increase or decrease the intermediate padding condenser while tuning back and forth across the signal with the station selector control until the maximum reading is obtained on the output meter. Re-check the 5100 KC adjustment.

**SHORT WAVE:** Set band switch on short wave position. Connect the antenna of the radio receiver to the output of the test oscillator through a 400 ohm carbon resistor. Set oscillator and receiver dial at 15 megacycles. Adjust the short wave antenna and short wave oscillator trimming condensers for maximum output as indicated by readings on the output meter. No other adjustments are necessary for aligning this band.

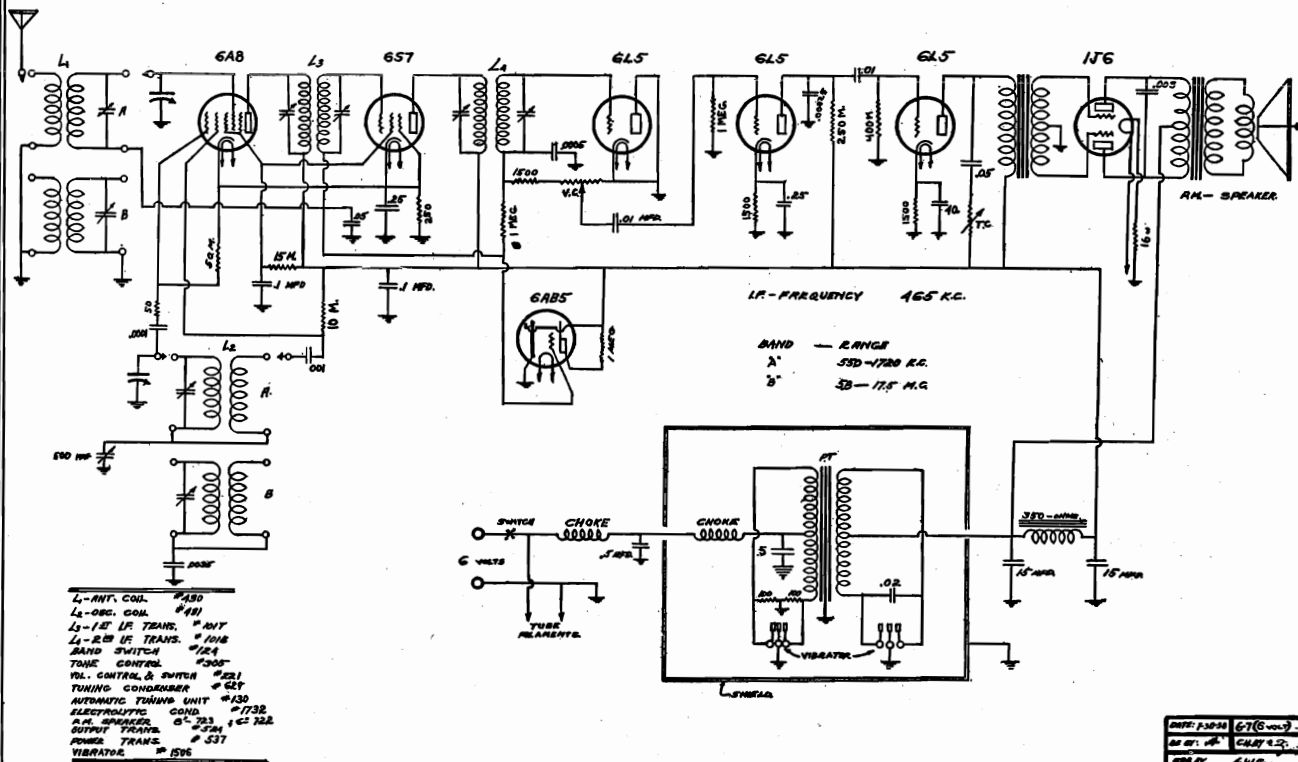

It is advisable to check the sensitivity at 8000 KC to determine whether the circuits are properly aligned. Should the receiver lack sensitivity at this frequency check the .0035 mica condenser for short circuit.

# Automatic Tuner Dual Range 6 Volt Superheterodyne

This receiver is designed to operate over two tuning ranges. The broadcast range which extends from 540 K.C. to 1730 and the foreign short wave band which extends from 5800 K.C. to 18000 K.C. The short wave range includes the five important short wave channels 19, 25, 31, 39 and 49 meter bands.

## ALIGNMENT DATA

The alignment of this receiver requires the use of a test oscillator that will cover the following frequencies, 465, 600, 1400, 6000, and 15000 K.C. and an output meter which is to be connected across the output transformer on the speaker. All alignments should be made with the volume control set at maximum and the output of the test oscillator set as low as possible to prevent the automatic volume control from operating and thus giving incorrect readings during alignment.

**INTERMEDIATE FREQUENCY:** Set oscillator to 465 KC. Feed this to the grid of the pentagrid (6A7) converter tube. Adjust trimmers on the intermediate frequency transformers for peak readings as indicated on the output meter which is to be placed across the output transformer.

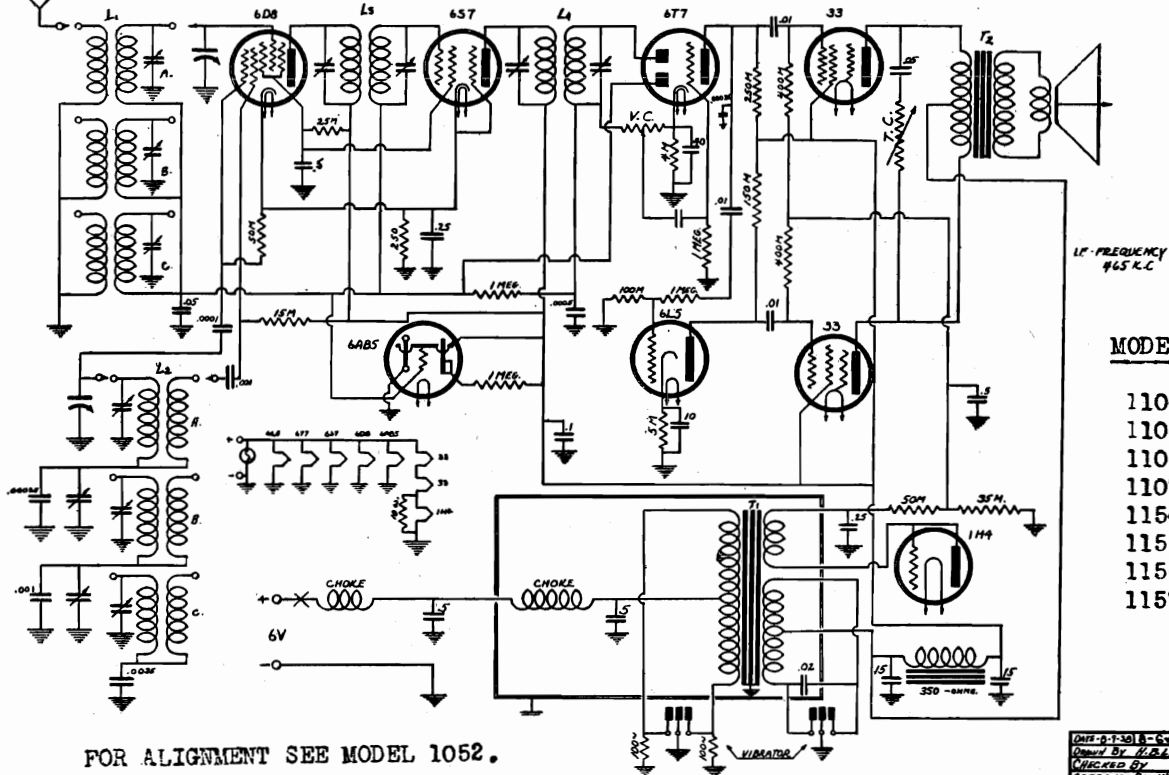

**BROADCAST BAND:** Set the band switch for broadcast reception. Adjust oscillator to 1400 KC and connect the output of the generator to the antenna connection at the rear of the chassis through a .0002 mid. mica condenser. Set the pointer on the dial to 1400 KC marking sure that the volume control is set at its maximum position. Adjust the broadcast antenna and broadcast oscillator trimmers for maximum signal (as indicated on the output meter). Re-set the dial pointer on the receiver and on the test oscillator to 600 KC. Slowly increase or decrease the broadcast padding condenser while tuning back and forth across the signal with the station selector knob until the maximum reading is obtained on the output meter. Re-check the 1400 KC alignment as the adjustment at 600 KC may have slightly disturbed the original 1400 KC setting.

**SHORT WAVE:** Set band switch on short wave position. Connect the antenna of the radio receiver to the output of the test oscillator through a 400 ohm carbon resistor. Set oscillator and receiver dial at 15 megacycles. Adjust the short wave antenna and short wave oscillator trimming condensers for maximum output as indicated by readings on the output meter. No other adjustments are necessary for aligning this band.

It is advisable to check the sensitivity at 6000 KC to determine whether the circuits are properly aligned. Should the receiver lack sensitivity at this frequency check the .0035 mica condenser for short circuit.

**TO ALIGN THE VARIABLE CONDENSER:**

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis and inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left front corner of the receiver) will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.8 MEGACYCLES.  
Rotate gang condenser so that plates are completely out of mesh and then tune in the 18.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.8 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.8 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillation trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.8 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.8 megacycles. Then vary the receiver dial slightly to the right and left of 17.8 megacycles, and if the fundamental peak was used in aligning at 18.8 megacycles the test oscillator signal will be heard at approximately 17.8 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.8 megacycle oscillator trimmer must be properly readjusted.
3. With band selector switch set for operation on 5.8 to 18.8 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 15 MEGACYCLES. Adjust 15 megacycle antenna and R.F. trimmers to maximum 15 megacycle signal sensitivity.
4. Leave band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial and set the test oscillator frequency to approximately 6 megacycles. While rocking gang condenser slightly to right and left adjust 6 megacycle oscillator padder for maximum sensitivity.
5. Place band selector switch for operation on 1.8 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES.  
Rotate gang condenser so that plates are completely out of mesh and then BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 5.8 megacycle oscillator trimmer.
6. With the band selector switch set for operation on 1.8 to 5.8 Megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna and R.F. trimmers for maximum 5 megacycle signal sensitivity.
7. Leave band selector switch for operation on 1.8 to 5.8 megacycle band, tune receiver dial and set test oscillator frequency to approximately 2 megacycles. While rocking gang condenser slightly to right and left adjust 2 megacycle oscillator padder for maximum sensitivity.
8. Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1730 kilocycle band and set test oscillator frequency to EXACTLY 1730 KILOCYCLES.  
Rotate gang condenser so that plates are completely out of mesh and BRING IN THE 1730 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1730 KILOCYCLE OSCILLATOR TRIMMER.
9. With band selector switch placed for operation on the 540 to 1730 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycles R. F. and antenna trimmers for maximum 1400 kilocycle signal sensitivity.
10. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

Alignment

**ALIGNMENT DATA**

The alignment of this receiver requires the use of a test oscillator that will cover the following frequencies, 465, 600, 1400, 6000, and 15000 K.C. and an output meter which is to be connected across the output transformer on the speaker. All alignments should be made with the volume control set at maximum and the output of the test oscillator set as low as possible to prevent the automatic volume control from operating and thus giving incorrect readings during alignment.

**INTERMEDIATE FREQUENCY:** Set oscillator to 465 KC. Feed this to the grid of the pentagrid (6A7) converter tube. Adjust trimmers on the intermediate frequency transformers for peak readings as indicated on the output meter which is to be placed across the output transformer.

**BROADCAST BAND:** Set the band switch for broadcast reception. Adjust oscillator to 1400 KC and connect the output of the generator to the antenna connection at the rear of the chassis through a .0002 mfd. mica condenser. Set the pointer on the dial to 1400 KC making sure that the volume control is set at its maximum position. Adjust the broadcast antenna and broadcast oscillator trimmers for maximum signal (as indicated on the output meter). Re-set the dial pointer on the receiver and on the test oscillator to 600 KC. Slowly increase or decrease the broadcast padding condenser while tuning back and forth across the signal with the station selector knob until the maximum reading is obtained on the output meter. Re-check the 1400 KC alignment as the adjustment at 600 KC may have slightly disturbed the original 1400 KC setting.

**SHORT WAVE:** Set band switch on short wave position. Connect the antenna of the radio receiver to the output of the test oscillator through a 400 ohm carbon resistor. Set oscillator and receiver dial at 15 megacycles. Adjust the short wave antenna and short wave oscillator trimming condensers for maximum output as indicated by readings on the output meter. No other adjustments are necessary for aligning this band.

It is advisable to check the sensitivity at 6000 KC to determine whether the circuits are properly aligned. Should the receiver lack sensitivity at this frequency check the .0035 mica condenser for short circuit.

## Push Button Station Selector

### ADJUSTMENT

The five stations wanted should be decided upon as this will determine which button must be used. Button number 1 as indicated in figure one is used for stations whose transmitting frequencies are between 920 K.C. and 1500 K.C. (as shown on the dial). Buttons 2 and 3 for stations whose frequencies are between 750 and 1400 K.C. Button number 4 for stations whose frequency is from 590 to 1150 and button 5 for those stations whose frequencies are between 540 and 1000 K.C.

FRONT VIEW FIGURE 1

If a desired station falls in the range of button 1, tune the radio to this station with the colored button on the push button control panel pressed in (this button releases the automatic tuner and provides for manual tuning of the receiver.)

Press in button 1 and with a screw driver turn adjusting screw 1B as shown in figure 2 until this same station is heard, then turn screw 1A until the station is heard with maximum volume as indicated by the closing of the electric eye on the front panel. Carefully re-adjust 1A and 1B again for maximum volume.

**DO NOT FORCE** the screws as the threads may be sheared and rendered useless. This may happen if you do not observe what range the station falls into, and thus use the wrong push button.

Proceed with button 2 in a similar way, first pressing in the manual tuning button and tuning to the desired station then pressing button 2 and adjusting screws 2B and 2A to the same program. Buttons 3, 4, and 5 are adjusted in a similar manner using screws 3B and 3A for the third button; 4B and 4A for the fourth button, etc.

CONNECTIONS REAR VIEW TO CHASSIS. FIGURE 2

**NOTE:**—In some models the odd color release button is located to the extreme left instead of to the right as indicated in figure one. Thus if the release button is to the extreme left the adjustment screws in figure 2 are reversed. Reading from left to right they become 5B-5A-4B-4A etc.

### CAUTION

It is important that the adjustments be carefully made otherwise the reception of the radio station will be distorted and lacking in volume. In some instances it is advisable to re-adjust all the screws a few days after the initial setting to compensate for any drift due to room temperature, humidity, etc.

### OPERATION

For manual tuning, press the release button and proceed to tune stations in the usual manner with the station selector knob.

Do not attempt to press more than one button at a time as this will not tune any additional stations. Although this will not in any way injure the unit, it may result in the radio receiver squealing and having excessive interference.

To operate the automatic station tuning control it is only necessary to press in any one of the five station tuning buttons. This automatically disengages the manual tuning control from the electrical circuit. Thus it is possible to leave the dial tuned to any station and yet use the automatic push button station selector.

**THE ODD COLORED RELEASE BUTTON SHOULD ALWAYS BE IN WHENEVER THE REGULAR TUNING KNOB IS USED TO SELECT THE STATIONS.**

Station Call Letters may be inserted in the spaces provided and can be changed at will.

MODELS 2064, 2065, 4014, 4064, 4066 (1937) Chassis 745  
MODELS 2070, 2071, 4076 (1937) Chassis 1105

FRONT OF CABINET

If desired the tuning dial may be left set to a station which is not set up on one of the buttons. The "Dial Tuning" button will then tune in this station when it is pressed. This will give an extra Instamatic tuned station, making a total of six different stations which can be instantly tuned in by simply pressing a button.

The approximate frequency coverage of each of the "Instamatic" control buttons is as follows:

- 1—Stations between 540 and 1000 K.C.
- 2—Stations between 540 and 1000 K.C.
- 3—Stations between 750 and 1200 K.C.
- 4—Stations between 750 and 1200 K.C.
- 5—Stations between 1000 and 1500 K.C.

## INSTAMATIC TUNING

The purpose of Instamatic tuning is to give the user instant, automatic tuning of any one of a selection of favorite broadcast stations. The control buttons are conveniently located just below the tuning dial. Pushing in any button will release any other button which happens to be already in. After the Instamatic tuning feature has been properly adjusted, this will instantly and automatically tune in the station selected by this button.

Before attempting to adjust or use Instamatic tuning, the "Installation" and "Operation" instructions must be carefully followed. When the receiver is operating satisfactorily using the tuning dial with the "Dial Tuning" button pressed in, the Instamatic feature may be easily adjusted by carefully following these instructions.

Located on the back of the chassis is a row of five pair of small bakelite adjustment knobs. Each pair of these knobs controls the tuning of the station for the Instamatic button which is in the same relative position.

With the receiver operating with the "Dial Tuning" button in and the wave switch on broadcast position, turn the tuning knob to the left until the 540 KC end of the band has been reached. Then turn the tuning knob to the right until a station, for which it is desired to have Instamatic tuning, is heard. Press in the Button No. 1: This is the button at the left hand end of the row. Reach around to the back of the receiver and turn upper knob of the Pair No. 1 until the same program is heard. Unless the wrong knob is being turned, several different stations will be heard during this procedure. If necessary to check that the same program is now tuned in, the "Dial Tuning" button may again be pressed. In this way it can be determined that the same station is tuned in with the Instamatic button as when the "Dial Tuning" button is in. If it is not the same station the adjustment knob should be turned again and these operations repeated until the same program is heard when either of these two buttons is pressed.

The bottom adjustment knob of the first pair is now turned until the station is heard the best. Both top and bottom knobs may then be adjusted to exact tuning by watching the magic eye and adjusting until the two edges of the green section are as close together as it is possible to get them.

The first Instamatic button is now properly adjusted for the station which was tuned in on the dial and the station's call letters may be pushed out of the station list, moistened on the back, and pressed into the hollow end of the button.

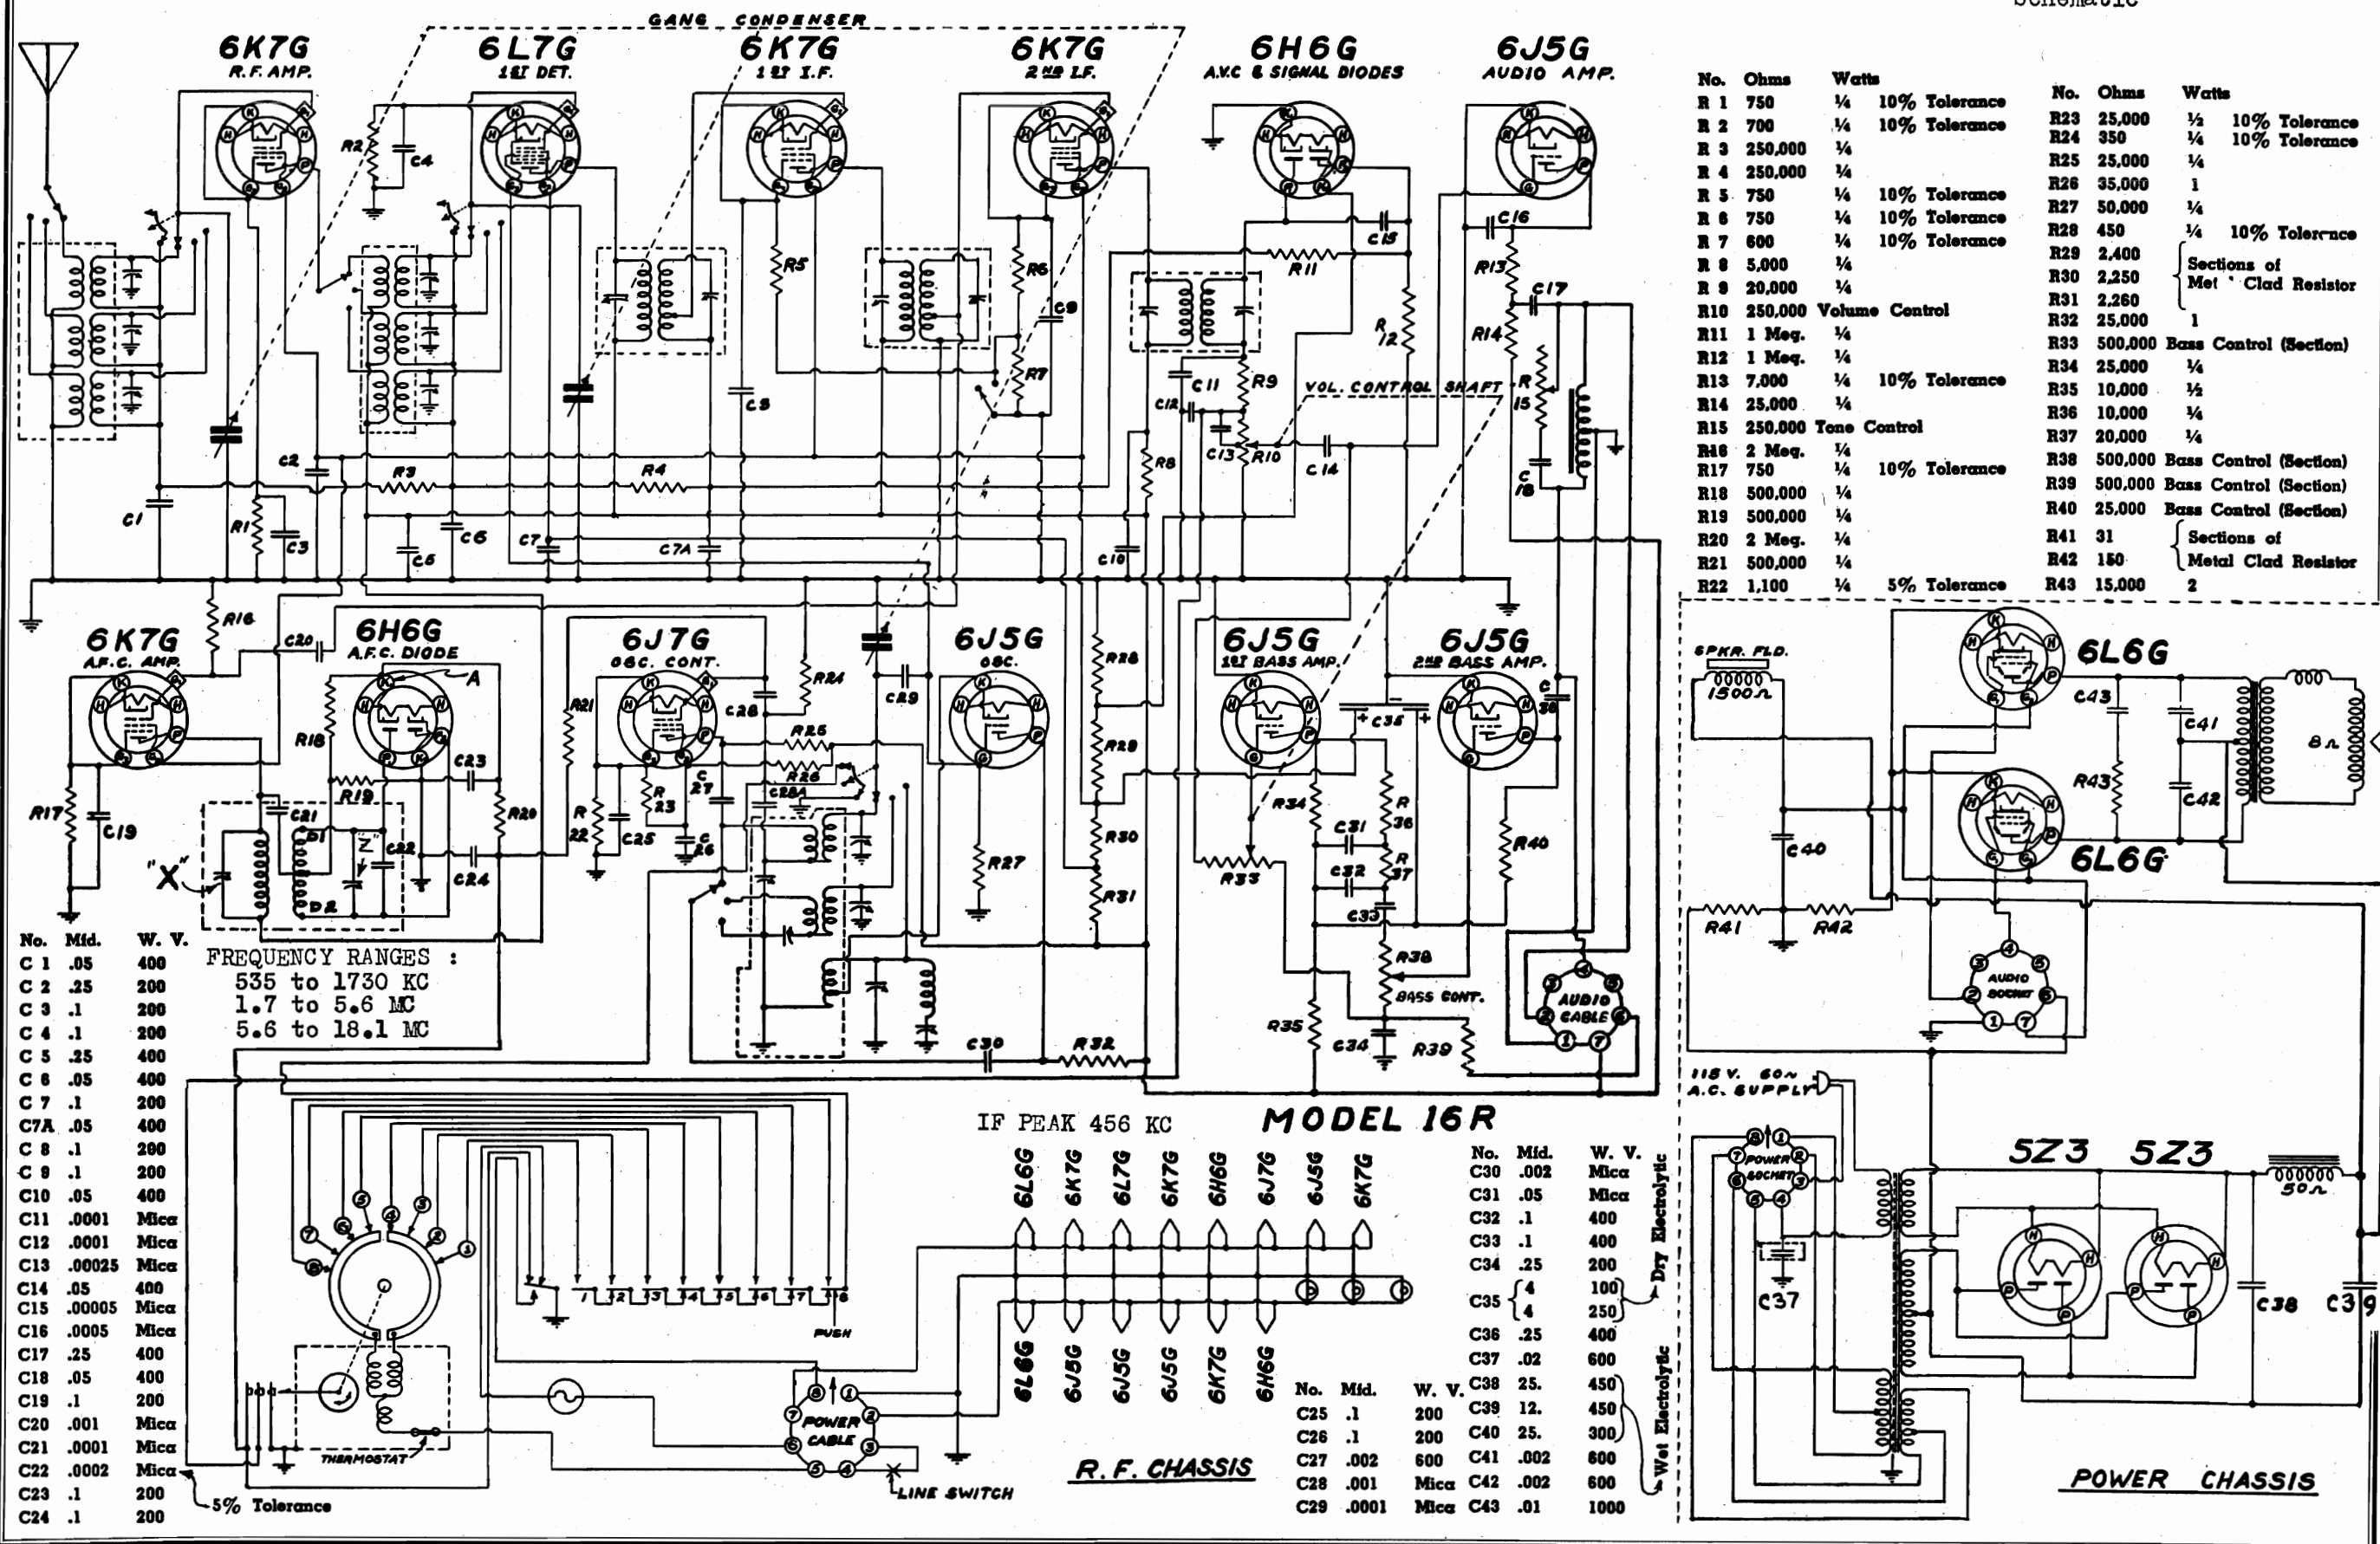

With the "Dial Tuning" button pressed in, the tuning knob is again turned to the right until the next station for which Instamatic tuning is wanted, is tuned in. The adjustment process for this station is the same as before, except that Button No. 2 and Pair No. 2 adjustment knobs are used. Proceeding in this way all five of the buttons may be properly adjusted for the stations desired.

It must be remembered that the "Dial Tuning" button must be pressed in whenever it is desired to tune in stations with the tuning knob, regardless of which wave band is in use. It must also be remembered that the wave switch must be in the broadcast position when Instamatic tuning is being used.

set frequency. After all eight (8) stations have been adjusted, check each adjustment by tuning in each station. NOTE: In the window above the white button, insert the word "OFF" found in the call letter sheet.

INSTRUCTIONS FOR ADJUSTMENT AND OPERATION OF THE ELECTRIC TUNER

It is very important to read the following instructions carefully before attempting to adjust the electric tuner. The electric tuner is made up of three integral units:

**PUSH BUTTON SWITCH** The push button switch consists of one (1) white button (extreme left) and eight (8) brown buttons whose numerical sequence is reckoned from left to right. The white button is provided for converting the set from automatic electric push button tuning to manual knob tuning. The brown buttons are provided for automatic electric tuning.

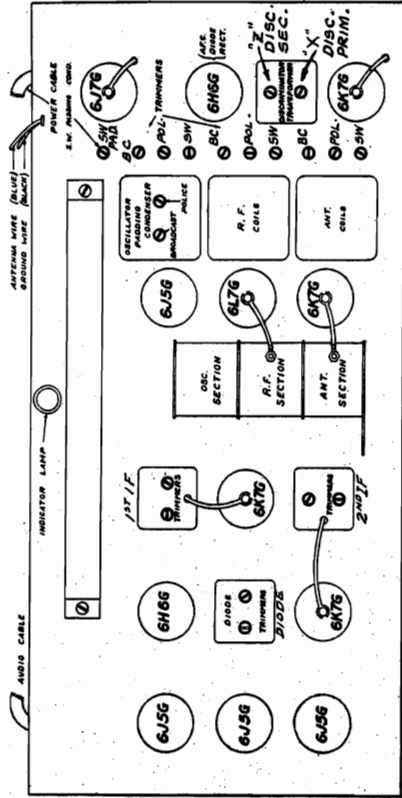

**SELECTOR MECHANISM** The selector mechanism consists of eight (8) thumb screws, and the adjustment light bulb.

ELECTRIC MOTOR

The power for this tuner is provided by a small, efficient electric motor, of the brushless variety. It is fitted with an automatic clutch and a silent gear train.

The bearings and the oil retainer hold sufficient oil to lubricate the motor for a lifetime. The first step to take in adjusting the electric push button tuner is to incorporate into the stations which can be received from excess fading. Turn on the receiver (broadcast band) and press in the white button; tune in the station of the lowest frequency, using the station selector knob. Now hold the white button in and press in button number one (1), next to the white button. (See Figure 1). Both buttons are now locked into place; a small pilot lamp located at the rear of the chassis will light up unless the thumb screw at the rear accidentally happens to be correctly set. Loosen thumb screw number one (See Figure 2). For order of thumb screws) enough to allow it to slide freely back and forth until the light goes out. Now tighten the thumb screw; the adjustment for the first station is now complete. Out of the station call letter sheet supplied remove the proper station call block and insert into the window directly above button number one (1). Now release button number one (1) by pressing the white button in as far as it will go.

With the white button still in, tune in the station of the next highest frequency and holding the white button, press in button number two (2). Both buttons are now locked into place. Loosen thumb screw number two (see Figure 2) and slide back and forth until a point is reached at which the pilot lamp in the rear goes out; tighten the thumb screw. Insert the proper station call into the window of button number two (2). Follow this same procedure for the remaining stations, always choosing the station with the next highest frequency.

**I.F. ALIGNMENT** - Generator at 456 KC, connected to control grid of 6L7 thru .05 MFD condenser, align 1st, 2nd, and Diode transformer trimmers to peak. Connect a 0-200 micro-ammeter between the ungrounded cathode of the 6H6 A.C. diode and ground. The cathode is indicated as point "A" in the schematic. Place a 100 MAFD condenser as point "B" and "D2" on the schematic. The condenser is used to detune the secondary circuit during the following primary adjustment: The primary is tuned by impressing an I.F. signal on the signal grid of the 6L7 and adjusting the trimmer marked "X" on the schematic and the chassis layout, to give a maximum meter indication. Signal strength should be approximately 100,000 microvolts for the adjustment. With reduced signal strength repeat the adjustments of the entire I.F. system, for maximum sensitivity. The volume control should be on full for all adjustments. Without disturbing the generator or any of the other adjustments, the trimmer "2" ("Disc. Sec.") should be adjusted as follows: Remove the 100 MFD condenser from across the discriminator secondary, increase the generator signal to approximately 100,000 microvolts, with volume control turned down to limit the meter will now probably read in reverse and off scale. Reverse trimmer adjustment bringing meter reading to zero. Used only a non-metallic screw driver. It is sometimes convenient to use an offset of "remote zero" setting of the micro-ammeter in making the adjustments so that zero current setting is higher on the scale. After the current has been brought to zero by the above described method the I.F. alignment and discriminator tuning is completed, and R.F. alignment may be accomplished.

**BROADCAST BAND** - Generator at 1790 KC, connected to the antenna thru a 200 MFD condenser, variable condenser at minimum, peak oscillator trimmer. Generator at 1400 KC, tuning in signal, peak the RP and antenna trimmers. Generator at 600 KC, while rooking variable condenser, peak the oscillator padding condenser.

**POLICE BAND** - Generator at 5600 KC, connected to antenna thru 400 Ohm resistor, variable condenser at minimum, peak oscillator trimmer. Generator at 5000 KC, tune in signal, peak RP and antenna trimmers. Generator at 1800 KC, while rooking variable across signals, pad the oscillator circuit for maximum response.

**SHORTWAVE BAND** - Generator at 18100 KC, gang condenser at minimum, peak oscillator trimmer. Generator at 16000 KC, locate signal on receiver, peak RP and antenna trimmers. Generator at 6000 KC, while rooking variable across signal, peak SW padding condenser.

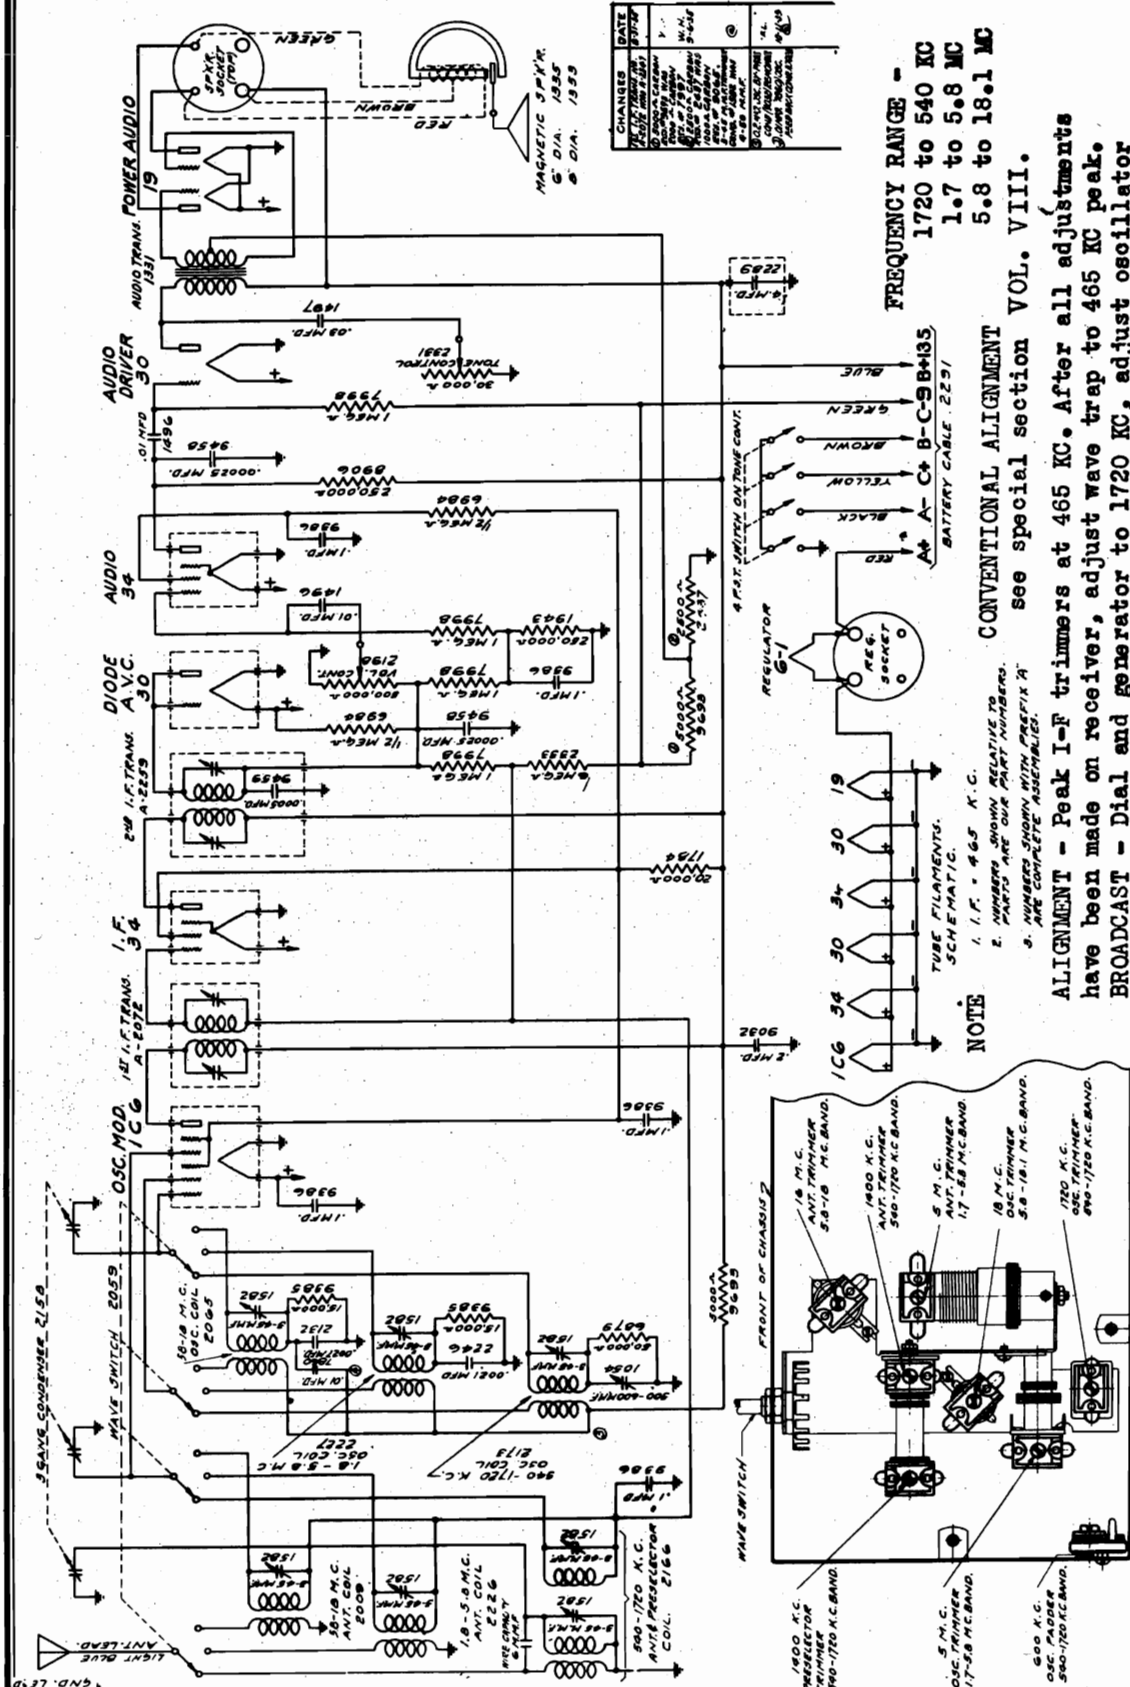

HOW TO TUNE IN STATIONS USING THE ELECTRIC PUSH BUTTON TUNER

In order to operate the receiver satisfactorily—using the electric push button tuner, the white button must be in released position, that is, all the way out. To tune in a station, merely press the selector button which designates the station desired. Notes: Should the station fail to come in clearly, check the cabinet ment by following the adjustment procedure described in the paragraph above. If by chance all of the buttons are pressed in, they may be released by pressing any one button all the way in.

DESCRIPTION

This receiver is a 7 tube alternating current operated superheterodyne. The tubes used are a 76 as oscillator, a 6A7 as modulator, a 6D6 as I. F. amplifier, a 75 as A. V. C. and audio rectifier and audio voltage amplifier, a 41 as power audio amplifier, an 80 as a power rectifier and a 6G5 as tuning indicator. This receiver is made to cover 2 tuning bands, the standard broadcast band which ranges from 1730 K.C. to 535 K.C. and the middle or police band which has a frequency range of from 6.4 M.C. to 2.1 M.C.

DESCRIPTION

This receiver is an 11 tube alternating current operated superheterodyne.

The tubes used are a 6C5G oscillator, a 6A8G modulator, a 6K7G I.F. amplifier, a 6C5G A.V.C. rectifier, a 6H6G detector, a pair of 6J7G audio amplifiers, a pair of 6V6G power amplifiers, an 80 rectifier, and a 6G5 tuning indicator or magic eye.

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C., to 535 K.C., the middle or police band which has a frequency range of from 5.4 M.C. to 1.7 M.C. and the high frequency or foreign band which is from 19 M.C. to 5.0 M.C.

Alignment

**ALIGNMENT PROCEDURE:**

Lack of sensitivity and poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, low battery voltage, open or grounded bias resistor, bypass condenser, inadequate, or excessively long antenna, etc. Never attempt to reclin set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE: IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER AND THAT THE PROCEDURE BE CAREFULLY FOLLOWED. OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT.**

THE TRIMMER AND PADDING CONDENSER WILL BE REFERRED TO BY THEIR FUNCTION, AS SHOWN IN PARTS DIAGRAM.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

- (a) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid of the 1C6 tube through a .02 Mfd. series condenser. **DO NOT REMOVE GRID CLIP.**
- (b) Set test oscillator to EXACTLY 465 KILOCYCLES and turn receiver volume control on full.
- (c) Peak each of the second I.F. transformer trimmers.
- (d) Peak each of the first I.F. transformer trimmers.

**ALIGNING 1730-530 KILOCYCLE BAND:**

- (a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.
- (b) Remove test oscillator lead from grid of 1C6 tube and connect to receiver antenna lead through a .00025 Mfd. series condenser.
- (c) Adjust band selector switch for operation on the 1730-530 kilocycle band.
- (d) Set test oscillator frequency and receiver dial to EXACTLY 1730 kilocycles. Turn chassis on end and adjust 1730 kilocycle oscillator trimmer for maximum 1730 kilocycle test oscillator signal sensitivity.
- (e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles and adjust 1400 K. C. antenna trimmer for maximum sensitivity.
- (f) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K.C. oscillator paddler for maximum sensitivity.

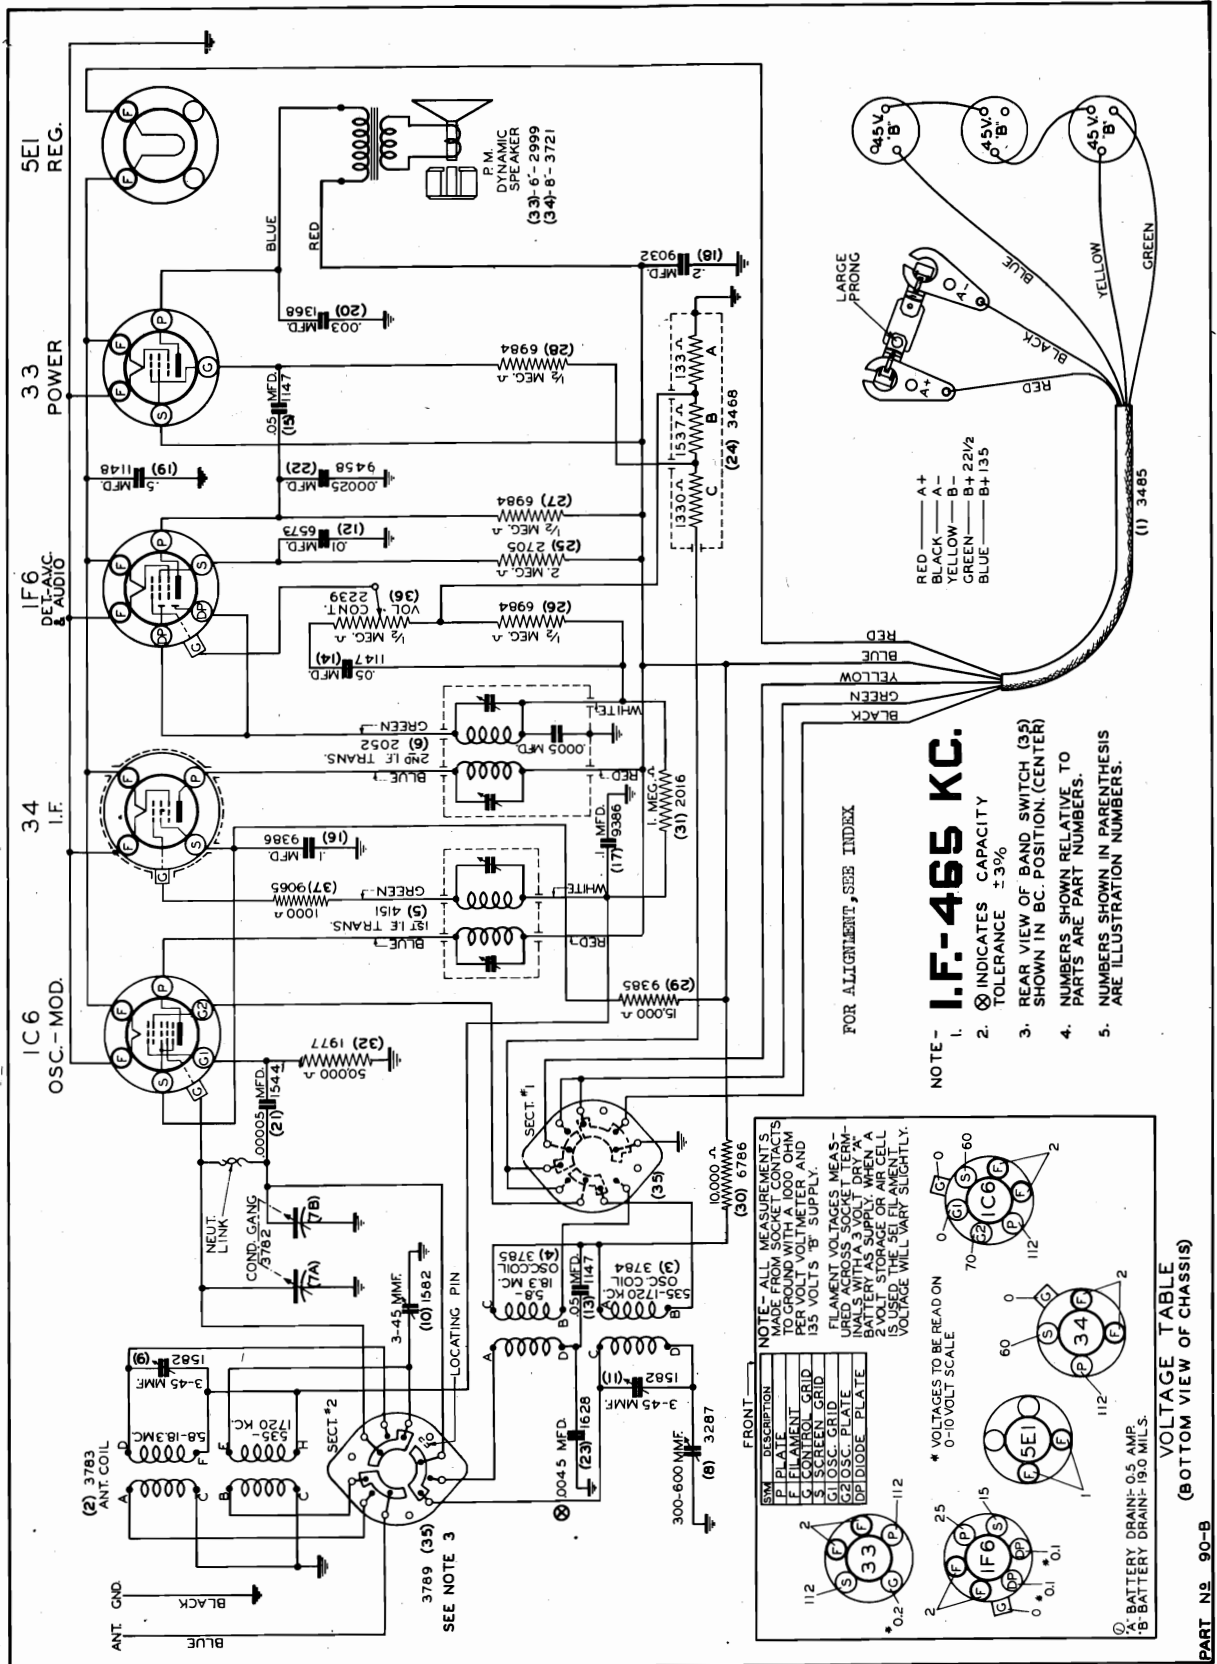

**ALIGNING 5.8-18.1 MEGACYCLE BAND:**

- (a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor, and place band selector switch for operation on 5.8-18.1 megacycle band.
  - (b) Tune receiver dial and set test oscillator frequency to approximately 15 megacycles.
  - (c) Rock gang condenser slightly to right and left and adjust 15 M.C. antenna trimmer for maximum 15 megacycle test signal response.
- To assure more accurate trimmer setting, repeat all above adjustments several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

Alignment

MODELS 2070 - 2071 - 4076 , 4004 - 4052 , 4068.

ALIGNMENT PROCEDURE

The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 10,000 ohms, to the two plate pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Press in the dial Tuning button. Models 2070, 2071, 4076 and 4068.

Connect the signal generator to the grid cap of the 6A7 tube through a 1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the signal generator connected to the grid cap of the 6A7, turn the wave switch to the right hand (short wave) position. Set the dial and the signal generator to 15.0 M.C. Tune in the signal by adjusting the 15.0 M.C. oscillator trimmer. The signal will be heard at two different settings of the trimmer. The proper setting is the one where the signal is heard when the trimmer is the loosest. Also when the dial of the receiver is turned the signal will be heard again at about 14.0 M.C. If the signal is heard at about 16.0 M.C. on the dial instead of 14.0 M.C. the wrong setting has been used and should be corrected.

Set the wave switch on broadcast position, turn the dial to the extreme high frequency end. Feed a 1680 K. C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer, and the 1500 K.C. broadcast preselector trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output while tuning the receiver back and forth across the signal from the generator. This completes the alignment of the broadcast band.

The police band is aligned by feeding a 4.0 M.C. signal to the receiver antenna lead through the .00025 mica condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output.

grid cap of the 6A8G tube Models 2070, 2071, and 4076.

The short wave band is aligned in the same way using a 15 M.C. signal and adjusting the 15 M.C. short wave antenna trimmer after having turned the wave switch to the right hand position.

MODELS 2064 - 2065 - 4014 - 4064 - 4066.

ALIGNMENT PROCEDURE

The following alignment procedure is for use only by competent service men having the proper equipment. Re-alignment is very seldom needed and is usually only required after some major part has been replaced because of damage to the receiver.

The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. With the wave switch on broadcast position, press in the dial tuning button and set the dial to about 1000 K.C. Then feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1730 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1730 K.C. broadcast oscillator trimmer until maximum output is shown. Set the generator to 1400 K.C. and tune in this signal on the receiver. Then adjust the 1400 K.C. broadcast antenna trimmer to maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output while tuning the receiver back and forth across the signal from the generator. This completes the alignment of the broadcast band.

The short wave band is aligned while feeding a 6.0 M.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Turn the wave switch to short wave position and tune in the 6.0 M.C. signal. Adjust the 6.0 M.C. short wave trimmer to maximum output.

SPIEGEL INC.

Lack of sensitivity, selectivity or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, improperly connected or low battery, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, etc. Never attempt to realign set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

**NOTE: BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING. OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT.**

IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.

**ALIGNING I.F. STAGE AT 465 KILOCYCLES:**

- (a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead of the test oscillator to the grid cap of the No. 6D8G modulator tube through a .02 Mfd. condenser. DO NOT REMOVE GRID CLIP.
- (b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.
- (c) Peak each of the second I.F. transformer trimmers.
- (d) Peak each of the first I.F. transformer trimmers.

To assure most accurate trimmer setting repeat above adjustment several times, always using lowest possible test oscillator output consistent with readable output meter scale deflection.

**ALIGNING ANTENNA AND OSCILLATOR CIRCUIT:**

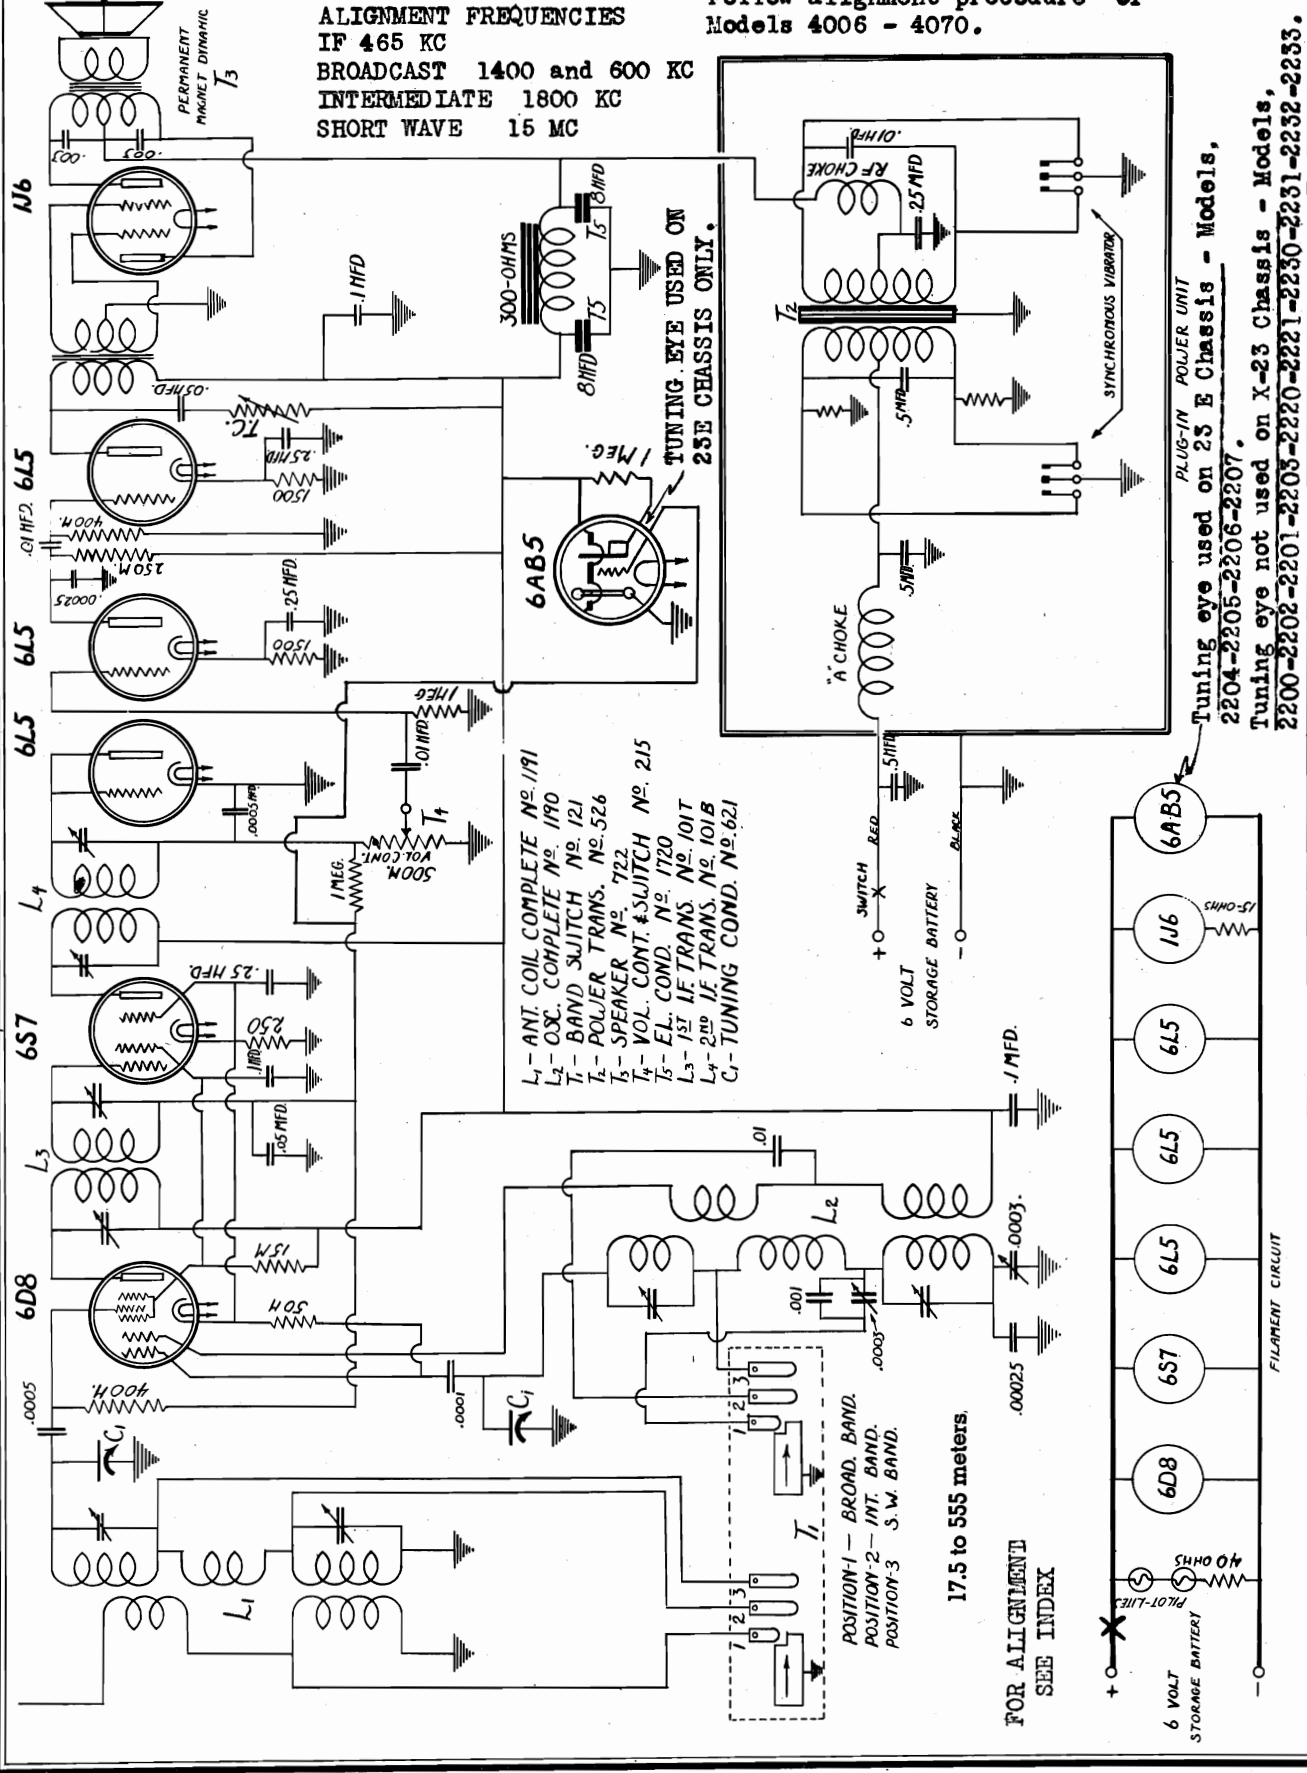

- (a) Connect the high output side of the test oscillator through a .00025 Mfd. condenser to the receiver antenna lead and the low side to the set ground.
- (b) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.
- (c) Set receiver dial and test oscillator frequency to EXACTLY 1720 kilocycles.
- (d) Bring in 1720 KC test oscillator signal to maximum output by adjusting the trimmer condenser mounted on top of the oscillator section of the gang condenser. Looking at the front of the receiver the rear section of the condenser is the oscillator section.
- (e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles.
- (f) Adjust trimmer on top of the front section gang condenser (antenna section) for maximum 1400 kilocycle test signal response.
- (g) Tune receiver dial and set test oscillator frequency to approximately 600 kilocycles.
- (h) While rocking the tuning condenser back and forth adjust 600 K.C. oscillator packer condenser which is accessible through the hole in the top of the chassis adjacent to the gang condenser for maximum 600 kilocycle signal response.

**I.F. ALIGNMENT.** Adjust the test oscillator to 175 K.C. and connect the output directly to the grid of the first detector tube (6A7), without the use of any series condenser or resistor; the omission of series condenser and resistor to block out the AVC action. The ground on the test oscillator can be connected to the chassis ground. Align the trimmers of the first and second I.F. transformers to peak or maximum reading on the output meter.

**R.F. ALIGNMENT.** The next step is to adjust the center and rear trimmers of the gang condenser to peak. The center section of the gang condenser tunes the antenna amplifier stage (6D6 tube), and the rear condenser section tunes the detector grid coil of the 6A7 tube.

**OSCILLATOR ALIGNMENT.** Adjust the test oscillator to 1400 K.C. and connect the output to the antenna through

IF PEAK 456 KC

DESCRIPTION

This receiver is an 8 tube alternating current operated superheterodyne. The tubes used are a 6A7 as oscillator modulator, a 6D6 as I.F. amplifier, a 75 as A.V.C. and audio rectifier and audio voltage amplifier, a 76 as audio phase inverter, an 80 as a power rectifier, a 6H5 as tuning indicator and two type 42 tubes as push pull audio power amplifiers.

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.6 M.C. to 1.7 M.C. and high frequency or foreign band which is from 20 M.C. to 5.4 M.C.

VOLTAGES MEASURED WITH 1000 OHM PER VOLT VOLTMETER.

**ALIGNMENT:** The alignment of this receiver requires the use of a test oscillator that will cover the following frequencies 456, 1400 and 4000 KC. The I.F. coils are aligned for maximum signal as indicated by an output meter which is to be connected across the output transformer. I.F. frequency is 456 KC. There are four adjustments for I.F. alignment.

To align broadcast band it is only necessary to align receiver at 1400 KC because of the initial setting at the factory. A 200 mmfd. condenser is necessary for a dummy antenna. This is inserted in series with the test oscillator and the antenna connection of the radio receiver. Set oscillator and pointer on dial to 1400 KC and adjust the two trimmer condensers on the tuning condenser for maximum output. Turn Band Switch to Short Wave position. Feed a 4000 KC signal from the test oscillator and check receiver.

DESCRIPTION

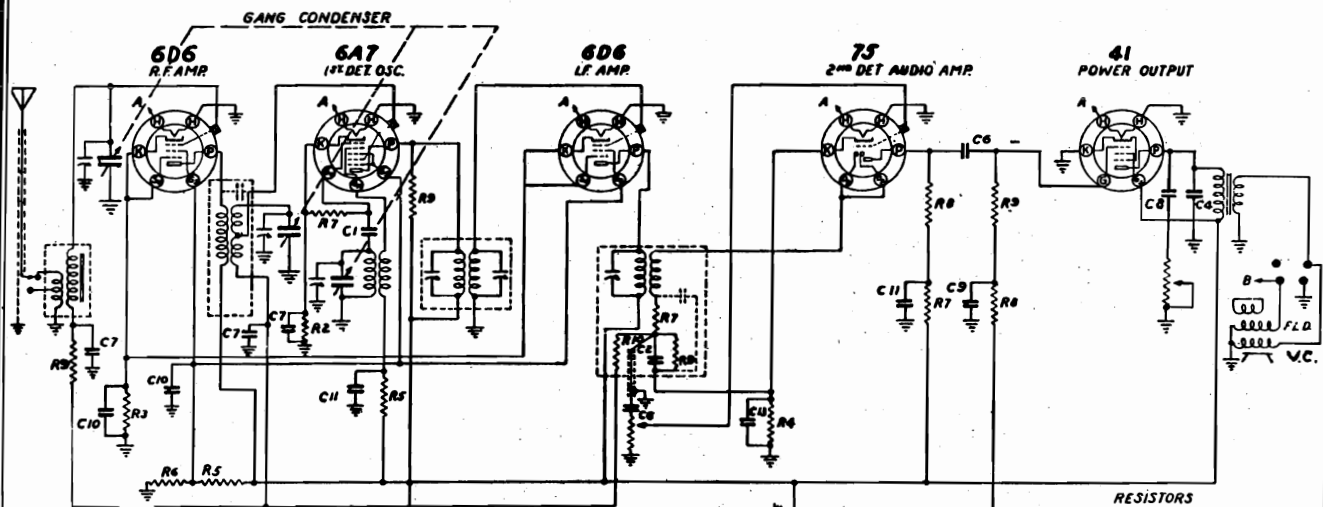

This receiver is an 8 tube alternating current operated superheterodyne.

The tubes used are a 6A7 as oscillator modulator, a 6D6 as IF amplifier, a 6H6G as A.V.C. and audio rectifier, a 6Y7G as audio voltage amplifier, an 80 as a power rectifier, a 6G5 as tuning indicator and two type 6V6G tubes as push pull audio power amplifiers.

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.4 M.C. to 1.7 M.C. and the high frequency or foreign band which is from 19 M.C. to 5.0 M.C.

Total "A" current - 6.2 amperes.

**INTERMEDIATE FREQUENCY:** Unless an intermediate transformer has become defective due to an open or burned out winding it should never be necessary to readjust the intermediate stage. Should this occur it is essential that an oscillator be used with some type of output measuring device to correctly tune the I.F. Transformers. Connect the high side of the oscillator output to the control grid cap (grid No. 4) of the 6A7 oscillator modulator tube leaving the grid cap disconnected. CONNECT A 50,000 OHM RESISTOR FROM THE CONTROL GRID CAP OF THE 6A7 TUBE TO THE ROTOR FRAME OF THE VARIABLE CONDENSER. If the output of the oscillator is too great the value of this resistor may be reduced. The ground side of the test oscillator should be connected to the chassis. Set the oscillator to 265 K.C. (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Align the first intermediate transformer by turning the intermediate frequency transformer trimmer screw up and down until maximum reading is obtained on the output meter. Both the primary and secondary trimmer screws should be adjusted in this manner. It is always best to recheck the grid side of the intermediate frequency transformer adjustment to make certain the alignment of the secondary has not been changed by the adjustment of the primary trimmer. The first I.F. transformer is double-tuned, the trimmers of which are accessible through the top of the I.F. can, one section of which is adjusted by turning the brass hex nut and other section by screwing in and out the set screw that is accessible through the hole provided in the brass hex nut. The second intermediate transformer has but one trimmer which is likewise accessible from the top of the intermediate transformer shield can. After both intermediate transformers are correctly adjusted the alignment of the intermediate stage is complete and the trimmers should not be further disturbed. The grid cap should be connected to the grid of the 6A7 tube and 50,000 ohm resistor removed.

**VARIABLE CONDENSER ALIGNMENT:** If the intermediate frequency stage has been realigned or if the antenna, R.F. or oscillator coil have been replaced it will be necessary to realign the variable condensers. If the receiver is not mounted in the set housing it will be necessary to place a metal shield along side of the variable condenser and flush against the side of the set chassis nearest the variable condenser trimmers. It is necessary to do this otherwise when the receiver is placed in the set housing the metal housing will detune the receiver. Three holes should be made in the shield to correspond with the hole provided in the set housing which permits alignment of the receiver when the set is in the housing. Be sure the shield is properly grounded to the receiver chassis. NOTE: When the receiver and "B" unite is removed from the set housing be sure to set the receiver on top of the "B" unit, otherwise considerable R.F. and audio hash will be encountered. Regardless of whether the receiver is mounted in the set housing or not the alignment procedure is the same. Adjust the variable condenser to minimum capacity. Connect the high output side of the set oscillator to set antenna lead and the low side to antenna shield lead or chassis. Then adjust the test oscillator to 1500 K. C. Next, BRING THIS SIGNAL IN BY ADJUSTING THE VARIABLE CONDENSER OSCILLATOR SECTION TRIMMER. Looking at the front of the receiver, the variable condenser trimmers are mounted on the left side of the set on the variable condenser and reading from the bottom up the trimmers are, oscillator, R.F. and antenna. After the oscillator section has been properly peaked, adjust the antenna and R.F. trimmers in the order mentioned. After the variable condenser trimmers have been correctly adjusted at 1500 K.C. tune the receiver to 600 K.C. and adjust the oscillator to this frequency. Then adjust the oscillator padding condenser which is located on the left hand side to the rear of the chassis, to obtain maximum reading on the output meter. If the set is mounted in the receiver housing the padding condenser is accessible through the small hole in the side of the set housing. It may be necessary to turn the variable condenser slightly to the right and left to find the point where greatest output is obtained. If the alignment procedure is correctly followed the receiver will now track correctly over the entire tuning range. It is always advisable to align the receiver with the tubes to be used in the set whenever possible.

TUNING CONTROLS AND TUBE SOCKET GUIDE

TRIMMER LAYOUT

BROADCAST BAND 535 TO 1800 KC

1. With test oscillator connected to antenna and ground through a 200 Mfd. condenser set oscillator and receiver dial to 1600 kilocycles.
2. Adjust broadcast oscillator trimmer (C4-E) to obtain maximum response.
3. Adjust prescaler trimmer (C2-F) for maximum output.
4. Adjust antenna circuit trimmer (C2-G) for maximum output.
5. Set test oscillator and dial to 600 kilocycles and tune in the signal, then adjust broadcast band tuning condenser (C3-D) for maximum output. This adjustment is made on the aluminum band tuning condenser (C3-D) adjust the dial to the maximum output. The maximum output of the chassis pan. Rock the condenser back and forth a degree or two in order to obtain proper maximum.
6. Repeat the 1600 KC adjustments described above for greater accuracy.

ALIGNMENT PROCEDURE

Correct alignment is of extreme importance in all-wave receivers. The receivers are properly aligned at the factory with precision equipment and readjustment should not be attempted by the service technician. The following steps are necessary for proper alignment:

1. A signal generator which will provide an accurately calibrated signal at any frequency from 456 kilocycles to 18 megacycles. The generator should have adjustable signal output of the speaker. This should be capable of providing a readable deflection for relatively low output levels to avoid the effects of overload.
2. An insulated or non-metallic screw driver for the adjustment of trimmers.

IF ALIGNMENT 456 KC

1. Connect the output meter (low scale) across the loud speaker voice coil. Turn the wave band switch to broadcast position. Turn the volume control to its maximum position.
  2. Connect the test oscillator ground to chassis and the "hot" lead from the test oscillator to the grid of the 6L7 converter tube through a series .1 Mfd. condenser. Set test oscillator to 456 KC.
  3. Adjust IF alignment screws of second IF transformer (directly behind tuning condenser) to maximum output, reducing output of test oscillator to keep the meter reading on scale as alignment procedure is described above.
  4. Adjust alignment of first IF transformer. (Always use the lowest possible output from the test oscillator to preclude the possibility of automatic volume control action confounding proper adjustment.)
  5. Readjust these trimmers for accurate alignment. Always use the lowest possible output from the test oscillator.
- NOTE: Since coils are used in series it is absolutely necessary to align the high frequency bands first, in the order indicated.

FOREIGN BAND 5.7 TO 18.5 MEGACYCLES

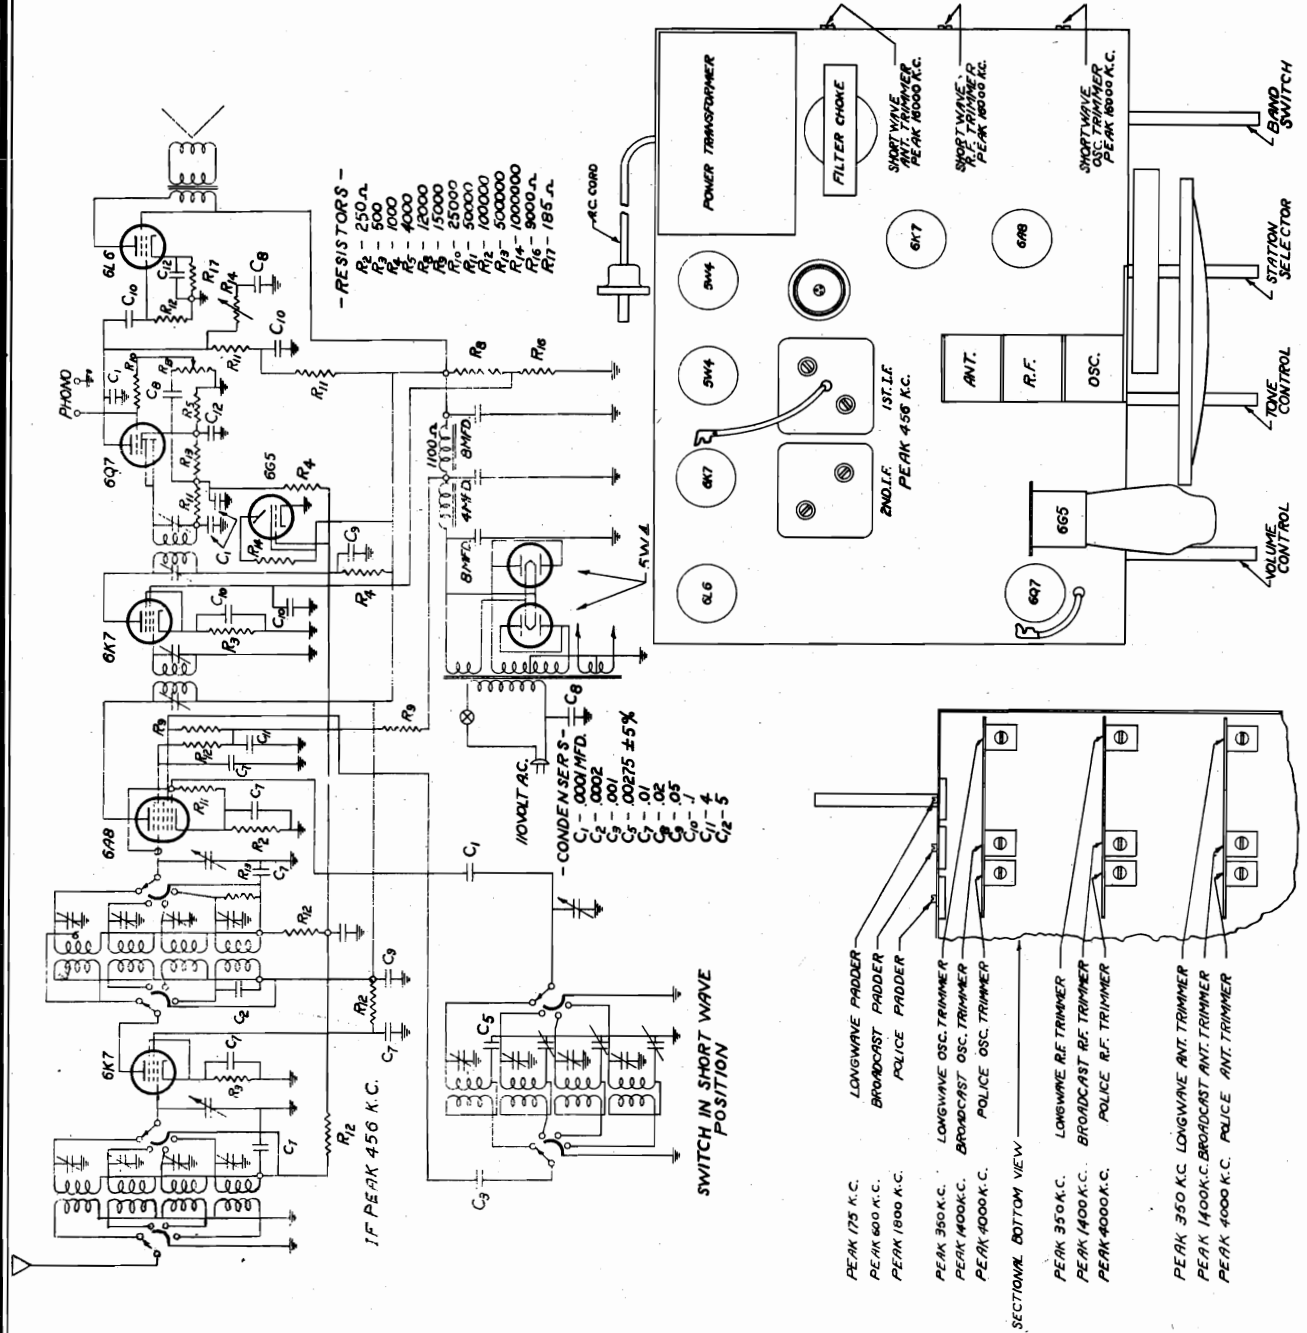

1. With test oscillator connected to the antenna and ground terminals through a 400 ohm resistor set oscillator at 16 megacycles.
2. Set the dial scale to 16 megacycles and adjust the oscillator trimmer condenser (C4-A) to resonance using the counterclockwise or low capacity point.
3. Adjust input circuit trimmer (C2-B) to maximum response, rocking the gang condenser back and forth a degree or two to obtain proper maximum.

POLICE OR MIDDLE BAND 1.75 TO 5.8 MEGACYCLES

1. With the test oscillator connected as above set the oscillator and dial to 5.5 megacycles.
2. Adjust oscillator trimmer condenser (C4-C) for maximum response using the counterclockwise or low capacity point.
3. Adjust input circuit trimmer (C3-D) to maximum response rocking the gang condenser as described above.

 SPIEGEL INC. Schematic, Socket, Trimmers, Alignment

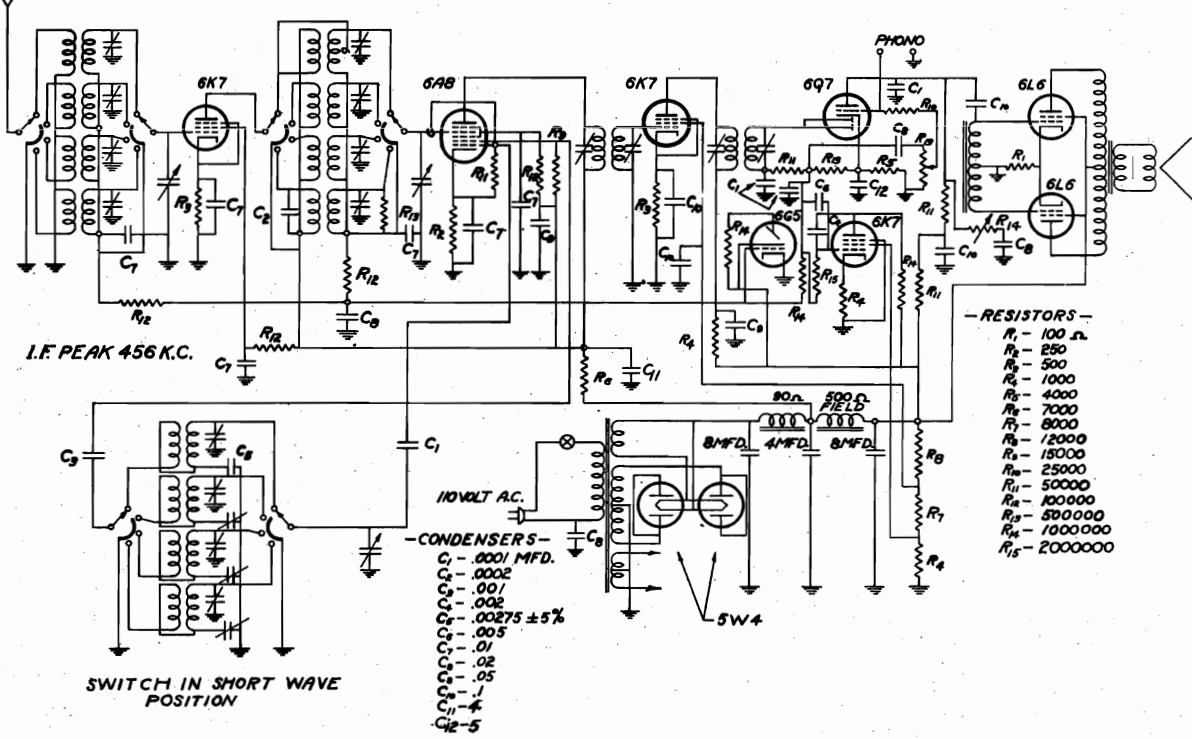

This radio receiver is designed for operation on standard American broadcasts, Police, Amateur, aviation, ships, foreign and U. S. governmental time and weather broadcasts. This vast coverage in radio entertainment and utility is divided into four parts or bands indicated on the tuning dial and the wave band indicating device.

The dial is calibrated with each band covering 340 degrees of tuning scale length and are each concentric with the center of the dial face. The innermost scale is calibrated from 150 to 375 K.C. (2000 to 800 meters) and covers the range necessary for receiving governmental time and weather reports. The second band from the center is for standard broadcasts covering from 550 to 1700 K.C. (175 to 545 meters). The third band from the center covers the intermediate short wave length broadcasts of Police, Amateur, Aircraft and ships and extends from 1700 to 5400 K.C. (55 to 180 meters). The fourth band covers all of the principle short wave channels for reception from countries all over the world. This band carries a calibration of from 5.5 to 18 megacycles (16.4 to 55 meters.) This short wave scale is the one which includes the five internationally assigned bands—the 19, 25, 31, 39 and 49 meter channels.

**7-Tube, 6-Volt Battery Operated Superheterodyne**

**R. F. Alignment:**

With the wave change switch in the broadcast position, set the oscillator to 1700 kilocycles and connect in series with a .00025 condenser to the antenna of the receiver. Rotate the variable condenser to the 1700 setting of the dial and adjust the trimmer condenser of the broadcast oscillator to resonance. This trimmer is located on the right side of the chassis, second position from the front. Reset the test oscillator to 1400 kilocycles and adjust the antenna trimmer located on rear section of variable condenser. Adjust 1st detector trimmer under the chassis across preselector. Now set oscillator to 600 kilocycles and adjust padder located on side of chassis. Check alignment at 1000 kilocycles.

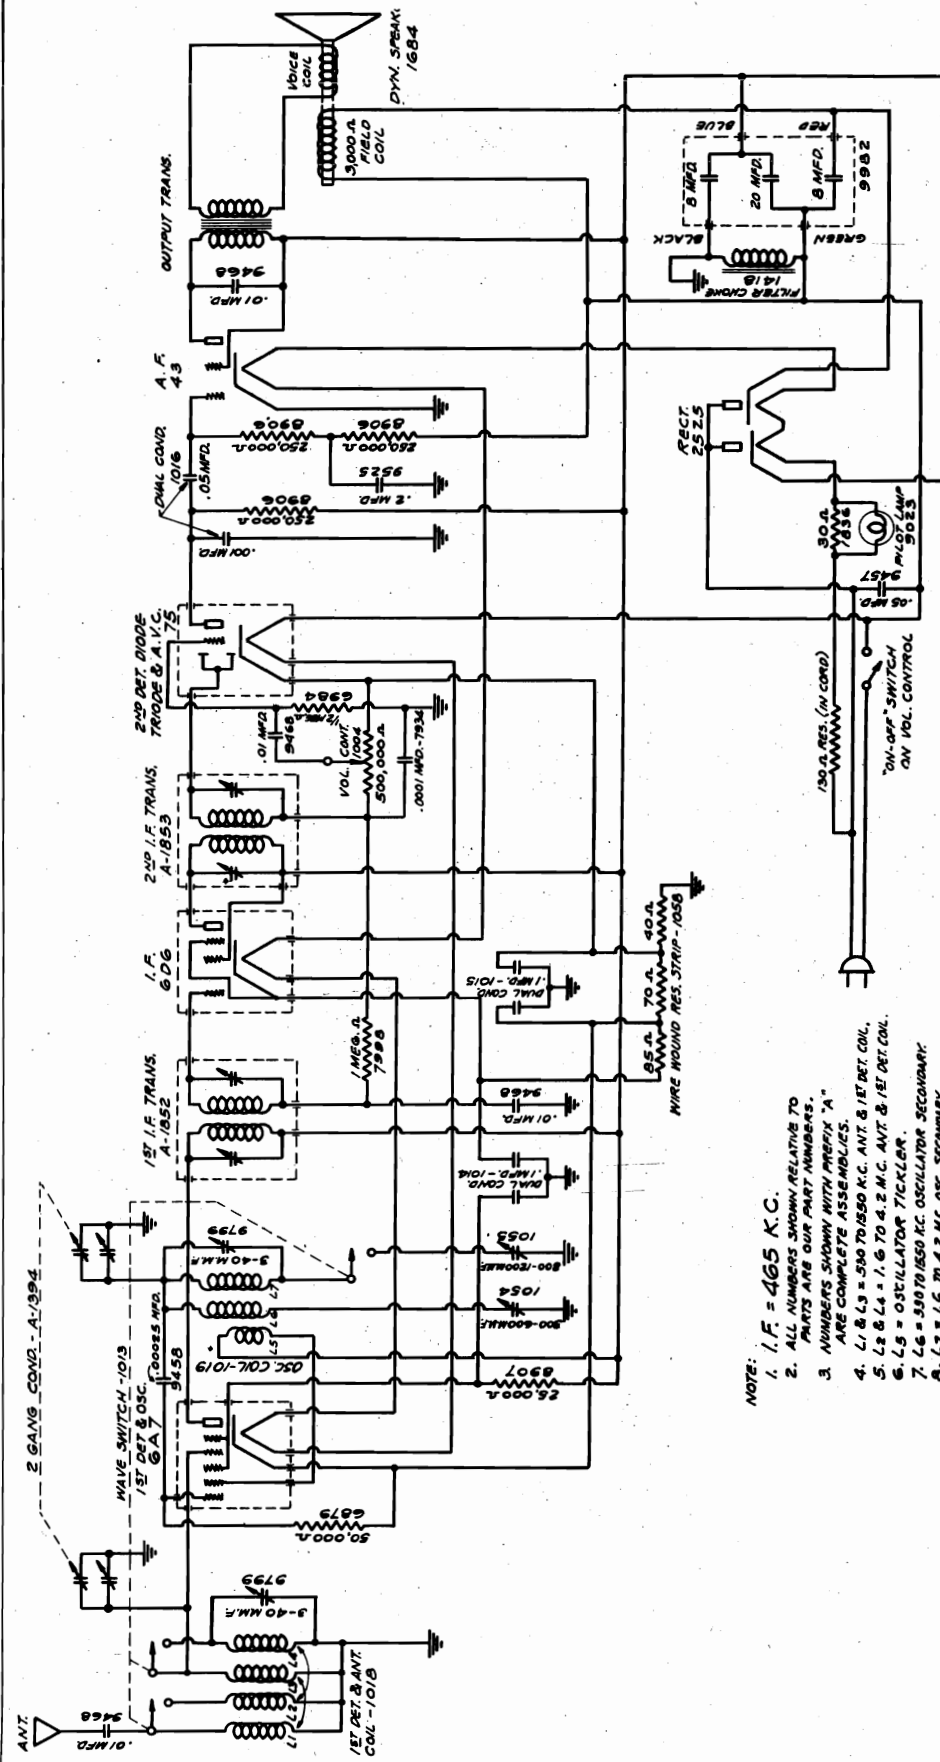

For aligning the police band, set test oscillator to 5 megacycles and switch to the police band position on the set. With the condenser rotated to this frequency setting as indicated on the dial, adjust oscillator trimmer located on the right side of the chassis, first position from the front. Now adjust antenna trimmer located on the front of the chassis, left position, to resonance.

The short wave band is aligned by setting the condenser to 18 megacycles and adjust the oscillator trimmer located on the right side of the chassis, third position from the front to resonance with an 18 megacycle signal from the test oscillator. Turn dial to 16 M. C. Set test oscillator to 16 M. C. and adjust antenna trimmer through right hand hole in front of chassis, rocking variable condenser slightly back and forth to get maximum peak.

 Alignment, Trimmers  
 Antenna Notes, Change

STEWART-WARNER CORP.

ALIGNMENT PROCEDURE

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator are required.

1. Solder the output meter leads from output plate (P<sub>1</sub>) to screen (S) of the 70L7GT tube (See voltage chart). The leads must be soldered since the bottom cover must be replaced during alignment. The output meter leads can be brought through the power cord opening.
2. Connect the ground lead of the signal generator through a .25 mfd. condenser to some portion of the chassis in the VICINITY OF THE GANG CONDENSER.
3. Remove the connector between the antenna terminals on the bottom of the set.
4. Turn the volume control to the maximum volume position and keep it in this position while aligning.
5. The tuning knob should be adjusted so that the nick which appears on the outer part of the knob is accurately centered and points away from the chassis when the gang condenser is in full mesh.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
.1 MFD. Condenser	Lug on bottom gang condenser	455 KC	Any point where it does not affect signal	1	2nd I.F.	Adjust for maximum output. Then repeat adjustment. (If the set oscillates, see precautions under heading "I. F. Oscillation".)
				2-3	1st I.F.	
200 MMFD. Mica Condenser	Antenna Terminal on bottom (Terminal nearest back of chassis)	1500 KC	1500 KC	4	Broadcast Oscillator (Shunt)	Adjust trimmer for maximum output.
200 MMFD. Mica Condenser	Antenna Terminal on bottom (Terminal nearest back of chassis)	1500 KC	Tune to 1500 KC Generator Signal	5	Broadcast Antenna	Adjust for maximum output.

I. F. OSCILLATION

When aligning this set, I. F. oscillation may be encountered if the following precautions are not observed:

1. Keep the bottom cover plate on during alignment.
2. Keep the signal generator leads as far from the chassis as possible in order to prevent unnecessary feed-back.
3. Connect the ground lead of the signal generator through a .25 mfd. condenser to some part of the chassis in the VICINITY OF THE GANG CONDENSER.
4. Keep the orange lead of the volume control away from the 2nd I.F. transformer. Separating this lead from the others surrounding it at the base of the 25B8GT tube will also help.

BUILT-IN ANTENNA SYSTEM

The Built-In Antenna incorporated in this receiver will generally give very satisfactory results in localities where powerful broadcast stations exist. This Built-In Antenna will function when the terminals on the bottom of the chassis are connected together. In cases where noise is excessive or greater sensitivity is desired, remove the jumper connecting these terminals and connect an external antenna to the terminal marked "External Aerial." This is the terminal nearest the back of the set.

The Built-In Antenna Condenser No. 12 couples the primary of the antenna coil to one side of the power line, which acts as the antenna. The R. F. choke No. 21 is an iron-core choke whose impedance is high at broadcast frequencies. This choke serves to prevent condenser No. 31 from by-passing the signal voltage picked up by the power line. It also prevents feed-back into the antenna circuit of radio frequency energy generated in the set itself.

When aligning this receiver, the jumper connecting the antenna terminals on the bottom of the set should be removed. This will prevent picking up signals which might interfere with the alignment procedure.

CHANGE IN VOLUME CONTROL CIRCUIT

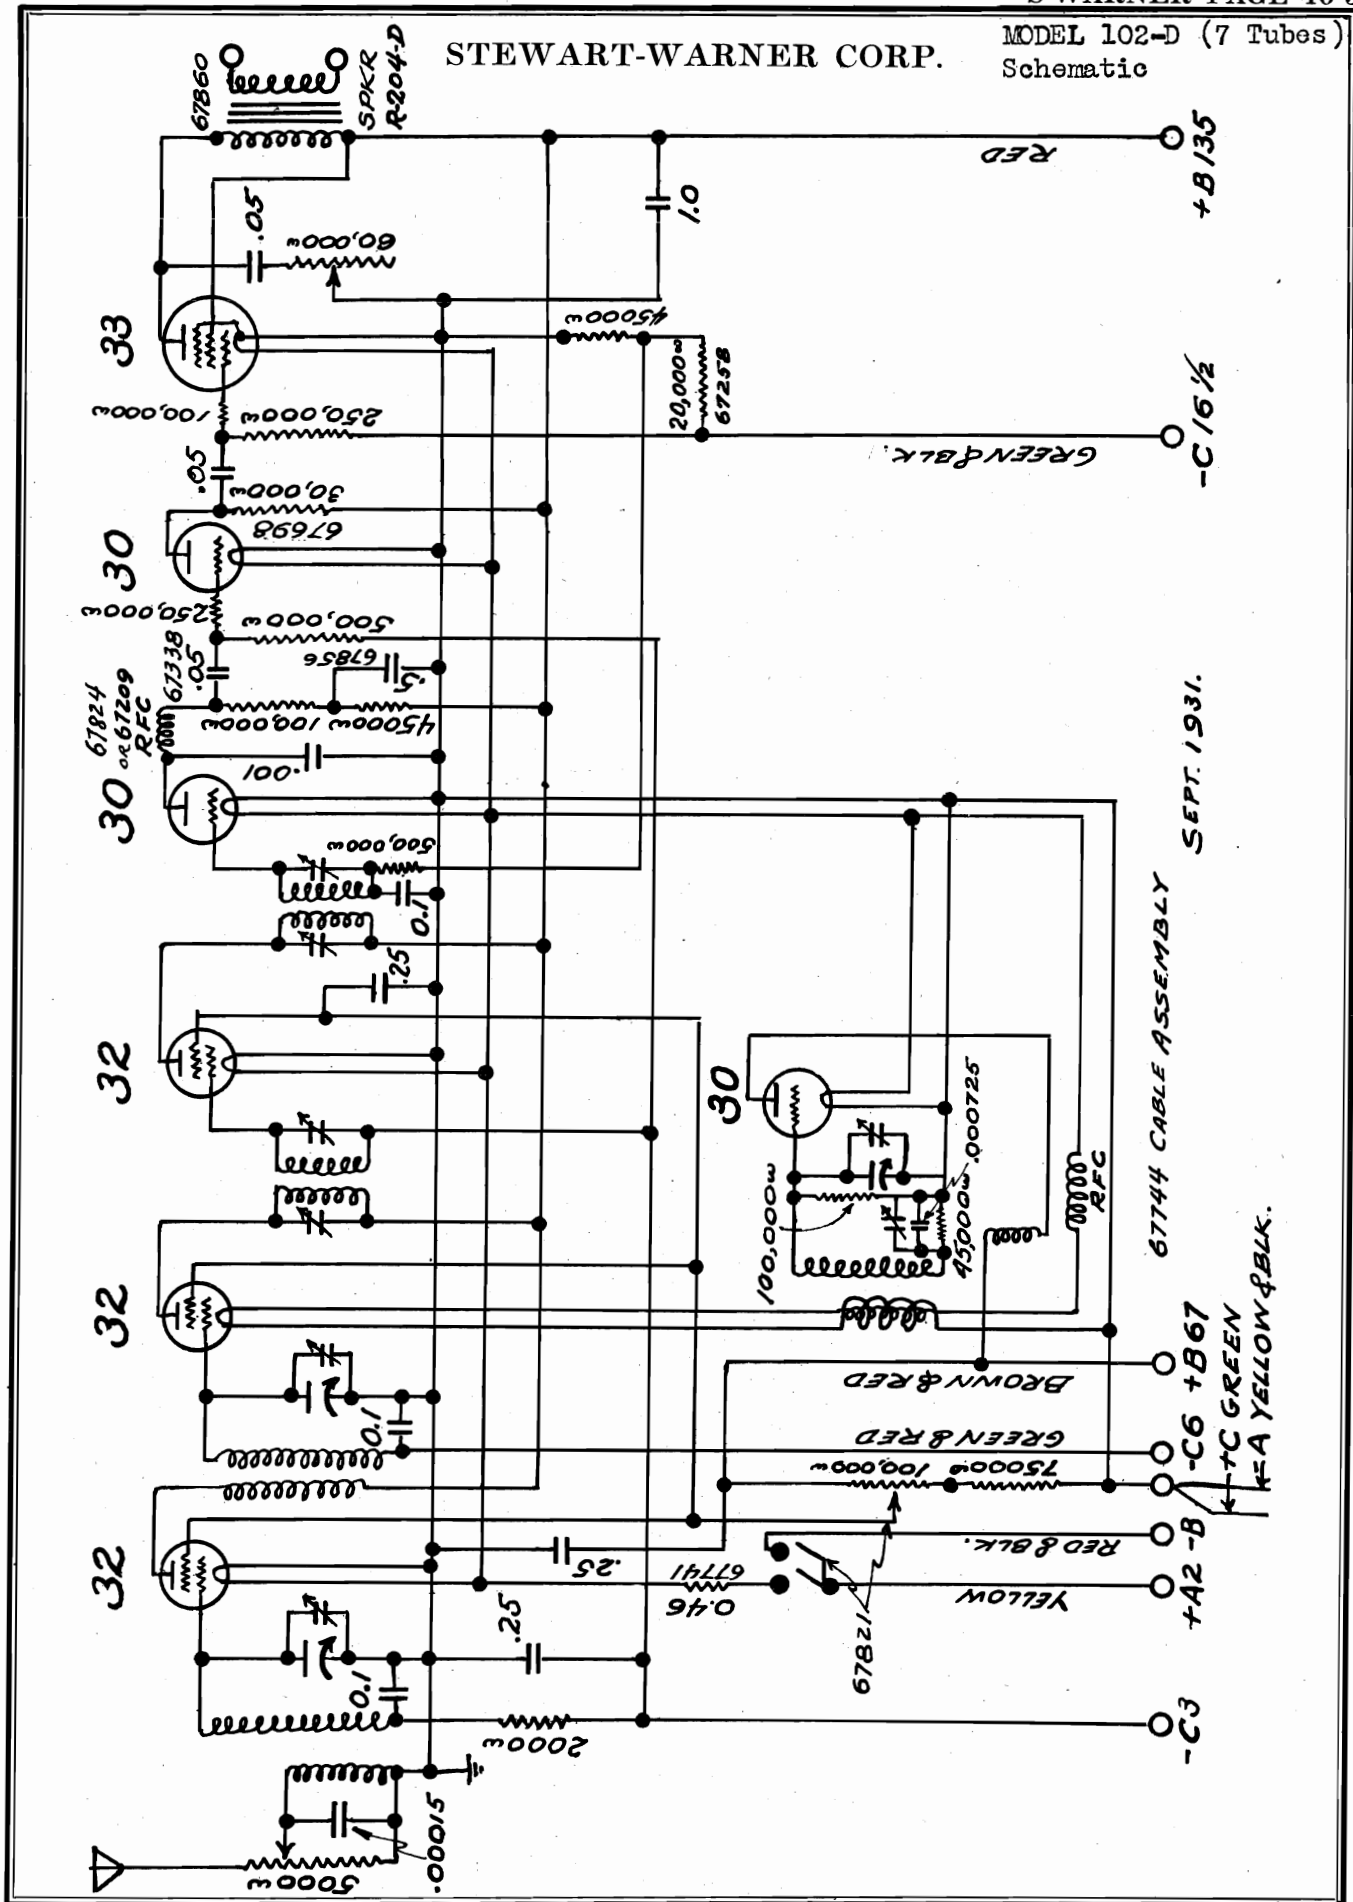

On early releases of this model, a volume control was used which required a 4700 ohm resistor connected as shown by the dotted lines in the circuit diagram. In later production sets, a volume control with a different taper was used so the 4700 ohm resistor was not required. This later volume control carries the same part number.

When replacing a control using the resistor with a later type control, the connections are the same but the 4700 ohm resistor is omitted. Only the new controls are carried in stock by Stewart-Warner.

 For alignment: An output meter, and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

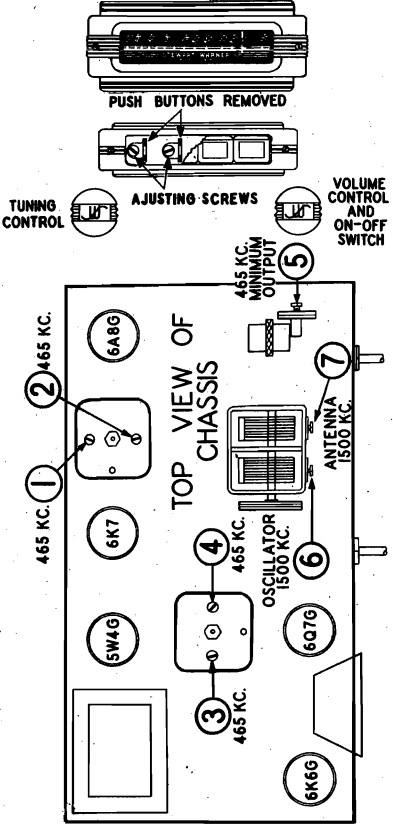

- 1 Connect the output meter across the voice coil or between the plate of the 6K6-G output tube and ground. (The more sensitive type should be connected across the voice coil.)
- 2 Connect the ground lead of the signal generator to the black (ground) wire or the chassis.
- 3 Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

With the gang condenser in full mesh, set the pointer to the last mark on the right end of the dial scale. If the pointer is only slightly off calibration, loosen the set-screw in the dial drive drum at the left end of the gang condenser, and turn the dial drive drum until the pointer is exactly on the mark. Release the set screw and turn the dial drive drum until the pointer is on the mark. Release it. Repeat this procedure until the pointer is on the mark. Then slide the pointer along the cord from the pointer drive cord by spreading the clip on the pointer. Then slide the pointer along the cord until it is set to the last dial division on the right end of the dial. Holding it in place, check to see if the gang condenser is in full mesh, and tighten the pointer clip, being carefully not to cut the cord. A drop of household or speaker cement on the cord and pointer clip to prevent the pointer from slipping.

CHASSIS HAVING MODEL NUMBERS WHICH INCLUDE THE LETTERS "WT" AS A SUFFIX, HAVE A WAVE TRAP AS SHOWN ON THE CIRCUIT DIAGRAM. CHASSIS HAVING MODEL NUMBERS WITHOUT THAT SUFFIX DO NOT HAVE A WAVE TRAP. MODEL 91-51 WT HAS A WAVE TRAP; MODEL 91-51 DOES NOT HAVE A WAVE TRAP.

ALIGNMENT OF CHASSIS HAVING WAVE TRAPS IS TO BE CARRIED OUT ACCORDING TO THE FOLLOWING TABLE. WHEN ALIGNING CHASSIS WITHOUT WAVE TRAPS, OMIT WAVE TRAP ADJUSTMENT (TRIMMER NO. 5) IN THE FOLLOWING TABLE.

RECEIVER TRIMMER NUMBER	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
1-2	465 KC	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1st I. F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.
3-4	465 KC	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	2nd I. F.	
5	465 KC	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	WAVE TRAP	ADJUST FOR MINIMUM OUTPUT USING A STRONG GENERATOR SIGNAL.
6	1500 KC	1500 KC	BROADCAST OSCILLATOR (Shunt)	ADJUST TRIMMER TO BRING IN SIGNAL.
7	1500 KC	TUNE TO 1500 KC FOR SIGNAL	BROADCAST ANTENNA (Shunt)	ADJUST FOR MAXIMUM OUTPUT.

910-511 to 910-519

STEWART-WARNER CORP. Tuner, Drive Cord Data

Voltage, Socket, Tuner, Drive Cord

Frequency	Voltage
60 cycles	117
25 cycles	117
50-133	100-240

These chassis are 5 tube, single band push-button tuning superheterodyne receivers. The tuning range is 540 to 1725 KC. The intermediate frequency is 460 KC.

Incorporated in each chassis is a four-button mechanical push-button tuner unit. These push buttons may be set to any station desired by the method described below under "How to Set Up the Push-Button Tuner".

The accuracy of tuning when using the push-button tuner, depends to a large extent upon the amount of "play" in the moving parts of this system. In cases where slight inaccuracy in tuning occurs check the following points:

1. The tension must be maintained between the anti back-lash gear on the left side of the unit in order that it functions properly--both anti back-lash springs must be in place in the gear and compressed slightly.
2. Note the small adjusting lug over the push-button shafts at the point where they slide into the tuner. The lug is held in place by a hex-head screw. These lugs should be adjusted for a minimum amount of "play". In other words the push-button shaft must have a minimum of movement in a vertical direction.

7. Place an eyelet (part number 85248) on the end of the cord close to the shaft, and squeeze it on so that the cord is taut. Then tie a large knot in the cord up close to the eyelet.
8. Carry the other end of the cord, run it down the front of the drum, around the tuning shaft. These five turns clockwise around the tuning shaft. These five turns should be placed on the shaft between holes Z and E.
9. Thread the end of the cord down through hole E and up through hole F in the tuning shaft and pull through the hole.
10. Place an eyelet on the end of the cord and squeeze as in step 8. Then tie a large knot in the cord up close to the shaft so the cord cannot slip back through the hole. The tension spring in place in the drum. This will take up any remaining slack in the cord.

- TO THREAD THE DIAL POINTER DRIVE CORD PROCEED AS FOLLOWS:
1. Close the gang condenser and thread one end of the cord through eyelet A, around the drum, and then around pulley H and then across to pulley I and counter-clockwise around it.
  2. Carry the other end of the cord over the drum to the front around pulley F and then across to pulley J and continue back to pulley J and down the front of the drum counter-clockwise around it.
  3. Carry the end of the cord on around the drum and thread eyelet G.
  4. Tie both ends extending through eyelet G to tension spring K, in so doing, allow enough slack in the cord so that it will be extended only a modest amount in the drum, it will be extended only a modest amount in the drum, it is extended too much, it will tend to make the push-button operate too hard because of overloading.
  5. Set the dial pointer to the last dial division mark on the tuning shaft to the cord. (Be sure the gang condenser is closed before clipping the pointer to the cord.)

**HOW TO SET UP THE PUSH-BUTTON TUNER**

Be sure that your set is connected to a good antenna system:

1. Turn on the set and allow it to operate at least one-quarter hour before setting up the push buttons.
2. Select the four nearby stations to which you wish to set up the buttons. Be sure to select nearby power stations, any button may be set to any desired station.
3. Pull off the entire button cap by grasping the button in the middle and turning it around until the cap is moved a round head adjusting screw will be exposed to view.
4. Insert a screw-driver in this screw and loosen it (about one turn counter-clockwise will be sufficient).
5. Keeping the screw-driver in the screw slot, PUSH AGAINST THE SCREW-DRIVER UNTIL THE PUSH BUTTON SHAFT IS FORCED ALL THE WAY IN. While the button is held in this position, grasp the tuning knob and tune in the station desired until reasonably tight.

**WARNING:** Do not attempt to turn the screw until it reaches a definite resistance. Do not turn further may result in damage to the mechanism.

The set-up for this button is now complete. Replace the push button by pushing it on firmly.

Set up the three remaining buttons in a similar manner.

Label each button with the call letters of the stations you have selected, using the call letters that find the station on the dial. The call letters should be printed on a paper tab should be inserted in the button by holding the ends and flexing it slightly, allowing it to snap into place. The celluloid cover tab should be flexed in a similar manner and placed on top of the paper tab.

10. To use your push-button tuner it is only necessary for you to push in the button labeled with the call letters of the station. Be sure that you push the button all the way in.

**HOW TO REPLACE THE DIAL CORD**

TO THREAD THE GANG CONDENSER DRIVE CORD PROCEED AS FOLLOWS:

1. Close the gang condenser. The set screw in the drum, Fig. 1, must be on the top side.
2. Take 19 inches of cord, double it in the middle and stick the loop end through eyelet A, Fig. 1, on the drum. Tie tension spring L to this loop end, inside the drum.
3. Take one of the free ends of the cord; carry it down around the back of the drum and over the front of pulley B.
4. Thread the end of the cord through hole C in the drum.
5. Taking half turn pass the cord over the front of the tuning shaft and around the shaft clockwise (when facing the unit).
6. Thread the end of the cord down through hole D in the drum and pull through the slack in the cord.

11. To use your push-button tuner it is only necessary for you to push in the button labeled with the call letters of the station. Be sure that you push the button all the way in.

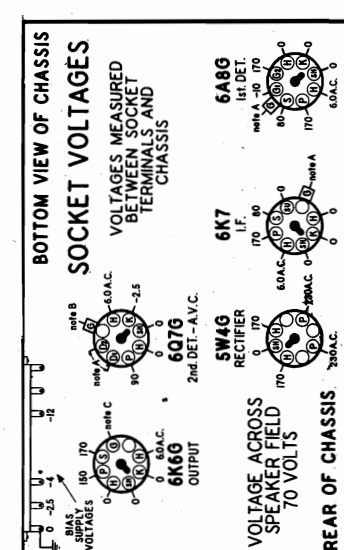

**HOW TO REPLACE THE DIAL CORD**

TO THREAD THE GANG CONDENSER DRIVE CORD PROCEED AS FOLLOWS:

1. Close the gang condenser. The set screw in the drum, Fig. 1, must be on the top side.
2. Take 19 inches of cord, double it in the middle and stick the loop end through eyelet A, Fig. 1, on the drum. Tie tension spring L to this loop end, inside the drum.
3. Take one of the free ends of the cord; carry it down around the back of the drum and over the front of pulley B.
4. Thread the end of the cord through hole C in the drum.
5. Taking half turn pass the cord over the front of the tuning shaft and around the shaft clockwise (when facing the unit).
6. Thread the end of the cord down through hole D in the drum and pull through the slack in the cord.

79008		Screw - #6-32 X 7/8 Ft. Hd. Mach. (for setting up push button) - Per C
81145		Retaining Ring - for drive shaft - Per C
85040		Screw - #6 Hex. Hd. for mtg. adjusting washer - Per C
85299		Screw - chassis mtg. #10 X 3/8" (for models 910-513; 98-513 & 91-513) - Per C
85427		Socket - octal base (standard)
85815		Spring - between gear sections
86346		Eyelet - for dial cord
89746		Washer - (paper) for back of knobs - Per doz.
110829		Washer - flat steel, for mtg. chassis

- 112745 - Clip - coil mtg. (osc. & ant.)
- 112762 - Pulley - dial cord drive (at left side)
- 112764 - Clip - dial scale retaining
- 112770 - Pointer - dial
- 112776 - Celluloid cover - over dial face
- 112798 - Clip - for mtg. wave trap coil
- 112871 - Cu. Washer for mtg. models 91-513; 98-513 & 910-513
- 112872 - Screw - chassis mtg. #8 X 1 1/4 O.H. (models 98-513; 910-513 & 91-513)
- 112874 - Screw - #10 X 1-1/8 chassis mtg.
- 112878 - Screw - escutcheon mtg. #2 X 3/8 (models 91-514; 98-514 & 910-514)
- 112879 - Screw - escutcheon mtg. #2 X 3/8
- 112914 - Escutcheon - dial
- 113022 - Knob - Round Volume or Tuning
- 113025 - Socket - octal base (with special ground)
- 113052 - Escutcheon for dial (models 91-514; 98-514 & 910-514)
- 113053 - Escutcheon - for push buttons
- 113054 - Escutcheon - for push buttons (models 91-514; 98-514 & 910-514)
- 113093 - Socket - for dial lamp
- 113103 - Push Button
- 113124 - Speaker Grille Bar - (chrome plate) (for models 91-514; 98-514 & 910-514)
- 113125 - Speaker Grille Support Track (for models 91-514; 98-514 & 910-514)
- 113136 - Knob - octagon - volume or tuning
- 113156 - Gear - & bushing assembly for dial drive
- 113169 - Spring - for key return
- 113170 - Adjusting Lug - for button shafts
- 113171 - Bracket - for dial & condenser mtg.
- 113174 - Dial Drum - and pinton assembly
- 113176 - Shaft - dial drive
- 113177 - Spring - dial cord tension
- 113178 - Cord - for dial drive (38" req.) supplied in 4 ft. lengths
- 113189 - Tab - celluloid - for push button - Per doz.
- 113232 - Mtg. plate - for spade models 91-513; 98-513 & 910-513
- 113321 - Tabs - station call letters (4 sheets) (brown) - Per set
- 113322 - Tabs - station call letters (4 sheets) (black) - Per set
- 113494 - Mechanical Tuner assembly - keys and housing only

DIAL TUNED TO 540. KC  
ANTENNA GROUND

Use a high resistance voltmeter of 1000 ohms per volt.

NOTE A: The bias for the control grids of the 6A8-G, 6K7, and the diode plates of the 6B7-G tubes is 2.5 volts measured across resistor 18C.

NOTE B: The bias for the control grid of the triode section of the 6B7-G is 4 volts measured across resistors 18B and 18C.

NOTE C: The bias for the control grid of the 6K6-G output tubes is -12 volts measured across resistors 18A, 18B and 18C.

Alignment, Trimmers

These chassis are 5-tube, two band, push-button tuning superheterodyne receivers. The tuning ranges are 540 to 1725 KC and 5.4 to 15.4 MC. The I. F. is 465 KC.

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 14 MC are required.

- ① Connect the output meter across the voice coil or between the plate of the 6K6-G output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- ② Connect the ground lead of the signal generator to the black (ground) wire or the chassis.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- ④ With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is incorrectly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

Tuner Data, Parts List

HOW TO SET UP THE PUSH-BUTTON TUNER

1. Be sure that the set is connected to a good antenna system.  
2. Turn on the set and allow it to operate for at least one-half hour before setting up the push buttons.  
3. Make a list of the five nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations, since weak signals will generally give poor results. Also BE SURE TO SELECT STATIONS FALLING WITHIN THE TUNING RANGE OF THE INDIVIDUAL BUTTONS, as indicated in Fig. 1.

Each of the buttons on the Push-Button Tuner has a definite operating range, as shown in Fig. 1; therefore, it is imperative that you select a station which is in the operating range of a button before attempting to set up that button for the particular station. AS THE TRIMMER SCREWS SHOULD NEVER BE TOO LOOSELY OR TOO TIGHTLY ADJUSTED, IT IS IMPORTANT THAT THE PROPER BUTTON BE SELECTED. For example, suppose you want to set a button associated with station WLM whose frequency is 700 KC. Refer to Fig. 1 which shows that this frequency falls within the operating range of buttons No. 1 and No. 2 whose range is 550 to 1000 KC. Therefore, either of these buttons may be set to WLM.

4. Remove the escutcheon surrounding the push-buttons by taking out the five screws holding it to the cabinet. This will expose to view ten trimmer adjustment screws each pair of which is used to set a button for a station.  
5. Push in the button which is labelled "Broadcast" and use the tuning knob to bring in the station that you desire on button No. 1. This is done so that you may identify the station by hearing its program.

6. Push in button No. 1 (See Fig. 1). You will note that when this button is pushed in, your station will probably not be heard. Using a small screw-driver, insert it in the second screw from the left (oscillator trimmer No. 1a, Fig. 1). Rotate the screw SLOWLY until the program that you have previously tuned in manually is again heard. If it cannot be heard, advance the volume control. BE SURE THAT YOU ADJUST THIS PARTICULAR TRIMMER SCREW (1a) TO THE POINT WHERE THE STATION IS HEARD WITH THE LEAST HISS OR DISTORTION AND NOT TO THE POINT OF GREATEST VOLUME. It is advisable that you turn the trimmer screw in and out so that it will tune across the station several times in order that you may be sure that you have located this correct point. Now insert the screw-driver in the first trimmer screw on the left (antenna trimmer No. 1b, Fig. 1). Adjust this screw until the program is received with the maximum volume. Reduce the volume as necessary. Now go back to trimmer screw No. 1a and see if any improvement in reception can be made by adjusting it. Also repeat this operation for trimmer screw No. 1b.

NOTE: Trimmer screws indicated by letter "a" are oscillator trimmers. Trimmer screws indicated by letter "b" are antenna trimmers.

In some instances it may be found necessary after the set has been operated for a month or more, to re-adjust the push-button trimmers to compensate for a slight drift due to extreme climatic changes.

HOW TO CHANGE THE OPERATING RANGE OF A BUTTON

The operating range of a button may be changed by merely changing the dual trimmer used with that button. Dual trimmers with the ranges indicated below can be obtained from your Stewart-Warner distributor, or directly from the Stewart-Warner Corporation, under the following part numbers:

Part Number	Tuning Ranges	List Price
112942	1100 to 1700 KC.	\$ 0.36
112943	770 to 1350 KC.	.45
112944	550 to 1000 KC.	.50

To make the change proceed as follows:

1. Remove the chassis from the cabinet.
2. By referring to Fig. 1, determine the dual trimmer associated with the button whose range you wish to change.
3. Unsolder the leads from the four terminals on the back of this dual trimmer.
4. Remove the 6/32 machine screw holding the dual trimmer to the front of the chassis.
5. From the above list select a dual trimmer which will cover the desired range.
6. Mount it on the front of the chassis with the 6/32 machine screw, and solder the leads to its four terminals in a similar manner, using trimmer screws No. 2a and No. 2b. Proceed to set the remaining buttons in the same manner.
7. Set up button No. 2 for the selected station in a similar manner, using trimmer screws No. 2a and No. 2b. Proceed to set the remaining buttons in the same manner.
8. Label each button with the call letters of the stations you have selected, using the call letter tabs and the celluloid covers packed with the receiver. The celluloid printed paper tab should be inserted in the button holding the ends and flexing it slightly, allowing it to snap into place. The celluloid cover tab should be flexed in a similar manner and placed on top of the paper tab.

Hum Elimination

1937 Models  
STEWART-WARNER CORP. Speaker Cone Replacements

HUM ELIMINATION IN THE MODEL R-147 CHASSIS November 26, 1936

FOR RESIDUAL HUM: (Between-station hum)

- Remove the .5 mfd. condenser, part number 89990, connected from chassis, to the mounting nut of the input electrolytic condenser (the one nearest the power transformer). Replace the .5 mfd. condenser with a 10 mfd. 25 volt electrolytic condenser, our part number 89053. The positive terminal of this condenser must be connected to the chassis. This change should always be made in combination with the following one, since either change may increase the hum if made alone.
- Locate the 210,000 ohm resistor connected from the plate of the 6C5 tube to one of the 5Z4 socket terminals.
  - Disconnect the end of this resistor going to the 5Z4 socket.
  - Connect the added 51,000 ohm resistor in series with the disconnected end of the above 210,000 ohm resistor and the lug on the 5Z4 socket from which it was unsoldered.
  - Connect the added .25 mfd. condenser from chassis to the junction of the above two resistors.
- Remove the twisted green and brown wires connecting to the tone control and replace them with the shielded twisted pair supplied by Stewart-Warner. Ground the shield at both ends. Route the shielded wire so that the shielding does not ground the mounting nut on the electrolytic condenser nearest the power transformer.
- Separate the single green volume control wire from the power transformer and the A.C. leads.
- In all cases of either residual or modulation hum, tighten down the power transformer mounting screws after the set is hot.
- Early production sets did not have the resistance-capacity filter consisting of the 260,000 ohm resistor and the .1 mfd. condenser in the grid circuit of the 6F5. In these early sets a 1.1 megohm resistor was connected from the 6F5 grid to the bias resistor network. The later sets used a 760,000 ohm resistor connected from the grid to the filter resistor and condenser. If you are working on any of the early sets which do not have the filter, you should add a 260,000 ohm, 1/4 watt resistor in series with the end of the 1.1 megohm grid resistor which connects to the bias network. Then connect a .1 mfd., 150 volt condenser from chassis to the junction of the 260,000 ohm and 1.1 megohm resistors.

- FOR MODULATION HUM: (On stations only) - Make this change even though no modulation hum is heard in the shop.
- Replace the .1 mfd. screen-grid by-pass condenser, diagram No. 28, connected to the 6A8 socket with the .5 mfd., 150 volt by-pass condenser, part number 88990 which was disconnected from the mounting nut of the input electrolytic condenser.

IMPORTANT

If there is still too much hum after making the above changes be sure to check for defective tubes.

The following material is required for this work:

- 1 - 89532 - .25 mfd. 200 volt Tubular Paper Condenser
- 1 - 89053 - 10 mfd., 25 volt Electrolytic Condenser
- 1 - 83080 - 51,000 ohm 1/4 watt Carbon Resistor
- 1 - Special Shielded Tone Control Cable

HUM ELIMINATION IN THE MODEL R-148 CHASSIS December 4, 1936

FOR MODULATION HUM: (On stations only) Make this change even though no modulation hum is heard in the shop.

- Remove the .1 mfd., 150 volt condenser connected to the screen grid circuit of the 6K7 R.F. tube.
- Replace it with a .5 mfd., 150 volt paper condenser, our part number 88990.

FOR RESIDUAL HUM: (Between-station hum)

- Locate the red-blue wire running from the 5V4G socket heater terminal to the speaker socket.
  - Disconnect one end of the wire and re-route the wire along the back of the chassis so that it is at least two inches above the 6H6 and 6C5 sockets when the chassis is upside down. Re-connect the wire.
- The blue and black twisted wire supplied by Stewart-Warner should be placed along the front of the chassis so it can be used to connect the heater terminals of the 6K7 R.F. and the 6L6 sockets. First connect the black wire to the grounded heater terminal of the 6K7 R.F. socket (the heater terminal near the front of the chassis) and the blue wire to the hot heater terminal of the same socket. The other end of the black wire must be connected to the grounded heater terminal of the 6L6 nearest the front of the chassis and the other end of the blue wire must be connected to the hot heater terminal of the other 6L6 socket (the one nearest the 6C5).
- Remove the input audio transformer mounting screw nearest the front of the set. Rotate the transformer around its other mounting screw until the free end is toward the rear of the chassis. There is a hole in the chassis at the proper point to mount the transformer by means of the small machine screw, lock-washer and nut. Pull the transformer leads away from the tube sockets. Sometimes an intermediate position of the transformer will result in less hum but this necessitates drilling either one or two new mounting holes.
- Tighten down the power transformer mounting bolts preferably when the set is hot.

SPEAKER CONE REPLACEMENT IN 1937 RADIO MODELS

We can now supply replacement cones which can be installed without special tools in all 1936-1937 Stewart-Warner speakers including staked spider models with the exception of some of the small five inch speakers. In describing the replacement of the cones we are dividing the various speaker models into three general groups as follows:

(A) - 8 and 12 INCH SPEAKERS WITH SPIDERS STAKED TO THE POLE PIECE

In order to facilitate the replacement of the cones in our 8 and 12 inch speakers with the spiders staked to the center of the pole piece, we will furnish special cones which can be installed without any special tools or equipment as described under "INSTALLING NEW CONES".

These cones have spiders fastened to the outside of the voice coils. The spiders are mounted on the speaker shells by means of screws. The necessary holes are already punched in the shell. The special cones are supplied complete with the necessary gaskets and mounting hardware under the part numbers in the table shown on page two of this bulletin.

(B) - SPEAKERS HAVING SPIDERS MOUNTED WITH SCREWS

The cones in these speakers can be replaced in the conventional manner as described later in this bulletin under "INSTALLING NEW CONES". The correct part numbers are tabulated below.

(C) - FIVE INCH SPEAKERS WITH SPIDERS STAKED TO THE POLE PIECE

Speakers in this group cannot be satisfactorily repaired without special equipment and therefore must be returned to the factory for repair. If the cone is damaged or if the speaker is out of the warranty the cost of replacing the cone will be the price of the cone plus a fifty cent labor charge. We will assume no transportation charges under these conditions.

INSTRUCTIONS FOR INSTALLING NEW CONES

- In staked spider models cut the old cone around the outer edge and break the spider away from the washer under which it is mounted. This washer should be left in place. In models having the spider fastened with screws, remove the screws and then cut out the cone around the outer edge. Remove the cone, voice coil and spider assembly and clean away all traces of the old cone and cement where the cone was cemented to the frame.
- Clean any particles from the air gap.
- Spread an even coat of quick drying household or speaker cement over the face of the speaker frame. If two complete cardboard gaskets are packed with the cone put the thin one on the frame and cover it with cement. If only one complete gasket is enclosed it should be applied later as described in paragraph 8.
- Set the replacement cone in place with the voice coil in the air gap. Make sure that the holes in the spider mounting line up with the holes in the speaker shell.
  - In the R-247-A, R-258-D and R-266-A speakers, place the small spacing bushings between the spider and the shell. Insert the screws through the shell, spacers and spider, then put on the lock washers and screw the nuts on loosely.
  - In other speakers place the small brackets, Part No. 89028, over the spider mounting bracket with the ends in the slots in the shell, and place the mounting screws through the holes in the shell and screw them into the brackets. Leave the screws loose.
- Insert three or four thin shims in the inside air gap to keep the voice coil centered.
- Firmly press down the edges of the cone.
- Cement the thick cardboard gasket to the edge of the cone, then lay the speaker on its face until the cement is thoroughly dry.
- Tighten the spider mounting screws, and then remove the thin shims from the air gap.
- Make sure that the voice coil is centered by pressing in on the cone near the outer edge and listening for evidence of rubbing. If the voice coil is rubbing, the spider mounting screws should be loosened and the voice coil centered so it does not rub.
- Solder the flexible voice coil leads to the proper terminals.

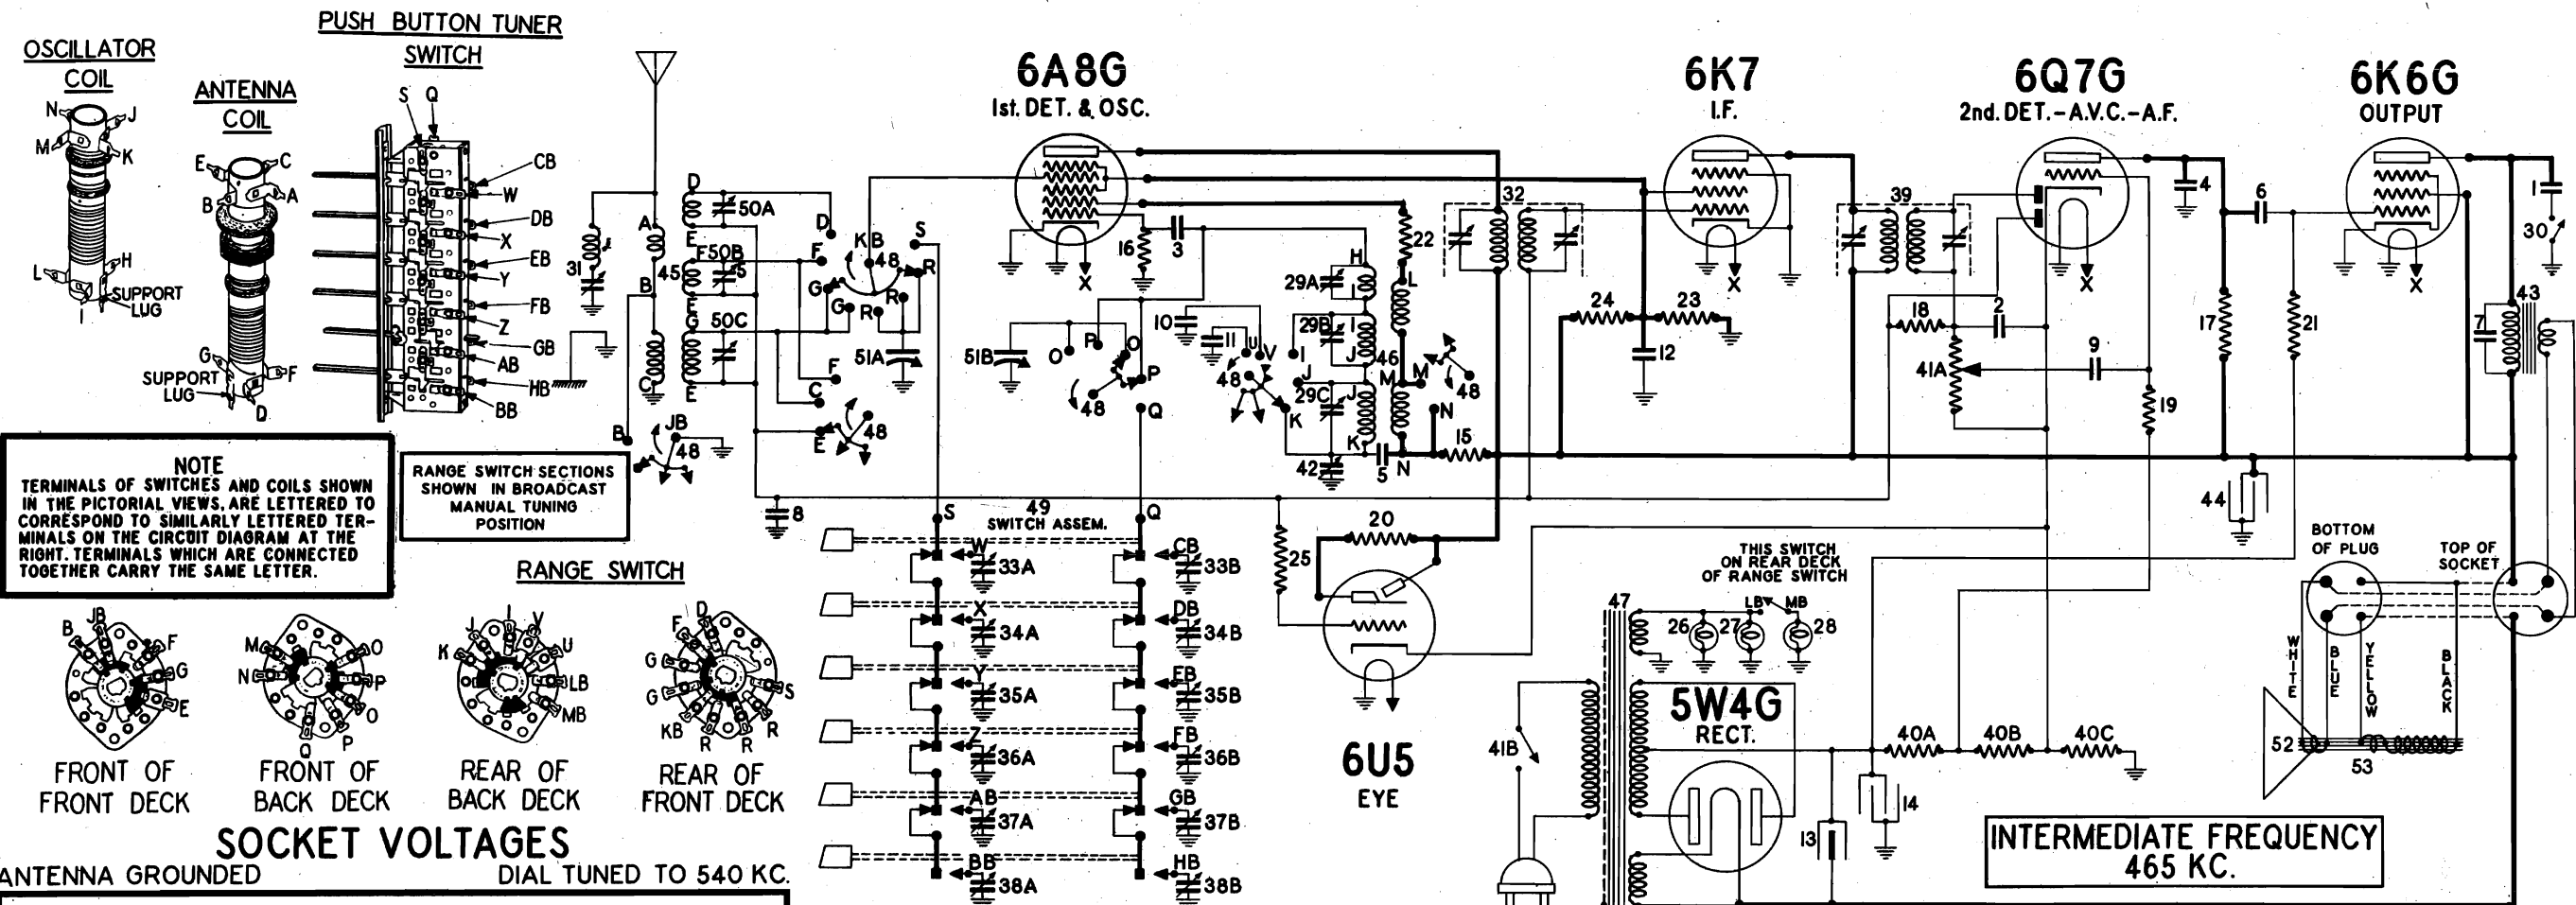

REPLACEMENT CONE PART NUMBERS

(FOR ALL 1936-1937 SPEAKER MODELS)

98-621 to 98-629  
910-621 to 910-629  
Tuner Data

**ALIGNMENT EQUIPMENT & PROCEDURE**

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 20 MC are required. Connect the output meter across the voice coil or between the plate of the 6K7 output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)

1. Connect the ground lead of the signal generator to the black (ground) wire on the chassis.

2. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

3. With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is inoperative, it is already necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

**Used in Receiver Models**  
91-611 to 91-619  
98-611 to 98-619  
910-611 to 910-619

**Voltage**  
117  
100-240

**Frequency**  
60 cycles  
55 cycles  
50-135

These chassis are 6 tube, three band, push-button tuning superheterodyne receivers. The tuning ranges are 540 to 1750 KC, 2.2 to 7.0 MC and 6.7 to 25 MC.

Incorporated in each chassis is a six-button tuner switch. Push-button tuning is obtained by substituting pre-set trimmers for the variable gang condenser. The push-button tuner switch provides a simple, rapid method of effecting this substitution.

When employing push-button tuning, the band switch must be in the Automatic ("A") position. This connects the tuner switch and disconnects the gang condenser, so that rotation of the tuning control will have no effect on the tuning.

**HOW TO SET UP THE PUSH-BUTTON TUNER**

1. Be sure that your set is connected to a good antenna system.

2. Turn on the set and allow it to operate at least one-half hour before setting up the push-buttons.

3. Make a list of the frequencies of six nearby stations to which you wish to set-up the buttons. Be sure to select nearby, powerful stations, since weak signals will not set the buttons. LIST THE FREQUENCIES OF THE STATIONS IN THE TUNING RANGE OF THE INDIVIDUAL BUTTONS, AS INDICATED IN FIG. 1.

Each of the buttons on your push-button tuner has a definite operating range, as shown in Fig. 1, therefore, it is imperative that you select a station whose frequency falls within the operating range of the particular button. AS THE ADJUSTING SCREWS SHOULD NEVER BE TOO LOOSELY OR TOO TIGHTLY SET, THE FREQUENCIES OF YOUR LOCAL STATIONS MAY BE OBTAINED FROM YOUR NEWSPAPER OR RADIO MAGAZINE. For example, suppose a 700 kHz local station calls itself "WABC". This frequency falls within the operating range of button No. 1 or No. 2, whose buttons are labeled "WABC". The "WABC" call letters are printed in green on the dial. THE "TUNING RANGE" OF THE GREEN LETTERS IS INDICATED BY THE "TUNING RANGE" OF THE GREEN LETTERS. IT IS ADVISABLE THAT YOU TURN THE SCREW IN THE ORDER THAT YOU HAVE LISTED IN THE TUNING RANGE OF THE GREEN LETTERS. ALSO REPEAT THIS OPERATION FOR EACH OF THE OTHER FIVE BUTTONS.

4. Remove the dust cap from the push-buttons by taking out the five screws holding it to the cabinet. This will expose to view twelve adjusting screws, each pair of which is used to tune a button to its correct position.

5. Turn the band switch knob (lower right) to the position "A" (Automatic). You will note as the knob is turned that the tuning knob (upper right) turns in the station you desire to set up. Turn the tuning knob until you identify the station by hearing its program.

6. Now turn the band switch knob until the "Tuner" position is reached. The "Tuner" position is indicated by the word "Tuner" on the dial. You will note as the knob is turned that the tuning knob (upper right) turns in the station you desire to set up. Turn the tuning knob until you identify the station by hearing its program.

7. Next insert the screw-driver in the first screw on the left (No. 1b Fig. 1) and turn until the program is received with maximum volume, and the correct position is reached. Now go back to the second screw (No. 2) and see if any improvement in reception can be obtained by adjusting it. Also repeat this operation for screws No. 3, 4, 5, and 6.

NOTE: Trimmer screws indicated by letter "A" are operating trimmer screws. Trimmer screws indicated by letter "B" are antenna trimmers.

8. Set up button No. 2 for the selected station in a similar manner, using screws No. 2a and 2b, and proceed to set up the remaining buttons in the same fashion.

FIG. 1  
9. Label each button with the call letters of the stations you have selected, using the call letter tabs and the screw-driver. The call letters should be printed on the tabs and the tabs should be inserted in the button by holding the ends and flexing them slightly, allowing the tab to snap into place. The celluloid cover tab should be flexed in a similar manner and placed over the paper tab.

**IMPORTANT**  
In some instances it may be necessary after the set is operated for a month or more, to reset the screws as they may drift due to heat, humidity, etc.

**HOW TO CHANGE THE OPERATING RANGE OF A BUTTON**

The operating range of a button may be changed by merely changing the dual trimmer used with that button. Dual trimmers with the ranges indicated below can be readily changed to the ranges indicated in the following part numbers:

Part Number	Tuning Range	List Price
112942	1100 to 1750 KC.	\$ 0.25
112943	550 to 1000 KC.	.50
112944	550 to 1000 KC.	.50

To make the change proceed as follows:

1. Remove the screws from the cabinet.

2. By referring to Fig. 1, determine the dual trimmer associated with the button whose range you wish to change.

3. Unsolder the leads from the four terminals on the back of this dual trimmer.

4. Remove the 6/32 machine screw holding the dual trimmer to the front of the chassis.

5. From the above list select a dual trimmer which will cover the desired range.

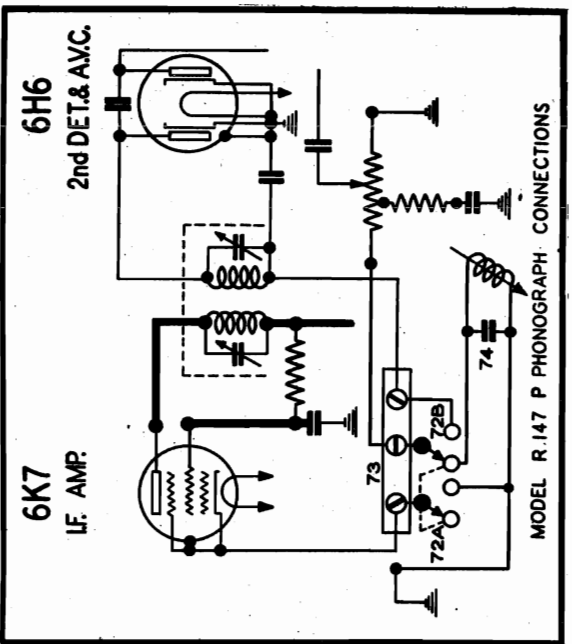

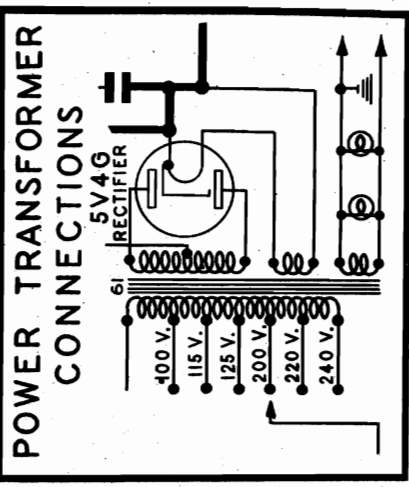

6. Mount it on the front of the chassis with the 6/32 machine screw, and solder the leads to its four terminals.

The button is now ready to be set to any strong station whose frequency is within the range of this new trimmer unit.

STEWART-WARNER CORP.  
Phonograph Connections  
Universal Transformer  
Data

**SUPPLEMENTARY SERVICE DATA  
MODELS R-146-X, R-147-X, AND R-147-P.**

The diagrams on this sheet show the phonograph and universal power transformer connections for the R-146-X, R-147-X and R-147-P chassis. Since these chassis are otherwise identical with the models R-146 and R-147, only additional parts for these models are listed to the right. All other parts and service data will be found in the R-146 or R-147 service manual.

**POWER TRANSFORMERS AND FUSES**

Since the models R-146-X, R-147-X and R-147-P can be operated on a range of line voltages ranging from 100 to 240 volts different fuses must be used for different voltages. Proper values for different voltages are listed below.

MODEL	PART NUMBER OF FUSE	CURRENT RATING OF FUSE	200 - 240 VOLTS CURRENT RATING OF FUSE
R-146-X	38641	1 Amp.	3/4 Amp.
R-147-X	89002	1.5 Amp.	1 Amp.
R-147-P	89002	1.5 Amp.	1 Amp.

**SPEAKERS AND OUTPUT TRANSFORMERS**

The R-268-A 8-inch dynamic speaker is used with model R-1471-X, and the R-265-A 12-inch dynamic speaker is used with model R-1475-X. Please note that these speakers require different output transformers. Speakers and output transformers are listed below for the models R-146-X, R-147-X and R-147-P respectively.

MODEL	SPEAKER	SIZE	OUTPUT TRANSFORMER PART NO.
R-1461-X	R-247-A	8-Inch	89529
R-1465-X	R-245-A	12-Inch	89796
R-1471-X	R-265-A	8-Inch	89622
R-1475-X	R-253-A	12-Inch	88970
R-1479-P	R-253-A	12-Inch	88970

These chassis are 6-tube, two band push-button tuning superheterodyne receivers. The tuning ranges are 540 to 1725 KC and 5.4 to 15.4 MC. The I. F. is 465 KC.

Incorporated in each chassis is an eight-button tuner switch. The first button on the left, labelled "Speech", is a tone control. The two buttons on the right, labelled "Broadcast" and "Foreign", are used for band change. The other five buttons are for push-button tuning.

Push-button tuning is secured by substituting pre-set trimmers for the variable gang condenser. The push-button tuner switch provides a simple, rapid method for effecting this substitution.

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 14 MC are required.

1 Connect the output meter across the voice coil or between the plate of the 6K6-G output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)

2 Connect the ground lead of the signal generator to the black (ground) wire of the chassis.

3 Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

4 With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is in- correctly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

TYPE OF ADJUSTMENT

ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.

ADJUST FOR MINIMUM OUTPUT BEING A STRONG GENERATOR SIGNAL.

ADJUST TRIMMER TO BRING IN SIGNAL.

ADJUST FOR MAXIMUM OUTPUT.

ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETURNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.

ADJUST TO BRING IN SIGNAL. CHECK TO SEE IF PROPER PEAK WAS OBTAINED BY TUNING IN IMAGE AT APPROX. 13.1 MC. IF IMAGE DOES NOT APPEAR RE-ALIGN AT 1.4 MC. WITH TRIMMER SCREEN FARTHER OUT. RECHECK IMAGE.

ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETURNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.

**INTERMEDIATE FREQUENCY 465 KC.**

**NOTE:**  
TERMINALS OF COILS SHOWN IN THE PICTORIAL VIEWS BELOW ARE LETTERED TO CORRESPOND TO SIMILARLY LETTERED TERMINALS ON THE CIRCUIT DIAGRAM ABOVE TERMINALS WHICH ARE CONNECTED TOGETHER CARRY THE SAME LETTER.

The triode section of the 6Q7G tube utilizes a circuit arrangement which gives a minimum of distortion and excellent gain with zero bias on the grid. At high signal levels, this circuit gives less distortion than if the tube is operated with a fixed bias. The proper operation of this circuit depends largely on the high resistance of the grid resistor, No. 24 in the circuit diagram. This resistor is rated at 10 megohms. Do not substitute any lower value since this would increase distortion and decrease amplification.

Alignment, Trimmers  
Phono. Data, Tuner Data

**ALIGNMENT EQUIPMENT & PROCEDURE**

For alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 1500 KC. are required.

- 1- Connect the output meter across the voice coil or between the plate of either of the 6K6G tubes and ground through a .1 mfd. condenser. (these tubes are connected in parallel, not push-pull). The connection will depend upon the type of meter. (The more sensitive type should be connected across the voice coil.)
- 2- Connect the ground lead of the signal generator to the chassis of the receiver and keep it connected in this manner throughout the entire alignment procedure.
- 3- Turn the volume control to the maximum volume position and leave it in this position throughout the entire alignment procedure.
- 4- With the gang condenser in full mesh, set the pointer to the last mark on the left end of the dial scale. If the pointer is only slightly off calibration, loosen the set screw in the pointer cord drive drum, which is the outer drum on the left hand side of the gang condenser and with the gang condenser in full mesh turn the drum until the pointer is in the correct position. If the pointer is off calibration several dial divisions, release it from the pointer drive cord by spreading the clip on the pointer. Then slide the pointer along the cord until it is set to the last division on the left end of the dial scale. Hold the pointer in place and check to see if the gang condenser is still fully meshed, then tighten the pointer clip being careful not to cut the cord. Place a drop of household or speaker cement on the cord and pointer clip to prevent the pointer from slipping.

110829	Washer - flat steel 2 for mtg. chassis	.01
89746	Washer - (paper) for back of knobs	.005

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

The connections to the phonograph unit are made at the terminal strip located on the back of the radio chassis. IMPORTANT: If the receiver chassis is removed from the cabinet for test, you must put a jumper wire between the two outside terminals of this terminal strip. Also the center terminal must be grounded to the chassis.

**HOW TO SET-UP AND USE THE PUSH BUTTON TUNER.**

1. Connect receiver to good antenna system.
2. Remove escutcheon surrounding push buttons.
3. Select five nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations, since weak signals will generally give better results when tuned manually. Any button may be used for a station on any part of the dial.
4. Loosen the screw at the side of the push button shaft (about one turn counter-clockwise will be sufficient).
5. Keep the screw driver inserted in the screw slot and push against the screw. At the same time tune in the station using the tuning knob. YOU MUST PUSH AGAINST THE SCREW DRIVER DURING THE ENTIRE TIME THAT YOU ARE TUNING. Be sure that you tune in the station to the point where the program is heard with the least hiss and deepest tone, and not to the point of greatest volume. Now, still pushing against the screw driver, retighten the screw, turning it to the right (clockwise) until it is REASONABLY TIGHT. To turn further may result in damage to the mechanism.
6. The set up for this button is now complete. Set-up the remaining buttons in the same manner and replace the escutcheon.

**PHONOGRAPH CONNECTIONS**

This receiver is equipped with a phonograph turntable and a crystal pickup unit for phonograph operation. The phonograph turntable motor is wired directly to the line cord. A socket is inserted in parallel with this power supply line into which is plugged the short power cord from the radio chassis.

The crystal pickup unit is switched into the audio amplifier section of the radio by means of a double pole double throw switch located in the top panel. With this switch in the phonograph position the receiver volume control is disconnected from the low side of the 2nd I.F. transformer and connected across the crystal pickup unit. The radio frequency section of the receiver is at the same time silenced by the opening of the cathodes of the 6AG6 and 6K7G tubes.

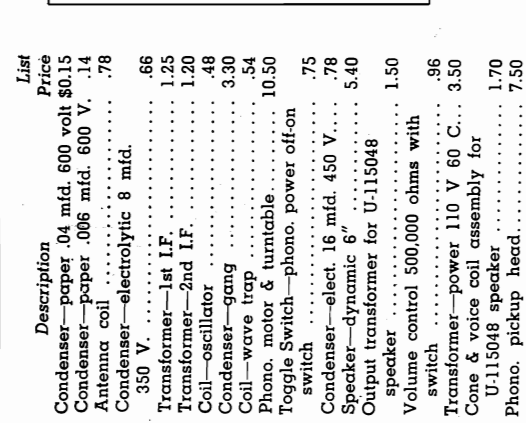

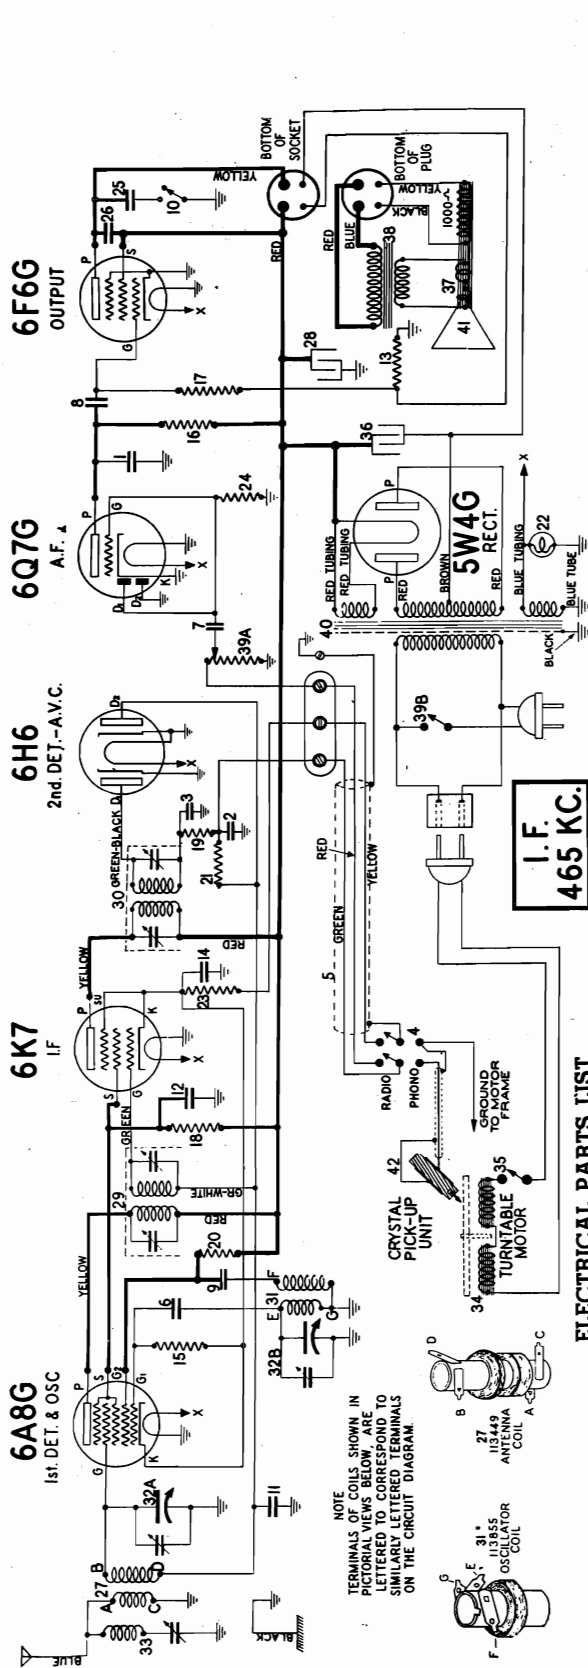

**TESTING**

When the phonograph pickup leads are disconnected as this model chassis is removed from the cabinet for testing, the set will not operate unless the proper connections are made at the phonograph terminal strip. The two outside terminals must be connected together and the center terminal must be grounded to the chassis.

### ALIGNMENT PROCEDURE

FOR ALIGNMENT, an output meter and an accurately calibrated signal generator are required.

1. Connect the output meter across the voice coil or between the plate of the 6F6G output tube and ground through a .1 mfd. condenser. The connection will depend upon the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the chassis of the receiver and keep it connected in this manner throughout the entire alignment procedure.
3. Turn the volume control to the maximum volume position and leave it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, the pointer should be at the last dial division at the left end of the dial scale. With the gang condenser in this position the set screw on the large drum should be nearly straight down.
5. IF YOU DISCONNECT THE PHONOGRAPH PICK-UP CABLE, PUT A JUMPER BETWEEN THE TWO OUTSIDE TERMINALS OF THE TERMINAL STRIP, AND GROUND THE CENTER TERMINAL TO CHASSIS.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment

### PHONOGRAPH CONNECTIONS

This receiver is equipped with a phonograph turntable and a crystal pickup unit for phonograph operation. The crystal pickup unit is switched into the audio amplifier section of the radio by means of a double-pole double-throw switch adjacent to the turntable. With this switch in the phonograph position (marked P) the receiver volume control is disconnected from the low side of the 2nd I.F. transformer and connected across the crystal pickup unit. The radio frequency

section of the receiver is at the same time silenced by the opening of the cathodes of the 6A8G and 6K7 tubes.

The connections to the phonograph unit are made at the terminal strip located on the back of the radio chassis. **IMPORTANT:** If the receiver chassis is removed from the cabinet for test, you must put a jumper wire between the two outside terminals of this terminal strip. Also the center terminal must be grounded to the chassis.

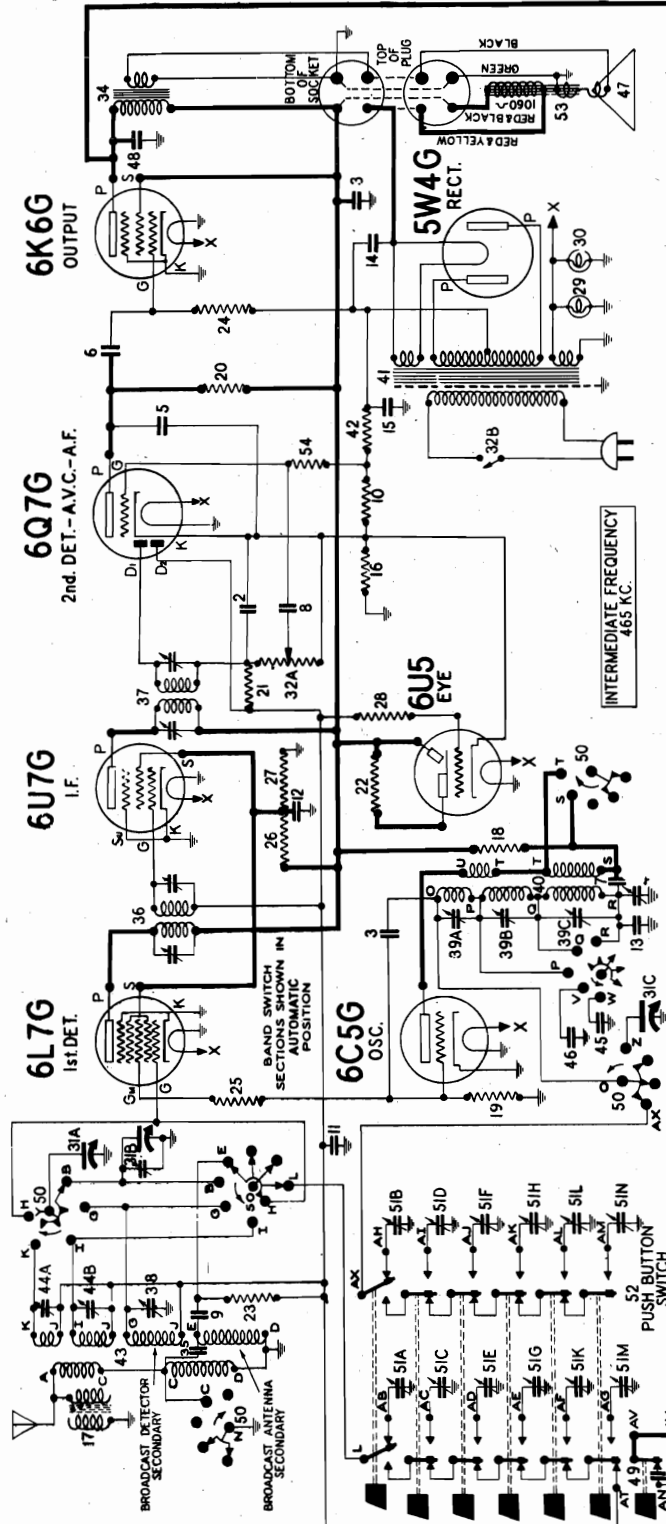

### HOW TO SET UP AND USE THE PUSH BUTTON TUNER

1. Connect receiver to good antenna system and operate for fifteen minutes, then remove escutcheon surrounding push buttons.
2. Select five nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations, since weak signals will generally give better results when tuned manually. Any button may be used for a station on any part of the dial.
3. Loosen the screw at the side of the push button shaft (about one turn counter-clockwise will be sufficient). Keep the screw driver, inserted in the screw slot and push against the screw. At the same time carefully tune in the station using the tuning knob. **YOU MUST PUSH AGAINST THE SCREW DRIVER DURING THE ENTIRE TIME THAT YOU ARE TUNING.** Now, still pushing against the screw driver, retighten the screw, turning it to the right (clockwise) until it is REASONABLY TIGHT. To turn further may result in damage to the mechanism.
4. The setup for this button is now complete. Set up the remaining buttons in the same manner and replace the escutcheon

Chassis 910-71

**SOCKET VOLTAGES**  
 ANTENNA GROUNDED  
 DIAL TUNED TO 510 KC.

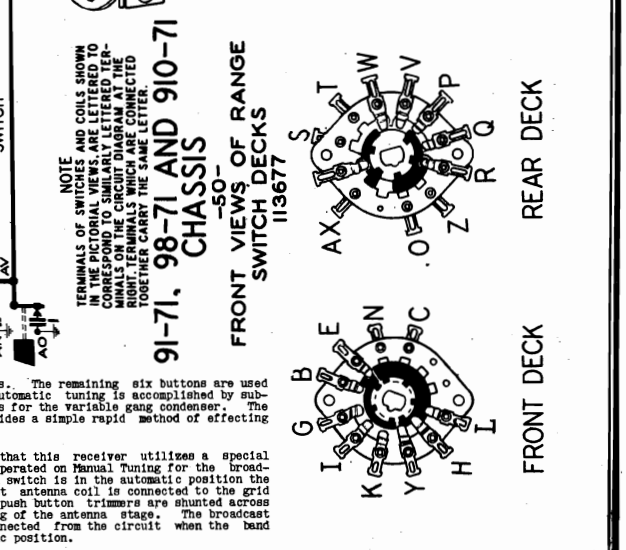

**REAR OF CHASSIS**

**IMPORTANT:** Use a high resistance voltmeter of at least 1,000 ohms per volt.

**NOTE A:** The bias for the control grids of the 6L7G, 6U7G, 6Q7G, 6K6G, and the diode plates of the 6Q7G is -2.5 volts measured across resistor number 10.

**NOTE B:** The bias for the control grid of the 6Q7G is -4 volts measured across resistors 10 and 16.

**NOTE C:** The bias for the control grid of the 6K6G output tube is -15 volts measured across resistors 10, 16 and 42.

Chassis Model	Used in Receiver Models	Voltage	Frequency
91-71	91-711 to 91-719	117	80 cycles
98-71	98-711 to 98-719	117	25 cycles
910-71	910-711 to 910-719	100-240	50-133

These chassis are 8 tube, three band, push button tuning superheterodyne receivers. The tuning ranges are 525 to 1780 KC; 1.7 to 5.6 MC; and 5.3 to 18.1 MC.

Incorporated in each chassis is an eight button tuner switch. The first two buttons on the left are tone controls. Four different tone qualities may be imparted to a program by properly

setting these tone buttons. The remaining six buttons are used for automatic tuning. Automatic tuning is accomplished by substituting pre-set trimmers for the variable gang condenser. The push button switch provides a simple rapid method of effecting this substitution.

It should be noted that this receiver utilizes a special preselector stage when operated on Manual Tuning for the broadcast band. When the band switch is in the automatic position the secondary of the broadcast antenna coil is connected to the grid of the 6L7G tube and the push button trimmers are shunted across this secondary for tuning of the antenna stage. The broadcast detector coil is disconnected from the circuit when the band switch is in the automatic position.

Alignment, Trimmers

**ALIGNMENT EQUIPMENT & PROCEDURE**

For alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 16.0 MC. are required.

- 1- Connect the output meter across the voice coil or between the plate of the 6K6 tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- 2- Connect the ground lead of the signal generator to the chassis of the receiver.
- 3- Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- 4- With the gang condenser in full mesh set the pointer on the last scale division on the low frequency end of the dial. This may be accomplished by releasing the clip on the pointer slider; where it attaches to the dial cord.

**IMPORTANT: THE BROADCAST BAND MUST BE ALIGNED AFTER THE SHORT-WAVE BAND.**

HOW TO REPLACE THE DIAL CORD

Before attempting to replace the dial cord, fully mesh the gear condenser. The holes in drum A should be in the top position as shown in the diagram above.

fig. 2

The pointer drive cord should be 33 inches or more in length. Place one end of the cord through the left hole in drum, then knot the end. Run the free end of the cord down around the drum and up to pass by the dial assembly to the dial cord drum. The dial cord drum is the tension spring so that the spring will be extended to about 1-1/8 inches, when hooked to the slot in the drum. Now place the pointer on its track so that it points to the last scale division on the low frequency end of the dial, then clip it to the cord.

DIAL DRIVE AND MISCELLANEOUS PARTS

26	111030	Escutcheon - with glass window	1.30
27	111085	Sleeve - felt for tuning eye	.03

HOW TO SET UP THE PUSH-BUTTON TUNER

1. Be sure that your set is connected to the customers antenna and that the push button trimmers are set-up using this antenna (not the antenna in the service shop) otherwise the antenna trimmer will be incorrectly aligned.

2. Turn the set on and allow it to operate at least one-quarter hour before setting up the push buttons.

3. Make a list of six nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations since weak signals will generally give poor results, also BE SURE TO SELECT STATIONS FALLING WITHIN THE TUNING RANGE OF THE INDIVIDUAL BUTTONS AS INDICATED IN FIG. 1.

Each of the buttons on your Push Button Tuner has a definite operating range, as shown in Fig. 1; therefore it is imperative that you select a station which is in the operating range of a button before attempting to set up that button on the particular station. AS THE TRIMMER SCREWS SHOULD NEVER BE TOO LOOSELY OR TOO TIGHTLY ADJUSTED, IT IS IMPORTANT THAT THE PROPER TRIMMER SCREWS ARE USED. The frequency of your local stations may be obtained from your newspaper or radio directory. To be sure you have the correct frequency, refer to the frequency table which is included in the operating manual. The frequency ranges of buttons No. 3 or No. 4, whose ranges are 550 to 1000 kilocycles, IT SHOULD BE NOTED THAT WHENEVER IT IS POSSIBLE TO USE BUTTONS, HAVING DIFFERENT RANGES, TO SET TO A GIVEN STATION, THE CORRECT BUTTON TO USE WILL BE THAT ONE FOR WHICH THE TRIMMER SCREWS ARE NOT TOO LOOSELY SET. "DRIFTING" IS A DIRECT RESULT OF LOOSE TRIMMER SCREWS AND THEREFORE SUCH SETTINGS OF TRIMMER SCREWS SHOULD BE AVOIDED IF POSSIBLE.

4. Remove the escutcheon surrounding the push buttons by taking out the five screws holding it to the cabinet. This will expose the volume trimmer adjusting screws, which are used to set each button to its correct station.

5. Turn the band switch to the BROADCAST MANUAL TUNING POSITION (position next to the extremes clockwise setting). Then use the tuning knob to bring in the station that you desire to set to button No. 3. This is done so that you may identify the station by hearing its program.

6. Now turn the band switch to the AUTOMATIC POSITION (extreme clockwise). You will note as this is done your station will not be heard.

7. Push in button No. 3 and turn your volume control to the maximum clockwise position.

8. Using a small screw driver, insert it in the second screw from the left (No. 3a in Fig. 1). Rotate the screw SLOWLY until the program that you had previously tuned in manually is again heard. BE SURE THAT YOU ADJUST THIS PARTICULAR SCREW TO THE POINT WHERE THE TWO OPEN ENDS OF THE GREEN CLOSURE TOGETHER. IT SHAPED SHADOW IN THE TUNING EYE ARE SCREW IN and out so that it will tune across the station several times in order that you may be sure that you have located this correct tuning point.

9. Now insert the screw driver in the first trimmer screw on the left (No. 3b Fig. 1) and turn until the program is received with maximum volume, and the correct position is indicated by the ends of the inverted "v" in the tuning eye being closest together. Now go back to trimmer screw No. 3a and see if any improvement in reception can be made by adjusting it. Also repeat this operation for trimmer screw No. 3b.

MODELS 91-811 to 91-819  
 Chassis 91-81  
 98-811 to 98-819  
 Chassis 98-81  
 910-811 to 910-819  
 Chassis 910-81

STEWART-WARNER CORP.

Tuner Data,  
 Drive Card Data

CHASSIS MODEL	USED IN RECEIVER MODELS	VOLTAGE	FREQUENCY
91-81	91-811 to 91-819	117	60 cycles
98-81	98-811 to 98-819	117	25 Cycles
910-81	910-811 to 910-819	100-240	50-133

These chassis are 8 tube, three band, push button tuning superheterodyne receivers. The tuning ranges are 530 to 1730 KC, 2.2 to 7.0 MC and 6.8 to 22.5 MC.

Incorporated in each chassis is an eight button tuner switch. The first two buttons on the left are tone controls. Four different tone qualities may be imparted to a program by properly setting these tone buttons. The remaining six buttons are used for automatic tuning. Automatic tuning is accomplished by substituting pre-set trimmers for the variable gang condenser. The push-button switch provides a simple rapid method of effecting this substitution.

It should be noted that the R.F. stage in this receiver operates only on the Broadcast Band. When the band switch is in the "Automatic", "Intermediate" or "Foreign" positions this R.F. stage is not utilized.

A feature of this set is the special push-pull output stage. Instead of using a push-pull input transformer or a separate phase inverter tube the phase inversion is accomplished as follows. One of the 6K6G output tubes has a 3,300 ohm load resistor in its screen circuit across which is built up an audio voltage which is 180 electrical degrees out of phase with respect to the input grid voltage. This phase inverted voltage obtained across the screen resistor is now applied to the grid of the other output tube in this push-pull output combination. NOTE: It can be readily seen from the above explanation that if the 6K6G output tube, from which the phase inversion voltage is obtained, is removed from the set or becomes defective, it will be impossible for any signal to be heard in the speaker.

HOW TO SET UP THE PUSH-BUTTON TUNER

1. Be sure that the customer has an adequate antenna system and that the push button trimmers are set-up using this antenna (not the antenna in the service shop) otherwise the antenna trimmer will be incorrectly aligned.
2. Turn on the set and allow it to operate at least one quarter-hour before setting up the push buttons.
3. Make a list of the frequencies, of six nearby stations to which you wish to set-up the buttons. Be sure to select nearby, powerful stations, since weak signals will generally give poor results. Also BE SURE TO SELECT STATIONS FALLING WITHIN THE TUNING RANGE OF THE INDIVIDUAL BUTTONS, as indicated in Fig. 1.

Each of the buttons on your Push Button Tuner has a definite operating range, as shown in Fig. 1, therefore, it is imperative that you select a station whose frequency is in the operating range of a button before attempting to set-up that button for the particular station.

AS THE ADJUSTING SCREWS SHOULD NEVER BE TOO LOOSELY OR TOO TIGHTLY ADJUSTED, IT IS IMPORTANT THAT THE PROPER BUTTON BE SELECTED. The frequencies of your local stations may be obtained from your newspaper or radio call magazine. For example, suppose you want to set a button to station WLW whose frequency is 700 kilocycles. Refer to Fig. 1 which shows that this frequency falls within the operating range of buttons No. 3 or No. 4, whose range is 550 to 1000 KC. Therefore either button No. 3 or No. 4 can be used for the automatic tuning of WLW.

IT SHOULD BE NOTED THAT WHENEVER IT IS POSSIBLE TO USE TWO BUTTONS HAVING DIFFERENT RANGES, TO SET TO A GIVEN STATION THE CORRECT BUTTON TO USE WILL BE THAT ONE FOR WHICH THE TRIMMER SCREWS ARE NOT TOO LOOSELY SET. "DRIFTING" IS A DIRECT RESULT OF LOOSE TRIMMER SCREWS AND THEREFORE SUCH SETTINGS OF TRIMMER SCREWS SHOULD BE AVOIDED IF POSSIBLE.

4. Remove the escutcheon around the push-button by taking out the six screws holding it to the cabinet. This will expose to view twelve adjusting screws, each pair of which is used to tune a button to its correct station. The trimmers associated with each button are shown in Figure 1.

Fig. 1

5. Turn the band switch control (Right hand knob) clockwise until the BROADCAST SCALE appears on the roller dial. Then using the tuning knob (center) tune in the station you desire to set to button No. 3. This is done so that you may identify the station by hearing its program.

6. Now turn the band switch knob to the extreme clockwise position (The words "MAGIC KEYBOARD" will now appear in the dial scale opening). You will note when this switch is turned the station tuned in will not be heard.

7. Now push in the third button from the left (No. 3 in Fig. 1). Using a small screw driver insert it in the second screw from the left (No. 3a in Fig. 1). Rotate the screw SLOWLY until the program that you have previously tuned in manually is again tuned in. If it cannot be heard, advance the volume control. BE SURE THAT YOU ADJUST THIS PARTICULAR SCREW (3a) TO THE POINT WHERE THE TWO OPEN ENDS OF THE INVERTED "V" SHADOW IN THE "TUNING EYE" ARE CLOSEST TOGETHER. It is advisable that you turn the screw in and out so that it will tune across the station several times in order that you may be sure that you have located this correct tuning point.

8. Next insert the screw-driver in the first screw on the left (No. 3b Fig. 1) and turn it until the program is received with maximum volume. The correct position is indicated by the ends of the inverted "V" in the "Tuning Eye" being closest together. Now go back to screw No. 3a and see if any im-

provement in the reception can be made by adjusting it. Also repeat this operation for screw No. 3b.

9. Set up button No. 4 for the selected station in a similar manner, using screws No. 4a and 4b, and proceed to set up the remaining buttons in the same fashion, always tuning in the station initially with the "a" screw for that particular button.

10. Label each button with the call letters of the station you have selected using the call letter tabs and celluloid covers packed with your receiver. The printed paper tab should be inserted in the button by holding the ends and flexing them slightly and then allowing the tab to snap into place. The celluloid cover tab should be flexed in a similar manner and placed over the paper tab.

IMPORTANT

11. In some instances it may be necessary, after the set is operated for a month or more, to reset the screws as they may change their setting due to heat, humidity, etc.

HOW TO CHANGE THE OPERATING RANGE OF A BUTTON

The operating range of a button may be changed by merely changing the dual trimmer used with that button. Dual trimmers with the ranges indicated below can be obtained from your Stewart-Warner distributor, or directly from the Stewart-Warner Corporation, under the following part numbers:

Part Number	Tuning Range	List Price
112942	1100 to 1700 KC.	\$0.36
112943	770 to 1350 KC.	.45
112944	550 to 1000 KC.	.50

To make the change proceed as follows:

1. Remove the chassis from the cabinet.
  2. By referring to Fig. 1, determine the dual trimmer associated with the button whose range you wish to change.
  3. Unsolder the leads from the four terminals on the back of this dual trimmer.
  4. Remove the 6/32 machine screw holding the dual trimmer to the front of the chassis.
  5. From the above list select a dual trimmer which will cover the desired range.
  6. Mount it on the front of the chassis with the 6/32 machine screw, and solder the leads to its four terminals.
- The button is now ready to be set to any strong station whose frequency is within the range of this new trimmer unit.

REPLACING THE ROLLER DIAL DRIVE CORD

1. Tie a tension spring, part number 113177, to one end of about 30" of special dial cord part No. 111302.
2. Tie a large knot in the cord, 6 3/4" from the tension spring.
3. Turn the range switch to the Short-Wave position—all the way counter-clockwise. Pulley A on the range switch shaft should be in the position shown in Fig. 2.

4. Place the knot on the cord in slot B.
5. With the long free end of the cord (not the end with the spring attached), take 1 1/2 turns clockwise around pulley A, then thread the end up through hole C back of pulley D and up to the front of pulley E.

6. Turn pulley E until the slot F is up as shown in the figure. Now, with the free end of the cord, wind clockwise; 1 1/2 turns around E, out through slot F, 1 turn around G, back through slot F, 1 turn around G, back through slot F, and 1 1/4 turns around E.

7. Bring the cord down back of pulley H and leave it hang for the time being.

8. With the end of the cord to which the tension spring is attached, take 1 1/2 turns counter-clockwise around pulley A, (when viewed from the right end) and bring the cord up through hole C.

9. Tie the free end of the cord hanging over pulley H, to the upper end of the tension spring. The spring should be extended so it is approximately 1 1/2" long when the tension in the cord system is equalized.

If the Short Wave scale on the dial is not in the proper position under the pointer, loosen the set screw in hub G, rotate the dial scale to the proper position and tighten the set screw.

Antenna Data

**ALIGNMENT EQUIPMENT & PROCEDURE**

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1.5MC are required.

1. Connect the output meter across the voice coil or, in series with .1 mfd. condenser, from the plate of the 6L6-G output tube to ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the "G" post on the antenna terminal strip at the rear of the chassis, or to the metal chassis. The ground and antenna terminals on the antenna terminal strip must be connected together throughout the alignment procedure.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

DUMMY ANT IN SERIES WITH SIGNAL GENERATOR	CONNECTION OF SIGNAL GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	PUSH IN BUTTON	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. CONDENSER	CONTROL GRID OF 6A8-G TUBE	465 KC.	PUSH IN ANY BUTTON EXCEPT NO. 1 OR 10	2	2ND I.F.	ADJUST FOR MAXIMUM OUTPUT THEN REPEAT ADJUSTMENT
200 MFD. CONDENSER	ANTENNA TERMINAL	465 KC.	#9 (TRIMMER #9a & 9b TUNED TO APPROXIMATELY 600 KC.)	5	WAVE TRAP	ADJUST FOR MINIMUM OUTPUT USING A STRONG GENERATOR SIGNAL.

- IMPORTANT -

RE-TUNE PUSH-BUTTON TRIMMERS TO STATIONS AS RE-ALIGNING THE I.F. STAGES MAY HAVE CAUSED DETUNING OF THE STATIONS TO WHICH THE BUTTONS WERE SET.

**DESCRIPTION OF ANTENNA CIRCUIT AND ITS FUNCTIONS**

Since the antenna circuit of this receiver differs radically from the conventional type, a detailed explanation of the functions of the various sections of this special circuit, and the reasons for the above alignment procedure is given below.

The purposes of this antenna circuit are (1) to transfer the incoming station signal, with maximum gain, to the grid of the first detector tube, (2) to reduce to a minimum, code interference or other undesired signals in the vicinity of the intermediate frequency (465 KC.), (3) to reduce to a minimum the response of image signals. The three coils which perform these functions are wound on a single form and are indicated by No. 65a, No. 65b and No. 65c in the figure at the lower right.

The primary circuit of this antenna system consists of an antenna in series with condenser No. 6, the condenser and coil combination between points E and D, the section of coil 65b between points B and A and the two condensers Nos. 63 and 45 to ground. The resistor No. 35 is shunted directly across this antenna primary circuit and its purposes will be covered later.

The secondary circuit consists of the two parallel condensers Nos. 63 and 45 which are in series with the section of the antenna coil between points A and B, also in series with the coil and condenser combination between points B and C, and the antenna section of the push button trimmer condenser No. 55b. The secondary circuit is tuned to resonance with the incoming station signal, by the push button trimmer condenser No. 55b.

Reduction of image response is accomplished with the aid of the section No. 65c of the antenna coil. This section of the antenna coil acts as a wave trap resonated 930 KC higher than the signal. It is a part of a series resonant circuit made up of the 65c section of the coil and the push button trimmer condenser #55b. This circuit will be approximately resonant to the image signals AT ALL TIMES and will effectively reduce image interference caused by code or police stations operating at the high frequency end of the broadcast band. The purpose of condenser No. 48 is to cause this image reduction circuit to "track" properly.

The wave trap circuit for reduction of 465 KC code signals is composed of the section DA of coil 65b which is in series with condensers No. 63 and 45 (condenser No. 63 is trimmer No. 5 in the above chart). It should be noted that coil section D-A is inductively coupled to the B-D section of the coil and is considered a part of the wave trap circuit. Trimmer condenser No. 63 is adjusted for minimum output with a 465 KC incoming signal at the antenna. At minimum output the voltage developed across coil A-B will be balanced out by the voltage developed across condensers No. 63 and 45 which is 180° out of phase with the voltage developed across the coil. Therefore, it will be seen that any 465 KC interference signals will only develop a very very small voltage between the control grid of the 6A8-G and ground thus effectively eliminating 465 KC code interference.

The 65a section of the antenna coil between points E and D when considered in series with section D-A and condenser 63 and 45, has a resonant peak at 600 KC. The purpose of this circuit being to increase the gain of the receiver on the low end of the broadcast band. Condenser No. 24 which is shunted across coil section 65a has for its purpose the reduction of image responses from signals in the vicinity of 2.5 MC.

Condenser No. 6 is a direct current blocking condenser which keeps the bias voltage and the voltage developed by the A.V.C. system from being shorted out to ground by resistor No.

35. Resistor No. 35 was shunted across the primary antenna circuit for two reasons: (1) to make the overall sensitivity of the receiver more uniform and (2) to eliminate detuning effects in the secondary antenna circuit when different types of antenna systems are used with this receiver.

MODELS 91-821 to 91-829  
98-821 to 98-829  
910-821 to 910-829  
Tuner Data, Phono., Notes

STEWART WARNER CORP.

Chassis Model	Used in Receiver Models	Voltage	Frequency
91-82	91-821 to 91-829	117	60 cycles
98-82	98-821 to 98-829	117	25 cycles
910-82	910-821 to 910-829	100-240	50-135

These chassis are 8 tube single band push button tuning superheterodyne receivers. The tuning range covered by the eight tuning buttons is 540 to 1750 kilocycles. These receivers also incorporate the new Peri-Dynamic speaker system which is an exclusive Stewart-Warner feature and was designed for the express purpose of giving you the ultimate in tone quality and high fidelity reception.

For greatest ease and simplicity in tuning, these chassis are provided with eight push buttons (Nos. 2 to 9 in Fig. 1). These buttons automatically tune in the stations for which they are labelled. Two other buttons are provided on the keyboard (Nos. 1 and 10 in Fig. 1). Button No. 1 is pushed in only WHEN IT IS DESIRED TO TURN THE RECEIVER OFF. Button No. 10 is pushed in when you desire to use the phonograph pick up. TO TURN THE RECEIVER ON MERELY PUSH ANY ONE OF THE BUTTONS FROM NO. 2 TO 9.

**HOW TO SET UP THE PUSH BUTTONS.**

The push buttons of your radio receiver are not previously set to stations at the factory. Therefore, unless your dealer has already set and labelled the various push buttons, it will be necessary to make the following adjustments before any stations can be received by using these buttons, proceed as outlined below:

1. Be sure that your set is connected to a good antenna system.
2. Turn on the set at least one quarter hour before setting up the push buttons.

12. In some instances it may be necessary, after the set is operated for a month or more, to re-set the trimmer adjusting screws as they may change their setting due to heat and humidity. Changes in the setting of the trimmer screws will cause poor tone quality.

**USE OF THE TUNING EYE.**

The tuning eye is located at the rear of the chassis (as shown in Fig. 1) and should be used when setting up the push buttons to the various stations. Its purpose is to indicate visually the exact point at which the receiver is correctly tuned to a station. Any station is correctly tuned in when the two open ends of the "V" shadow in the tuning eye are closest together. On strong signals the ends will come together - on weaker stations, they will be more separated. REGARDLESS OF WHETHER YOU ARE TUNING IN A STRONG OR A WEAK STATION, THE TRIMMER SCREWS SHOULD ALWAYS BE ADJUSTED TO THE POINT WHERE THE ENDS OF THE "V" IN THE EYE ARE CLOSEST TOGETHER.

NOTE: This tuning eye should be removed from its socket in the chassis after the push buttons have all been set-up. Failure to remove this tube may result in buzzing or rattling sounds such as described below under "Rattles and Buzzes".

**CONNECTING A PHONOGRAPH PICK-UP UNIT.**

The connections to your receiver from a high impedance pick-up unit are made to the terminal strip on the back of the chassis (see Fig. 1, back view, for this terminal strip labeled "PHONOGRAPH"). The two leads from the phonograph pick-up unit are connected to the two terminals on this strip. In case hum is encountered when using this unit, reverse the connections to this terminal strip. If the hum persists, make sure that the receiver has a ground wire connected to it as described under "GROUND CONNECTIONS."

**HOW TO CHANGE THE OPERATING RANGE OF A BUTTON.**

The operating range of a button may be changed by merely changing the dual trimmer used with that button. Dual trimmers with the ranges indicated below can be obtained from your Stewart-Warner distributor, or directly from the Stewart-Warner Corporation, under the following part numbers:

Part Number	Tuning Range	List Price
113953	1170 to 1750 KC.	.46
113954	650 to 1300 KC.	.50
113955	540 to 770 KC.	.52

To make the change proceed as follows:

1. Remove the chassis from the cabinet.
2. By referring to Fig. 1, determine the dual trimmer associated with the button whose range you wish to change.
3. Unsolder the leads from the four terminals on the back of this dual trimmer.
4. Remove the 6/32 machine screw holding the dual trimmer to the front of the chassis.
5. From the above list, select a dual trimmer which will cover the desired range.
6. Mount it on the chassis with the 6/32 machine screw, and solder the leads to its four terminals.

The button is now ready to be set to any strong station whose frequency is within the range of this new trimmer unit.

**RATTLES & BUZZES.**

If during normal operation, buzzing or rattling sounds are heard in the receiver, they will in all probability originate in one or more of the sources listed in this paragraph. These rattles or buzzes generally occur with the tone control in the bass position and with the volume control advanced to a fairly loud level. Check the following for probable sources of noise.

- (1) Loose tube shields. See that shields are properly located, and making good mechanical contact with tube shield base.
- (2) Loose elements in any of the tubes. This applies especially to the 6U5 tuning eye tube. This tube should be removed from the chassis after the buttons have been set-up.
- (3) Loose escutcheon or cabinet parts. Check for mechanical vibration of any parts not securely fastened.

3. Make a list of the frequencies of eight nearby stations to which you wish to set up the buttons. Be sure to select the most powerful nearby stations, since weak signals will not give as satisfactory results.

4. Each of the buttons on your push button tuner has a definite tuning range, as shown in Fig. 1 (both back and front view of cabinet.) It is imperative that, in setting up the buttons, you select stations whose frequency is in the indicated tuning range of that button. The correct frequencies of your local stations may be obtained from your newspaper or radio call magazine. EXAMPLE: This example illustrates the proper way to select a station to be set to a particular button. Suppose you want to set station WLM, whose frequency is 700 KC., to some button on your receiver. Referring to Fig. 1 will show that this frequency falls within the operating range of Buttons No. 4, 5, 6 and 7. Therefore any of these buttons may be used to set up this station. Failure to select the proper button will result in the incorrect setting of the trimmer adjusting screw and will also cause "drifting".

5. Place the receiver in such a position that the back of the cabinet is readily accessible. Refer to Fig. 1 (showing the back of the cabinet.) In the figure, the eight pairs of trimmer adjusting screws are numbered to correspond to the numbers of push buttons shown in the front view of Fig. 1. These screws are used to tune the receiver to the station selected for each button.

6. Push in Button No. 2. Then insert a screw driver in Trimmer Screw No. 2a and turn this screw to the left or right until the desired station is heard. The point at which the screw will be correctly set will be indicated when the open ends of the "V" shadow in the tuning eye are closest together. If the station cannot be heard, advance the volume control. By having available a daily radio log from your newspaper, you can identify the station by knowing what its scheduled program is.

7. Now insert the screw driver in Trimmer Screw No. 2b and turn it to the right or left until the open ends of the "V" shaped shadow in the tuning eye are closest together. Now re-check the setting of Trimmer Screw No. 2a using the tuning eye shadow to indicate the correct setting.

8. The set-up for Button No. 2 is now complete.

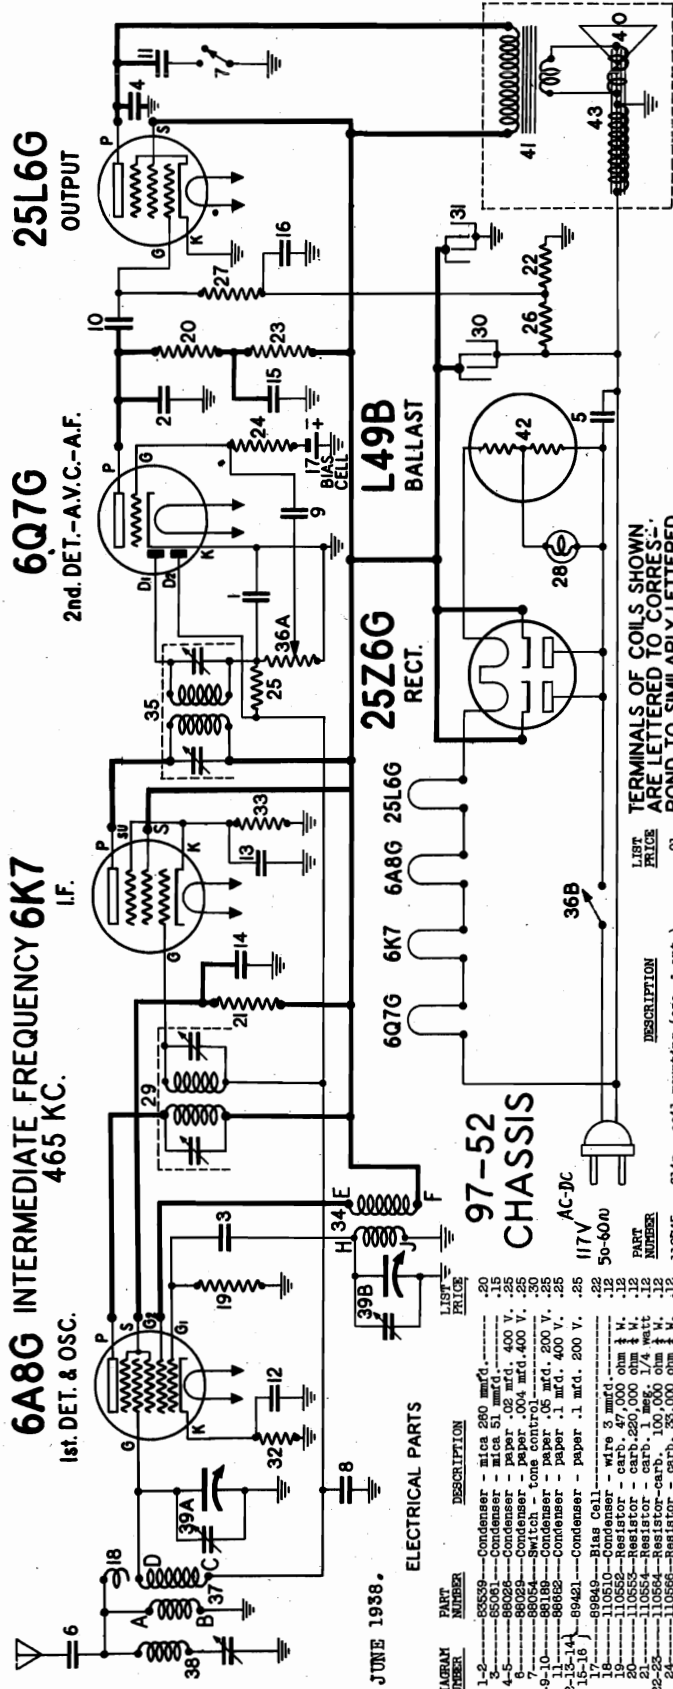

9. Push in Button No. 2 and set up trimmers No. 3a and 3b to the desired station in a similar manner.

10. Set up the remaining six buttons using their corresponding trimmer screws.

11. Call letter tabs are supplied with your receiver, with which to label the various push buttons. Select the tabs bearing the call letters of the stations to which you have set the buttons, moisten them on their gummed side, and insert them in their proper place in the escutcheon openings above the push buttons.

STEWART WARNER CORP.

Alignment, Trimmers

Chassis Model

97-52

Used In Receiver Models

97-521 to 97-529

Voltage

117 volts A.C. or D.C.

This chassis is a 5 tube, single band push-button tuning superheterodyne receiver. It is designed for operation on either alternating or direct current, and incorporates an L-49-B ballast resistor tube. The tuning range of this receiver is 540 to 1725 KC. The intermediate frequency is 465 KC.

Incorporated in each chassis is a four-button mechanical push-button tuner unit. These push buttons may be set to any station desired by the method described below under "How To Set Up The Push-Button Tuner".

The accuracy of tuning when using the push-button tuner, depends to a large extent upon the amount of "play" in the moving parts of this system. In cases where slight inaccuracy in tuning occurs check the following points:

1. Check to see that the button is correctly set to the station. If not, reset the button.
2. The tension must be maintained between the two sections of the anti back-lash gear on the left side of the unit in order that it functions properly--both anti back-lash springs must be in place in the gear and compressed slightly.
3. Note the small adjusting lug over the push-button shafts at the point where they slide into the tuner. The lug is held in place by a hex-head screw. These lugs should be adjusted for a minimum amount of "play" In other words the push-button shaft must have a minimum of movement in a vertical direction.

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

- ① Connect the output meter across the voice coil or between the plate of the 25L6-G output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- ② Connect the ground lead of the signal generator to the chassis of the receiver through a .1 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as one side of the power line may be grounded in the signal generator.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- ④ With the gang condenser in full mesh, set the pointer to the last mark on the right end of the dial scale. If the pointer is only slightly off calibration, loosen the set-screw in the dial drive drum at the left side of the gang condenser and set the pointer to the last mark on the right end of the dial when the gang condenser is in full mesh. If the pointer is off calibration several dial divisions, release it from the pointer drive cord by spreading the clip on the pointer. Then slide the pointer along the cord until it is set to the last dial division on the right end of the dial. Holding it in place check to see if the gang condenser is in full mesh, and tighten the pointer clip, being careful not to cut the cord. Place a drop of household or speaker cement on the cord and pointer clip to prevent the pointer from slipping.

**HOW TO SET UP THE PUSH-BUTTON TUNER.**

STEWART WARNER CORP.

1. Be sure that your set is connected to a good antenna system.
2. Turn on the set and allow it to operate at least one-quarter hour before setting up the push buttons.
3. Select the four nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations, since weak signals will generally give poor results. Any button may be set to any desired station.

4. The large tuning knob at the side of your set has a screw located in the center. Grasp this tuning knob firmly and then using a screw-driver or a coin turn the screw counter-clockwise not more than two whole turns. (When viewed from the side of the cabinet.)
5. Push down any one of the four buttons that you wish to set to a station. Be sure to push the button all the way down, otherwise the setting will be incorrect.
6. Holding the push-button down firmly, turn the tuning knob until the station you desire is tuned in. Tune in strong nearby stations for best results. Be sure to tune in the stations correctly by tuning to the point where the program is heard with the least hiss or distortion and not to the point of greatest volume.
7. Release the push button that you have just set up. **WARNING:** Do not attempt to use any button until you have completed the set-up of all four buttons. Do not re-tighten the set-up screw until all buttons have been set-up.
8. Proceed to set-up the next button by pushing down on the button firmly and tuning in the desired station, using the tuning knob. The rest of the buttons should be set-up in a similar manner.
9. After all of the buttons have been set-up **YOU MUST RE-TIGHTEN THE SCREW IN THE TUNING KNOB; OTHERWISE ALL SETTINGS OF THE BUTTONS WILL BE DESTROYED. GRASP THE KNOB FIRMLY AND THEN USE A SCREW DRIVER OR A COIN TO TIGHTEN THE SCREW SECURELY.**
10. The push buttons should now be labelled with their proper call letters. The call letter sheets are supplied with your receiver. The individual call letter tab should be moistened on its gummed side and stuck to the small square in the cabinet panel just above the push button.

**97-56 CHASSIS ONLY****THE INTERMEDIATE FREQUENCY AMPLIFIER.**

This 97-56 chassis employs one stage of intermediate frequency amplification. The intermediate frequency transformer is adjusted to 465 KC and is tuned in the usual manner. In addition to the two trimmers used in tuning the windings to their proper frequency, this transformer has mounted on it an additional trimmer condenser which is used to feed back a portion of the intermediate frequency signal appearing in the plate circuit of

the 6J7-G tube. This signal is introduced into the 6J7-G grid circuit through a coupling coil, which is a part of the secondary coil. This regeneration increases the amplification and selectivity obtainable from this stage, and makes the performance of this set comparable to that which is obtained from a set employing an additional I.F. transformer.

When aligning the intermediate frequency amplifier, the output of the signal generator is set at 465 KC and is coupled to the grid of the 6A8-G tube in the customary manner. The primary and secondary windings are tuned by adjusting Trimmer Screws No. 1 and No. 2 until a maximum deflection is obtained on the output meter. If the set has a tendency to oscillate when adjusting these trimmer screws, turn Trimmer Screw No. 5 to the left (counter-clockwise) until the oscillation ceases. The signal generator is next coupled to the antenna lead, and Trimmers No. 3 and No. 4 are aligned for maximum output, using a generator frequency of 1500 KC. Now connect the set to the CUSTOMER'S antenna and tune in a station on the low frequency end of the dial. The regeneration control, Trimmer No. 5 is now adjusted to give maximum output of the set, consistent with good stability and tone quality. After changing the setting of Trimmer No. 5 it is necessary to re-adjust Trimmers No. 1 and No. 2, as their setting will be found to have changed slightly. The output of the signal generator is set at 465 KC and is coupled to the grid of the 6A8-G tube through a .1 mfd. condenser and Trimmers No. 1 and No. 2 adjusted, as was done previously.

**A-C OPERATION**

When the set is used on alternating current, all D-C potentials are supplied by a 25Z6G rectifier tube and its associated filter circuit. The tube is connected for half-wave rectification of the A-C supply.

If any hum is noticed when the set is used on A-C, reversing the power plug in the receptacle will sometimes reduce the hum level. When the set has not been used for some time, or the filter condensers have been replaced, a slight hum may be audible when the set is first turned on. This hum may not clear up immediately upon reversal of the power plug. However, it will probably be eliminated after approximately five minutes operation by which time the anode plates of the electrolytic capacitors in the filter system will have reformed.

**D-C OPERATION**

If the set fails to operate after allowing time for the tubes to reach their normal operating temperatures, reverse the power plug in the receptacle. When the set is used on direct current, the 25Z6G rectifier tube and the filter system remains in the circuit and serve two purposes. If the power cord should be plugged in with incorrect polarity, the 25Z6G tube protects the filter condensers from damage. On correct D-C polarity the 25Z6G tube passes the D-C and the filter circuit aids in smoothing the supply voltage, thus minimizing line noises.

**97-56-S CHASSIS ONLY****I.F. TRANSFORMER & REGENERATION CONTROL**

This 97-56-S chassis employs only one intermediate frequency transformer, the windings of which are capacitively coupled. The two trimmers used to tune the primary and secondary of this transformer are mounted on the transformer assembly, and are accessible from the rear of the chassis. Also associated with this intermediate frequency transformer is an additional trimmer condenser, which is accessible through a hole in the rear of the chassis. This condenser is used to feed back a portion of the intermediate frequency signal appearing in the plate circuit of the 6J7-G tube. This signal is introduced into the 6J7-G grid circuit through a coupling coil, which is a part of the secondary coil. The regeneration obtained increases the amplification and selectivity obtainable from the intermediate frequency transformer, and makes the performance of this set comparable to that which is obtained from a set employing an intermediate frequency stage.

**ADJUSTMENT OF REGENERATION CONTROL.**

**IF DISTANT STATIONS COME IN WITH INSUFFICIENT VOLUME:** Through the opening near the bottom of the center of the back of the cabinet, you will see an adjusting screw. Using a non-metallic instrument (a piece of wood whittled in the shape of a screw driver will serve the purpose), turn this screw to the left (counter-clockwise). As you turn counter-clockwise the volume will be increased up to a certain point at which the set will begin to squeal. Turn the screw back until the squeal just disappears and good tone quality is obtained.

**IF THE RECEIVER HOWLS OR SQUEALS:** Using the same screw mentioned above and a non-metallic instrument (a piece of wood whittled in the shape of a screw driver will serve the purpose) turn the screw clockwise very, very slightly until the squeal or howl ceases.

STEWART WARNER CORP.

Alignment, Trimmers

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

- ① Connect the output meter across the voice coil or between the plate of the 25L6-G output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- ② Connect the ground lead of the signal generator to the chassis of the receiver through a .1 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as one side of the power line may be grounded in the signal generator.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- ④ With the gang condenser in full mesh, set the indicator to the last mark on the top end of the dial scale. If the pointer is only slightly off calibration, it may be possible to slip the dial drum just enough to correct for this slight mis-calibration. If the dial is several divisions off calibration, loosen the set screw on the condenser shaft. Then grasp the end of the tuning shaft and turn the dial until the last division of the scale is directly under the indicator, when the gang is in full mesh. Then retighten the set-screw.
- ④ TO CALIBRATE THE DIAL:- Remove the chassis from the cabinet and set it on a flat surface (insulated from ground). Release the set screw in the collar which connects the gang condenser shaft with the tuning unit. Holding the gang in full mesh turn the dial until the last dial division (just below 55) on the low frequency end is exactly 4 3/8 inch above the table surface. Now retighten the set screw in the coupler collar. The 4 3/8 inch division on the ruler (when measured vertically from table surface) is to be used as the dial indicator for all calibrations and alignment.

DUMMY ANT. IN SERIES WITH SIG. GEN.	CONNECTION OF SIG. GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. CONDENSER	CONTROL GRID OF 6A8-G TUBE	465 KC	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1-2	I. F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT. IF OSCILLATION OCCURS TURN REGENERATION CONTROL TRIMMER #5 ONE-QUARTER TURN

Chassis Model

97-56

Used in Receiver Models

97-561 to 97-569

Voltage

117 volts A.C. or D.C.

This chassis is a 5 tube single band push-button tuning superheterodyne receiver. It is designed for operation on either alternating or direct current, and incorporates an L-55-B ballast resistor tube. The tuning range of the receiver is 540 to 1720 KC.

**IMPORTANT:** In cases where it is found that the push-button tuner does not tune in stations correctly due to extreme sharpness in tuning it is only necessary to back off (turn counter clockwise) the regeneration control trimmer (#5) slightly. This will make tuning broader and will result in more accurate tuning when using the push button tuner.

Chassis Model

97-56-S

Used in Receiver Models

97-561 to 97-569

Voltage

117 Volts A.C. or D.C.

This chassis is a 5 tube single band push-button tuning superheterodyne receiver. It is designed for operation on either alternating or direct current, and incorporates an L-55-B ballast resistor tube. The tuning range of the receiver is 540 to 1720 KC.

**IMPORTANT:** In cases where it is found that the push-button tuner does not tune in stations correctly due to extreme sharpness in tuning it is only necessary to turn the regeneration control trimmer (#5) slightly clockwise. This will make tuning broader and will result in more accurate tuning when using the push button tuner.

 Schematic, Voltage  
 Socket, Changes

SEE 97-56 CHASSIS.

**MODELS 97-571 to 97-579  
 97-57 CHASSIS**

SOCKET VOLTAGES  
 DIAL TUNED TO 540 KC

**REAR OF CHASSIS**  
 Use a high resistance voltmeter of at least 1000 ohms per volt.  
 NOTE A:- The bias for the control grid of the 25L6-G tube is -6.7 volts, measured across resistor number 38.

DIAGRAM NO. 23  
 PART NO. 113449

DIAGRAM NO. 22  
 PART NO. 113042

**NOTE**  
 TERMINALS OF COILS SHOWN IN PICTORIAL VIEWS ARE LETTERED TO CORRESPOND TO SIMILARLY LETTERED TERMINALS ON THE CIRCUIT DIAGRAM ABOVE. TERMINALS WHICH ARE CONNECTED TOGETHER CARRY THE SAME LETTER.

FEBRUARY 1939.

**CIRCUIT CHANGE**

Resistor No. 18 connected in parallel with the dial bulb has been changed to a 3 watt molded wire wound resistor, Part No. 116479. This size is being used in place of the original 1/2 watt rating, to prevent failure of the resistor if the dial bulb burns out. The 3 watt resistor should be used for replacement in all cases.

**TUBE CHANGE**

A small percentage of these chassis was equipped with 6K7 metal I.F. tubes but most of them are using the 6K7G glass tube. Because of shield requirements, these tubes cannot be used interchangeably. In other words, a metal tube must be used to replace a metal tube, while in a chassis originally equipped with a glass I.F. tube, a glass tube must be used as a replacement.

**CORRECTING OSCILLATION & SQUEALING**

If a "squeal" develops with the volume control fairly well advanced, separate the 6Q7G grid lead and the speaker wires as much as possible by pulling the grid lead to the side of the 6Q7G nearest the variable condenser. If there is a loud heterodyne whistle when tuning in stations, the I.F. stage may be oscillating. If this happens, move the lead from the 6A8G cathode to the 6Q7G cathode as close to the chassis and as far from other wires as possible. If necessary, connect a .05 mfd. 200 volt condenser to one of the above cathode terminals which does not already have such a condenser connected directly to it.

MODELS 97-571 to 97-579  
Alignment, Trimmers, Parts  
Antenna Notes

STEWART WARNER CORP.

ALIGNMENT EQUIPMENT & PROCEDURE

FOR ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

- ① Connect the output meter across the voice coil or between the plate of the 25L5-G output tube and ground through a .1 mfd. condenser, depending upon the type of meter. The more sensitive type should be connected across the voice coil.
- ② Connect the ground lead of the signal generator to the chassis of the receiver through a .25 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as the signal generator may be connected to one side of the power line, or it may be grounded externally.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

- ④ TO CALIBRATE THE DIAL:-- Remove the chassis from the cabinet and set it on a flat surface (insulated from ground). Release the set screw in the collar which connects the gang condenser shaft with the tuning unit. Holding the gang in full mesh turn the dial until the last dial division (just below 55) on the low frequency end is exactly 4 3/8 inch above the table surface. Now retighten the set screw in the coupler collar. The 4 3/8 inch division on the ruler (when measured vertically from table surface) is to be used as the dial indicator for all calibrations and alignment.

BUILT-IN ANTENNA SYSTEM

The Built-In Antenna incorporated in this receiver will generally give very satisfactory results in localities where powerful broadcast stations exist. This Built-In Antenna will function when terminals A and A<sub>1</sub> on the back of the chassis are connected together. In cases where noises are excessive or greater sensitivity is desired, remove the jumper connecting terminals A and A<sub>1</sub> and connect an external antenna to terminal A. In some locations, due to peculiar power line conditions, hum or noise may be excessive when the Built-In Antenna is used. In such cases reverse the power line plug. If this doesn't correct the condition, remove the connector between A and A<sub>1</sub> on the back of the chassis, and connect an external antenna to A.

Table with 3 columns: DIAGRAM NUMBER, DESCRIPTION, LIST PRICE. Continues the list of components from the previous table, including various types of resistors and transformers.

NOTE A: The bias for the control grids of the 6L7 1st Det., 6K7 R.F., 6K7 1st I.F. and 6K7 2nd I.F. tubes, also the voltage on the 6H6 diodes and cathodes and the control grid of the 6J7, is -3.6 volts measured across resistor number 101.

1851W to 1859W Alignment

STEWART WARNER CORP.

MODELS 1851 to 1859 1851A to 1859A 1851B to 1859B

The model R-185 chassis, is all tube, three band, automatic tuning, superheterodyne receiver. It has an intermediate frequency of 465 KC. and tuning range of 525 KC. to 18,100 KC. The circuit is of the latest design

Incorporating such refinements as a special high efficiency R.F. unit, automatic frequency control, reactance dimmer, tuning indicator, and iron core I.F. transformers.

ALIGNMENT EQUIPMENT & PROCEDURE

Before attempting to align the receiver check to see that the dial pointer is opposite the last scale division on the low frequency end of the dial when the gang condenser is in full mesh. Also when the gang condenser is in full mesh the stop pin on the left side of the tuner should be resting against the back stop. If after examination it is found that the gang is in full mesh and the stop pin is against the back stop, but the pointer is set to the wrong position, it will only be necessary to loosen the set screw on the dial drive gear at the left side of the mechanism, then grasp the large drum on the same side of the tuner and turn it until the pointer is set correctly. Now retighten the set screw on the gear being careful to see that the gear is meshing properly.

tighten the set screw in the flexible coupler and proceed to set the pointer to its correct position by the method described in the previous paragraph.

On the other hand if the stop pin does not rest against the back stop with the gang condenser in full mesh, loosen the set screw on the gang condenser side of the flexible coupler. Then turn the tuning knob until the stop pin rests against the back stop on the tuner. Now re-

Connect the output meter across the two plates of the two 6V6 power output tubes or across the voice coil of the speaker, depending on the type of meter. The more sensitive type should be connected across the voice coil.

Connect the ground lead of the signal generator to the chassis and leave it there throughout the entire alignment procedure.

Turn the volume control to the maximum volume position.

Keep the Ground and Doublet connections on the antenna terminal strip connected together throughout the entire alignment terminal.

Table with columns: TYPE OF DUMMY ANT. IN SERIES WITH SIG. GEN., POINT TO CONNECT OUTPUT OF SIGNAL GENERATOR, SIGNAL GENERATOR FREQUENCY, RANGE SWITCH POSITION, RECEIVER DIAL SETTING, TRIMMER NUMBER (see diag- next page), TRIMMER DESCRIPTION, TYPE OF ADJUSTMENT.

A.F.C. ALIGNMENT.

IMPORTANT: The following adjustment must be made after every re-adjustment of the I.F. and broadcast band trimmers.

The A.F.C. Discriminator should be adjusted as follows:

- 1. Be sure no buttons are depressed. Loosely couple the output of the signal generator to the 6L7 control grid by clipping the signal generator output lead to the insulation on the control grid wire, or connect to the grid clip through a 50 mfd. mica condenser. BE SURE THE RANGE SWITCH IS IN THE BROADCAST (COUNTER-CLOCKWISE) POSITION.
2. Adjust the signal generator to resonance with I.F. system by tuning the signal generator dial for maximum output meter deflection. Be sure that the receiver dial is at some point where it has no tuning effect on the generator signal. Switch off the modulation.
3. With the signal generator connected and operating as in #2, connect antenna and manually tune in powerful local station in region of 1000 KC. or lower. (Avoid stations around 930 KC. which might beat with second harmonic of test oscillator.)
4. Adjust receiver tuning dial to obtain zero beat between the test oscillator and the incoming signal. (A very slight adjustment is all that is required. Be careful not to tune off signal.)
5. Refer to the figure on the right. It is now necessary to open the A.F.C. contacts & allow it to function. This may be done by placing a piece of smooth cardboard between the A.F.C. contacts as shown in the figure. Be careful not to bend or deform the switch in any way.
6. Now, adjust the secondary of the discriminator transformer (Trimmer #11) to restore zero beat. NOTE: This trimmer should be adjusted to the point where the frequency of the beat note increases rapidly if the trimmer is turned in either direction. Other zero beat points may be found with the trimmer all the way in or all the way out, but these settings are incorrect.

THE AFC MUST NOW BE ALIGNED.

If this operation has been performed correctly, the opening or closing of the A.F.C. contacts on the side switch by inserting or removing the cardboard, should not change the beat note by more than a slight rumble.

NOTE: Where a second signal generator is available step #3 above may be varied as follows: Connect second signal generator (set at about 1000 KC.) to antenna and tune in its signal. Switch off modulation and proceed as before.

This method is somewhat preferable to the first as the zero beat setting is more easily determined when both signals are unmodulated.

Trimmers, Phono. Data "Magic Keyboard" Data Parts List

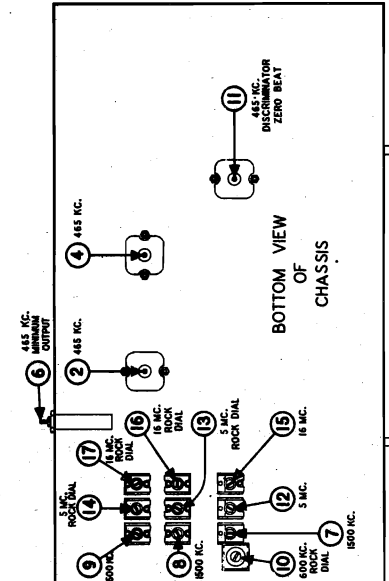

DIAL DRIVE & MISCELLANEOUS PARTS.

FOR A COMPLETE PARTS LIST SEE THE SPECIAL "MAGIC KEYBOARD" LIST. Wherever the word RIGHT or LEFT appears in the following list, it is understood that you are standing in front of the receiver.

Table with columns: PART NUMBER, DESCRIPTION, LIST PRICE.

TESTING THE A.F.C. SYSTEM.

A.F.C. system is not as marked at stations near the low frequency end of the dial scale as it is at the higher broadcast frequencies. This is characteristic of A.F.C. systems. However, if opening the A.F.C. contacts on the side switch by inserting the piece of cardboard between the A.F.C. contacts, the A.F.C. system will function and the beat note will change in one direction only, check the receiver as follows:
1. Re-align I.F., broadcast band, and discriminator trimmers.
2. Check all the tubes in the receiver. Defective 6H6 and 6J7 tubes may cause poor A.F.C. action.
3. If the above procedure fails to remedy the defect in A.F.C. action, check the entire A.F.C. circuit itself for possible troubles.

HOW TO SET-UP THE "MAGIC KEYBOARD"

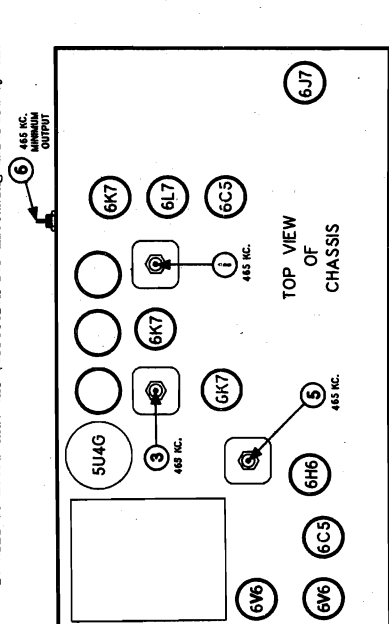

10. To release the last button grasp the set-up knob on the station selector knob and push it in until the last button is released. Then pull the knob out again.
11. Turn the set-up knob to the LEFT (Counter-clockwise). CONTINUE TO TURN THE KNOB TO THE LEFT UNTIL THE POINTER REACHES THE END OF THE dial scale. FORCE THE KNOB COUNTER-CLOCKWISE TO A DEFINITE STOP.
12. Push the "set-up" knob back into the cabinet again and replace the large tuning knob.
13. Your "Magic Keyboard" is now ready for operation.

PHONOGRAPH CONNECTIONS FOR MODEL R-1855-W

CONNECTING THE PROPER STATIONS.

When setting up the "Magic Keyboard" select powerful nearby stations. Avoid weak or fading stations. LABELLING THE PUSH BUTTONS: Call letter labels are supplied with each set. To label any button remove the cap of the push button, BY PULLING ON THE TOP END. Remove the black cardboard disc, and insert the call letter tab. IN REPLACING THE CAP SPREAD AT THE BOTTOM AND PRESS ON THE TOP.
STEP BY STEP PROCEDURE:
1. Connect a good outside aerial to the receiver and allow the receiver to operate for 20 minutes before setting-up.
2. Pull off the large tuning knob. As this knob is removed another small "set-up" knob on the same shaft will appear, partly hidden behind the panel face.
3. Pull out this set-up knob AS FAR AS IT WILL GO.
4. Rotate the set-up knob clockwise. After dial pointer reaches the end of the dial scale continue to turn the knob clockwise until you have forced it to a definite stop. This last twist unlocks the cams.
5. Push any button you wish to set to a station. The tuner will operate and carry the pointer to some point on the dial scale.
6. Tune the receiver to the desired station with the dial set-up knob. TUNE CAREFULLY AND WATCH THE "REACTANCE DIMMER" FOR THE POINT OF MINIMUM ILLUMINATION SO THAT THE RECEIVER WILL BE CORRECTLY TUNED TO THE STATION.
7. Push in the next button you want to set up for a station. This automatically causes its button to pop out. Do not push in any buttons that are already set up and which you do not wish to change, since pushing a button with the cams unlocked will shift its setting.
8. Tune in the station for the button that is now depressed.
9. Set-up other buttons as desired in the same manner, that is, push in the button, tune in the station, then push in the next button.

**R-190-D CHASSIS**

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

The Model R-190-D chassis is a five tube battery receiver using "A" and "B" batteries. The standard superheterodyne circuit which this receiver employs includes automatic volume control and a class A single pentode output system. The tuning range covers the standard broadcast range from 540 to 1720 KC. and the popular short wave bands from 5.7 to 16.3 MC. Automatic volume control is accomplished by supplying the filtered A.V.C. voltage to the control grids of both the IC6 and 34 tubes. An unusual arrangement of a combined off-on switch and range switch is also utilized in the circuit of this receiver. The action of this switch open. 1. In the extreme counter-clockwise position the receiver is turned off with both the "A" and "B" supply circuits open. 2. With the switch in the middle position the "A" and "B" supplies are connected and the antenna and oscillator coils for the broadcast band are now in circuit to permit tuning on that band. 3. In the extreme clockwise position, the receiver will tune in the short wave band.

MODELS 1901 to 1909  
 Chassis R-190D  
 Alignment, Trimmers  
 Battery Connections

STEWART-WARNER CORP.

**POWER SUPPLY & BATTERY CONNECTIONS**

The power supply of this receiver consists of three "B" batteries and one "A" battery. No "C" battery is needed as the first 22-1/2 volts of the "B" battery supply serves as a "c" battery. Proper intermediate bias voltages are secured from the tapped candohm resistor number 32.

The +22-1/2 volt tap on the "B" battery is the negative connection for the plate supply and it is connected to "A" and ground. This allows a maximum plate supply voltage of 113-1/2 volts with fresh batteries.

The "A" supply may be a 2-1/2 volt Air Cell, a 3 volt dry battery, or a 2 volt storage battery since the filaments of all tubes in the receiver are supplied through a type 5E1 voltage regulator tube. The purpose of this tube is to maintain a safe filament voltage with battery voltages ranging from 2 to 3 volts. The voltage drop across the tube will decrease as the battery voltage decreases thus maintaining nearly a constant filament potential.

If a 2 volt storage cell is to be used and the tubes in the receiver are not new it is desirable to remove the 5E1 voltage regulator tube and replace it by a plug which merely shorts out the two large terminals of the 5E1 tube socket. This plug may be made up by removing the base of an old 4 prong tube and connecting the two large pins together with a piece of wire. **BE CAREFUL NOT TO CONNECT ANYTHING TO EITHER OF THE SMALL PINS OR THE OTHER TUBES MAY BE BURNED OUT.**

In order to simplify connections to the batteries, plugs are provided and the method of connection to the batteries is shown in the diagram on the right.

**ALIGNMENT EQUIPMENT & PROCEDURE**

For proper alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 16 MC. are required.

- ① Connect the output meter across the voice coil or between the plate of the 33 tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- ② Connect the ground lead of the signal generator to the chassis of the receiver.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- ④ With the gang condenser in full mesh set the pointer on the horizontal black line below 540 KC. on the dial.
- ⑤ Using a bakelite screw driver proceed to align in exactly the same order as shown in the table below.

ORDER OF ALIGN.	DUMMY ANT. IN SERIES WITH SIG. GEN.	CONNECTION OF SIG. GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	RANGE SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
A	.1 MFD. CONDENSER	CONTROL GRID OF 34 TUBE (Do not remove grid clip)	465 KC.	BROADCAST (Center Position)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1 2	2ND. I.F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.

C	400 OHM CARBON RESISTOR	ANTENNA LEAD	1700 KC.	DITTO	1700 KC.	5	BROADCAST OSCILLATOR (Shunt)	ADJUST TRIMMER TO BRING IN SIGNAL.
D	DITTO	DITTO	1500 KC.	DITTO	TUNE TO 1500 KC. GENERATOR SIGNAL	6	BROADCAST ANTENNA	ADJUST FOR MAXIMUM OUTPUT.
E	DITTO	DITTO	600 KC.	DITTO	TUNE TO 600 KC. GENERATOR SIGNAL	7	BROADCAST OSCILLATOR (Series Pad)	ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETUNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.
F	DITTO	DITTO	16 MC.	SHORT-WAVE (Clockwise)	TUNE TO 16 MC. GENERATOR SIGNAL	8	SHORT-WAVE ANTENNA	ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETUNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.

NOTE A: Now repeat adjustment of trimmers 3 and 4 again for greater sensitivity. This may cause oscillation. If oscillation occurs repeat steps A and B and disregard the adjustment mentioned in this note, i.e., after adjusting 1 and 2, do not repeat adjustment of 3 and 4. Important: Please note that in repeating step A, the signal generator must be connected to the 34 control grid. In step B, the connection is to the 1C6 grid.

Circuit Data

### CIRCUIT DESCRIPTION

The model R-191-D chassis is a six volt battery powered superheterodyne receiver. It has an intermediate frequency of 465 KC. and the tuning range is from 540 to 1720 KC.

The incoming signal picked up by the antenna is induced in the tuned secondary of the antenna coil and impressed on the control grid of the 6A8G first detector and oscillator tube. The oscillator circuit is tuned to a frequency 465 KC. higher than that of the incoming signal, and the resultant 465 KC. output is amplified in the I.F. stage, using a 6S7G tube. The amplified I.F. voltage is impressed on the grid of the 6L5G second detector tube. The plate of the 6L5G tube is grounded and the grid acts as the plate of a linear diode detector and A.V.C. source. The direct current voltage developed across the 1/2 megohm diode load resistor is used as A.V.C. voltage and applied to the control grids of the 6A8G and 6S7G (I.F.) tubes through a resistance capacity filter system. Self bias is obtained across the cathode resistor 2S to maintain bias at all times.

The potentiometer type volume control 49 serves as a continuously variable voltage divider of the audio voltage developed. Any portion of the audio voltage can be applied to the control grid of the 6S7G A.F. tube. It should be noted that the bias for the 6S7G A.F. tube is obtained from a bias cell. The 6S7G A.F. tube is resistance coupled to the 4I power output tube. Grid bias for the output tube is obtained across the cathode resistor 36.

The continuously variable resistor type tone control regulates the high note content of the audio output.

All tube heaters are connected directly to the six volt supply circuit. "B" voltage is supplied by a synchronous full wave vibrator (48). The complete "B" supply, consisting of vibrator, power transformer, chokes and condensers, is housed in a metal shield to eliminate interference. R.F. filter chokes in the power supply input and output circuit prevent interference from getting into the "A" and "B" leads.

### ALIGNMENT EQUIPMENT & PROCEDURE

For proper alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 1800 KC. are required.

- 1 Connect the output meter between the plate of the 4I tube and ground, or across the voice coil, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- 2 Connect the ground lead of the signal generator to the chassis of the receiver.
- 3 Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure. Turn tone control to brilliant position.
- 4 With the gang condenser in full mesh set the pointer on the black horizontal line below 550 KC. on the dial.
- 5 Proceed to align in exactly the same order as shown in the table below.

STEWART-WARNER CORP.

# MODEL R-192-D CHASSIS (RECEIVER MODELS 1921 to 1929)

The model R-192-D is a six volt battery powered superheterodyne receiver. The circuit employed includes automatic volume control and a push pull class B output system.

The 6L5G second detector is connected as a diode, the plate being grounded and the control grid acting as a diode plate. "B" voltage is supplied by a synchronous full-wave vibrator.

## ALIGNMENT EQUIPMENT & PROCEDURE

For proper alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 18 MC. are required.

- ① Connect the output meter across the plates of the 19 tube, or across the voice coil, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- ② Connect the ground lead of the signal generator to the chassis of the receiver and keep it connected in this manner throughout the entire alignment procedure.
- ③ Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure. Turn tone control to brilliant position.
- ④ With the gang condenser in full mesh set the pointer on the black horizontal line below 550 KC. on the dial.
- ⑤ Proceed to align in exactly the same order as shown in the table below.

STEWART-WARNER CORP.

MODELS 3041 to 3049 Chassis R-304, R-304A

**SOCKET VOLTAGES**

The model R-304 chassis is a five tube superheterodyne receiver. It has an intermediate frequency of 465 KC. and a tuning range from 540 to 1720 KC.

VOLUME CONTROL ON FULL DIAL TUNED TO 540 KC. IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt.

NOTE A: The bias for the control grids of the 6A8G, 6K7G and the diode plates of the 6Q7G is -2.0 volts measured across section AB of resistor number 22.

NOTE B: The bias for the control grid of the 6Q7G is -3.5 volts measured across section AC of resistor number 22.

NOTE C: The bias for the control grid of the 6K6G output tube is -10 volts measured across section AD of resistor number 22.

## ALIGNMENT EQUIPMENT & PROCEDURE

For proper alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 1600 KC. are required.

- 1 Connect the output meter between the plate of the 6K6G tube and ground, or across the voice coil, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
- 2 Connect the ground lead of the signal generator to the chassis of the receiver.
- 3 Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
- 4 With the gang condenser in full mesh set the pointer to the 540 KC. division on the dial.
- 5 Proceed to align in exactly the same order as shown in the table below.

ORDER OF ALIGN.	DUMMY ANT. IN SERIES WITH SIG.-GEN.	CONNECTION OF SIG. GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
A	.1 MFD. CONDENSER	CONTROL GRID OF 6A8G TUBE	465 KC.	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1 2	1ST I.F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.
B	.1 MFD. CONDENSER	CONTROL GRID OF 6A8G TUBE	465 KC.	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	3 4	2ND I.F.	ADJUST TRIMMERS 3 & 4 FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT OF TRIMMERS NO. 1 & 2.
C	400 OHM CARBON RESISTOR	ANTENNA LEAD	1600 KC.	1600 KC.	5	OSCILLATOR	ADJUST TO BRING IN SIGNAL. SEE NOTE BELOW TABLE.
D	400 OHM CARBON RESISTOR	ANTENNA LEAD	1500 KC.	TUNE TO 1500 KC. GENERATOR SIGNAL	6	ANTENNA	ADJUST FOR MAXIMUM OUTPUT.

NOTE: The oscillator section of the gang is provided with two trimmers, connected in parallel, one on the top (No. 5) and one on the bottom. Normally the bottom trimmer will require no adjustment, but if trimmer No. 5 has to be turned too far out or too far in the bottom trimmer should be adjusted until trimmer No. 5 peaks about half way in.

DIAL CORD INSTALLATION: The dial cord to be used should be approximately 27 inches long.

Open the gang condenser all the way (plates all out) and unclip the tension spring from drum A.

1. Thread both ends of the dial cord through the opening at the top of drum A and tie them to one end of the tension spring.
2. Wind one complete turn counter-clockwise around drum A. (Use only one end of the cord).
3. Run the cord around pulley B from back to front, then across to the front of pulley C.
4. Run the cord around pulley C, over drum A (in back of windings) down to shaft D.
5. Wind three complete turns around shaft D.
6. Run the cord up to drum A and wind one complete turn counter-clockwise around the drum.
7. Fasten the tension spring to the clip inside the drum.
8. With the gang condenser fully closed clip the pointer to the dial cord so that it comes opposite the 540 KC. marking on the dial.

WIND THREE COMPLETE TURNS AROUND SHAFT "D"

MODELS  
3041 to 3049  
CHASSIS  
R-304,  
R-304-A

ELIMINATION OF OSCILLATION: Some of the model R-304 receivers may oscillate or "growl" especially when tuned to weak stations or between stations. This oscillation can always be eliminated by connecting a ground to the receiver. However, if the set is to be used without a ground, it can be kept from oscillating by connecting a buffer condenser from one side of the power line to the chassis within the receiver. The condenser should have a capacity of .01 mfd. and a voltage rating of 1000 volts. Later production receivers are built with such a line buffer condenser to prevent oscillation. Sets using the condenser can be identified by the letter "S" on the back of the chassis also on the packing carton near the serial number.

## ALIGNMENT EQUIPMENT & PROCEDURE

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 14 MC are required.

1. Connect the output meter across the voice coil or between the plate of the 6F6-G output tube and depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the black (ground) wire or the chassis.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is incorrectly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Band Switch Position	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
.1 MFD. Condenser	Control Grid of 6A8-G Tube	465 KC	Broadcast Clockwise	Any Point Where It Does Not Affect The Signal	1-2 3-4	2nd I. F. 1st I. F.	Adjust for maximum output. Note repeat adjustment.
200 MMFD. MICA CONDENSER	Antenna Terminal or Antenna Lead	465 KC	Broadcast Clockwise	Any Point Where It Does Not Affect The Signal	5	Wave Trap	Adjust for minimum output using a strong generator signal. Check for maximum output.
400 OHM Carbon Resistor	Antenna Terminal or Antenna Lead	14 MC	Foreign (Counter-Clockwise)	14 MC	6	Foreign (Shunt) Antenna	Adjust for maximum output. Check to see if proper peak was obtained by tuning in the range of 14 MC. If image does not appear reading at 14 MC with trimmer screw adjusted, increase frequency. Try to increase output by adjusting trimmer and retaining output is obtained.
600 OHM Resistor	Antenna Terminal or Antenna Lead	14 MC	Foreign (Counter-Clockwise)	14 MC	7	Foreign Antenna	Adjust for maximum output.
200 MMFD. MICA CONDENSER	Antenna Terminal or Antenna Lead	1500 KC	Broadcast Clockwise	1500 KC	8	Broadcast (Shunt) Antenna	Adjust for maximum output.
200 MMFD. MICA CONDENSER	Antenna Terminal or Antenna Lead	1500 KC	Broadcast Clockwise	Tune To 1500 KC Generator Signal	9	Broadcast Antenna	Adjust for maximum output.
200 MMFD. MICA CONDENSER	Antenna Terminal or Antenna Lead	600 KC	Broadcast Clockwise	Tune To 600 KC Generator Signal	10	Broadcast Oscillator (Series Feed)	Adjust for maximum output. Try to increase output by decreasing volume control until maximum output is obtained.

# 01-52, 08-52 and 010-52 CHASSIS

## ALIGNMENT EQUIPMENT & PROCEDURE

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

1. Connect the output meter across the voice coil or between the plate of the 6F6-G output tube and ground. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the black (ground) wire or the chassis.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is incorrectly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.
5. Push in the "MANUAL" button, and keep it depressed during the entire alignment procedure.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Trimmer Number	Trimmer Description	Receiver Dial Setting	Type of Adjustment
.1 MFD. CONDENSER	CONTROL GRID OF 6A8-G TUBE	465 KC	1-2 3-4	2nd I.F. 1st I.F.	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	ADJUST FOR MAXIMUM OUTPUT, THEN REPEAT ADJUSTMENT.
200 MMFD. MICA CONDENSER	ANTENNA LEAD (Blue Wire)	465 KC	5	USED ONLY ON HIGH-FREQUENCY SIGNAL	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	ADJUST FOR MINIMUM OUTPUT USING A STRONG GENERATOR SIGNAL.
200 MMFD. MICA CONDENSER	ANTENNA LEAD (Blue Wire)	1500 KC	6	BROADCAST OSCILLATOR (Shunt)	1500 KC	ADJUST TRIMMER TO BRING IN SIGNAL.
200 MMFD. MICA CONDENSER	ANTENNA LEAD (Blue Wire)	1500 KC	7	BROADCAST ANTENNA (Shunt)	TUNE TO 1500 KC GENERATOR SIGNAL	ADJUST FOR MAXIMUM OUTPUT.

When setting up buttons, always allow the set to warm up thoroughly so that all parts of the chassis may attain normal operating temperatures. This will minimize frequency drift in the tuned circuit.

Select the most powerful nearby stations for automatic tuning, since weak signals will not give as good results. Also select stations whose frequencies fall within the range indicated in Fig. 2. It is often possible to set the trimmers to tune in stations falling outside of the indicated frequency ranges, but the trimmers are then too tight or too loose and may not hold their settings.

### SETTING UP PUSH BUTTONS

Fig. 2 is a bottom view of the cabinet, showing the station selection buttons. The arrows in this diagram indicate the two trimmers for each button.

In setting up a station on any push button, the trimmer marked "a" is the oscillator trimmer and must be adjusted first to tune in the desired station. The trimmer marked "b" is the antenna trimmer, and is to be adjusted until the desired station is heard with the deepest tone.

ALIGNMENT EQUIPMENT & PROCEDURE

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 14 MC are required.

1. Connect the output meter across the voice coil or between the plate of the 6K6-G output tube and ground in series with a .1 mfd. condenser depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the black (ground) wire of the chassis.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is incorrectly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Band Switch Position	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
1 MFD. Condenser	Control Grid of 6B7-G Tube	465 KC	Broadcast Clockwise	Any Point Where It Does Not Affect the Signal	1-2	2nd I. F.	Adjust for maximum output. Then repeat adjustment.

01-54, 01-54S, 08-54, 010-54, and 010-54S CHASSIS  
ALIGNMENT EQUIPMENT & PROCEDURE

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

1. Connect the output meter across the voice coil or between the plate of the 6F6-G output tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the black (ground) wire of the chassis.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, set the pointer to the last mark on the right end of the dial scale. If the pointer is only slightly off calibration, loosen the set-screw in the dial drive drum at the left side of the gang condenser and set the last mark on the right end of the dial when the gang condenser is in full mesh. If the pointer is off calibration several dial divisions, release it from the pointer drive cord by spreading the cord along the pointer. Then slide the pointer along the cord until it is set to the last dial division on the right end of the dial. Holding it in place check to see if the gang condenser is in full mesh, and tighten the pointer clip, being careful not to cut the cord. Place a drop of household or speaker cement on the cord and pointer clip to prevent the pointer from slipping.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
1 Mfd Condenser	Control Grid of 6B7-G Tube	465 KC	Any Point Where It Does Not Affect the Signal	1-2	1st I.F.	Adjust for Maximum Output
200 MMFD. Mic. Condenser	Antenna Lead (Blue Wire)	465 KC	Any Point Where It Does Not Affect the Signal	3-4	2nd I.F.	Adjust for Minimum Output using a strong signal.
200 MMFD. Condenser	Antenna Lead (Blue Wire)	1500 KC	1500 KC	5	Not Used In Chassis Model 01-54	Adjust for Minimum Output using a strong signal.
200 MMFD. Condenser	Antenna Lead (Blue Wire)	1500 KC	1500 KC	6	Broadcast Oscillator (Shunt)	Adjust Trimmer to Bring In Signal.
200 MMFD. Condenser	Antenna Lead (Blue Wire)	1500 KC	Tune To Generator Signal	7	Broadcast Antenna (Shunt)	Adjust for Maximum Output.

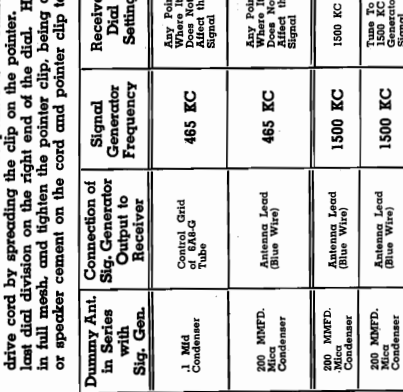

**HOW TO REPLACE DIAL POINTER DRIVE CORD**

1. Close the gang condenser and thread one end of the cord through pulley H and then across to pulley I and counter-clockwise around pulley H and then across to pulley J and down the front of the drum.
2. Carry the other end of the cord over the drum to the front around pulley H and then across to pulley I and counter-clockwise around pulley H and then across to pulley J and down the front of the drum.
3. Continue back to pulley I and down the front of the drum. Carry the end of the cord around the drum and thread through eyelet G.
4. Both ends extending through eyelet G to tension spring K. IMPORTANT: In so doing, allow enough slack in the cord so that when spring K is hooked in place in the drum, it will be extended only a very little. If the spring is extended too much, it will tend to make the push button operate too hard because of over-tensioning.
5. The tension spring is closed, then set the dial pointer to the last dial division mark on the right and clip it to the cord.

HOW TO SET UP PUSH BUTTONS

1. Before setting up a push button, pull out the button cap by grasping the button and pulling outward on it. When the button is removed, the screw-driver in this screw and loosens it (about one turn counter-clockwise will be sufficient). The screw slot, PUSH AGAINST THE SCREW DRIVER UNTIL THE PUSH BUTTON SHAFT IS FORCED ALL THE WAY IN. While the button is held in this position, tighten the adjusting screw, turning clockwise until reasonably firm. Do not attempt to turn the screw until it reaches a definite stop. Merely turn until you meet with appreciable resistance. To turn further may result in damage to the mechanism.

**HOW TO REPLACE THE DIAL DRIVE CORD**

1. Remove the cord from the top side. The set screw in the drum, Fig. 1, must be on the top side.
2. The one end of the dial cord at the spring L, and thread the other end of the cord around the drum, then over pulley B and up the rear side of the drum.
3. The cord around the shaft, then over pulley B and up the rear side of the drum.
4. The cord around the shaft, then over pulley B and up the rear side of the drum.
5. The cord around the shaft, then over pulley B and up the rear side of the drum.

 Alignment, Trimmers

**ALIGNMENT EQUIPMENT & PROCEDURE**

ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 14 MC are required.

1. Connect the output meter across the voice coil or between the plate of the 6F6G output tube and ground, in series with a .1 mfd. condenser depending upon the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the receiver chassis or to the "G" terminal at the back of the chassis. NOTE:—The "G" and "D" terminals on this terminal strip must be connected together.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the alignment procedure.
4. With the gang condenser in full mesh, set the pointer to the last mark on the left end of the dial scale. If the pointer is incorrectly set, it is only necessary to loosen the set screw on the dial cord drive drum and push the gang condenser in full mesh with the pointer properly set, then retighten the set screw.

 Tuner, Drive Cord Data  
 STEWART-WARNER CORP.

**CIRCUIT FEATURES**

This chassis is an 8 tube, two band, push button tuning superheterodyne receiver. The tuning ranges are 530 to 1730 KC and 5.5 to 16 MC.

Incorporated in each chassis is an eight button tuner switch. The first two buttons on the left are tone controls. Four different tone qualities may be imparted to a program by properly setting these tone buttons. The remaining six buttons are used for automatic tuning. Automatic tuning is accomplished by substituting pre-set trimmers for the variable gang condenser. The push-button switch provides a simple rapid method of effecting this substitution.

It should be noted that the R.F. stage in this receiver operates only on the Broadcast Band. When the band switch is in the "Automatic," "Intermediate" or "Foreign" positions this R.F. stage is not utilized.

**HOW TO SET UP THE PUSH BUTTON TUNER**

1. Connect your set to a good antenna system.
2. Turn on the set and allow it to operate at least one-quarter hour before setting up the push buttons.
3. Make a list of the frequencies of six nearby stations to which you wish to set up the buttons. Be sure to select nearby, powerful stations, since weak stations will generally give better results when tuned manually. Also be sure to select stations falling within the tuning range of the individual buttons, as indicated in Fig. 1.

Each of the buttons on your "Magic Keyboard" can be made to tune in stations in a definite frequency range as shown in Fig. 1. It is imperative that you select a station whose frequency is in the operating range of a button before attempting to set-up that button for the particular station. IT IS IMPORTANT THAT THE PROPER BUTTONS BE SELECTED AS THE ADJUSTING SCREW SHOULD NEVER BE TOO LOOSELY OR TOO TIGHTLY ADJUSTED. For example, suppose you want to set a button to station KDKA whose frequency is 980 kilocycles. Refer to Fig. 1, which shows that this frequency falls within the operating range of buttons No. 6 or No. 7, whose range is 630 to 1490 KC or of button No. 8 whose range is 720 to 1700 KC. Therefore either buttons No. 6, No. 7 or No. 8 can be used for the automatic tuning of stations KDKA.

4. Remove the escutcheon around the push buttons taking out the six screws holding it to the cabinet. This will expose to view six pairs of adjusting screws, each pair of which is used to tune in a station that you wish to set-up on a particular button.
5. Turn the band switch (Right hand knob) to the center (B) position, as indicated by the notch on the band switch knob. Then using the tuning knob (center) tune in the station you desire to set to button No. 3. This is done so that you may identify the station by hearing its program.
6. Now turn the band switch knob to the extreme clockwise position. The notch on the band switch knob will now indicate the "A" (Automatic) position. You will note when this switch is turned, the station previously tuned in will not be heard.
7. Now push in the third button from the left (No. 3 in Fig. 1). Using a small screw driver, insert it in the second screw from the left (No. 3a in Fig. 1). Rotate the screw SLOWLY until the program that you have previously tuned in manually is again tuned in. If it cannot be

heard, advance the volume control. BE SURE THAT YOU ADJUST THIS PARTICULAR SCREW (3a) TO THE POINT WHERE THE PROGRAM IS HEARD WITH THE DEEPEST TONE. It is advisable that you turn the screw in and out so that you will tune across the station several times in order that you may be sure you have located the correct tuning point.

8. Next insert the screw driver in the first screw on the left (No. 3b, Fig. 1) and turn it until the program is received with deepest tone. Now go back to screw No. 3a and see if any improvement in the reception can be made by adjusting it. Also repeat this adjustment for screw No. 3b.
9. Set up button No. 4 for the selected station in a similar manner, using screws No. 4a and 4b, and proceed to set up the remaining buttons in the same fashion, always tuning in the station initially with the "a" screw for that particular button.
10. Call letter tabs and celluloid windows are supplied with your receiver. The tabs are used to label the six push buttons set up for stations. The celluloid tabs are supplied as a perforated sheet which is to be broken into eight sections. Select the proper call letter tabs from the station call letter sheets supplied. Place the call letter tab in back of the celluloid window and insert it in its proper slot in the push button escutcheon.
11. Replace the escutcheon with its six retaining screws.
12. In some instances it may be necessary, after the set is operated for a month or more, to reset the screws as they may change their setting due to heat, humidity, etc.

**IMPORTANT**

**REPLACING THE DIAL POINTER DRIVE CORD**

1. Tie a large knot in one end of about 51" of special dial cord, part No. 111302.
2. Thread the free end of the cord through hole A in drum C (threading from the inside of the drum out) See Fig. 2.
3. After pulling the cord through hole A, make one half turn around the drum C in a counter-clockwise direction (viewed from the front), using the front groove in the drum.

4. Continuing, draw the cord up around the back of pulley E to pulley D. From this point continue across to pulley G and around to pulley F.
5. Go over pulley F and down to the bottom of the front groove on drum C. Continue up around the drum to hole B.

6. Draw the cord through hole B and tie it to the end of the tension spring in such a manner that when the spring is clipped on to lug H it will be extended to about 1 1/2" long.

**HUM**

In some of the first sets produced Resistor No. 23 in the 6F6G grid circuit was 470,000 ohms, also condenser No. 9 and Resistor No. 27 were omitted. The hum level in these sets can be reduced by adding these two parts and Changing Resistor No. 23 to 220,000 ohms. All chassis with this circuit change are stamped with the letter "8" on the back.

NOTE A: The bias for the control grid of the IC5G tube is -7.5 volts measured across resistor 18.  
 NOTE B: Due to the high resistance of plate Resistor No. 83 only a slight deflection will be obtained when using a meter having a resistance of 1000 ohms per volt.

In this receiver, the loop antenna on the back of the cover of the case, takes the place of the antenna coil. Thus when the trimmer in this circuit is aligned, the chassis, the loop antenna, and the batteries must be mounted in the cabinet in their correct position.

Holes are provided in the bottom of the case to permit the adjustment of both antenna and oscillator trimmers with the receiver completely assembled. These two adjustments should be made with a signal generator but without an output meter since it is impractical to keep the output meter connected when the back is mounted on the cabinet. That is, the antenna and oscillator trimmers can be adjusted by ear using a signal generator. The I F trimmers must be adjusted with an output meter in the conventional way.

 Chassis O2-41  
 Alignment, Trimmers  
 Loop, Battery Data

STEWART-WARNER CORP.

### ALIGNMENT EQUIPMENT & PROCEDURE

FOR ALIGNMENT an output meter and an accurately calibrated signal generator are required.

1. Connect the output meter across the voice coil or between the plate of the 1C5G output tube and ground through a 0.1 Mfd. condenser, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the Ground Terminal or the chassis.
3. Turn the volume control to the maximum volume position and keep it in this position while aligning.
4. With the gang condenser in full mesh, set the dial pointer in a horizontal position. If the pointer is incorrectly set, it is merely necessary to move the pointer to the correct position by hand, while holding the gang in the full mesh position.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
.1 MFD. Condenser	Control Grid of 1A7G	465 KC	Any Point Where It Does Not Affect Signal	1	2nd I.F.	Adjust for maximum output. Then repeat adjustment.
				2-3	1st I.F.	
Before proceeding further with alignment, disconnect the output meter, and replace chassis, batteries and loop in cabinet, being sure to connect the loop. Using a weak signal from the signal generator, make the following adjustments by ear. The trimmers may be reached through the holes in the bottom of the cabinet by removing corks.						
400 Ohm Carbon Resistor	Antenna Terminal On Bottom Of Cabinet	1500 KC	1500 KC	4	Broadcast Oscillator (Shunt)	Adjust trimmer for maximum output.
400 Ohm Carbon Resistor	Antenna Terminal On Bottom Of Cabinet	1500 KC	Tune To 1500 KC Generator Signal	5	Broadcast Antenna	Adjust for maximum output.

#### LOOP ANTENNA

A built-in loop antenna is incorporated in this receiver. Due to the directional effect of this type of antenna it will often be possible to increase the signal volume by rotating the entire set.

In some locations it may be desirable to install an external antenna to increase the volume of weak or distant stations. This external antenna should be connected to the screw marked A on the terminal strip located on the bottom of the receiver case. Connect a ground wire to the post marked G on the same terminal strip.

NOTE: You must connect a ground wire to this receiver when using a separate outside aerial, otherwise you will not obtain a satisfactory increase in signal pickup.

#### INSTALLATION OF BATTERIES

The following 1½ volt "A" batteries will fit the space provided: Burgess No. 4FAP1, Eveready No. 742, or Ray-O-Vac No. P94A.

"B" batteries of the proper size are Burgess B30PI, Eveready No. 762 and Ray-O-Vac No. 5303.

A plug and clip connection on the loop is provided to facilitate the installation of batteries. Before replacing the back of the cabinet always be sure that this plug is pushed into the clip and that the blocks are holding the batteries firmly in their positions.

Do not permit any of the battery cable plugs to come in contact with the receiver chassis or any battery terminal other than that to which it is to be connected.

# ALIGNMENT PROCEDURE

ALIGNMENT: An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

Connect the output meter across the voice coil or between the plate of the 25L6-GT output tube and ground through a .1 mfd. condenser, depending upon the type of meter. The more sensitive type should be connected across the voice coil.

Connect the ground lead of the signal generator to the chassis of the receiver through a .25 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as the signal generator may be connected to one side of the power line, or it may be grounded externally.

Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

Remove the connector between Terminals A and A<sub>1</sub>.

## MISCELLANEOUS PARTS

### BUILT-IN ANTENNA SYSTEM

The Built-In Antenna incorporated in this receiver will generally give very satisfactory results in localities where powerful broadcast stations exist. This Built-In Antenna will function when terminals A and A<sub>1</sub> on the back of the chassis are connected together. In cases where noises are excessive or greater sensitivity is desired, remove the jumper connecting terminals A and A<sub>1</sub> and connect an external antenna to terminal A.

Refer to the circuit diagram on the opposite page. Condenser No. 35 couples the primary of the antenna coil to one side of the power line, which acts as the antenna. The R. F. choke No. 36 is an iron-core choke whose impedance is high at broadcast frequencies. This choke serves to prevent feed-back into the antenna circuit, of radio frequency energy generated in the set itself. It also prevents condenser No. 18 from by-passing the signal voltage picked up by the power line.

When aligning this receiver, the jumper connecting terminals A and A<sub>1</sub> should be removed. This will prevent picking up signals which might interfere with the alignment procedure. When the I. F. channel is being aligned, the gang condenser should be set at a point where no interfering signal will be received.

**ALIGNMENT PROCEDURE**

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator are required.

1. On the 07-51H, connect the output meter across the voice coil or between the plate of the 35L6GT output tube and chassis through a .1 mfd. condenser, depending upon the type of meter. The more sensitive type should be connected across the voice coil. THE CONNECTIONS FOR THE 07-55 ARE THE SAME EXCEPT CONNECT THE GROUND LEAD TO THE POINT SHOWN IN FIG. 2 INSTEAD OF TO CHASSIS.
2. When aligning the 07-51H chassis, connect the ground lead of the signal generator to the chassis of the receiver through a .25 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. FOR THE GROUND LEAD CONNECTION TO THE 07-55 CHASSIS, REFER TO "BOTTOM VIEW," FIG. 2.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. Remove the connector between Terminals A and A<sub>1</sub>.

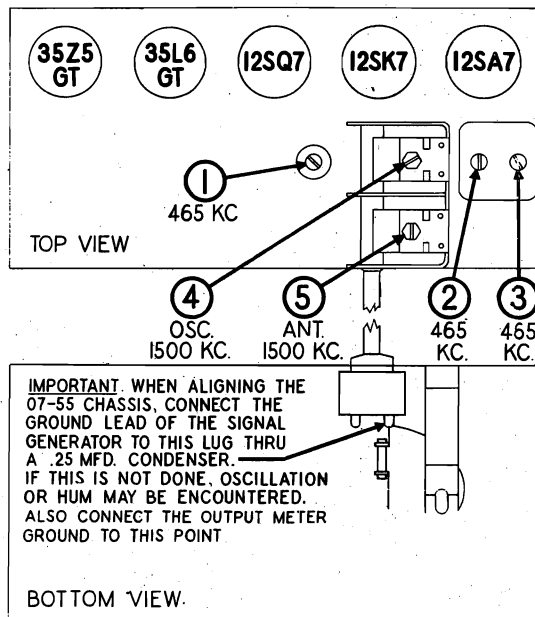

Fig. 2

**BUILT-IN ANTENNA SYSTEM**

The Built-In Antenna incorporated in this receiver will generally give very satisfactory results in localities where powerful broadcast stations exist. This Built-In Antenna will function when terminals A and A<sub>1</sub> on the back of the chassis are connected together. In cases where noise is excessive or greater sensitivity is desired, remove the jumper connecting terminals A and A<sub>1</sub> and connect an external antenna to terminal A.

The Built-In Antenna Condenser No. 27 couples the

primary of the antenna coil to one side of the power line, which acts as the antenna. The R. F. choke No. 28 is an iron-core choke whose impedance is high at broadcast frequencies. This choke serves to prevent condenser No. 19 from by-passing the signal voltage picked up by the power line. It also prevents feed-back into the antenna circuit of radio frequency energy generated in the set itself.

When aligning this receiver, the jumper connecting terminals A and A<sub>1</sub> should be removed. This will prevent picking up signals which might interfere with the alignment procedure.

STEWART-WARNER CORP.

## ALIGNMENT EQUIPMENT & PROCEDURE

**FOR ALIGNMENT:** An output meter and an accurately calibrated signal generator with a tuning range from 465 KC to 1500 KC are required.

1. Connect the output meter across the voice coil or between the plate of the 25L6-G output tube and chassis through a .1 mfd. condenser, depending upon the type of meter. The more sensitive type should be connected across the voice coil.
2. Connect the ground lead of the signal generator to the chassis of the receiver through a .25 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as the signal generator may be connected to one side of the power line, or it may be grounded externally.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh, set the pointer to the last mark on the right end of the dial scale. If the pointer is only slightly off calibration, loosen the set-screw in the dial drive drum at the left side of the gang condenser and set the pointer to the last mark on the right end of the dial when the gang condenser is in full mesh. If the pointer is off calibration several dial divisions, release it from the pointer drive cord by spreading the clip on the pointer. Then slide the pointer along the cord until it is set to the last dial division on the right end of the dial. Holding it in place check to see if the gang condenser is in full mesh, and tighten the pointer clip, being careful not to cut the cord. Place a drop of household or speaker cement on the cord and pointer clip to prevent the pointer from slipping.

Dummy Ant. in Series with Sig. Gen.	Connection of Sig. Generator Output to Receiver	Signal Generator Frequency	Receiver Dial Setting	Trimmer Number	Trimmer Description	Type of Adjustment
200 MMFD. Mica Condenser	Control Grid of 6A8-G Tube	465 KC	Any Point Where It Does Not Affect The Signal	1-2	1st I.F.	Adjust for Maximum Output. Then Repeat Adjustment.
				3-4	2nd I.F.	
200 MMFD. Mica Condenser	Antenna Lead (Blue Wire)	465 KC	Any Point Where It Does Not Affect The Signal	5	Wave Trap	Adjust for Minimum Output Using a Strong Generator Signal.
200 MMFD. Mica Condenser	Antenna Lead (Blue Wire)	1500 KC	1500 KC	6	Broadcast Oscillator (Shunt)	Adjust Trimmer to Bring in Signal.
200 MMFD. Mica Condenser	Antenna Lead (Blue Wire)	1500 KC	Tune To 1500 KC Generator Signal	7	Broadcast Antenna (Shunt)	Adjust for Maximum Output.

### HOW TO SET UP PUSH BUTTONS

1. Before setting up buttons, turn on set for at least 15 minutes. To set up a push button, pull off the button cap by grasping the button and pulling upward on it. When the button is removed, the set-up screw will be exposed to view (See Fig. 1). Insert a screw-driver in this screw and loosen it (about one turn counter-clockwise will be sufficient).
2. Keeping the screw-driver in the screw slot, PUSH AGAINST THE SCREW-DRIVER UNTIL THE PUSH BUTTON SHAFT IS FORCED ALL THE WAY IN. While the button is held in this position, grasp the tuning knob and tune in the desired station. Then retighten the adjusting screw, turning clockwise until reasonably tight.

**WARNING:** Do not attempt to turn the screw until it reaches a definite stop. Merely turn until you meet with appreciable resistance. To turn further may result in damage to the mechanism.

### HOW TO REPLACE THE DIAL DRIVE CORD

1. Close the gang condenser. The set screw in the drum, Fig. 1, must be on the top side.
2. Tie one end of the dial cord to the spring L and thread the other end through hole A and down the front of the drum to the tuning shaft. Continue around the shaft, then over pulley B and up the rear side of the drum.

FIG. 1

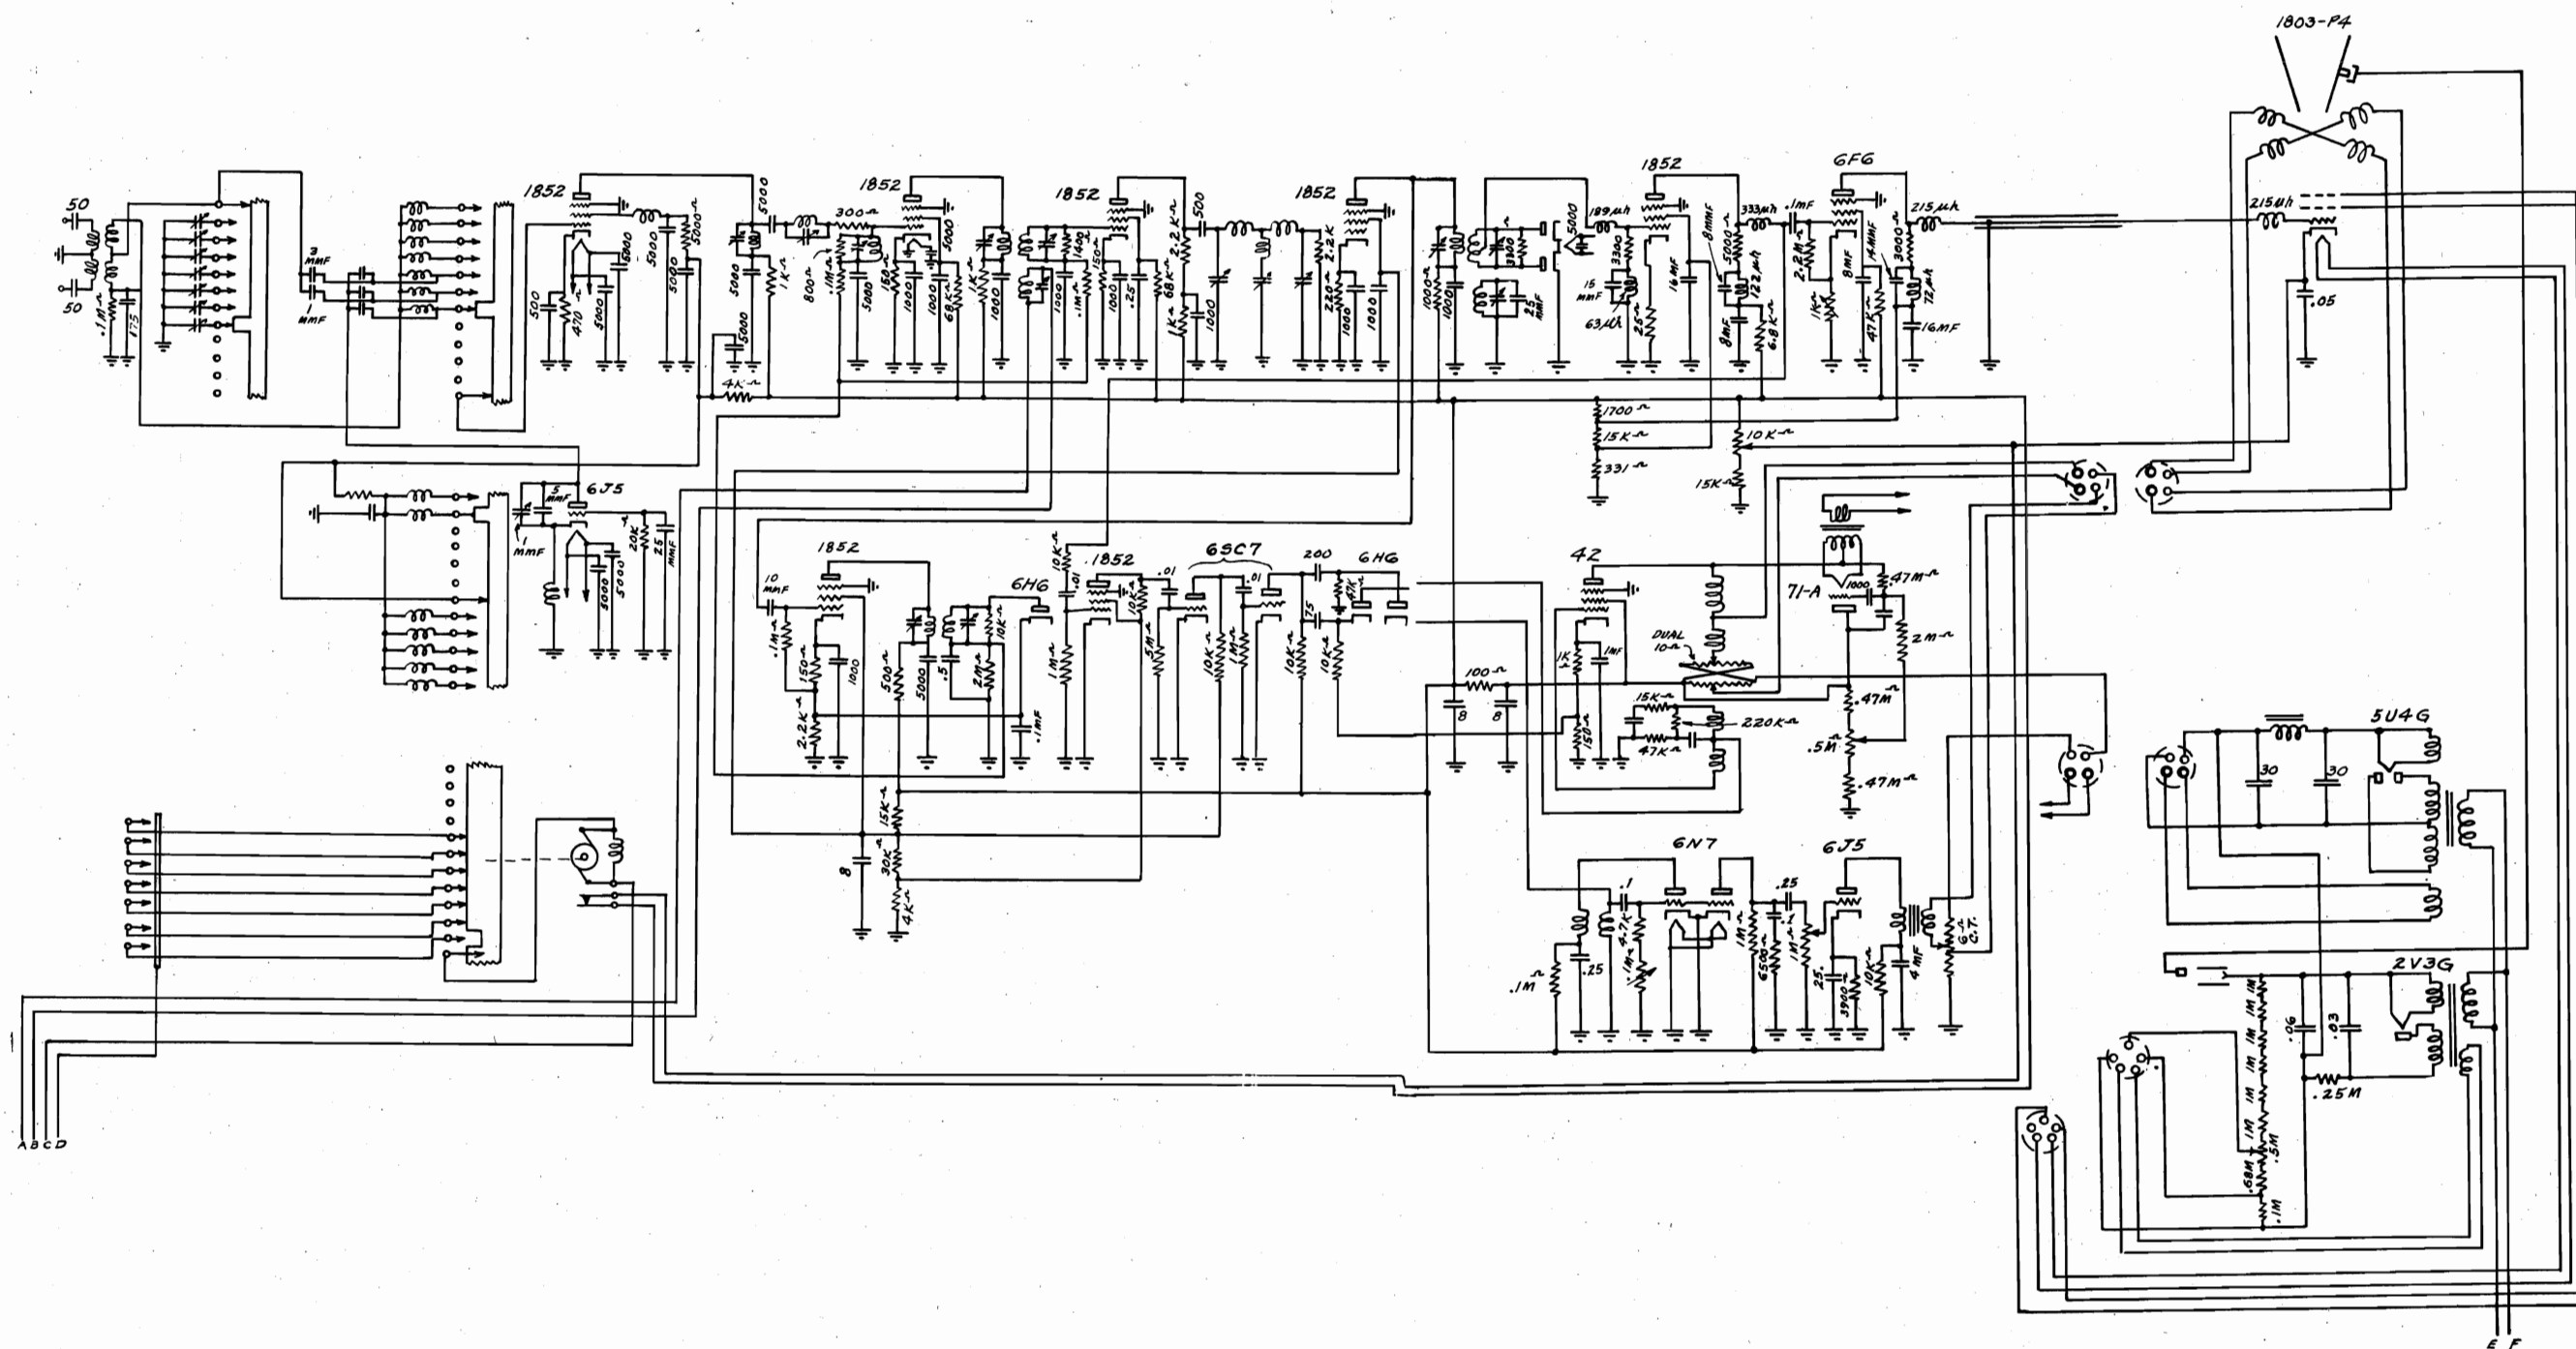

3. Thread the cord through hole A and tie the other end to spring L. Tie the cord so that spring L will be extended to about 3/4 inch.

### HOW TO REPLACE DIAL POINTER DRIVE CORD

1. Close the gang condenser and thread one end of the cord through eyelet G and tie it to spring K.
2. Carry the other end of the cord over the drum to the front around pulley H and then across to pulley I and counter-clockwise around it.
3. Continue back to pulley J and down the front of the drum. Carry the end of the cord on around the drum and thread through eyelet G.
4. Tie both ends extending through eyelet G to tension spring K. **IMPORTANT:** In so doing, allow enough slack in the cord so that when spring K is hooked in place in the drum, it will be extended only a very little. If the spring is extended too much, it will tend to make the push button operate too hard because of overloading.
5. Be sure the gang condenser is closed, then set the dial pointer to the last dial division mark on the right and clip it to the cord

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the sections tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1 shows the terminal layout of the sockets with the appropriate numbers.

Table with columns: Tube, Circuit, Cap, Terminals of Sockets (1-5), Heater Voltages Between Heater Terminals (Socket Numbers, Polarity, Value). Rows include 6K7, 6A8, 6J7, 6K7, 6B6, 6F5, 6C5, 6L6 No. 1, 6L6 No. 2, 6C5, 6U4G, and Speaker Socket.

A. C. voltages are indicated by italics. Receiver tuned to 1000 kc., no signal.

Fig. 1. Terminal Layout for Voltage Measurement Chart and Location of the Various Adjusting Apparatus.

CONTINUITY TEST FOR NO. 255 RECEIVER. Nov. 1, 1937.

For making a continuity test on the No. 255 Receivers, use the same test chart and instructions as are used on the No. 250 Receivers with the addition of the following tests for the Flash Tuner Unit:

- 1. Remove Flash Tuner Lamp Plug from Flash Tuner Lamp Socket. (This socket is located next to the speaker socket on rear of chassis).
2. Operate A.F.C. to "ON" position (This switch is located directly under dial on front of chassis). Operate tuning dial until Finger No. 2 on Flash Tuner Unit makes contact on Switch (See Flash Tuner Sketch on Page 8 of Engineering Data Sheet for the No. 255 Receiver for the correct location of fingers). Read from No. 1 terminal of Flash Tuner Socket to chassis base, reading should be "5". Operate A.F.C. switch to "Off" position. Reading should be "0".
3. Operate A.F.C. switch to "Off" position. Read from No. 3 terminal of Flash Tuner socket to chassis base, reading should be "0".
4. Proceed in the same manner to test the rest of this circuit. Operate the A.F.C. Switch to "On" position. Operate the tuning dial until the next finger of the meter makes contact on switch. Move the test prong of the meter to the terminal of the Flash Tuner socket which corresponds to the terminal to be tested. The readings for each of the contacts should be 10" with A.F.C. Switch operated to "ON" position and "0" with A.F.C. Switch in "Off" position.

NOTE: The readings from the Flash Tuner Socket are usually taken from the top of the socket. Therefore, the terminals will be numbered in a counter-clockwise direction.

MODELS 255L, 255LB Phonograph Data STROMBERG-CARLSON TEL. MFG. CO. Flash Tuner Assembly

Fig. 4. Showing Flash Tuner Lamp Unit With Escutcheon Plate Removed (Top Figure) and Rear View of Receiver Showing Flash Tuner Mechanism (Bottom Figure).

PROCEDURE FOR OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

A socket having three contacts is provided on the rear of the chassis base, and is wired to the "Off-On-Off" switch assembly located on the front of the receiver. A three prong plug is also inserted in the socket so that if at any time it is desired to use an electric pick-up and phonograph unit in conjunction with this receiver, it may readily be accomplished. In order to obtain the best quality of phonograph reproduction when using an electric pick-up and phonograph unit with this receiver, a Stromberg-Carlson No. 10 Record Player is recommended. This record player is furnished with a specially equalized circuit to attach this instrument to a No. 255 Receiver. It is only necessary to remove the three-prong plug furnished with the receiver and insert the three-prong plug which comes with the unit into the three-prong socket located on the rear of the chassis base. Then, the power supply plug of the phonograph unit should be inserted into a suitable power supply receptacle, and the unit will be ready for use.

Fig. 5. Section View of Flash Tuner Contactors Assembly.

If the Stromberg-Carlson No. 10 Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a "matching transformer" between the three-prong plug and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong plug and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

# STROMBERG-CARLSON TEL. MFG. CO. Alignment, Part 1

MODELS 255L, 255LB

sary to make use of a signal generator whose high frequency range does not extend beyond 20 megacycles, using harmonics of 20 megacycles for aligning this range on 60 megacycles.

In aligning the radio frequency circuits for this range, replace the 0.1 mfd. capacitor which was placed in series with the tuning dial with a 100-ohm resistor. The signal generator output should be connected to the antenna binding post marked "U. H. A." located on the rear of the receiver chassis. The ground terminal (or low side) of the signal generator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "E" range position and set the signal generator's frequency and the receiver's tuning dial to 60 megacycles.
2. Adjust the aligning capacitor C-46 until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 20 megacycles and adjust the "E" range trimming loop, L-54, until maximum voltage output is obtained on the output meter. The adjustment of this loop is obtained by distorting its normally circular shape until it offers the correct inductive effect. If the oscillator does not track with the tuning dial scale at this frequency, it will be necessary to also adjust the oscillator's tuning loop.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 60 megacycles and repeat operation No. 2.

## Alignment of Short-Wave Range (Also referred to as "D" Band)

In aligning the radio frequency circuits for this range use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminals of the signal generator. The Ultra-Short Wave Range antenna binding post marked "A" located on the rear of the receiver chassis, and align as follows:

1. Operate the Range Switch on the receiver chassis to the "D" range position and set the signal generator's frequency and the receiver's tuning dial to 20 megacycles.
2. Adjust aligning capacitors C-45, C-22, and C-8 respectively; and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 11 megacycles and adjust aligning capacitors C-46, C-25, and C-12 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 20 megacycles and repeat operation No. 2.

## Alignment of Short-Wave Range (Also referred to as "C" Band)

In aligning the radio frequency circuits for this range use the same artificial antenna and binding post on the receiver chassis as was used for aligning the "D" range.

1. Operate the Range Switch on the receiver chassis to the "C" range position and set the signal generator's frequency and the receiver's tuning dial to 10 megacycles.
2. Adjust the aligning capacitors C-44, C-21, and C-7 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 5 megacycles and adjust the aligning capacitors C-39, C-23, and C-11 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 10 megacycles and repeat operation No. 2.

## Alignment of Aircraft Range (Also referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna and antenna binding post as was used for aligning the "C" range, and align this range as follows:

1. Operate the Range Switch on the receiver chassis to the "B" range position and set the signal generator's frequency and the receiver's tuning dial to 4.5 megacycles.
2. Adjust the aligning capacitors C-43, C-20, and C-6 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 1.8 megacycles and adjust the aligning capacitors C-38, C-24, and C-10 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 4.5 megacycles and repeat operation No. 2.

## Alignment of Standard Broadcast Range (Also referred to "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm resistor in series with the signal generator's output with a 200-micro-microfarad capacitor and align this range as follows:

1. Operate the Range Switch to the "A" range position and set the signal generator's frequency and the receiver's tuning dial to 1.5 megacycles (1500 Kilocycles).
2. Adjust the aligning capacitors C-42, C-19, C-4, and C-5 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.

## ALIGNMENT DATA

### Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. The tuning dial is set correctly with respect to the gang tuning capacitor, using the "Range Station Selector" knob in a counter-clockwise direction so that the gang tuning capacitor is set to its maximum capacity over the dial. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

### Intermediate Frequency and A. F. C. Circuit Adjustments

The intermediate frequency system employed in this receiver is a complex circuit. The first I. F. amplifier is coupled to the second I. F. amplifier through the No. 6K7 tube. The second and third I. F. transformers are coupled through the pentode section of the No. 6B8 tube. The third I. F. transformer is in effect a distributing network rather than a transformer only; it contains a primary winding coupled to two other networks. One of these networks links the diode stage (Demodulator-A. V. C.) with the I. F. signal, while the other network resembles the secondary of a push-pull transformer. The No. 6B8 tube supplies the characteristic voltage demanded by the Discriminator network, the No. 6B6 tube supplies the characteristic voltage demanded by the circuit. The fourth I. F. transformer feeds the diode plates of the No. 6B8 tube.

The intermediate frequency used in these receivers is 465 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve of these stages in tuning, it is recommended that unless a suitable system is available, the adjustments be made in the factory. These adjustments are made using a milliwattmeter which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed:

1. Operate the Range Switch of the receiver to the "A" range position, and set the tuning dial to its extreme low frequency position. Set the Fidelity Control to its "Normal" position, the Automatic Frequency Control knob to the "Off" position and the "Off-On-Bass" Control knob to its "Normal" position. Never attempt to align the R. F. or I. F. circuits of this receiver with the Fidelity Control knob set at any position other than the "Normal Fidelity" position, and the Automatic Frequency Control knob set at the "On" position unless specifically directed in the following paragraphs.
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator tube, a modulated signal of 465 kilocycles from the signal generator, using a 0.1 Mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or the ground binding post terminal.
3. Now noting from Figure 1, the alignment adjustments for the First, Second, Third, and Fourth I. F. Transformers, align the I. F. circuits in the following manner:

Adjust the third I. F. transformer primary circuit for maximum output.

Adjust the fourth I. F. transformer circuit for maximum output.

Adjust the third I. F. transformer "Discriminator" circuit midway between the peaks where maximum output is obtained.

Adjust the second I. F. transformer secondary circuit for maximum output.

Adjust the second I. F. primary circuit for maximum output.

Adjust the first I. F. secondary circuit for maximum output.

Adjust the first I. F. primary circuit for maximum output.

Carefully make all the above adjustments, watching carefully the output meter and reduce the output of the test oscillator as required.

To make the final adjustment of the "Discriminator" circuit proceed as follows:

Check the position of the A. F. C. control knob which should be set to the "off" position. Before making this circuit adjustment be sure that the I. F. Amplifier is tuned exactly to 465 kilocycles. With the signal generator still set at a frequency of 465 kilocycles, adjust the signal generator output for a reading of the milliwattmeter of 50/100 to 100/100. The "Discriminator" circuit is checked by rotating the A. F. C. control knob to the "on" position, and observe whether there is any difference in the reading of the milliwattmeter. When this circuit is correctly adjusted, there should be no difference in the reading of the milliwattmeter when the A. F. C. Control knob is rotated from the "off" to the "on" position. If there is any difference in the milliwattmeter reading while rotating the Automatic Frequency Control knob to the "off" and "on" position, at a rate of about two cycles per second, adjust the "Discriminator" circuit by rotating the A. F. C. Control knob to the "off" position, and adjust the "Discriminator" circuit until the same value, regardless of whether the A. F. C. Control knob is rotated to the "on" or "off" position. When this condition is obtained the "Discriminator" circuit of these receivers is properly adjusted.

### Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, the A. F. C. Control knob should be rotated to the "off" position, the Fidelity Control knob should be set for "Normal" operation, and the "Off-On-Bass-Phono-graph" Control knob should also be set for "Normal" operation.

### Alignment of Ultra-Short Wave Range (Also referred to as "E" Band)

In order to align the circuits of this range, it is desirable to have a signal generator whose high frequency range will go to 60 megacycles. Such equipment, however, is rare and costly, and in most cases it will be necessary to make use of a signal generator whose high frequency range does not extend beyond 20 megacycles, using harmonics of 20 megacycles for aligning this range on 60 megacycles.

- 3. Set the signal generator's frequency and the receiver's tuning dial to 0.6 megacycles (600 kilocycles) and adjust the aligning capacitor C-37; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 1.5 megacycles and repeat operation No. 2.
Adjustment of 10 Kilocycle Audio Out-Of Filter
The adjustment of this filter is correctly made at the factory and no additional adjustment is required.
Instructions for Setting Up the A. F. C. Flash Tuning Unit
1. Remove the flash tuner lamp unit escutcheon plate by removing the four screws.
2. Remove the lists of station letters from the P-28420 package assembly which is tacked inside of the cabinet.
3. Remove the seven paper squares on which are printed the words "Tone", "Beauty", "Value", "Action", "Flash", "Tuning", and "Radio" from the square frames located on the rear side of the lamp unit escutcheon plate.
4. Remove the station letters of the seven stations which it is desired to set up in the flash tuning unit from the list of stations. It will be noted that the letters of the stations are printed on partly cut squares to facilitate ease in removing the desired letters. Insert one of these seven station letters into each frame of the flash tuner lamp unit. The recommended method of inserting these station letters into the frames of the escutcheon plate is to arrange them according to the frequency of the stations as follows:
Looking at the front of the escutcheon plate the station having the highest frequency should appear in the top right-hand frame, and then in successive order according to frequency the remaining station letters should be inserted into the other frames; the top left-hand frame containing the station letters of this station having the lowest frequency. When tuning the station letters into the frames be sure to have the letters located between two pieces of transparent material.
5. Fasten the escutcheon plate again to the lamp unit by means of the four screws. The receiver is now ready to be operated and the flash unit contactors located on the rear of the chassis base adjusted for the seven favorite stations.
6. Rotate the "On-Off-Bass-Phonograph" Control knob from its complete counter-clockwise position, slightly clockwise from this position which turns the set "on" (indicated by illumination of the dial). The station letters which are printed on the escutcheon plate should be visible through the transparent material. The Control knob which should be rotated to the "Off" position and set the Fidelity Control knob to the "Normal" position. Now carefully tune in the desired station having the highest frequency, watching the tuning indicator so that the receiver will be exactly tuned to this station.
7. After carefully tuning in the desired station rotate the A. F. C. Control knob to the "On" position. Now noting from Figure 4, the sketch which shows the contactor clamping frame and knurled nut, hold the clamping frame with one hand and loosen the knurled nut with the other hand. Then move the contactor, numbered 2, so that its point is engaged between the two small rollers of the switching mechanism as also shown in Figure 4. When the point is properly engaged between the rollers, the lamp of the manual unit is open. The next step is to rotate the escutcheon plate and the station letters held the gang tuning capacitor and the contactors from rotating by means of the extended portion of the contactor clamping frame. It is extremely important to keep the gang tuning capacitor and the contactors from rotating when tightening the large knurled nut.
8. Now rotate the A. F. C. Control knob to the "off" position and note whether the tuning has been shifted by watching the tuning indicator. If a change is noted it will be necessary to repeat operation No. 7.
9. When no change is noticed after performing the above operations Nos. 7 and 8, the remaining six favorite stations should be set up in the same manner.
With the A. F. C. flash tuning unit in operation, the receiver will be automatically kept in tune with any one of the seven stations as long as the station is operating or, provided there has no unusual disturbance in the station, the receiver will continue to tune in the station. If the tuning is not in either adjacent channel. This same phenomenon will occur if two stations in adjacent channels are almost of equal signal strength with the weakest signal fading slightly; with this condition the strong signal will have a tendency to "pull in" when the receiver is tuned to the station which is slightly weaker and fading.

Alignment, Parts

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these alignment adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-27687 and P-27688 aligning tools be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator. (See Figure 1, page 10-12.) This oscillator should be connected to the test oscillator post on the sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any circuits in these receivers be sure that the "Off-On-Tone" control knob is set for maximum treble response (position where knob is rotated from its maximum over the treble, lower right-hand border line (line immediately below the 35 megacycle calibration mark on all of the aligning capacitors in these receivers).

In making any alignment adjustments on these receivers, it will not be necessary to remove the chassis from the cabinet. The aligning capacitors for the intermediate frequency circuits of these receivers are easily accessible either through the bottom of the cabinet or through the bottom of the cabinet shelf depending upon the style of cabinet.

Dial Adjustment

Before aligning the circuits of any of these receivers, the tuning dial must be properly aligned to track with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the gang tuning capacitor in this position, the dial pointer should center over the "Broadcast" scale.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 455 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.

1. Rotate the Range Switch control knob to the Standard Broadcast Range position (arrow on knob pointing in direction of letters BR).

Set the dial pointer to the extreme low frequency position on the receiver's dial. Rotate the "Off-On-Tone" control knob slightly clockwise from its maximum counter-clockwise position which is the "normal" position. Rotate the Volume control knob to its maximum clockwise position (maximum volume).

Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 455 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or binding post terminal) of the test oscillator should be connected to either the chassis base or the ground binding post terminal.

3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:
  - Secondary of second I. F. transformer.
  - Primary of second I. F. transformer.
  - Primary of first I. F. transformer.

Adjusting the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

Alignment of Short Wave Range (Also Referred to as "C" Range)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead with the I. F. aligning units with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Rotate the Range Switch control knob to the Short Wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.
2. Adjust the oscillator's "C" range high frequency aligner for maximum output.

3. Adjust the antenna's "C" range high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Standard Broadcast Range (Also Referred to as "A" Range)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-microfarad capacitor and align these circuits as follows:

1. Rotate the Range Switch control knob to the Standard Broadcast ("A") range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the oscillator's "A" range high frequency aligner for maximum output.
3. Adjust the antenna's "A" range high frequency aligner for maximum output.
4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
5. Adjust the oscillator's "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2 and 3.

Wave Trap Adjustment

In adjusting the wave trap circuit, set the Range Switch control knob to the Standard Broadcast range position and set the dial pointer to 1000 kilocycles.

Connect a 200-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, adjust the wave trap signal to the receiver and adjust the wave trap aligner until a minimum modulation is obtained on the output meter.

PROCEDURE FOR OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

In order to obtain reproduction of phonograph records in conjunction with the No. 320 Receiver, the following instructions should be followed:

To equip these receivers for phonograph operation, it will be necessary to purchase and install a Stromberg-Carlson P-28909 Switch Assembly. The rear of the chassis base of these receivers is already drilled for mounting this switch assembly. Complete instructions on how to install and operate this switch are furnished with each P-28909 Switch Assembly.

To obtain the best quality of phonograph reproduction from these receivers, a Stromberg-Carlson Record Player is recommended. The record player is equipped with a correctly designed single record playing motor unit, and uses a crystal type pick-up in conjunction with a specially equalized circuit.

If a Stromberg-Carlson Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a low capacity shielded cable between the three-prong socket and plug of the P-28909 Switch Assembly and the pick-up. This shielded cable should be of the low capacity type and the shielded cable should be connected to the ground binding post on the chassis. The shielded cable having high capacity is used. The length of the shielded cable used should be kept as short as possible.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong socket and plug of the P-28909 Switch Assembly, and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

PROCEDURE FOR OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

FOR NO. 335 RECEIVERS ONLY  
To equip these receivers for phonograph operation, it will be necessary to purchase and install in the receiver the No. P-28977 Switch Assembly. Complete instructions on how to install and operate this switch are furnished with each P-28977 Switch Assembly.

To obtain the best quality of phonograph reproduction when using an electric pick-up and phonograph amplifier, it is necessary to connect a low capacity shielded cable between the three-prong socket on the P-28977 Switch Assembly and the three-prong socket on the amplifier. When a shielded cable having high capacity is used, the length of the shielded cable used should be kept as short as possible.

If the Stromberg-Carlson Record Player is not used and the electric pick-up to be used is of the high impedance type, it is necessary to connect a high impedance shielded cable between the three-prong socket on the P-28977 Switch Assembly and the three-prong socket on the amplifier. When a shielded cable having high capacity is used, the length of the shielded cable used should be kept as short as possible.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the pick-up and the amplifier. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

MODELS 325, 335, 336, 337, 340, 341, 345, AND 350  
INSTRUCTIONS FOR SETTING UP THE ELECTRIC TUNING ARRANGEMENT

- 1. Before proceeding to set up the stations for electric tuning, the radio receiver should be turned "on" for approximately twenty to thirty minutes.
- 2. Set the Range Switch Control Knob to the manual tuning position for the Standard Broadcast range (arrow on knob pointing in direction of the letters BR).
- 3. If the particular model is a No. 336-P Receiver, check the position of the "Radio-Phono" control knob. If this knob should be rotated so that the arrow on the knob points in the direction of the word "radio".
- 4. Remove the list of station letters from the P-28781 package assembly which is tucked inside of the cabinet.
- 5. Remove the two screws which hold the electric tuning escutcheon plate (metal plate). Then, remove from the escutcheon, the strip of transparent material and the strip of paper on which the six stars are printed.
- 6. Remove the five screws which hold the electric tuning escutcheon to the front panel.
- 7. From the list of stations, remove the call letters of the six stations which it is desired to set up for electric tuning. These call letters should preferably be selected and set up in the daytime so that the best service will be obtained at all times.
- 8. CAUTION: Each button adjustment for electric tuning has assigned frequency limits. These limits are designated for each adjustment on the cover plate which covers the electric tuning adjusting capacitors. It is important that the frequency of each station will be within the assigned frequency limits of its assigned push button.
- 9. It will be noted that the station letters are printed on partially cut squares to facilitate ease in removing and setting station letters. In setting up these six favorite stations, the following order should be followed: Looking at the front of the receiver, the station letters of the station having the highest frequency should be inserted into the farthest left-hand square of the escutcheon. Then, in successive order, according to the electric tuning escutcheon, the station letters of the station having the lowest frequency being inserted into the farthest right-hand square of the escutcheon.
- 10. After the six station call letters have been inserted into the escutcheon, the transparent strip should be electric tuning escutcheon by means of the two screws.
- 11. The tuning adjustments for the six favorite stations can now be made, starting with the station having the highest frequency and proceeding as follows: slotted shaft of the Electric Tuning Switch, which is located at the rear of the chassis base, so that the slotted shaft points in the direction of the word, "Set-up" (maximum clockwise rotation).
- 12. With the receiver turned "on" and the Range Switch control knob set to the standard broadcast position (arrow on knob pointing in direction of the letters BR), tune the receiver in the conventional manner for setting up in the electric tuning arrangement and carefully note the program which it is broadcasting. Then, rotate the Range Switch control knob to the electric tuning position (arrow on knob pointing in direction of the word "Set-up").
- 13. With the electric tuning escutcheon still removed from the cabinet, push in the push button and for the station having the highest frequency (provided, of course, that the station chosen has a frequency which is within the assigned frequency limits for this button). Now, looking in on the electric tuning unit, designate 1500 to 1600 kilocycles to the position where the desired station is received.
- 14. In order to check whether the program being received is from the desired station, simply rotate the Range Switch control knob to the manual tuning position (arrow on knob pointing in direction of the letters BR). Then, rotate the Range Switch control knob back to the electric tuning position. Exact resonance with the desired station should be obtained by observing the tuning indicator.
- 15. IMPORTANT: Always use the tuning indicator unit when setting up stations for electric tuning in order to determine when resonance with the desired station is obtained.
- 16. When the oscillator tuning adjustment has been properly made as mentioned in paragraph 9 above, the tuning indicator should be rotated in the direction of the word "Operate" until the tuning indicator shows exact resonance with the desired station. It is again obtained by observing the tuning indicator.
- 17. When these adjustments have been properly made, the station having the highest frequency is correctly set up for electric tuning selection.
- 18. Now proceed to set up the remaining five stations in the same manner as mentioned in Paragraphs 7, 8, 9 and 10 above, proceeding according to the frequency of the remaining stations.
- 19. After the six favorite stations have been set up, the tuning indicator should be rotated in the direction of the word "Set-up" until the tuning indicator shows exact resonance with the desired station. The slotted shaft of the Electric Tuning Switch located on the rear of the chassis base, should be rotated in the direction of the word "Operate" (maximum counter-clockwise rotation).
- 20. The electric tuning escutcheon should then be refastened into its position on the cabinet by means of the five special screws.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments with the "Tom" control knob in set for maximum treble response (position where knob is rotated from its maximum counter-clockwise position, slightly clockwise to position where set for "on"). When adjusting the electric tuning switch, always rotate the electric tuning switch so that the slotted shaft of the Electric Tuning Switch, located at the rear of the chassis base, is rotated back to the "Operate" position. Figure 1, shows the location of all the aligning capacitors in these receivers.

In making any alignment adjustments on the No. 335 receivers, it will not be necessary to remove the chassis from the rear of the receiver, and the aligning capacitors for the radio frequency circuits are easily accessible either through the bottom of the cabinet or through the bottom of the cabinet shelf depending upon the style of cabinet.

In making any aligning adjustments of the radio frequency circuits of the No. 336-P Receiver, it will be necessary to remove the chassis from the rear of the receiver, and the aligning capacitors for the intermediate frequency circuits of these receivers are easily accessible through the bottom of the cabinet.

Dial Adjustment

Before aligning the circuits of any of these receivers, the tuning dial must be properly aligned to track with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitors, the following procedure should be followed: Set the tuning dial to the maximum capacity position. Then, with the gang tuning capacitor in this position, the dial pointer should be placed on the horizontal center line of the dial. To do this, align the pointer with the short black line located at the extreme right-hand edge of the dial plate.

Intermediate Frequency Adjustments

- The intermediate frequency used in these receivers is 455 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.
- 1. Set the Electric Tuning and Range Switch control knob to the manual tuning standard broadcast position (arrow on knob pointing in direction of letters "BR"). Set the dial pointer by means of the Station "Tom" control knob slightly extreme low frequency position on the receiver dial, about the "Off-On" position. By aid of a screwdriver rotate the slotted shaft of the Electric Tuning Switch located at the rear of the chassis base, so that the slotted shaft points in the direction of the word "Set-up" (maximum clockwise rotation). Rotate the Volume control knob to its maximum clockwise position (maximum volume).
- 2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 tube, a 0.1-microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground binding post terminal, the test oscillator should be connected to other the chassis base or the ground binding post terminal.
- 3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:
  - Primary of second I. F. transformer.
  - Secondary of second I. F. transformer.
  - Primary of first I. F. transformer.
  - Secondary of first I. F. transformer.
- 4. Adjust the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

Alignment of Short Wave Range (Also Referred to as "C" Range)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignment, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal of the test oscillator should be connected to the ground binding post on the rear of the receiver.

- 1. For the Electric Tuning and Range Switch control knob, set the Short Wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.
- 2. Adjust the oscillator's "C" range high frequency aligner for maximum output.
- 3. Adjust the antenna's "C" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Standard Broadcast Range (Also Referred to as "A" Range)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

- 1. Rotate the Electric Tuning and Range Switch control knob to the manual tuning, Standard Broadcast ("A") range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
- 2. Adjust the oscillator's "A" range high frequency aligner for maximum output.
- 3. Adjust the antenna's "A" range high frequency aligner for maximum output.
- 4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
- 5. Adjust the oscillator's "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
- 6. Adjust the antenna's "A" range low frequency aligner for maximum output.

Wave Trap Adjustment

In adjusting the wave trap circuit, set the Electric Tuning and Range Switch control knob to the manual tuning, Standard Broadcast position (arrow on knob pointing in direction of letters "BR"). Set the dial pointer to 1000 kilocycles and the Electric Tuning Switch, located on the back of the receiver chassis, to the "Set-Up" position.

Connect a 200-ohm microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate frequency, rotate the Volume control knob to its maximum volume and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

IMPORTANT: When all the aligning adjustments have been completed, it is important that the Electric Tuning Switch (located on the rear of the receiver chassis) be reset to the "Operate" position.

Tuner Data

is easily obtainable by simply rotating the Range Switch control knob so that the arrow on the knob points in the direction of the designation for the desired type of tuning. When manually tuning the receiver in either the Standard Broadcast or Short Wave ranges, the electric tuning arrangement is made inoperative and the dial of the Range Switch control knob pointing in direction of the start of the electric tuning (arrow on Range Switch control knob) is set for electric tuning. When manually tuning these receivers, when setting up the six desired stations for electric tuning, resonance with a signal is indicated by means of the tuning indicator tube which operates on the cathode-ray principle.

1. Set the Electric Tuning and Range Switch control knob to the manual tuning standard broadcast position (arrow on knob pointing in direction of letter "A"). Set the dial pointer by means of the Station Selector knob to the extreme low frequency position on the receiver's dial. Rotate the "Off-On-Tone" control knob to the "On" position. When the tuning indicator tube becomes illuminated, rotate the Range Switch control knob to the "Set-Up" position. By aid of a screwdriver, rotate the slotted shaft of the Electric Tuning Set-Up Switch located at the rear of the chassis base, so that the slot of the shaft points in the direction of the word "Set-Up" (maximum clockwise rotation). Rotate the Volume control knob to its maximum clockwise position (maximum volume).
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6K3 modulator-oscillator tube, a modulated signal of 455 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6K3 tube. The connection between the test oscillator should be connected to either the chassis base or the ground binding post terminal.
3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:
  - Secondary of second I. F. transformer.
  - Primary of second I. F. transformer.

Secondary of first I. F. transformer.

Primary of first I. F. transformer.

Secondary of second I. F. transformer.

Primary of first I. F. transformer.

1. Rotate the Electric Tuning and Range Switch control knob to the Short Wave ("B") range position, and set the test oscillator's frequency and the receiver's tuning dial to 20 megacycles.
2. Adjust the receiver's oscillator "C" range high frequency aligner for maximum output.
3. Adjust the antenna "C" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

#### Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

**CAUTION:** Be sure that the Electric Tuning Set-Up Switch is set to the "Set-Up" position.

#### Alignment of Short Wave Range (Also Referred to as "C" Range)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver's chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Rotate the Electric Tuning and Range Switch control knob to the Short Wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 20 megacycles.
2. Adjust the receiver's oscillator "C" range high frequency aligner for maximum output.
3. Adjust the antenna "C" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

#### Alignment of Short Wave Range (Also Referred to as "B" Range)

In aligning the radio frequency circuits for this range, use the same artificial antenna and antenna binding post as was used for aligning the "C" range, and align this range as follows:

1. Rotate the Electric Tuning and Range Switch control knob to the Short Wave ("B") range position, and set the test oscillator's frequency and the receiver's tuning dial to 7 megacycles.
2. Adjust the receiver's oscillator "B" range high frequency aligner for maximum output.
3. Adjust the antenna "B" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

#### Alignment of Standard Broadcast Range (Also Referred to as "A" Range)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Rotate the Electric Tuning and Range Switch control knob to the manual tuning, Standard Broadcast ("A") range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the receiver's oscillator "A" range high frequency aligner for maximum output.
3. Adjust the antenna "A" range high frequency aligner for maximum output.
4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
5. Adjust the receiver's oscillator "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2 and 3.

#### OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

These receivers are equipped with a three-contact phono-graph socket, which is connected to the receiver circuit by a short, shielded cable which extends from the chassis base. A three-prong plug is also furnished for connecting the pick-up cable to the phono-graph socket.

To obtain the best quality of phonograph reproduction from these receivers, a Stromberg-Carlson Record Player is recommended. The Record Player is equipped with a specially equalized record playing motor unit, and uses a crystal type pick-up with a specially equalized circuit.

In order to prevent radio signals from interfering with the phonograph reproduction, it is necessary to set the station selector knob to the "On" position. When the turntable has attained speed, raise the tone arm and gently on to the record so that the needle point enters the outside groove. The volume (sound level) and the tone for phonograph reproduction can be controlled the same as for radio reception, i. e., by means of the "Volume" and "Off-On-Tone" control knobs located on the front panel of the radio receiver.

If the Stromberg-Carlson Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a shielded cable between the three-prong socket plug and the pick-up. For best reproduction, this shielded cable should be of the low capacity type. The length of this shielded cable should be approximately 10 feet. The shield of the cable is to be fastened to the chassis base. The metal cover of the plug and solder on the shield of the cable to that prong which is furthest away from the other two prongs; a short connecting wire must also be soldered from this prong to the upper right-hand prong when looking at the rear of the plug, that is, the side opposite to the prong side. The inside wire conductor of the shielded cable should then be soldered to the other terminal of the plug.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong socket plug and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

#### Instructions for Setting Up the Electric Tuning Arrangement

1. Before proceeding to set up the stations for electric tuning, the radio receiver should be turned "on" for approximately twenty to thirty minutes.
2. Set the Range switch control knob to the manual tuning position for the Standard Broadcast range (arrow on knob pointing in direction of the letter "A").
3. Remove the list of station letters from the P-28781 package assembly which is tacked inside of the cabinet.
4. Remove the two screws which hold the electric tuning escutcheon plate (metal plate). Then, remove from the escutcheon, the strip of transparent material and the strip of paper on which the six stars are printed.
5. Remove the five screws which hold the electric tuning escutcheon to the front panel.
6. From the lists of stations, remove the call letters of the six stations which it is desired to set up for electric tuning. These six stations should preferably be selected and set up in the daytime so that the best service will be obtained at all times.

**CAUTION:** Each button adjustment for electric tuning has assigned frequency limits. These limits are designated for each adjustment on the cover plate which covers the electric tuning adjusting capacitors. The frequency of each station should be selected so that the frequency of the station is within its assigned frequency limits of its associated push button.

It will be noted that the station letters are printed on partially cut squares to facilitate ease in removing the desired station letters. In setting up these six favorite stations, the following order should be followed:

Looking at the front of the receiver, the station letters of the station having the highest frequency should be inserted into the farthest left-hand square of the escutcheon. Then, in successive order, according to the frequency, insert the station letters of the remaining five stations into the other five squares of the electric tuning escutcheon; the station letters of the station having the lowest frequency being inserted into the farthest right-hand square of the escutcheon.

After the six station call letters have been inserted into the escutcheon, the transparent strip should be replaced over the station call letters, and the escutcheon plate then fastened into its position on the electric tuning escutcheon by means of the two screws.

The tuning adjustments for the six favorite stations can now be made, starting with the station having the highest frequency and proceeding as follows:

7. **IMPORTANT:** By aid of a screwdriver, rotate the slotted shaft of the electric tuning switch, which is mounted on the rear of the receiver, so that the slot of the shaft points in the direction of the word, "Set-Up" (maximum clockwise rotation).

8. With the receiver turned "on", and the Range Switch control knob set to the standard broadcast position (arrow on knob pointing in direction of letter "A"), tune the receiver in the conventional manner for the station having the highest frequency. When the tuning indicator tube becomes illuminated, set the Range Switch control knob to the electric tuning arrangement and carefully note the program which it is broadcast. Then, rotate the Range Switch control knob to the electric tuning position, arrow on knob pointing in direction of the small star (large star and station letters become illuminated).

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with all the tubes in their respective sockets except the No. 6U5 tube. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value, in which case the 300 volt scale was used.

A special temperature controlled compensating capacitor is used in the oscillator circuit of these receivers when operating the electric tuning arrangement in order to eliminate drift in the oscillator's frequency. These receivers also contain a novel automatic volume control system which maintains the volume control current so that balanced reproduction is obtained for any setting of the volume control.

NORMAL VOLTAGE READINGS

The values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in full operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

Arrangement, appearing on page of this book. Manual or electric tuning for the Standard Broadcast range is easily obtainable by simply rotating the Range Switch control knob so that the arrow on the knob points in the direction of the designation for the desired type of tuning. When manually tuning the receiver in either the Standard Broadcast or Short Wave ranges, the electric tuning arrangement is made inoperative and the dial of the receiver is set for manual tuning. The electric tuning arrangement is made inoperative and the dial of the receiver is set for manual tuning. The electric tuning arrangement is made inoperative and the dial of the receiver is set for manual tuning. The electric tuning arrangement is made inoperative and the dial of the receiver is set for manual tuning.

A special temperature controlled compensating capacitor is used in the oscillator circuit of these receivers when the receiver is tuned to a frequency in the Standard Broadcast range. The oscillator's frequency. These receivers are also provided with a low level bias frequency compensating circuit in conjunction with the volume control circuit so that balanced reproduction is obtained for any setting of the volume control.

In addition to the above features, the No. 340-P Receiver is also equipped with a single record playing phonograph unit, and the No. 341-P Receiver is equipped with an automatic record changer phonograph unit. These phonograph units use a crystal type pick-up in conjunction with a specially equalized circuit.

The chassis used in the table models differ from the chassis used in the console models in that the receivers from the chassis used in the No. 340 Receivers in the type of electrolytic filter capacitors which are used. Also, the radio phonograph models are equipped with a radio-phonograph switch.

The various tubes are used in these receivers as follows: The No. 6A8 tube functions as both the Modulator and Oscillator tube. The No. 6K7 tube is used in the I. F. Amplifier and the No. 6H6 tube is used as both the Detector and Automatic Volume Control tube. The No. 6E5 tube is used in the Audio Amplifier and the No. 6U5 tube is used in the Audio Power Output Stage. The No. 6I5 tube is used for indicating resonance in the tuning indicator system and the No. 80 tube is the Rectifier tube of the Power Supply Unit.

**NORMAL VOLTAGE READINGS**  
The values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in full operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper voltage given for a line voltage of 120 volts, and allowances should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 1000 volt scale was used.

Due to the use of the 120 ohm resistor, 120 ohms in the chassis used in table models, some socket terminals in the table models are not equipped with this resistor, and the upper voltages are those obtained from chassis not equipped with this resistor.

**CIRCUIT DESCRIPTION**

These receivers are nine tube, instantaneous "Electric Tuning" superheterodyne receivers employing metal tubes and a highly efficient dynamic speaker. There are two tuning ranges, the frequency limits of each range being listed under the "Electrical Specifications", given above.

The electric tuning circuit is actuated by means of the push buttons. Local and other stations that give the best daytime and evening service should be selected. To properly set up the electric tuning arrangement for the eight favorite Standard Broadcast stations, read the section, "Instructions for Setting Up the Electric Tuning

Alignment

**ALIGNMENT DATA**

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-24608 aligning tool be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator (Signal Generator), the output voltage of which can be varied. In conjunction with this test oscillator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any circuits in these receivers be sure that the "Off-On-Tone" control knob is set for maximum treble response (position where knob is rotated from its maximum counter-clockwise position, slightly clockwise to position where set turns "on"), and that the slotted shaft of the electric set-up switch, located on the rear of the chassis base, is in the direction of the word "Set-Up". When the test oscillator is set up, the slotted shaft of the electric set-up switch should be rotated so that the slot points in the direction of the word, "Operate". Figure 1, shows the location of all the aligning capacitors in these receivers.

**Dial Adjustment**

Before aligning the circuits of any of these receivers, the tuning dial must be properly aligned to track with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitors, rotate the "Station Selector" knob in a clockwise direction so that the gang tuning capacitors are set to their maximum capacity position. Then, with the gang tuning capacitors in this position, the dial pointer should be placed on the horizontal center line of the dial. To do this, align the pointer with the short black line located at the extreme right-hand edge of the dial plate.

**Intermediate Frequency Adjustments**

The intermediate frequency used in these receivers is 455 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.

1. Set the Electric Tuning and Range Switch control knob to the manual tuning standard broadcast position (arrow on knob pointing in direction of letters "BR."). Set the dial pointer by means of the Station Selector knob to the extreme low frequency position on the receiver's dial. Rotate the "Off-On-Tone" control knob slightly clockwise from its most counter-clockwise position, which is the "normal" position. By aid of a screwdriver rotate the slotted shaft of the Electric Tuning Set-Up switch located at the rear of the chassis base, so that the slotted shaft points in the direction of the word "Set-Up" (maximum volume). Rotate the Volume control knob to its maximum clockwise position.

2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 455 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the tube. Do not connect the chassis grid lead connecting to this tube. The output terminal of the test oscillator should be connected to either the chassis base or the ground binding post terminal.

3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:

- Secondary of second I. F. transformer.
- Primary of second I. F. transformer.
- Secondary of first I. F. transformer.
- Primary of first I. F. transformer.

Adjusting the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

**Radio Frequency Adjustments**

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

**Alignment of Short Wave Range (Also Referred to as "C" Range)**

In aligning the radio frequency circuits for this range, replace the 0.1 microfarad capacitor which was placed in the test oscillator circuit with a 200-microfarad capacitor with 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Rotate the Electric Tuning and Range Switch control knob to the Short Wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.

2. Adjust the oscillator's "C" range high frequency aligner for maximum output.

3. Adjust the antenna's "C" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

**Alignment of Standard Broadcast Range (Also Referred to as "A" Range)**

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Rotate the Electric Tuning and Range Switch control knob to the manual tuning, Standard Broadcast range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the oscillator's "A" range high frequency aligner for maximum output.
3. Adjust the antenna's "A" range high frequency aligner for maximum output.
4. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
5. Adjust the oscillator's "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2 and 3.

**Wave Trap Adjustment**

In adjusting the wave trap circuit, set the Electric Tuning and Range Switch control knob to the manual tuning, Standard Broadcast position (arrow on knob pointing in direction of letters "BR."). Set the dial pointer to 1000 kilocycles and the Electric Tuning Set-Up Switch, located on the back of the receiver chassis, to the "Set-Up" position.

Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator as shown in Figure 2. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, 455 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

**IMPORTANT:** When all the aligning adjustments have been completed, it is important that the Electric Tuning Set-Up Switch (located on the rear of the receiver chassis) be reset to the "Operate" position.

**OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS FOR NOS. 340 AND 341 RECEIVERS NOT EQUIPPED WITH A RECORD PLAYING UNIT**

In order to obtain reproduction of phonograph records in conjunction with these receivers, the following instructions should be followed.

To equip these receivers for phonograph operation, it will be necessary to purchase and install a Stromberg-Carlson, P-23712 Package Assembly. The rear of the chassis base of the receiver is already drilled for this assembly. Complete instructions on how to install and operate this assembly are furnished with each P-23712 Package Assembly.

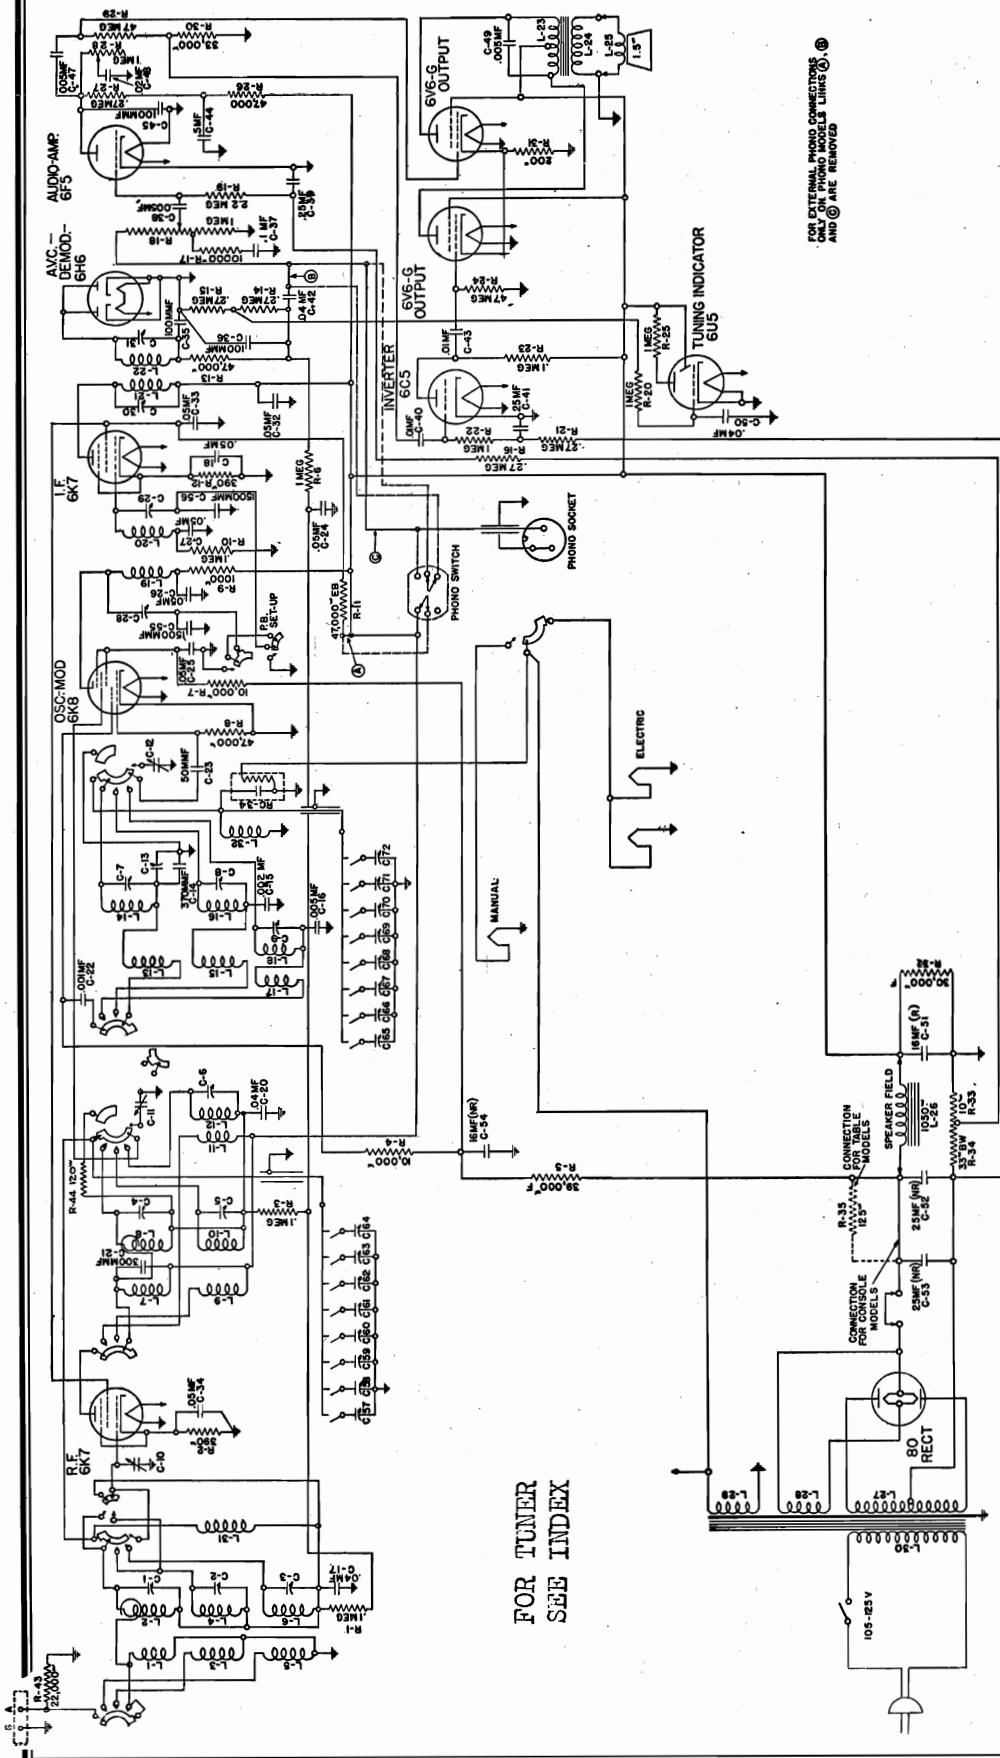

To obtain the best quality of phonograph reproduction from these receivers, a Stromberg-Carlson Record Player, and uses a crystal type pick-up in conjunction with a specially equalized circuit.

If the Stromberg-Carlson Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a low capacity shielded cable between the three-prong socket and plug of the P-23712 Package Assembly, and the pick-up. This shielded cable should be of the low capacity type. The length of the shielded cable used should be kept as short as possible.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong socket and plug of the P-23712 Package Assembly, and the pick-up. The transformer should be located as near to the receiver as possible in which case it will not be necessary to use a shielded cable.

Voltage Alignment

NORMAL VOLTAGE READINGS

The values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tube in place. The receiver is therefore, in the "On-Operate" position. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter, with a range of 0-1000 volts, should be used for measuring the D.C. voltages. The meter should be set on the lowest possible scale of a meter for measuring the following ranges: 0-2.5, 0-10, 0-100, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no re-adjustments are necessary. However, should it become necessary to make any re-adjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-2400B aligning tool be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator (Signal Generator), the output voltage of which can be varied. In conjunction with this test oscillator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

**IMPORTANT:** In making any R. F. or I. F. alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any R. F. or I. F. circuits in these receivers be sure that the "Off-Operate" control knob is set for the "Set-Up" position. When the aligning adjustments have been completed the Electric Tuning Set-Up Switch should be rotated back to the "Operate" position. Figure 1, shows the location of all the aligning capacitors in these receivers.

Dial Adjustment

Before aligning the circuits of any of these receivers, the tuning dial must be properly aligned to track with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitors, rotate the "Station Selector" knob in a clockwise direction so that the gang tuning capacitors are set to their maximum capacity position. Then, with the gang tuning capacitors in this position, the dial pointer should be placed on the horizontal center line of the dial. To do this, align the pointer with the short black line located at the extreme right-hand edge of the dial plate.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 455 kilocycles. In making these circuit adjustments always align the circuits in the order given in these instructions.

1. Set the Electric Tuning and Range Switch control knob to the manual tuning Standard Broadcast range position (arrow on knob pointing in direction of letter "A"). Set the dial pointer to the "A" position. Rotate the Station Selector knobs to the extreme low frequency position on the receiver's dial.

"Tone" control knob slightly clockwise from its most counter-clockwise position. By aid of a screw-driver rotate the slotted shaft of the Electric Tuning Set-Up Switch located at the rear of the chassis base, so that the slot points in the direction of the word "Set-Up". Rotate the Volume control knob to its maximum clockwise position (maximum volume).

2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6K8 modulator-oscillator tube, a modulated signal of 455 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the 6K8 tube. In this connection the ground binding post should be connected to either the chassis base or ground (or low side) terminal of the test oscillator should be connected to either the chassis base or the ground binding post terminal of the receiver.

3. Now, noting from Figure 1, the aligning capacitors for the first and second I. F. transformers, align the I. F. circuits in the following manner:
  - Secondary of second I. F. transformer.
  - Primary of second I. F. transformer.
  - Secondary of first I. F. transformer.
  - Primary of first I. F. transformer.

1. Adjust the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

**CAUTION:** Be sure that the Electric Tuning Set-Up Switch is set to the "Set-Up" position.

Alignment of Short Wave Range, "C"

In aligning the radio frequency circuits for this range, replace the 0.1 microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver's chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Rotate the Electric Tuning and Range Switch control knob to the "C" Short Wave range position, and set the test oscillator's frequency and the receiver's tuning dial to 20 megacycles.
2. Adjust the receiver's oscillator "C" range H. F. aligner for maximum output.
3. Adjust the R. F. transformer "C" range H. F. aligner for maximum output and at the same time rotate the gang tuning capacitors back and forth through resonance until maximum output is obtained.
4. Adjust the antenna "C" range H. F. aligner for maximum output and at the same time rotate the gang tuning capacitors back and forth through resonance until maximum output is obtained.

Alignment of Short Wave Range, "B"

In aligning the radio frequency circuits for this range, use the same artificial antenna (400 ohm resistor) and antenna binding post as was used for aligning the "C" range, and align as follows:

1. Rotate the Electric Tuning and Range Switch control knob to the "B" Short Wave range position, and set the test oscillator's frequency and the receiver's tuning dial to 7 megacycles.
2. Adjust the receiver's oscillator "B" range H. F. aligner for maximum output.
3. Adjust the R. F. transformer's "B" range H. F. aligner for maximum output and at the same time rotate the gang tuning capacitors back and forth through resonance until maximum output is obtained.
4. Adjust the antenna "B" range H. F. aligner for maximum output and at the same time rotate the gang tuning capacitors back and forth through resonance until maximum output is obtained.

Alignment of Standard Broadcast Range, "A"

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Rotate the Electric Tuning and Range Switch control knob to the manual tuning Standard Broadcast range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the receiver's oscillator "A" range H. F. aligner for maximum output.
3. Adjust the R. F. transformer's "A" range H. F. aligner for maximum output.
4. Adjust the antenna "A" range H. F. aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
6. Adjust the receiver's oscillator "A" range L. F. aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitors slightly back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2, 3 and 4.

**NORMAL VOLTAGE READINGS**

The values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base with the receiver in the full operating condition. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowances should be made for differences when the line voltage is higher or lower. A meter having a scale of 1000 ohms resistance is used for the following D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-100, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

output control so that a signal of 50,000 to 100,000 microvolts is fed into the No. 6A8 modulator tube. Now, observe the reading of the milliammeter which is connected in series with the cathode of the No. 6F8-G oscillator control tube, and rotate the Range Switch control knob to the "Electric" position, observing the reading of the milliammeter. When the range is correctly adjusted, there should be no difference in the reading of the milliammeter when the Range Switch control knob is rotated from the manual tuning Standard Broadcast to the "Electric" position. If there is any difference in the milliammeter reading while rotating this control knob from the manual tuning Standard Broadcast to the "Electric" position and vice versa, adjust the "Discriminator" circuit by means of the screw adjustment until the meter reading has the same value regardless of whether the Range Switch control knob is rotated to the manual tuning Standard Broadcast or "Electric" position. When this condition is obtained, the Discriminator circuit is properly adjusted.

### Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, the Fidelity Control knob should be set for "Normal" operation, and the "Off-On-Bass" control knob should also be set for "Normal" operation.

#### Alignment of Short Wave Range (Also Referred to as "C" Range)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the short wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 16 megacycles.
2. Adjust the receiver's oscillator "C" range high frequency aligner for maximum output.
3. Adjust the antenna "C" range high frequency aligner for maximum output. At the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Set the test oscillator's frequency and the receiver's tuning dial to 6 megacycles.
5. Adjust the receiver's oscillator "C" range low frequency aligner (series aligner), and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and the receiver's tuning dial to 16 megacycles and repeat operations Nos. 2 and 3.

#### Alignment of Medium Wave Range (Also Referred to "B" Range)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the Medium Wave ("B") range position, and set the test oscillator's frequency and the receiver's tuning dial to 5 megacycles.
2. Adjust the receiver's oscillator "B" range high frequency aligner for maximum output.
3. Adjust the antenna "B" range high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

#### Alignment of Standard Broadcast Range (Also Referred to as "A" Range)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Operate the Range Switch to the manual tuning Standard Broadcast "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the receiver's oscillator "A" range high frequency aligner for maximum output.
3. Adjust the R. F. interstage "A" range high frequency aligner for maximum output.
4. Adjust the antenna's "A" range high frequency aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial to 0.8 megacycles.
6. Adjust the receiver's oscillator "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2, 3 and 4.

### Wave Trap Adjustment

In adjusting the wave trap circuit, set the Electric Tuning and Range Switch control knob to the manual tuning Standard Broadcast position (arrow on knob pointing in direction of gold dot). Set the tuning dial to 1000 kilocycles.

Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, 455 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

### ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the procedure given in these instructions should be carefully followed. The preferred method of aligning these receivers is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

To accurately align circuits in these receivers, it is necessary to use a high grade signal generator capable of being modulated 30% and having an output voltage of at least 100,000 microvolts; it will also be necessary to have this output voltage controlled so that only a few microvolts may be fed into the receiver. In conjunction with the signal generator, a sensitive output meter should be used for determining the maximum signal voltage developed across the output meter. The alignment procedure should be carried out in the following order: making a final adjustment in series with that cathode of the No. 6F8-G tube which is used in the oscillator control circuit by means of an adapter plug inserted between the tube and its socket. The leads to the meter should not be longer than 15", and should be shunted at the socket connections by a capacitor of not less than 0.25 Mfd.

In order to make the aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-24608 aligning tool be used.

Before proceeding with the alignment of any circuits in these receivers, except when specifically directed, be sure that the Fidelity Control knob is in the "Normal" position. The "Off-On-Bass" control knob should also be set for the "Normal" position. In making any alignment adjustments, the output voltage to the output meter should be set at the minimum value where a good alignment may still be obtained, except when specifically directed in these instructions. Figure 1 shows the location of all the aligning capacitors or adjustments for this receiver.

### Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. The dial is set correctly with respect to the gang tuning capacitor, rotate the "Radio Station Selector" knob in the clockwise direction until the dial indicator is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line is set to its exact center over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

### Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 455 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve of these stages in a high fidelity receiver, it is recommended that less it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed:

1. Operate the Range Switch of the receiver to the manual tuning, Standard Broadcast range position, and set the tuning dial to its extreme low frequency position. Set the Fidelity control knob to its "Normal" position, and the "Off-On-Bass" control knob to its normal position.

**CAUTION:** Never attempt to align the R. F. or I. F. circuits of this receiver with the Fidelity control knob set at any position other than the "Normal" position and the Range Switch control knob set at the "Electric" tuning position unless specifically directed in the following paragraphs. Also, do not make any aligning adjustments of the R. F., I. F., or "Discriminator" circuits with the A. F. C. switch (which is located on rear of the chassis base) set at the "set-up" position.

2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator tube, a modulated signal of 455 kilocycles from the signal generator, using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or the ground binding post.

3. Now, noting from Fig. 1, the alignment adjustments for the First and Second I. F. transformers, align the I. F. circuits in the following order:

Adjust the First I. F. transformer primary circuit for maximum output.

Adjust the Second I. F. transformer secondary circuit for maximum output.

Adjust the First I. F. transformer secondary circuit for maximum output.

Adjust the Second I. F. transformer primary circuit for maximum output.

Carefully make all of the above adjustments, watching carefully the output meter so that the peak reading is obtained for each adjustment. As each adjustment is made reduce the output of the test oscillator as required.

4. To adjust the Discriminator circuit proceed as follows:

Check the position of the Range Switch control knob which should be set to the manual tuning Standard Broadcast position.

**CAUTION:** Before adjusting this circuit be sure that the I. F. amplifier is tuned exactly to 455 kilocycles. With the signal generator still set at a frequency of 455 kilocycles, adjust the signal generator's

Continuity Test

Continuity test chart for No. 235 Receivers.

Jan. 17, 1938.

1. Test speaker socket with speaker left out.
2. Plug speaker in speaker socket for all other tests.
3. Set A.F.C. Switch on rear of chassis base to "Operate" position for all tests unless otherwise specified.
4. Before making continuity test, disconnect one end of the spring from the Manual-Electric switch lever. Pull Manual-Electric switch lever out for "Manual" operation. Push Manual-Electric switch lever in for "Electric" operation.

A. Operate A.F.C. switch on rear of chassis to "Set Up" position; should read 120W.

Operate A.F.C. switch on rear of chassis to "Operate" position; should read 4 M.

B. Operate A.F.C. switch on rear of chassis to "Set Up" position; should read 550,000W.

Operate A.F.C. switch on rear of chassis to "Operate" position; should read 4 M.

C. Operating volume control clockwise should read from "S" to 800,000W.

FOR OTHER SERVICING  
DATA, SEE INDEX

Other tests not shown on chart.

Test from Electric tuning pilot lamp socket. Operate Manual-Electric switch to "Manual" position; should read "0". Operate Manual-Electric switch to "Electric" position; should read "S".  
 Test from main dial pilot lamp socket. Operate Manual-Electric switch to "Manual" position; should read "S". Operate Manual-Electric switch to "Electric" position; should read "0".  
 Test from Ant. terminal on back of chassis base. Operate range switch to "A" band; should read 8W. Operate range switch to "B" band; should read 1W. Operate range switch to "C" band; should read .5W.  
 Test from Grd. terminal on back of chassis base; should read "S".  
 Test from terminals of A.C. plug to chassis base; should read "0".  
 Test between terminals of AC plug; should read 8W with A.C. switch closed; should read "0" with A.C. switch open.  
 Test from the Stator Plates of the oscillator section of the variable capacitor (located near front of chassis) to the switch side of the .001 capacitor (located next to the "A" and "B" band series aligner). Operate range switch to "A" band; should read 10W. Operate range switch to "B" band; should read 2W. Operate range switch to "C" band; should read 1W.

STROMBERG-CARLSON TEL. MFG. CO.

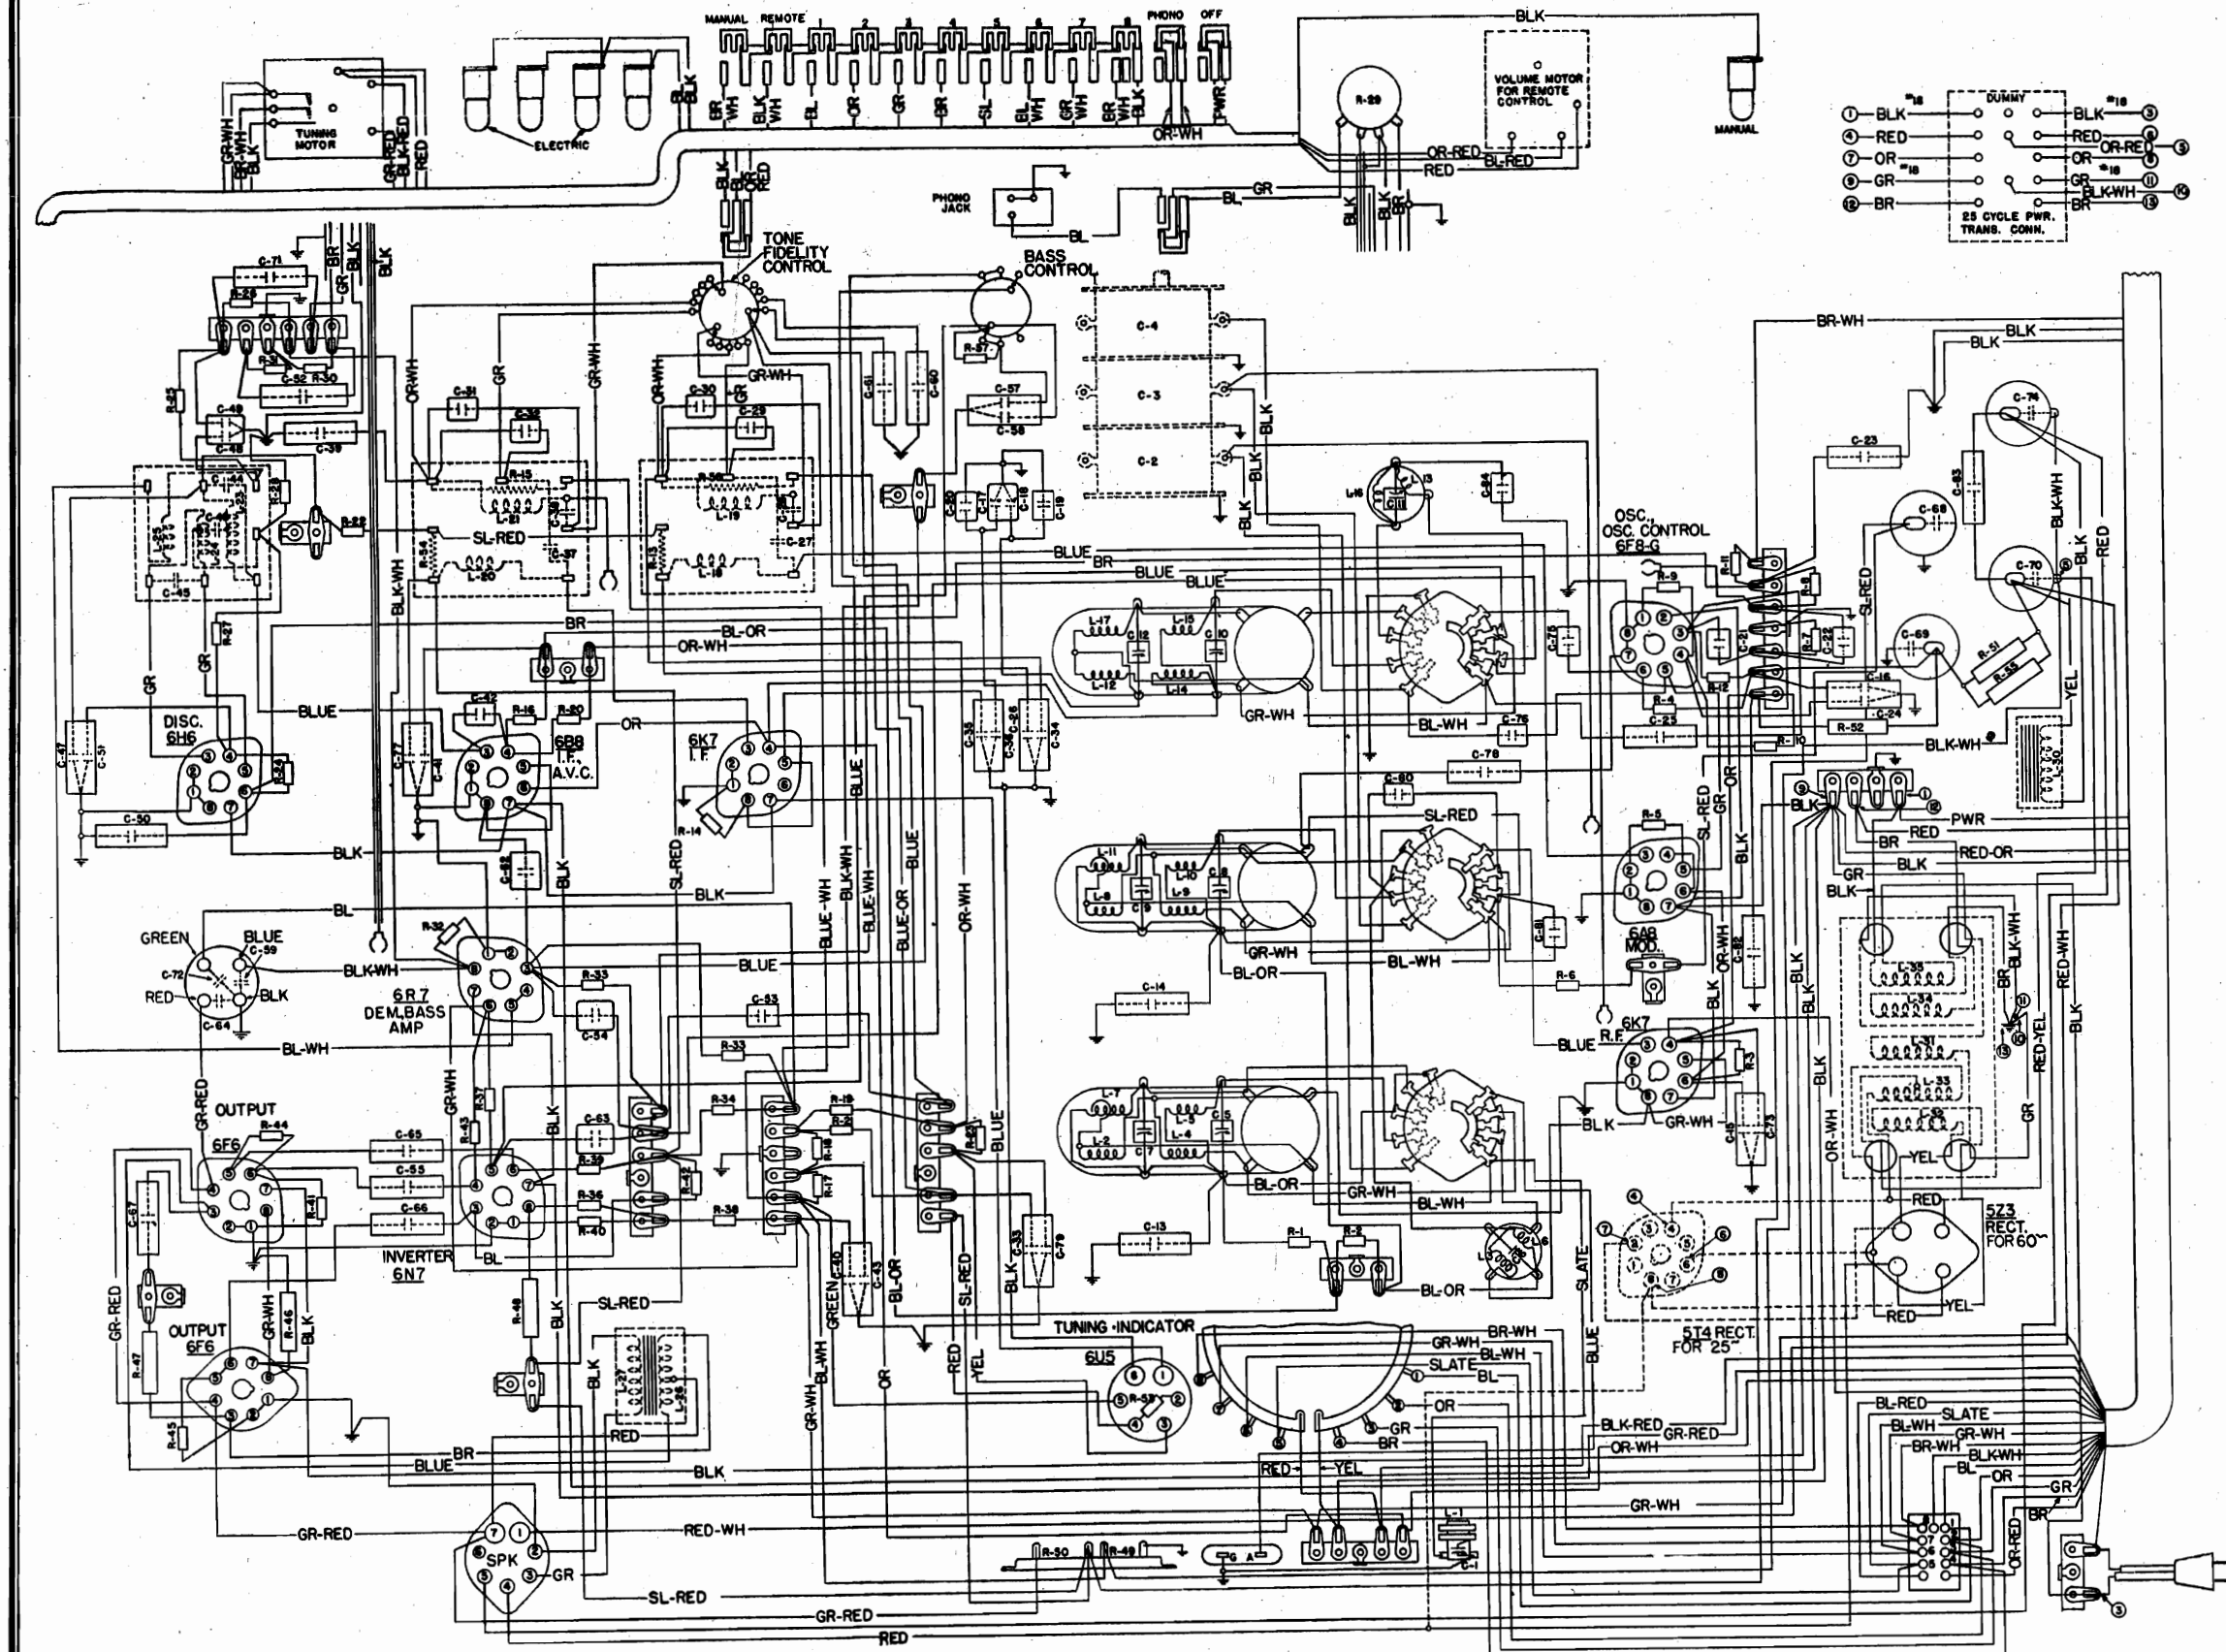

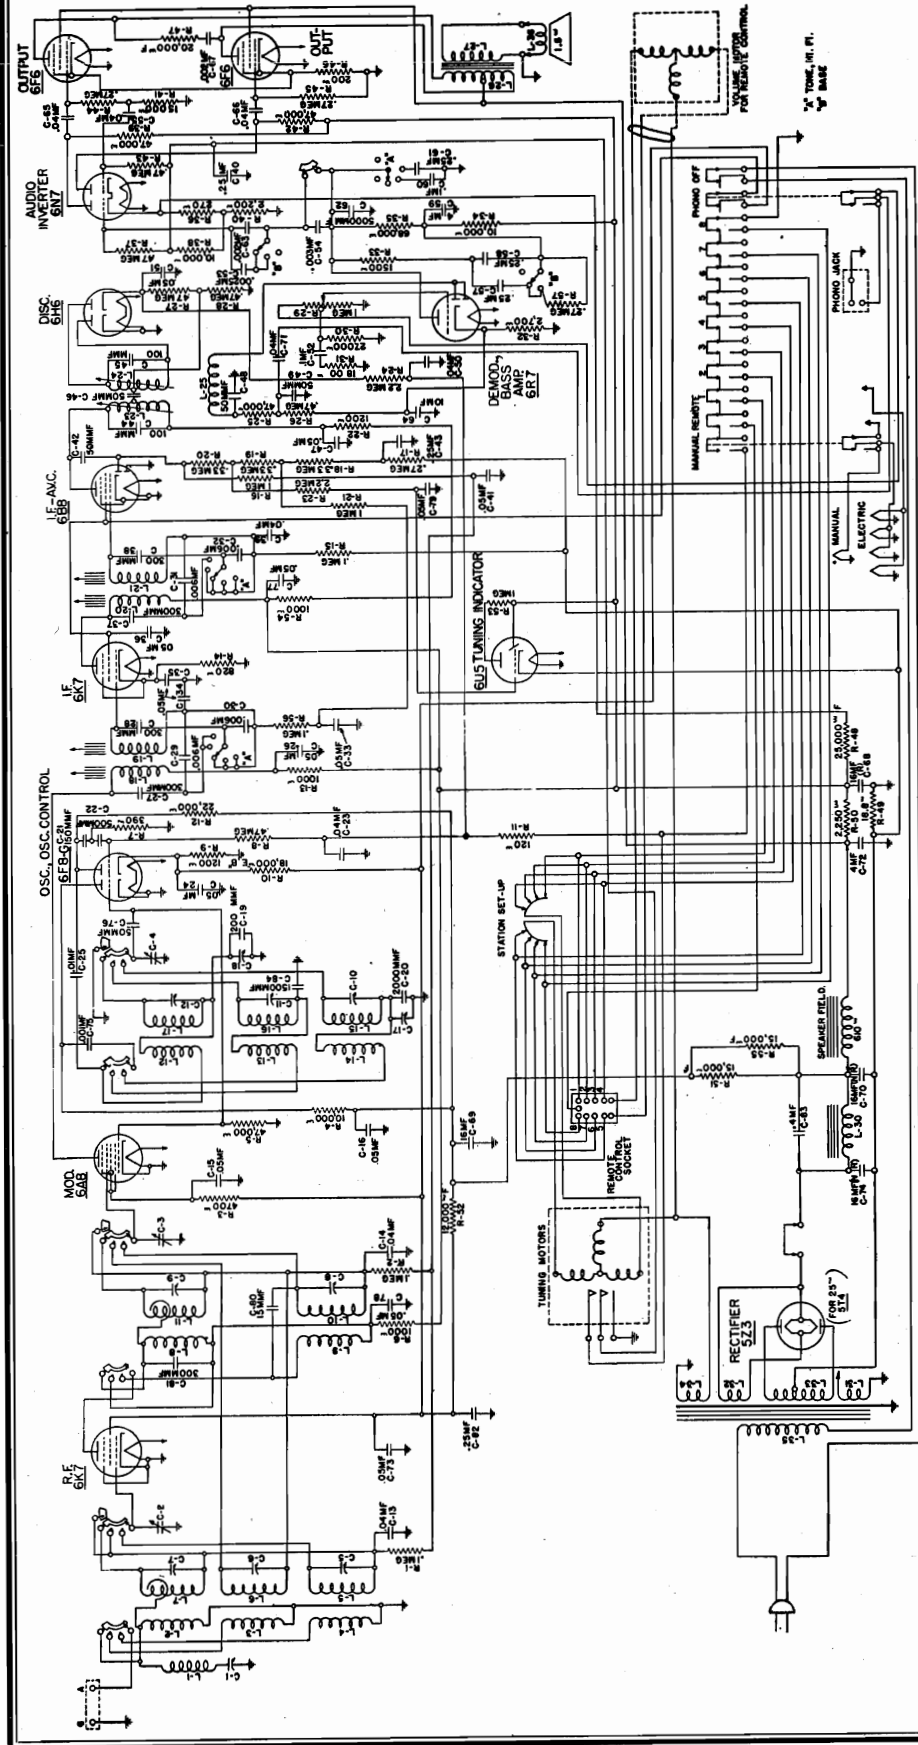

Fig. 3. Wiring Diagram of Chassis.

CIRCUIT DESCRIPTION

The Stromberg-Carlson No. 360 Radio Receivers are twelve tube, "Electric Tuning", adjustable high fidelity receivers with three tuning ranges. The electric tuning circuit combines a highly efficient motor and selector circuit in combination with an automatic frequency control circuit. The electric tuning circuit is arranged so that eight favorite stations located in the Standard Broadcast range may be set up for selection by means of the push buttons (local and other stations that give the best daytime and evening service should be selected).

These receivers are also provided with a low level bass frequency compensating circuit in conjunction with the volume control circuit so that balanced reproduction is obtained for any setting of the volume control. A separate "Bass" control is also provided to increase or decrease the response at the lower (bass) audio frequencies if this is desired.

These receivers are also equipped with a special arrangement of the Stromberg-Carlson Selector dial indicator. This design of dial arrangement enables the operator to easily identify the service and frequency range to which the range switch control knob is set by means of the yellow disc (located at the right-hand edge of the dial), which moves in a vertical direction in conjunction with the rotation of the Range Switch control knob.

For data on setting up electric tuning system and remote control see Index.

Fig. 2. Schematic Circuit of Receiver. ELECTRICAL SPECIFICATIONS

- Type of Circuit ----- Superheterodyne with A. F. C. Electric Tuning
- Tuning Ranges ----- A—530 to 1700 Kc.; B—1700 to 5600 Kc.; C—5600 to 18,000 Kc.

- No. 360-MB Receiver ----- 25 to 60 Cycles; P-29069 Chassis; P-29072 Speaker

**Alignment**

To accurately align circuits in these receivers, it is necessary to use a high grade signal generator capable of being modulated 50% and having an output range of at least 10,000 microvolts. The signal generator should be set for the "Normal" position. In making adjustments, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker. In addition to this equipment, it will be necessary when making a final adjustment of the "Discriminator" tuned circuit to use a high resistance voltmeter having a resistance of at least 1000 ohms per volt.

In order to make the aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson F-2408 aligning tool be used.

Before proceeding with the alignment of any circuits in these receivers, be sure that the Treble Control knob is set for the "Normal" position. The "bass" control should also be set for the "Normal" position. In making adjustments, the "Manual Electric" control should be set for the "Manual" position. The "Manual Electric" control should be set for the "Manual" position. The "Manual Electric" control should be set for the "Manual" position. The "Manual Electric" control should be set for the "Manual" position.

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitors. To do this, the tuning dial must be rotated in a clockwise direction so that the gang tuning capacitors are at their maximum capacity position. With the gang tuning capacitors at this position, the dial pointer should be centered over the two dial alignment marks located near the extreme right-hand edge of the dial. One of these marks is a vertical line located beneath the standard broadcast scale, and the other mark is a small triangle mark located at the bottom of the dial pointer assembly. The dial pointer assembly should be loosened so that the pointer can be centered over the two marks. When this has been accomplished the screw should be securely tightened again.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 455 kilocycles. Because of the necessity of obtaining the correct intermediate frequency, it is essential that these I. F. adjustments be unobscured. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed:

1. Push in the push button which is located under the designation, "Manual On". Operate the Range Switch of the receiver to the Standard Broadcast range position, and set the tuning dial pointer to their normal positions.
2. Apply the test oscillator to the antenna binding post of the receiver and the grid of the No. 6A8 modulator tube, a modulated signal of 455 kilocycles from the signal generator, using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 modulator tube. The signal generator should be adjusted so that a signal of 10,000 microvolts is fed into the modulator tube. Under these conditions the voltmeter connected across C-31 should read 200 microvolts.
3. Now, noting from Figure 1, the alignment adjustments for the First, Second, and Third I. F.—Discriminator transformers, align the I. F. circuits in the following order:
  - Secondary of Third I. F.—Discriminator transformer for maximum output.
  - Primary of Second I. F.—Discriminator transformer for maximum output.
  - Primary of Second I. F. transformer for maximum output.
  - Secondary of First I. F. transformer for maximum output.
  - Primary of First I. F. transformer for maximum output.

Carefully make all of the above adjustments, watching the output meter so that the peak reading is obtained for each adjustment. As each adjustment is made reduce the output of the test oscillator as required.

Adjustment of the Discriminator Circuit

Before making this circuit adjustment be sure that the I. F. amplifier and signal generator are exactly in resonance at 455 kilocycles.

All controls should be set the same as instructed for the intermediate frequency adjustments. Connect the signal generator to the antenna binding post of the receiver and the grid of the No. 6A8 modulator tube in the same manner as connected when making the aligning adjustments of the intermediate frequency amplifier circuits. The signal generator's output control should be adjusted so that a signal of 10,000 microvolts is fed into the modulator tube. Under these conditions the voltmeter connected across C-31 should read 200 microvolts.

Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground amplifier, 455 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustment is necessary. However, should it become necessary to make any readjustments, the procedure given in this section should be followed. The alignment of the receiver is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

If the above conditions are not obtained, the signal generator should be set to exact resonance with the intermediate frequency amplifier (455 kilocycles) as mentioned in 1 above and the secondary adjustment of the Third I. F. Discriminator transformer should be rotated so zero voltage is indicated on the voltmeter connected across C-31.

Now, adjust the signal generator's frequency a slight amount (approximately 5 kilocycles) each side of 455 kilocycles. The signal generator's frequency should be adjusted so that the voltmeter shows an increase in the signal generator's frequency (455 kilocycles) should make the voltmeter give an increased reading from zero and an increased indication from zero.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, all controls should be set at the positions mentioned for the Intermediate Frequency adjustments.

Alignment of Short Wave Range (Also Referred to as "C" Range)

- In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which is placed in series with the antenna binding post located on the rear of the receiver chassis. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.
1. Operate the Range Switch on the receiver chassis to the short wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial to 16 megacycles.
  2. Adjust the receiver's oscillator "C" range high frequency aligner for maximum output.
  3. Adjust the R. F. interstage "C" range high frequency aligner for maximum output and at the same time rotate the gang tuning capacitors back and forth through resonance until maximum output is obtained.
  4. Adjust the antenna "C" range high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
  5. Set the test oscillator's frequency and the receiver's tuning dial to 6 megacycles.
  6. Adjust the receiver's oscillator "C" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
  7. Reset both the test oscillator's frequency and the receiver's tuning dial to 16 megacycles and repeat operations Nos. 2, 3 and 4.

Alignment of Medium Wave Range (Also Referred to as "B" Range)

- In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.
1. Operate the Range Switch on the receiver chassis to the Medium Wave ("B") range position, and set the test oscillator's frequency and the receiver's tuning dial to 5 megacycles.
  2. Adjust the receiver's oscillator "B" range high frequency aligner for maximum output.
  3. Adjust the antenna "B" range high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Standard Broadcast Range (Also Referred to as "A" Range)

- In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:
1. Operate the Range Switch to the manual tuning Standard Broadcast "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 15 megacycles.
  2. Adjust the receiver's oscillator "A" range high frequency aligner for maximum output.
  3. Adjust the R. F. interstage "A" range high frequency aligner for maximum output.
  4. Adjust the antenna's "A" range high frequency aligner for maximum output.
  5. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
  6. Adjust the receiver's oscillator "A" range low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
  7. Reset both the test oscillator's frequency and receiver's tuning dial to 15 megacycles and repeat operations Nos. 2, 3 and 4.

Wave Trap Adjustment

In adjusting the wave trap circuit, set the Range Switch control knob to the Standard Broadcast position (arrow on knob pointing in direction of gold dot). Push the push button located under the designation "Manual On" and set the tuning dial to 1000 Kilocycles.

MODEL 370

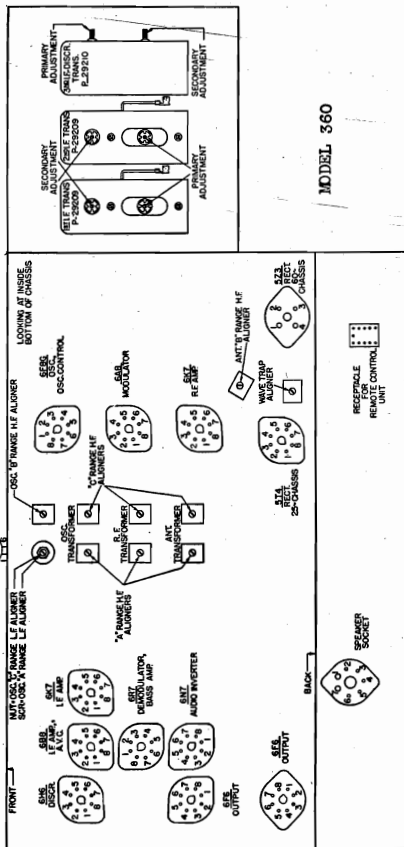

CIRCUIT DESCRIPTION

The Stromberg-Carlson No. 370 Radios, Receivers are fourteen tube, "Electric Tuning", adjustable high fidelity receivers with four tuning ranges. The electric tuning control circuit is adjustable, and the selector circuit in combination with an automatic frequency control circuit. The electric tuning circuit is arranged so that eight favorite stations located in the Standard Broadcast range may be set up for selection by means of the push buttons (local and other stations that give the best daytime and evening service should be selected). To properly set up the electric tuning arrangement for the eight favorite broadcast stations, read the section, "Instructions for Setting Up Electric Tuning Arrangement".

When manually tuning these receivers or when setting up the eight desired stations for electric tuning, resonance with a signal is indicated by means of the tuning indicator tube which operates on the cathode-ray principle. The strength of a received signal may be determined by observing the size of the aperture appearing on the target of the tube; the stronger a received signal the greater the reduction in the size of the aperture. These receivers are also provided with a low level bass frequency compensating circuit in conjunction with the volume control circuit so that balanced reproduction is obtained for any setting of the volume control. A variable bass control is also provided to increase or decrease the response at the lower (bass) audio frequencies if this is desired.

These receivers are also equipped with a special arrangement of the Stromberg-Carlson, Selector dial indicator. This design of dial arrangement enables the operator to easily identify the service and frequency range to which the range switch control knob is set by means of the yellow disc (located at the right-hand edge of the dial), which moves in a vertical direction in conjunction with the rotation of the range switch control knob.

The various tubes are used in these receivers as follows: One No. 6K7 is used in the R. F. Amplifier and the other two are used in the I. F. Amplifier. The No. 6A8 tube is used as the Modulator tube and the No. 6F8-G tube is used for both Oscillator and Oscillator Control tube. One No. 6H6 tube is used as the Demodulator and Automatic Volume Control tube and the other No. 6H6 tube is used in the Discriminator circuit for Automatic Frequency control. The No. 6H6 tube is also used in the Phase Inverter tube of the Audio Amplifier circuit and the two No. 6FL6 tubes are used in the Audio Power Output Stage. The No. 6Y5 tube is used for indicating resonance in the Tuning Indicator System. The No. 5Z3 tube is the Rectifier tube of the power supply for these receivers designed for operation on a power supply having a frequency of 50 to 60 cycles; models of these receivers designed for operation on a power supply having a frequency of 25 to 60 cycles, use a No. 574 tube as the Rectifier tube of the power supply.

MODEL 360

Fig. 1. Terminal Layout for Voltage Measurement Chart and Location of the Aligning Adjustments.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with all the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-25, 0-100, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value, in which case the 500 volt scale was used, or when a double asterisk appears the 1000 volt scale was used.

circuits. The signal generator's output control should be adjusted so that a signal of 10,000 microvolts is fed into the modulator tube. Under these conditions the voltmeter connected across the capacitor, C-74, should read zero.

The above conditions are not obtained, the signal generator should be set to exact resonance with the signal generator. The secondary winding of the transformer (455 kilocycles) as mentioned in 1 above, and the secondary adjustment of the third I. F. discriminator should be rotated so zero voltage is indicated on the voltmeter connected across the capacitor, C-74.

Now, adjust the signal generator's frequency a slight amount (approximately 5 kilocycles) each side of 455 kilocycles, noting at the same time the reading of the voltmeter; a decrease in the secondary voltage from 455 kilocycles should make the voltmeter give an increased reading from zero. An increase in the signal generator's frequency (455 kilocycles) should make the voltmeter give a decreased indication from zero.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified. When making any aligning adjustments of these circuits, all controls, with the exception of the "Manual Stations" control, should be set at the positions mentioned for the Intermediate Frequency adjustments.

Alignment of 11 to 22 Megacycles Short Wave Range (Referred to as "D" Range)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon resistor. This resistor should then be connected to the antenna binding post located on the rear of the receiver chassis. The test terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

- 1. Operate the Range Switch on the receiver chassis to the 11 to 22 megacycles short wave ("D") range position, and set the test oscillator's frequency and the receiver's tuning dial pointer to 20 megacycles.
2. Adjust the receiver's oscillator "D" range H. F. (high frequency) aligner for maximum output.
3. Adjust the R. F. interstage "D" range H. F. aligner for maximum output.
4. Adjust the antenna "D" range H. F. aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial pointer to 11 megacycles.
6. Adjust the receiver's oscillator "D" range L. F. (low frequency) aligner for maximum output.
7. Adjust the R. F. interstage "D" range L. F. aligner for maximum output.
8. Adjust the antenna "D" range L. F. aligner for maximum output.
9. Repeat operations Nos. 2, 3, and 4.

Alignment of 4.8 to 11 Megacycles Short Wave Range (Referred to as "C" Range)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

- 1. Operate the Range Switch on the receiver chassis to the 4.8 to 11 megacycles short wave ("C") range position, and set the test oscillator's frequency and the receiver's tuning dial pointer to 10 megacycles.
2. Adjust the receiver's oscillator "C" range H. F. aligner for maximum output.
3. Adjust the R. F. interstage "C" range H. F. aligner for maximum output.
4. Adjust the antenna "C" range H. F. aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial pointer to 5 megacycles.
6. Adjust the receiver's oscillator "C" range L. F. aligner for maximum output.
7. Adjust the R. F. interstage "C" range L. F. aligner for maximum output.
8. Adjust the antenna "C" range L. F. aligner for maximum output.
9. Repeat operations Nos. 2, 3, and 4.

Alignment of Medium Wave Range (Referred to as "B" Range)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short wave ranges.

- 1. Operate the Range Switch on the receiver chassis to the Medium Wave ("B") range position, and set the test oscillator's frequency and the receiver's tuning dial pointer to 4.5 megacycles.
2. Adjust the receiver's oscillator "B" range H. F. aligner for maximum output.
3. Adjust the R. F. interstage "B" range H. F. aligner for maximum output.
4. Adjust the antenna "B" range H. F. aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial pointer to 1.8 megacycles.
6. Adjust the receiver's oscillator "B" range L. F. aligner for maximum output.
7. Repeat operations Nos. 2, 3, and 4.

Alignment of Standard Broadcast Range (Referred to as "A" Range)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

4

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the procedure given in these instructions should be carefully followed. The preferred method of aligning these receivers is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

To accurately align circuits in these receivers, it is necessary to use a high grade signal generator capable of being modulated 30% and having an output voltage of at least 100,000 microvolts; it was also necessary to use a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator. The preferred method of aligning these receivers is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

In order to make the aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-24008 aligning tool be used.

Before proceeding with the alignment of any circuits in these receivers, be sure that the Trouble Control knob is in the "Normal" position, and that the "Manual Stations" control is in the "Normal" position. After making any alignment adjustments always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained, except when specifically directed otherwise in these instructions. Figure 1 shows the location of all the aligning capacitors or adjustments for these receivers.

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitors. To check whether the dial is set correctly with respect to the gang tuning capacitors, rotate the "Manual Stations" selector knob in a clockwise direction so that the gang tuning capacitors are set to their maximum capacity position. With the gang tuning capacitors at this position, the dial pointer should be centered over the two dial alignment marks located near the extreme right-hand edge of the dial. One of these marks is the "Normal" position, and the other is the "Broadcast" position. If the dial pointer does not center over these two marks, the screw located at the bottom of the dial pointer assembly should be loosened so that the pointer can be centered over the two marks. When this has been accomplished the screw should be securely tightened again.

Intermediate Frequency Adjustments

The intermediate frequency curve of these receivers is 455 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve in a high fidelity receiver, it is recommended that tuning is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed.

- 1. Push in the push button which is located under the designation, "Manual On". Operate the Range Switch on the receiver to the Standard Broadcast range position, and set the tuning dial pointer to its normal position. Set the Trouble control knob and the Bass control knob to their normal positions.

CAUTION: Never attempt to align the R. F. or I. F. circuits of this receiver with the Trouble control knob in the "Manual On" position. The "Manual On" position is used for aligning the I. F. circuits only. Under the designation "Manual On" pushed in.

- 2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator tube, a modulated signal of 455 kilocycles from the signal generator; using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or the ground binding post.

Now, noting from Figure 1, the alignment adjustments for the First, Second, and Third I. F. Discriminator transformers, align the I. F. circuits in the following order:

- Secondary of Third I. F. Discriminator transformer for maximum output.
Primary of Third I. F. Discriminator transformer for maximum output.
Secondary of Second I. F. Discriminator transformer for maximum output.
Primary of Second I. F. Discriminator transformer for maximum output.
Secondary of First I. F. Discriminator transformer for maximum output.
Primary of First I. F. Discriminator transformer for maximum output.

Carefully make all of the above adjustments, watching the output meter so that the peak reading is obtained for each adjustment. As each adjustment is made reduce the output of the test oscillator as required.

Adjustment of the Discriminator Circuit

- 1. Before making this circuit adjustment be sure that the I. F. amplifier and signal generator are exactly in resonance at 455 kilocycles.

All controls should be set the same as instructed for the intermediate frequency adjustments. Connect a high resistance voltmeter having a resistance of at least 100,000 ohms in series with the secondary of the No. 6A8 modulator tube, and the primary of the I. F. discriminator transformer. The voltmeter should be connected in the same manner as connected when making the aligning adjustments of the intermediate frequency amplifier.

Tuner Data

STROMBERG-CARLSON TEL. MFG. CO. Alignment, Part 2 Voltage, Tuner Data

Voltage, Tuner Data

- 10. After the eight favorite stations' brushes have all been positioned in the commutator's slot as mentioned in paragraphs 7, 8, and 9 above, the tuning screw of the tuning indicator. Remove the metal cap from the tuning indicator unit to rest on the chassis base with the end of the tuning indicator tube facing the rear of the receiver.
11. Repeat the operation mentioned in paragraph 7 above, for the favorite station having the highest frequency, being careful to obtain exact resonance with this station by adjusting the tuning indicator. When resonance with this station is obtained, watch the aperture appearing on the tuning indicator tube and push in the button which is located under the station's letters (dial illumination ceases and station letters become illuminated). If the aperture of the tuning indicator changes, move the adjustable station brush slightly in either direction and recheck for resonance by switching back to the tuning indicator tube. When the station is obtained where there is no change in the aperture of the tuning indicator tube when the station is switched from manual to electric tuning.
12. Proceed to check the settings of the adjustable station brushes for the remaining seven chosen stations according to frequency in exactly the same manner as mentioned in 11, above.

When this has been accomplished, again mount the tuning indicator unit into its proper operating position. This completes the operations necessary for setting up the eight favorite stations. IMPORTANT: With the electric tuning system in operation, the receiver will be automatically kept in tune with any one of the eight favorite stations as long as the station is operating or provided it has the proper characteristics. If a distant station which is very weak is set up in the electric tuning unit, it will be tuned in. The control circuit will not hold this station if a strong signal is present in either adjacent channel. This condition is normal. The receiver in adjacent channels are almost of equal signal strength with the weakest signal fading slightly. This condition the strong signal will have a tendency to "pull in" when the receiver is tuned to the station which is slightly weaker and fading.

Table with columns: Tube, Circuit, Cap, Terminals of Sockets (1-8), Heater Voltages Between Heater Terminals (Socket Numbers, Volts). Rows include R. F. Amp., Modulator, Oscillator and Control, 1st I. F. Amp., 2nd I. F. Amp., Demodulator and A. V. C., Discriminator, Bass Amp., Audio Amp., Audio Inv., Audio Output, Audio Output, Tuning Ind., Rectifier, and Speaker Socket.

Receiver tuned manually to 1000 kc., no signal. A. C. voltages are indicated by italics.

7

- 1. Operate the Range Switch on the receiver chassis to the Standard Broadcast ("A") range position and set the test oscillator's frequency and the receiver's tuning dial pointer to 1.5 megacycles.
2. Adjust the receiver's oscillator "A" range H. F. aligner for maximum output.
3. Adjust the R. F. interstage "A" range H. F. aligner for maximum output.
4. Adjust the Bi-Resonator's aligner for maximum output.
5. Adjust the antenna's "A" range H. F. aligner for maximum output.
6. Set the test oscillator's frequency and the receiver's tuning dial pointer to 0.6 megacycles.
7. Adjust the receiver's oscillator "A" range L. F. aligner for maximum output.
8. Repeat both the test oscillator's frequency and receiver's tuning dial pointer to 1.5 megacycles and repeat operations Nos. 2, 3, 4, and 5.

Adjustment of 10 Kilocycle Audio Cut-Off Filter

The adjustment of this filter is correctly made at the factory and no additional adjustment is required.

INSTRUCTIONS FOR SETTING UP ELECTRIC TUNING SYSTEM

Before proceeding with setting up the eight favorite broadcast stations for electric tuning, it is preferable that the radio receiver be turned "on" for approximately twenty minutes. This is accomplished by simply pushing in the push button immediately below the designation, "Manual On" (indicated by illumination of the dial).

- 2. Check the position of the "Trouble" control knob. When setting up or tuning in stations, this control knob should be set at the "Normal" position (pointer on knob pointing in direction of gold dot).
3. Set the Range switch control knob to the "Broadcast" position (pointer on knob pointing in direction of gold dot).
4. Remove the lists of station letters from the P-26781 package assembly which is tacked inside of the cabinet.

The five screws which hold the electric tuning escutcheon plate (metal plate) to the electric tuning escutcheon. Then, remove from the escutcheon, the strip of transparent material and the strip of paper on which the eight stars are printed.

From the lists of stations, remove the call letters of the eight stations which it is desired to set up for electric tuning. These eight stations should preferably be selected and set up in the daytime so that the best service will be obtained at all times.

CAUTION: When setting up these stations it is necessary to see that the separation of these stations on the dial is sufficient to allow adjacent "Adjustable Station Brushes" to be properly located in the desired station letters. In setting up these eight favorite stations, the following order should be followed: Looking at the front of the receiver, the station letters of the station having the highest frequency should be inserted into the farthest left-hand square of the escutcheon. Then, in successive order, according to the frequency, insert the station letters of the station into the other seven squares of the escutcheon, the station letters of the station having the lowest frequency being inserted into the farthest right-hand square of the escutcheon.

After the eight station call letters have been inserted into the escutcheon, the transparent strip should be replaced over the station call letters, and the escutcheon plate then fastened into its position on the electric tuning escutcheon by means of the three screws.

The tuning adjustments for the eight favorite stations can now be made, starting with the station having the highest frequency and proceeding as follows:

- 7. With the Range switch control knob set to the "Broadcast" position, and the "Manual On" button pushed in, tune the receiver in the conventional manner by means of the "Manual Stations" (Station Selector) control knob to that station having the highest frequency. IMPORTANT: When manually tuning a station, and then setting up a station in the electric tuning escutcheon, resonance with the desired station should always be obtained by observing the tuning indicator.

Facing the rear of the receiver, it will be observed that the commutator assembly located on the rear of the tuning escutcheon has eight brushes, each with a dial pointer. After manually tuning in the favorite broadcast station as mentioned in paragraph 7 above, it will be seen that the commutator dial's pointer also indicates the frequency of the station; now, slide the "Adjustable Station Brush" (which is nearest to the high frequency end of the commutator dial) in the slot until it is directly in line (and centered) with the end of the commutator's dial pointer.

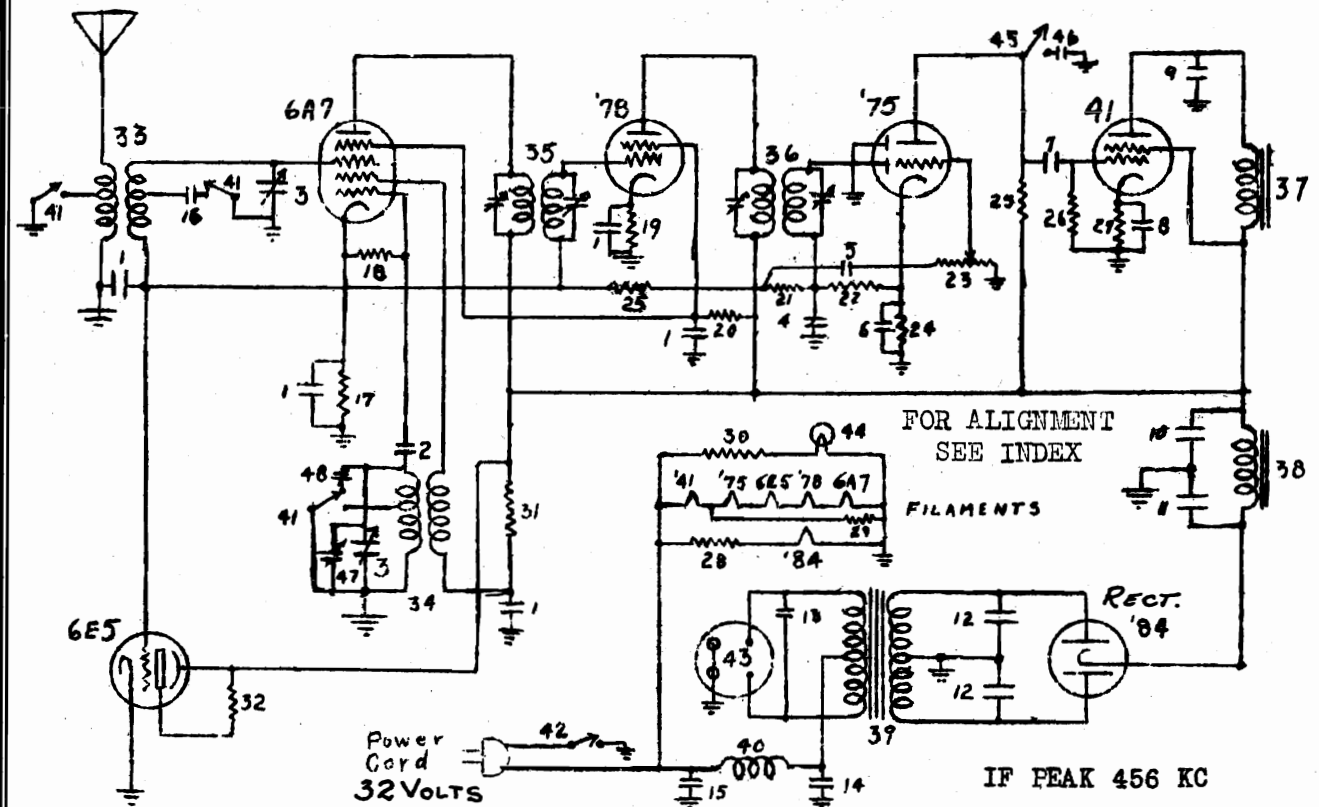

Now, in successive order, according to frequency, proceed to set up the remaining seven favorite stations in the same manner as was mentioned in paragraphs 7 and 8 above for the favorite station having the highest frequency.

When the eight adjustable station brushes have all been set up for the eight stations, the brush nearest to the low frequency end of the commutator's dial should be set at the frequency of the station having the lowest frequency.

Alignment, Socket Trimmers

L'TATRO MFG. CO.

MODELS EQ-39, FQ-39  
MODEL HQ-39  
MODELS SP-67, TP-67  
MODELS AQ-69, BQ-69

**ALIGNMENT PROCEDURE**  
Model AQ-69, BQ-69  
Adjust IF coils to 456 KC.  
Switch to shortwave band; turn dial to 5 MC and adjust trimmer on the rear section of the gang condenser to maximum output.  
Switch to broadcast band and turn dial to 1400 KC. Adjust trimmer connected to switch to maximum output. Track antenna by adjusting trimmer on the antenna section of the gang condenser.  
Switch to shortwave, turn dial to 5 MC and track antenna by adjusting trimmer on top of the antenna coil.

Model RF has the same circuit as the QP plus a tuning eye. The type 6A8G tube has been found to give better oscillator performance than the 6D8G and is used in all Model RF's except those built in the earlier part of the season.

Model HQ-39 may be operated on either 32 volts DC or 110 volts AC. To switch the set for 110 volt operation, the following instructions must be carried out:

1. Disconnect set from 32 volt line.
2. Remove cover from power rack and pull out vibrator.
3. Replace cover and fit switch lever back into slot in switch shaft.
4. Remove screw holding lever and throw switch to right.
5. Reset screw in hole at the right.

If set is inoperative, check fuse. (2 amp. 250 volt. An ordinary car fuse may be substituted). The fuse protects the set from lightning as well as from line voltage overloads.

**ALIGNMENT PROCEDURE**  
Turn dial to closed gang position and make certain that the dial needle coincides with the end of the scale. Turn dial to about midpoint and adjust IF coils to 456 KC.  
Switch to shortwave band, set dial needle to 15 MC and adjust bottom trimmers on antenna and oscillator coils to maximum output.  
Switch to police band (middle band) and set dial at 5 MC. Adjust second trimmers from the bottom to maximum output.  
Switch to broadcast, set dial at 1400 KC and adjust the third trimmers from the bottom. Then adjust the padder located on the front section of the gang condenser. Turn to 600 KC and adjust the top trimmer in the oscillator coil. This is the series tracking condenser.

**ALIGNMENT PROCEDURE**  
Model EQ-39 and FQ-39  
Adjust IF coils to 456 KC.  
Switch to shortwave band; turn dial to 5 MC and adjust trimmer on the rear section of the gang condenser to maximum output.  
Switch to broadcast band and turn dial to 1400 KC. Adjust trimmer connected to switch to maximum output. Track antenna by adjusting trimmer on antenna section of the gang condenser.  
Switch to shortwave, turn dial to 5 MC and track antenna by adjusting trimmer on top of the antenna coil.

Model FQ chassis layout  
Adjust IF coils to 456 KC.  
Switch to shortwave band; turn dial to 5 MC and adjust trimmer on the rear section of the gang condenser to maximum output.  
Switch to broadcast band and turn dial to 1400 KC. Adjust trimmer connected to switch to maximum output. Track antenna by adjusting trimmer on antenna section of the gang condenser.  
Switch to shortwave, turn dial to 5 MC and track antenna by adjusting trimmer on top of the antenna coil.

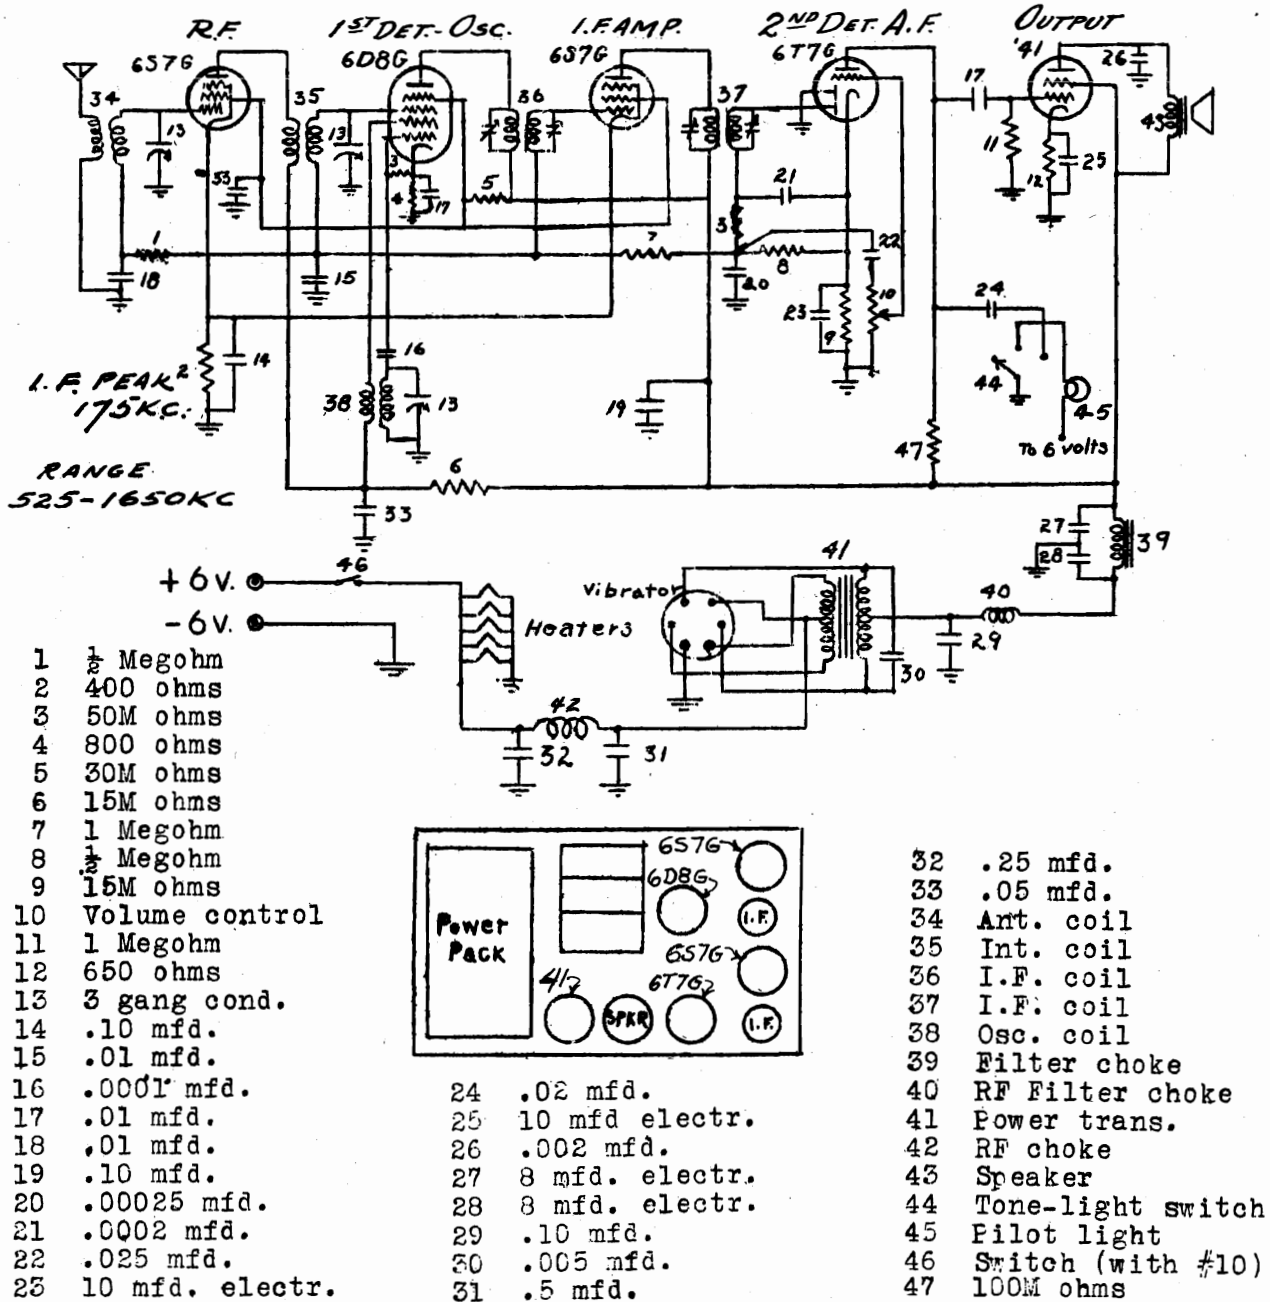

**ALIGNMENT PROCEDURE**  
Turn dial to closed gang position to make certain that the dial needle coincides with the end of the scale. Turn dial to about midpoint and adjust the I.F. coils to 456 KC.  
Switch to shortwave band, set dial needle to 15 MC and adjust bottom trimmers in antenna and oscillator coils to maximum output.  
Switch to police band (middle band) set dial at 5 MC and adjust the second trimmers from the bottom to maximum output.  
Switch to broadcast, set dial at 1400 KC and adjust the third trimmers from the bottom. Then adjust the padder located on the front section of the gang condenser. Turn to 600 KC and adjust the top trimmer in the oscillator coil. This is the series tracking condenser.

The type 6A8G tube has been found to give better oscillator performance than the 6D8G and is used in present production. The switch which turns the tuning eye and dialites off and on is located on the back of the panel.

MODELS NO-65,00-65  
Schematic, Socket  
Trimmers, Alignment

L'TATRO MFG. CO.

**Alignment procedure**

To adjust I.F. coils Oscillator at 175KC to grid of 6D8G tube; adjust I.F. trimmers to maximum output.

To adjust R.F. coils Set oscillator at 1400 KC connect to antenna lead, dial at 1400 KC, adjust oscillator padder located on the rear of the gang condenser, to maximum. Then adjust the two other padders on the gang condenser to maximum output.

**Voltages:** (As measured by a 1000 ohm per. volt meter)

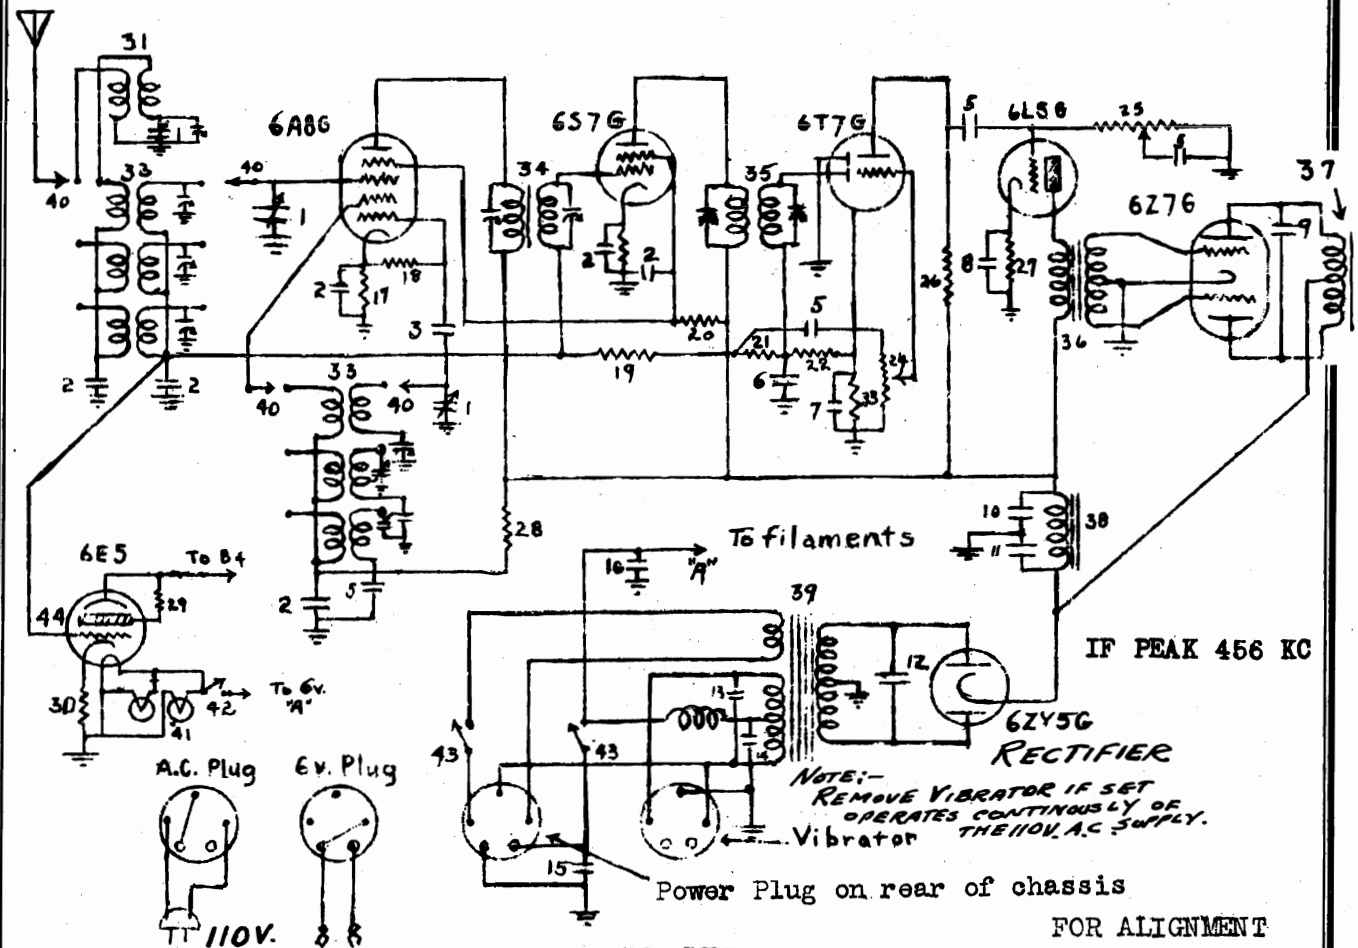

B+ 140 - 150 volts	Cathode voltages
Anode grid 6D8G 60-70 v.	6S7G's 2 volts
Plate RF 6S7G 60-70 v.	6D8G 2.5 volts
Screens 6D8G & 6S7G 50-60 v.	6T7G 1 volt
	41 11 volts

Voltages on the Model NO(table model) are somewhat lower than the above. Some changes in circuit constants in sets built prior to Aug. 1937, will be found. "Motorboating on this set can be corrected by separating the grid leads on the gang condenser as far as possible.

L'TATRO MFG. CO.

and oscillator grid of 6A8G	6T7G	.5 v.
Plate 6T7G	6L5G	.5 v.
Screens 6A8G and 6S7G		

Voltages when set is on AC are higher.

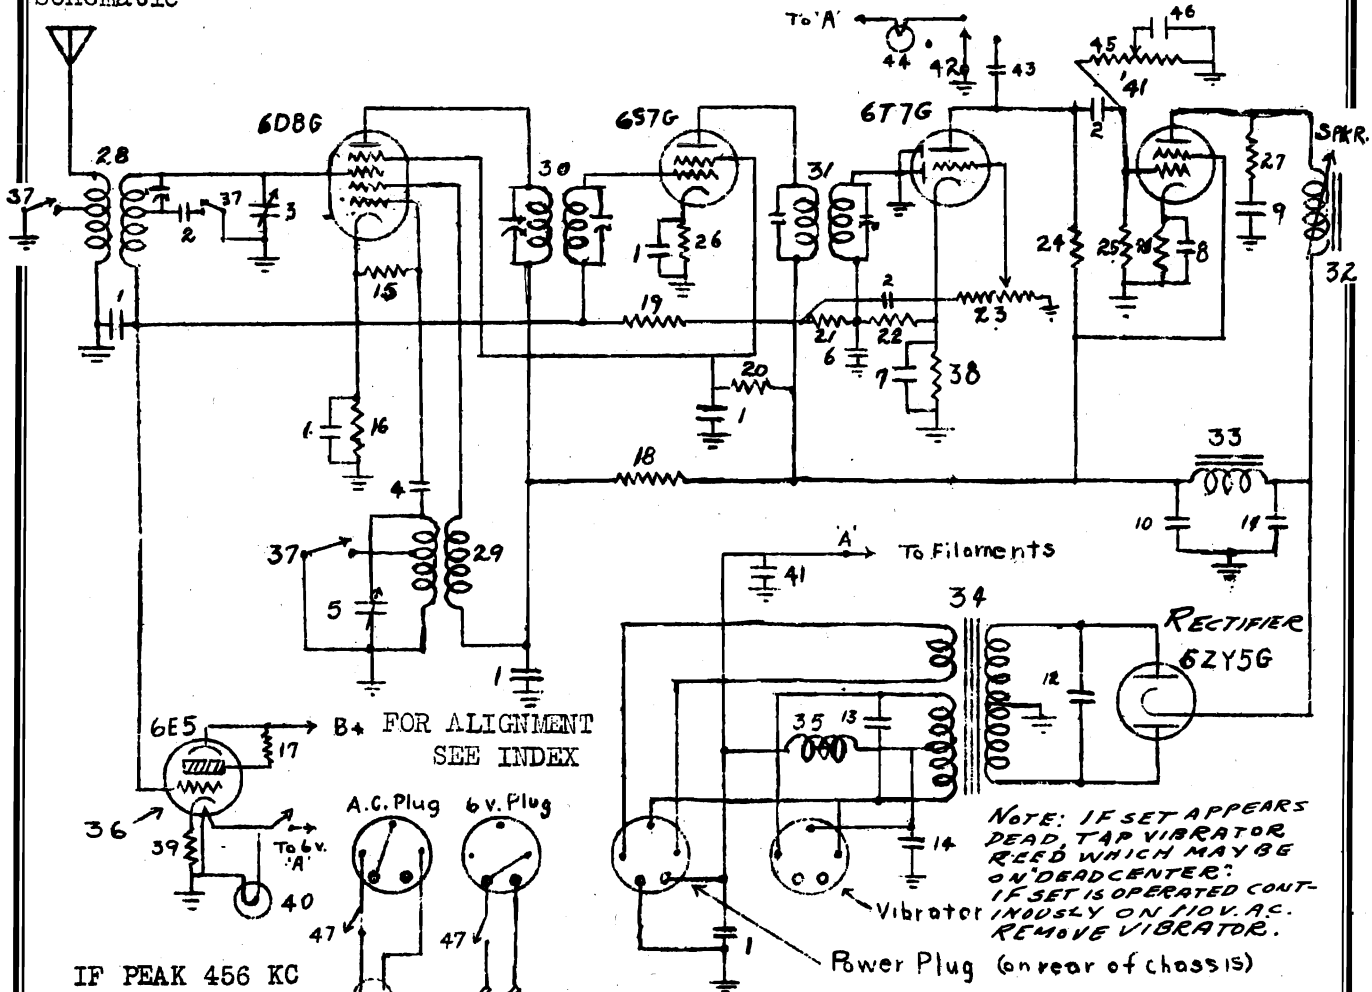

1	Gang condenser	16	.25 mfd.	31	Preselector coil
2	.10 mfd.	17	400 ohms	32	Antenna coil
3	.00025 mfd	18	25M ohms	33	Oscillator coil
4	.002 mfd.	19	1 megohm	34	Iron core I.F.
5	.01 mfd.	20	50M ohm	35	I.F. coil
6	.00025 mfd.	21	25M ohm	36	Input trans.
7	10 mfd. electr.	22	1/2 megohm	37	Speaker
8	5 mfd. electr.	23	5M ohms	38	Filter choke
9	.0025 mfd.	24	1/2 meg. control	39	Power trans.
10	8 mfd. electr.	25	Tone control	40	Band switch
11	16 mfd. electr.	26	1/4 megohm	41	Pilot lights
12	.005 mfd. 1600 v.	27	1500 ohms	42	Tuning eye and dialite switch
13	10 mfd. electr.	28	10M ohms	43	Power switch
14	.5 mfd.	29	1/2 megohm.	44	Tuning eye
15	.10 mfd.	30	1500 ohms		

The TP-67 is a console model; the SP-67 is a table model. The antenna should be as high as possible and about 100 feet long. A good ground is essential for good reception. The blue wire from the set is the antenna lead. If the set is to be operated on 110 volts continuously, the vibrator should be removed.

TRANSFORMER CORP. OF AMER.

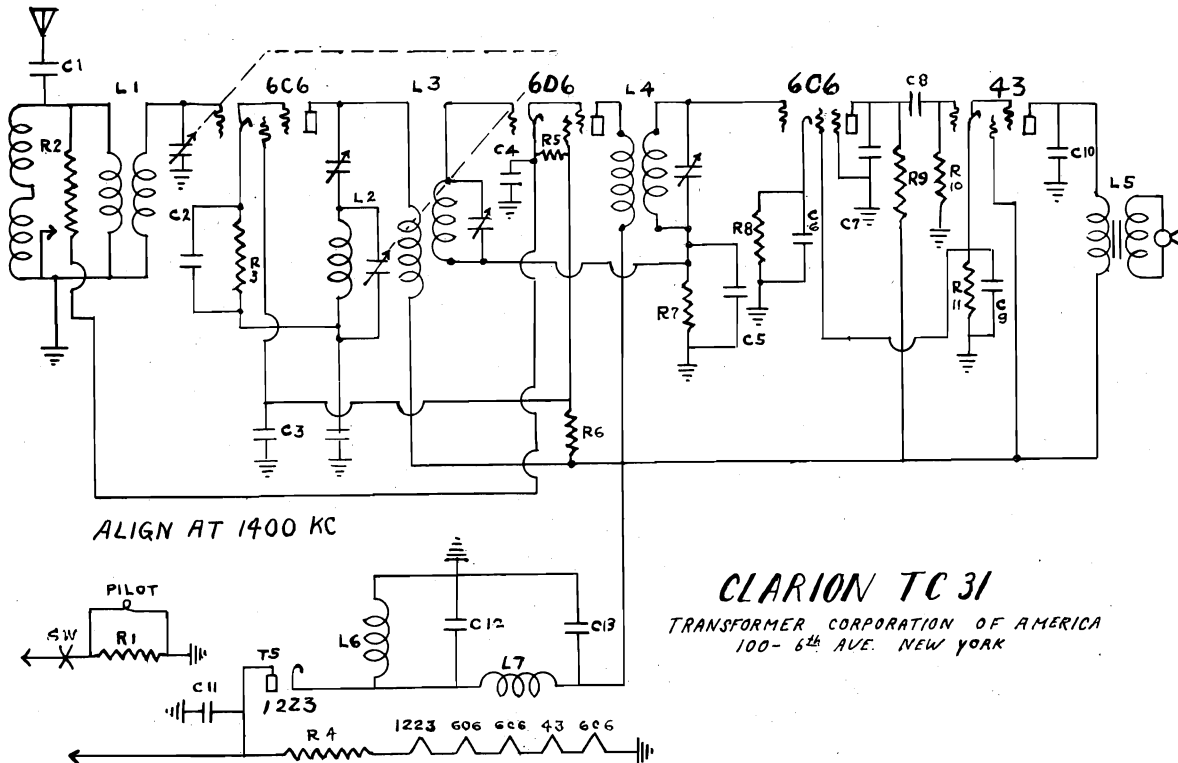

MODEL TC-31  
Schematic  
Alignment

**SERVICE SUGGESTIONS**  
CIRCUIT: The receiver uses a superhet circuit. The tubes used are: type 6C6 as oscillator and modulator, a type 6D6 in the I.F. stage, a type 6C6 as second detector and audio amplifier and a type 43 output tube. The I.F. is 456 K.C.

ALIGNING THE SET: Only in rare cases will it be found necessary to adjust any trimmers. If the volume is low, everything else should be checked before attempting to align the set. The only case where the fault is in the alignment is when both low volume and poor selectivity are present. To align the I.F.: set the test oscillator to 456 K.C. and connect it to the grid of the first 6C6 tube and adjust the upper screw on the first I.F. transformer and the screw on the second I.F. (small round can) for maximum output. Now set the test oscillator to 1400 K.C. The signal should come in between 15 and 20 on the dial. Adjust the two trimmers on the tuning condenser for maximum output. Check at 600 K.C. The lower trimmer on the first I.F. transformer is the oscillator coupling condenser and should not be changed.

SUPPLY VOLTAGE

This receiver operates from any 110 volt light socket of any frequency AC or straight DC. When operating on a DC socket, the plug may have to be reversed in the socket to obtain the correct polarity, as it will work only in one position on DC current.

IF Peak

MODEL 645 E

CURRENT SUPPLY

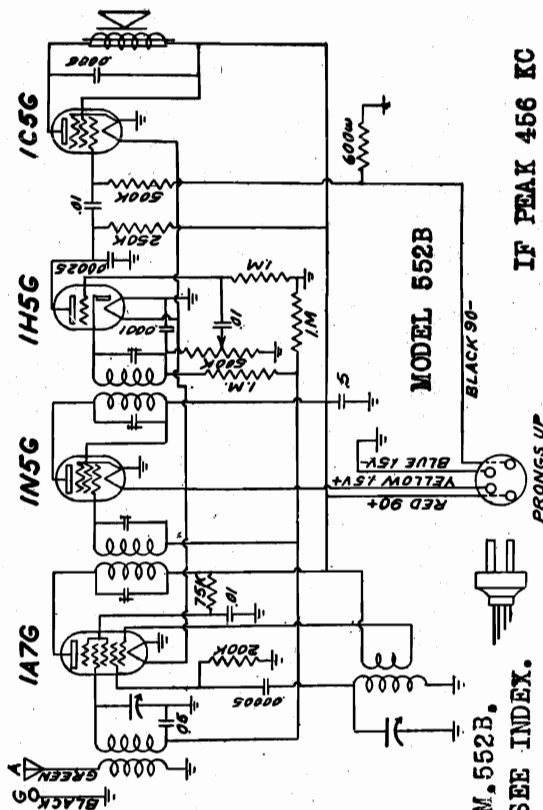

The current supply switch at the rear of the chassis must be set to 115 or 230 volts to correspond to the available current and should never be changed while that current is being used! Be absolutely sure this switch is set right before you plug in the radio. If it is set for 115 volts and 230 volts is used, the transformer will burn out.

Tuner Data

**ALIGNMENT:** 8 TUBE BATTERY OR A.C. and MODEL 539M.

**I. F. ALIGNMENT**

From a good signal generator, connect the proper leads, one to the radio chassis, the other thru a .1 mfd. condenser to the grid cap of the 6K8 with the set's grid lead still in place. Set the radio dial to 1720 K.C. and the signal generator to 456 K.C. With the set's volume control full on, increase the generator output until the signal is heard in the radio speaker. Adjust the I.F. trimmers for maximum output, starting with the third I.F. and working back. Decrease the generator output as the speaker output increases.

**LONG WAVE ALIGNMENT**

Connect the signal generator lead thru a .0002 mfd. condenser as dummy antenna, to terminal "A1," with the metal strip connected across A2 and G. Set the dial and generator to 362 K.C. and adjust the L.W. oscillator trimmer for maximum output. Align the L.W. RF and ANT trimmers at 320 K.C. Align the L.W. oscillator pad for maximum output at 200 K.C. by adjusting the dial and padder together. Check the alignment again at 320 K.C.

**BROADCAST BAND ALIGNMENT**

Using the .0002 mfd. condenser as dummy antenna, adjust the B.C. oscillator trimmer at 1720 K.C. Align the RF and ANT trimmers at 1400 K.C. Align the B.C. oscillator padder at 600 K.C. by adjusting the dial and padder together. Check the alignment again at 1400 K.C.

**INTERMEDIATE BAND ALIGNMENT**

Using a 400 ohm resistor as dummy antenna, adjust the Intermediate Band oscillator trimmer at 6.7 M.C. and the R.F. and Antenna trimmers at 6 M.C.

Check for alignment at 2.2 M.C.

**SHORT WAVE BAND ALIGNMENT**

Using the 400 ohm resistor as dummy antenna, adjust the S.W. oscillator trimmer at 24.5 M.C., and the R.F. and Antenna trimmers at 22 M.C.

Check for alignment at 8 M.C.

**NOTICE**

If a Standard All Wave dummy Antenna is available, it should be used in place of the .0002 mfd. condenser, and the 400 ohm resistor. On all bands the oscillator trimmers are adjusted with the variable condenser full open.

**ALIGNMENT:** MODELS 6Tube Battery or A.C., 437M, 436M, 466M, 465M, 536M, and 645E.

**NOTE:** No intermediate band on Models 465M and 466M.

**I.F.** From a good signal generator, connect the proper leads, one to the radio chassis, the other thru a .1 mfd. condenser to the grid cap of the 6K8 with the set's grid lead still in place. Set the radio dial to 1720 K.C. and the signal generator to 456 K.C. With the set's volume control full on, increase the generator output until the signal is heard in the radio speaker. Adjust the I.F. trimmers for maximum output, decreasing the generator output as the speaker output increases.

**B.C.1.** Connect the signal generator lead thru a .0002 mfd. condenser as dummy antenna to the "A1" terminal, with the metal strip connected across A2 and G. Set the signal generator and radio dial to 1720 K.C. and adjust the B.C. oscillator trimmer for maximum output.

2. Set the signal generator and radio dial to 1400 K.C. and adjust the B.C. R.F. and ANT. trimmers for maximum output.

3. Set the signal generator to 600 K.C. and the radio dial to approximately 600 K.C., and adjust the B.C. oscillator padder for maximum output by adjusting dial and pad together.

Check the alignment again at 1400 K.C.

**I.N.T.** Connect the signal generator lead thru a 400 ohm resistor as dummy antenna to A1. Set the dial and generator to 6700 K.C. and adjust the P.B. oscillator trimmer for maximum output. Adjust the R.F. and ANT. trimmers at 6000 K.C. and check for alignment at 2200 K.C.

**S.W.** Still using the 400 ohm resistor as dummy antenna, adjust the S.W. oscillator trimmer at 24.5 M.C. on dial and generator. Adjust the R.F. and ANT. trimmers at 22 M.C. and check for alignment at 8. M.C.

**ALIGNMENT: 6 TUBE AUTO RADIO**

1. Set variable condenser with rotor plates in open position. Set signal generator to 268 kc., connect generator lead to grid cap of 6A7 using a .1 mfd. condenser as a dummy antenna. Adjust IF trimmers for maximum output, reducing signal generator output as signal increases.
2. Set signal generator to 1620 kc., connecting generator lead to antenna lead on set using a .00025 condenser as dummy antenna. Rotate oscillator trimmer until signal is picked up. Set generator at 1400 kc., pick up signal by rotating variable condenser then adjust RF and antenna trimmers for maximum signal, reducing generator output as speaker signal increases. Set signal generator to 600 kc., rotate variable condenser to pick up signal then adjust for maximum sensitivity by rotating oscillator padder while rocking variable condenser.
3. Recheck alignment adjustments at 1620 and 1400 kc.

**PUSH BUTTONS;** MODELS 6 and 8 Tube Battery or A.C., 425, 426, 436M, 437M, 465M and 466M.

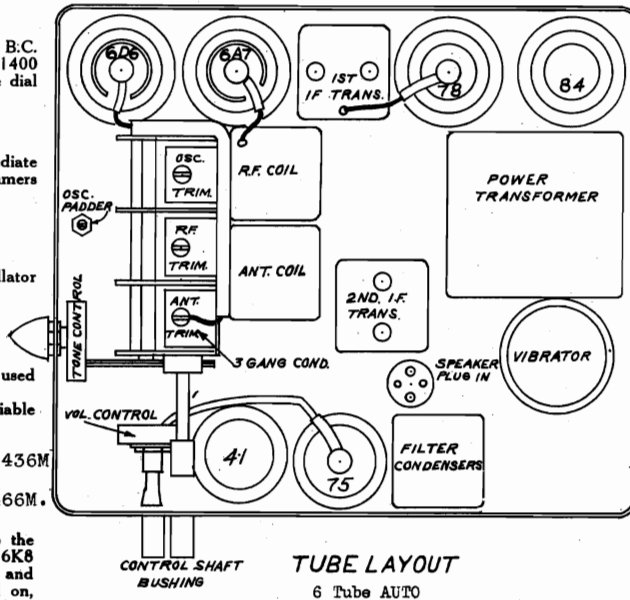

Six Push Button Station Selectors are incorporated in this receiver. Each button may be adjusted to select any station or frequency in the Broadcast Band. To adjust each button, perform the following operations:

1. Tune in a desired station with the Selector knob, watching the eye for the narrowest shadow.
2. Twist the Push button you want set up for this station, to the left about one full turn to loosen the mechanism.
3. Push this Push Button in as far as it will go, while holding the Selector knob firmly so the station will not be detuned.
4. With the Push Button pressed all the way in, twist it to the right until it is tight, and then release it.

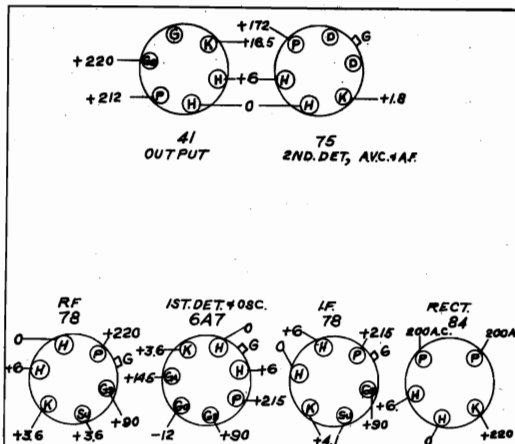

Follow this procedure with the other five Push Buttons, setting each for a different station.

Now, when any button is pushed, the station for which that button is set should become perfectly tuned in. If it is not tuned in perfectly, repeat the above procedure until satisfactory results are obtained.

Select the Call Letter Tabs to correspond to the stations the Push Buttons are set up for, and insert them in the places provided above each button.

**VOLTAGE DATA 6 TUBE AUTO RADIO**

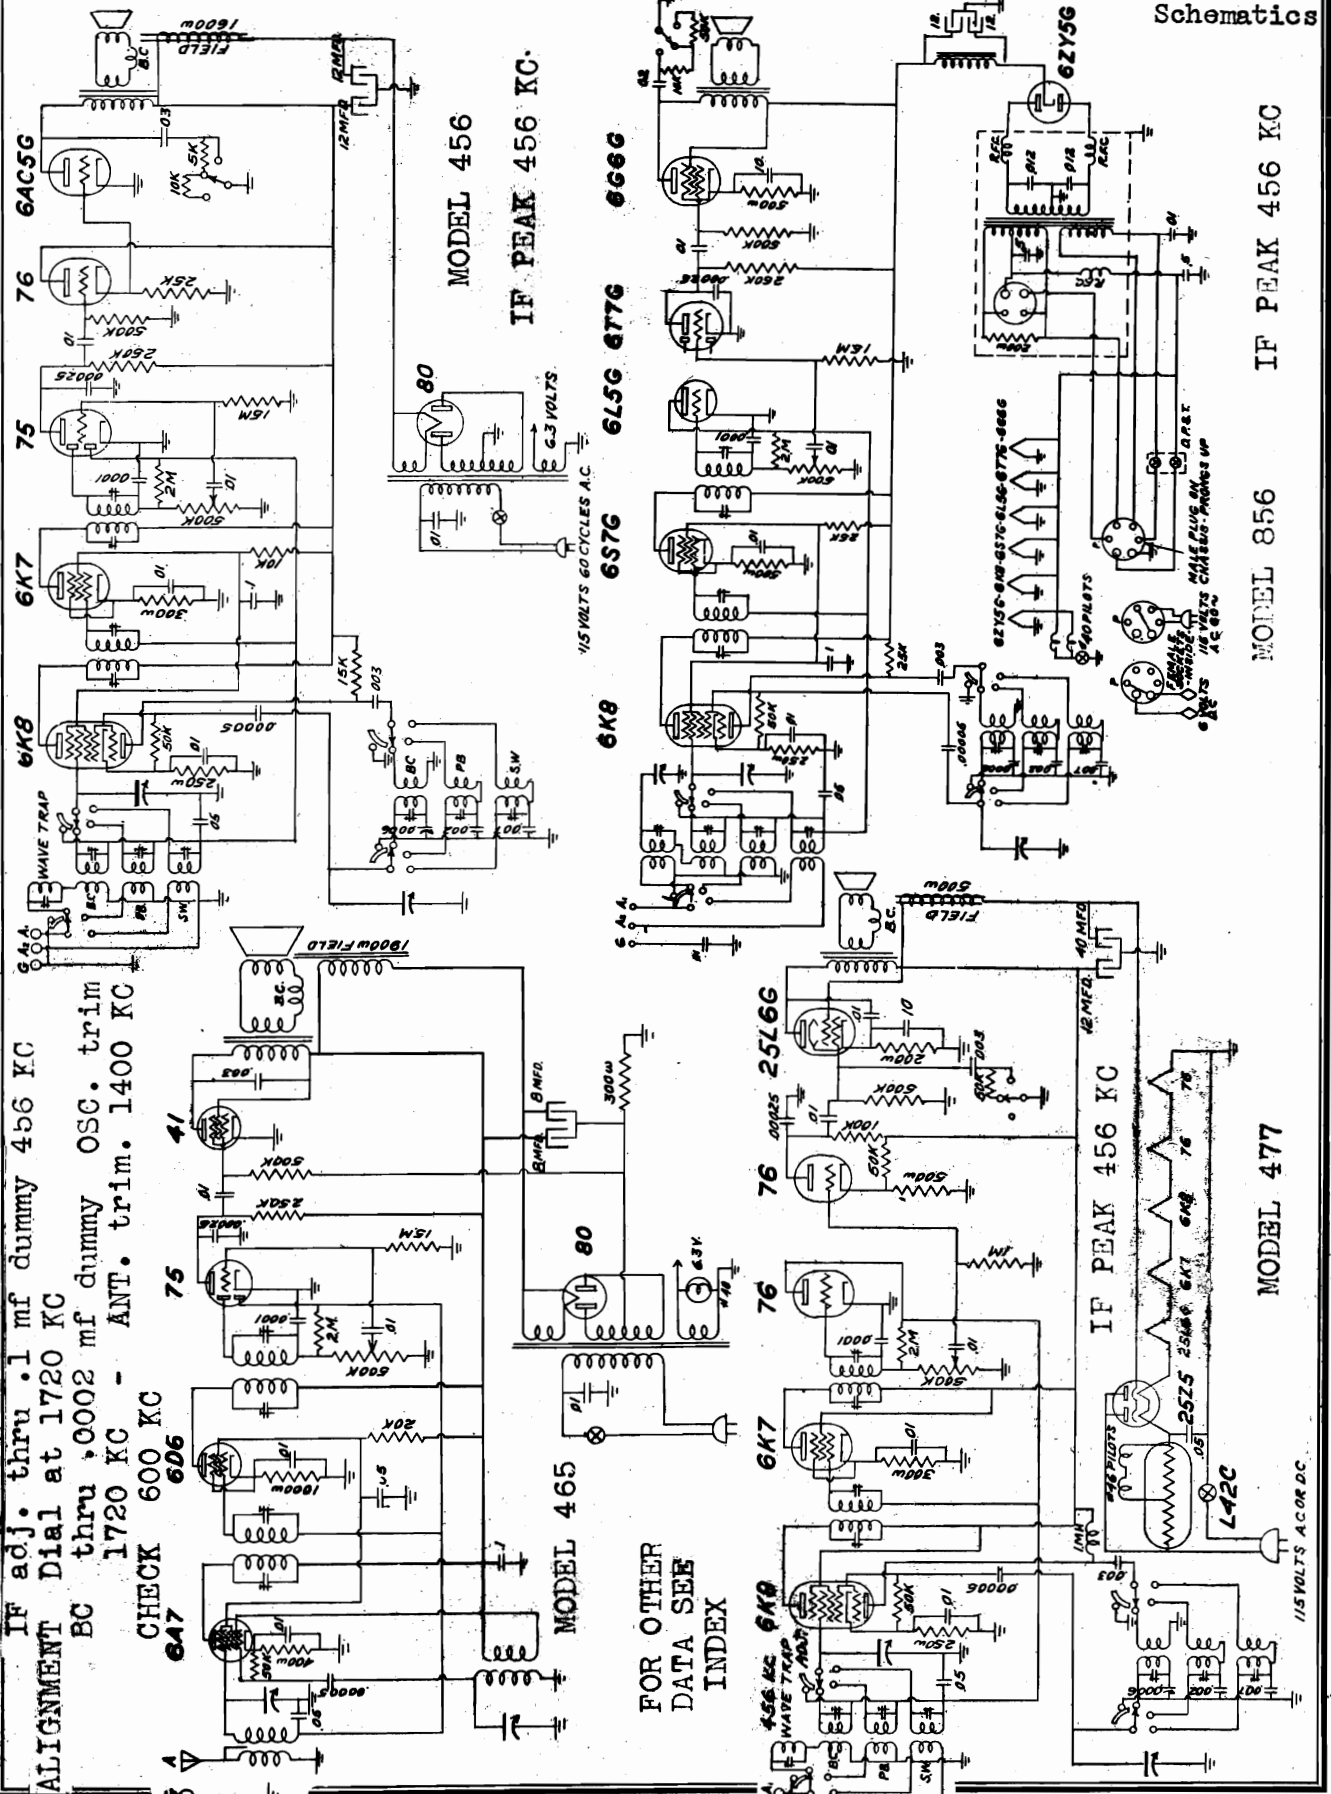

Bottom view of 6-tube auto set showing socket positions and voltages from socket terminals to ground. All voltage measurements taken with volume control at maximum and with no signal applied. Use volt-meter of 1000 ohms per volt.

MODELS 877 & 889  
TECHNICAL INSTRUCTIONS

A good output meter should be used in all alignment adjustments.

I. F. ALIGNMENT

From a good signal generator, connect the proper leads, one to the radio chassis, and the other thru a .1 mfd. condenser to the grid cap of the 6K8, with the tube's grid lead still in place. Set the radio dial to 1720 K.C. and the signal generator to 456 K.C. With the set's volume control full on, increase the generator output until the signal is heard in the radio speaker. Adjust the I. F. trimmers for maximum output, decreasing the generator output as the radio output increases.

LONG WAVE ALIGNMENT

Connect the signal generator lead thru a .0002 mfd. condenser as dummy antenna, to the "A" terminal, with the metal strip connected across A<sub>1</sub> and G<sub>1</sub>. Set the dial and generator to 362 K. C. and adjust the oscillator trimmer for maximum output. Align the L.W., R.F. and antenna trimmers at 320 K.C.

Align the L.W. oscillator padder at 200 K.C. by adjusting the dial and padder together. Check the alignment again at 320 K.C.

BROADCAST BAND ALIGNMENT

Using the .0002 mfd. condenser as dummy antenna, adjust the B.C. oscillator trimmer at 1720 K.C. for maximum output. Align the R.F. and antenna trimmers at 1400 K.C. Align the B.C. oscillator padder at 600 K.C. by adjusting the dial and padder together. Check the alignment again at 1400 K.C.

INTERMEDIATE BAND ALIGNMENT

Using a 400 ohm resistor as dummy antenna, adjust the Intermediate Band oscillator trimmer at 6.7 M.C. and the R.F. and Antenna trimmers at 6 M.C.

Check for alignment at 2.2 M.C.

SHORT WAVE BAND ALIGNMENT

Using the 400 ohm resistor as dummy antenna, adjust the S.W. oscillator trimmer at 24.5 M.C., and the R.F. and Antenna trimmers at 22 M.C. Check for alignment at 8 M.C.

MODELS 487, 456, 477, & 856

TECHNICAL INSTRUCTIONS

A good output meter should be used in all alignment adjustments

I. F. ALIGNMENT

From a good signal generator connect the proper leads, one to the radio chassis, the other thru a .1 mfd. condenser to the grid cap of the 6K8, with the set's grid lead still in place. Set the radio dial to 1720 kilocycles and the signal generator to 456 K.C. With the set's volume control "full on," increase the generator output until the signal is heard in the radio speaker. Adjust I. F. trimmers for maximum output, decreasing the generator output as the speaker output increases.

B. C. ALIGNMENT

1. Connect the signal generator lead thru a .0002 mfd. condenser as dummy antenna to the "A1" terminal, with the metal strip connected across A2 and G. Set the signal generator and radio dial to 1720 K.C. and adjust the B.C. oscillator trimmer for maximum output.

2. Set the signal generator and radio dial to 1400 K.C. and adjust the B.C. R.F. and ANT. trimmers for maximum output.

3. Set the signal generator to 600 K.C. and the radio dial to approximately 600 K.C., and adjust the B.C. oscillator padder for maximum output by adjusting dial and pad together.

Check the alignment again at 1400 K.C.

INTERMEDIATE BAND ALIGNMENT

Connect the signal generator lead thru a 400 ohm resistor as dummy antenna to A1. Set the dial and generator to 6700 K.C. and adjust the P.B. oscillator trimmer for maximum output. Adjust the R.F. and ANT. trimmers at 6000 K.C. and check for alignment at 2200 K.C.

SHORT WAVE ALIGNMENT

Still using the 400 ohm resistor as dummy antenna, adjust the S.W. oscillator trimmer at 24.5 M.C. on dial and generator. Adjust the R.F. and ANT. trimmers at 22 M.C. and check for alignment at 8 M.C.

MODELS 456, 465, 477, 856, 877 & 889

PUSH BUTTON OPERATION

Six Push Button Station Selectors are incorporated in this receiver. Each button may be adjusted to select any station or frequency in the Broadcast Band. To adjust each button, perform the following operations:

1. Tune in a desired station with the Selector knob.
2. Twist the Push Button you want set up for this station, to the left about one full turn to loosen the mechanism.
3. Push this button in as far as it will go, while still holding the Selector knob firmly so the station will not be detuned.
4. With the button pressed all the way in, twist it to the right until it is tight and then release it.

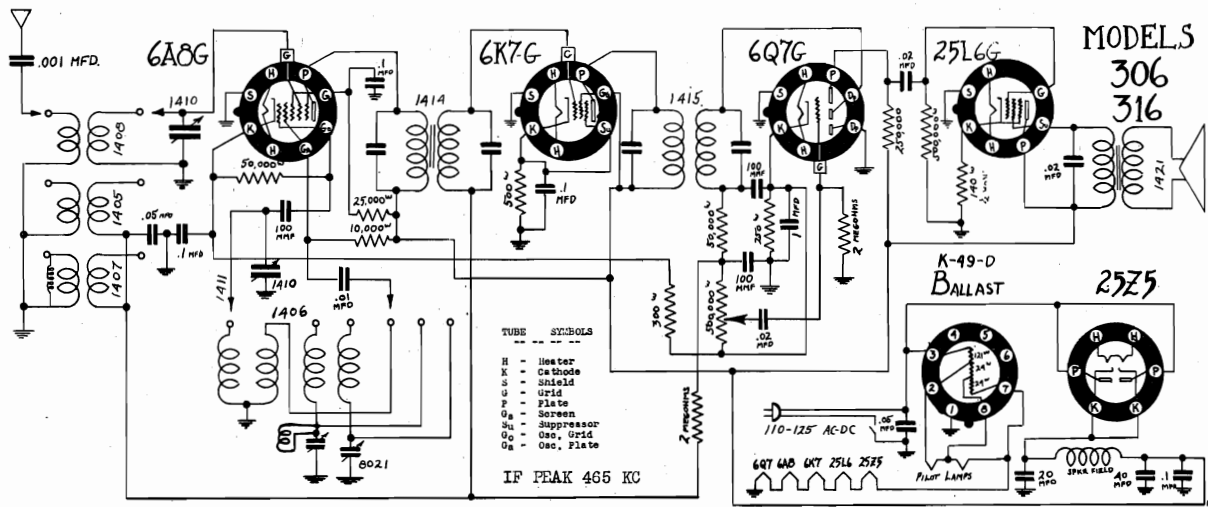

Follow this procedure with the other five buttons, setting each for a different station.

Now, when any Push Button is pressed, the station for which that button is set, should appear perfectly tuned in. If it is not perfectly tuned, repeat the above procedure until satisfactory results are obtained.

Select the Call Letter Tabs to correspond to the stations the buttons are set for, and insert them in places provided above each button.

(c) Repeat adjustments made under "Aligning at 1400 K.C."

5. Checking I-F Band Spread

The Model 165 Cathode Ray Oscillograph should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustment of the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Connect Cathode Ray from connection "I" (Fig. 4) to ground.

FIG. 3--PARTS LAYOUT--Top View

CONNECT CATHODE RAY AT THIS POINT & AT GRD.

FIG. 4--PARTS LAYOUT--Bottom View

ALIGNMENT FOR MODELS R663, R664, R665, R666, R667, R668, and R669.

NOTE:- FIGURE REFERENCES IN THE TEXT REFER TO FIGURES SHOWN WITH EACH MODEL.

1. Aligning I-F Stages at 262 Kilocycles

- (a) Connect the ground lead of the Signal Generator to the chassis case. Connect the signal lead of the Signal Generator to the grid cap of the 6AG6 tube, through a .1 mfd. condenser, leaving the tube's grid clip in place.
- (b) Connect output meter from plate of 6AV6, 6, 7, tube to ground.
- (c) Set Signal Generator to exactly 262 kilocycles and turn volume control on full.

(d) Turn condenser gang to a position where no squeals or beat notes can be noticed, also so that when the tuning condenser is rotated within narrow limits there is no appreciable change in output.

(e) Adjust trimmers A-E-D through the cut outs on the side of the chassis (illus. 13 & 14, Fig. 4) carefully for maximum output.

(f) Repeat adjustments of I-F trimmers A-E-C-D with as low an output from the Signal Generator as possible, for more accurate alignment.

2. Aligning at 1530 Kilocycles

(a) Leave Signal Generator leads connected the same as for I-F adjustments.

(b) Turn tuning condenser plates all the way out and against high frequency stop.

(c) Set Signal Generator to exactly 1530 kilocycles and adjust oscillator trimmer "G" (Fig. 3) on middle section of condenser gang carefully for maximum output.

3. Aligning at 1400 Kilocycles

(a) Remove signal lead of Signal Generator from grid cap of 6AG6 tube and connect to antenna terminal of receiver through a .0002 mfd. mica condenser.

(b) Set the Signal Generator to 1400 kilocycles and tune the receiver to this signal.

(c) Adjust the parallel trimmers "F" and "H" (Fig. 3) of the condenser gang carefully for maximum output. Do not disturb the 1530 kilocycle adjustment of the middle section of the condenser gang.

4. Aligning at 600 Kilocycles

(a) Set Signal Generator to approximately 600 kilocycles and turn condenser gang plates until this signal is tuned in with maximum output.

(b) Adjust trimmer "E" on Delco Syncro-Tuning condenser (illus. 12, Fig. 4) located next to antenna receptacle on bottom of chassis, rocking gang condenser plates back and forth through the signal until maximum output is obtained. (It will be necessary to re-adjust this condenser to the car antenna upon installation of the set.)

Operating and Service

Notes, Part 1

**GENERAL:** The Delco Model R-667 is a six tube, two unit auto radio with "Delco-Matic" Flash tuning. The service parts and alignment procedure are identical to the Delco Model R-666.

The Delco Model R-669 is a seven tube, two unit auto radio with "Delco-Matic" Flash tuning. The service parts and alignment procedure are identical to the Delco Model R-666.

SETTING-UP "DELCO-MATIC" TUNER

- (a) Press a button and allow the selector mechanism to come to rest.
- (b) Continue to hold the button down, and tune in the desired station by manual control.
- (c) Release button, and set up remaining buttons in the same manner.

When the button is held down after the mechanism has come to rest, the pawl is held in the cam slot, locking the cam in position. The cam is allowed to slip on its shaft during the manual tuning process, by a clutch spring which is a part of the cam shaft assembly.

OPERATION OF "DELCO-MATIC" TUNER

The "Delco-Matic" Tuner is a motor driven mechanical device for tuning in stations quickly and silently by remote push button control. When a button is depressed, a relay coil pulls a corresponding pawl against a selector cam (Fig. 1). At the same time, a hold down coil in the control head holds the button down until the cycle of operation is complete. A trigger on the pawl presses against a switch operating trip rod, which in turn operates the power switch. The degree of movement of the trip rod, which is controlled by a high and low side on the selector cam, determines the direction of motor rotation. When the cam is rotated to a position where the pawl drops into the selector cam slot, the degree of movement of the trip rod opens the ground contact on the power switch which cuts the current to the motor and magnetic clutch and releases all relays.

1. PUSH BUTTON HEAD

The push buttons in the control head complete the circuit for the operation of the hold-down magnet, master relay and the corresponding station selector magnet. The buttons are held down magnetically until released by the "cut-off" switch on the tuner unit, actuated by the station selector pawl dropping into the slot in the selector cam.

2. STATION SELECTOR PAWLS

The station selector pawls are magnetically operated and controlled directly from the contacts in the push-button head. Upon pressing a button in the control head, a circuit is closed, energizing a station selector magnet coil which pulls a corresponding pawl down on a station selector cam. The pawl rides on the cam until it drops into the cam slot and cuts the motor off and releases all relays.

3. STATION SELECTOR CAMS

The station selector cams are circular discs with high and low sides for operation of the motor reversing switch and a stop slot for operation of the motor cut-off switch. Six of these cams are provided on a shaft, each with a friction clutch which allows the cam to be slipped on the shaft in setting the cam on the desired station.

4. REVERSING AND CUT-OFF SWITCH

The reversing and cut-off switch is a combination switch actuated by the trigger on the station selector pawl. The reversing switch causes the motor to run in the right direction for direct to the station tuning and the cut-off switch cuts the motor off when a station is tuned in, and also releases the push-button hold-down magnet and the magnetic clutch.

The forward and reverse positions of the reversing switch are dependent upon whether the station pawl is pulled against the high or low side of the station selector cam. The cut-off switch is actuated when the pawl drops into the cam slot as a station is tuned in.

5. MAGNETIC CLUTCH

The magnetic clutch consists of an electro magnet and two iron discs which are held together magnetically when the field is energized. One of the discs is coupled to the motor and the other to the condenser gang.

The clutch is designed to cut the motor driving power from the tuning condenser gang at the same instant the pawl drops into the cam slot and actuates the motor cut off switch.

6. MASTER RELAY

The master relay is controlled directly from the push-button head and the purpose is to allow the motor current to be fed directly to the motor rather than through the push-button circuits. A set of "mute" contacts are provided along with the "A" power contacts for muting the audio system of the set while the motor is driving the tuning mechanism.

SERVICE PROCEDURE

The logical procedure to employ in servicing the automatic tuner will depend to a large extent upon the nature of the trouble encountered and

whether the tuner is partially or totally inoperative. However; in most cases the solution to the trouble will be found by checking the below points in the order named:

1. TUNING CONTROL and CABLE
2. BATTERY VOLTAGE AT TUNER
3. STATION SELECTOR PAWLS
4. PUSH BUTTON HEAD
5. REVERSING AND CUT-OFF SWITCH

The tuning control and tuning cable should be checked along with the battery voltage at the "A" terminal on tuner before removing chassis or push button head from car for servicing on the bench. Make all checks on bench with a tuning control connected to the tuner for proper procedure. Detailed procedure for checking the above points is as follows:-

Checking Tuning Control and Cables

In order for the automatic tuner to operate properly it is necessary that the tuning control be free from kinks and binds, so as not to impose an excessive load on the tuner motor. Turn tuning control knob manually and note if drag is excessive or if any kinks or binds are apparent. If trouble is evident, disconnect flexible tuning cable from chassis case bushing and turn tuning knob to determine whether trouble is in set or tuning control. If trouble is in set, a careful check of the large die-cast gears should be made for proper meshing.

Checking Battery Voltage at "A" Terminal on Tuner

The magnets, relays and the motor in the automatic tuner have been designed to operate satisfactorily on voltages as low as 4.5 volts measured at the "A" terminal on the tuner unit with the motor running. Low battery voltages will cause erratic operation of the tuner.

BEFORE ATTEMPTING ANY TUNER REPAIRS, FIRST MEASURE THE "A" VOLTAGE AT THE LARGE "A" TERMINAL ON THE TUNER UNIT WITH THE TUNER MOTOR OPERATING. In order to allow the motor to run long enough to get an accurate reading before it cuts off, set two cams which appear to be working normally at opposite ends of the dial and press corresponding buttons, reading meter carefully while motor is running. If voltage is lower than 4.5 volts, check all connectors and terminals for poor contact. Measure voltage at car ammeter with set load only. This should be 5.5 volts or more.

NOTE: In testing these automatic tuners on UMS Radio Test Panels, it is very important that proper voltage be available for test, otherwise incorrect diagnosis of the trouble will be made. A heavy duty battery and a Power Unit should be used. Also, all connections should be clean and heavy "A" supply leads used for connecting sets to "A" supply terminals. On the #552 Test Panel it is recommended that all automatic tuner tests be made using the power supply terminals on the left side of the panel. This will give a slightly higher "A" voltage to test.

Checking Station Selector Pawls

In most instances a visual inspection will determine if the station selector pawls are operating satisfactorily. A check can be made by simply pressing the push buttons and noting if the corresponding pawls pull down against the selector cam. Failure of the pawl to operate may be caused by excessive spring tension on the pawl spring, open selector magnet circuit or low voltage.

To reduce spring tension on pawl spring, unhook top end of spring with a pair of long nose pliers and stretch spring slightly. Be careful not to stretch spring too far or pawl will have a tendency to stick in the cam slot when a station is tuned in.

Voltage measured at selector magnet coil terminals on bakelite terminal board should not be less than 4.5 volts.

Checking Push Button Head

The push button head is working normally when the following actions take place.

1. Buttons should stay down magnetically when pressed, until station is tuned in or pawl drops in cam slot.
2. Corresponding station pawl in tuner should pull down against cam.
3. Both the button pressed and its corresponding station pawl in the tuner should release when a station is tuned in or when the pawl drops into cam slot.

It should be noted that buttons will not release unless tuner motor is operating and station pawl trips the cut-off switch.

If push button head does not function as covered above and a duplicate head (Part #1880122) is not available for substitution, make complete check of head as follows with push button cable plug disconnected from receiver-chassis.

UNITED MOTORS SERVICE, INC. Delco-Matic Tuner Service Notes, Part 2

TESTING PUSH BUTTON HEAD

A. MECHANICAL TEST OF PUSH BUTTON HEAD:

- (a) Disconnect push button control plug from receiver chassis.
- (b) Press buttons down and release slowly. Note if any button or buttons have a tendency to stick or do not extend out the full distance when released. Failure of a button to release to the full extent will cause the station selector pawl to stick in the cam slot when a station is tuned in (See Paragraph "C").
- (c) If sticking buttons are encountered, remove the mechanism from the die-cast head, removing the back cover plate and taking out the four round head screws. A small burr on either the small bakelite insulators or the push-button shaft, or in the push button holes in the die-casting or wires touching the button shafts will cause the buttons to stick. Removal of the burrs with fine sandpaper will eliminate this sticking.

NOTE: Do not hold the control head in an inverted position when removing mechanism from case.

B. CHECKING MAGNET FOR HOLD-DOWN

FIG. 5--CONTROL CABLE PLUG Facing Plug

- (a) Remove control cable plug from receiver chassis.
- (b) Connect 4 volts D.C. across prongs #8 and #10 as shown.
- (c) Press buttons one at a time, interrupting battery circuit to release button after each test.
- (d) If none of the buttons will stay down when pressed, make continuity check across prongs #8 and #10 for open circuit in hold down magnet or cable wiring.
- (e) If one or two buttons will not stay down when pressed, first check to see if any wires are caught behind button shafts. If not, then remove mechanism from die-cast head and check for excessive spring tension in switch contact springs or the button shaft kick-out spring.

C. CHECKING PUSH BUTTON SWITCH CONTACTS:

FIG. 6--CONTROL CABLE PLUG Facing Plug

- (a) The switches in the control head start to make contact during the first 1/8" of downward travel. It is, therefore, important that the buttons extend out the full distance when released by the hold down magnet, as covered in the "Mechanical Test of Push-Button Head".
- (b) The switch contacts may be checked by applying 4 volts D.C. across the prongs 8 and 9, pressing each button under test, and interrupting the circuit after each test. Check remaining contacts similarly as follows:

Press Button No.	Apply 4 volts D.C. across--
1	Prong #8 and 1
2	" 8 " 2
3	" 8 " 3
4	" 8 " 4
5	" 8 " 5
6	" 8 " 6

It will be noted that if the switch contacts are making proper contact and all preceding checks made, the hold down magnet in the head will be energized as each button is pressed.

Checking the Reversing and Cut-Off Switch

Proper operation of the switch mechanism on the tuner is of vital importance. Erratic action of the tuner due to low battery voltage very often results in the trouble being erroneously diagnosed as switch trouble. It is therefore important that all other points be checked first for possible causes of the trouble before attempting any adjustments to the switching mechanism.

There are four positions of the switch mechanism, "normal", "pawl on high side of cam", "pawl on low side of cam" and "pawl in slot". Figures 7 to 10 illustrate the exact position of the switch contacts in each of the four switch positions. These contacts can be checked visually by observing their

FIG. 7--NORMAL POSITION

action under actual operating conditions or by disconnecting the "A" power and duplicating the position by pressing the pawls down against the cams manually. Before making any adjustments it should first be definitely known that an adjustment is necessary.

In the normal position it will be noted that one set of reversing contacts are closed and that the ground contact on the switch arm is making contact. Also, there should be a slight gap ("A" on Fig. 7) between the trigger and the trip bar to prevent any movement of the switch arm when the pawl is pressed against the high side of the cam.

FIG. 8--PAWL ON HIGH SIDE OF CAM

In this position the contacts should be in exactly the same position as in the "normal position". The trigger rests against the trip bar but there should not be sufficient movement of the trip bar to open the normally closed reversing contacts at any point on the high side of the cam.

FIG. 9--PAWL ON LOW SIDE OF CAM

In this position the pawl is riding on the low side of the cam and a complete change has taken place in the reversing switch. The set of contacts which were normally closed when the pawl was riding on the high side of the cam have opened and the other set of contacts are now closed. The ground contact on the switch arm remains closed.

FIG. 10--PAWL IN SLOT

It will be noted in this position that the set of contacts which are closed when the pawl is riding on the low side of the cam remain closed and the ground contact on the switch arm which has remained closed through each of the three previous positions is now open.

SWITCH ADJUSTMENTS

In the case where not more than two or three cams are not working satisfactorily, individual adjustments can be made to the station selector pawls by bending the small trigger arms up or down with a pair of pliers, to obtain proper action of the reversing and cut-off switches.

In making these adjustments it is very important that the triggers be adjusted so that they do not open the reversing contacts normally closed when the pawl is riding on the high side of the cam. Also, there should be a slight gap in the ground contact on the cut-off switch arm when the pawl drops to the bottom of the cam slot. This ground gap should be kept as small as possible, retaining sufficient clearance so that the contacts will remain open when the condenser gang is turned from one end of its travel to the other, with the station pawl holding the cam stationary.

In cases where the switching mechanism does not operate satisfactorily on any cam, a careful check should be made of the switch trip bar to see that it does not move the switch lever when the pawls are pressed against the high side of the cams.

DO NOT CHANGE POSITION OF EITHER THE REVERSING SWITCH OR SWITCH ARM AS SPECIAL EQUIPMENT IS REQUIRED TO OBTAIN ACCURATE ALIGNMENT OF THESE PARTS.

The normal position of the phosphor bronze switch springs with the switch arm pulled back should be as shown in Fig. 10 illustrating the switch position with the pawl in the cam slot.

If a complete test of the tuning mechanism indicates that it cannot be repaired or adjusted as outlined, a replacement of the complete chassis should be made in accordance with Mr. C. D. Wymer's letter of April 11, 1938, Subject--"Service Policy--Delco Auto Radio Models R-667 and R-669 Automatic Tuners".

UNITED MOTORS SERVICE, INC.

MODEL R673 Delco  
Alignment

1. Aligning I-F Stages at 262.5 Kilocycles
  - (a) Connect the ground lead of the Signal Generator to the chassis case. Connect the signal lead of the Signal Generator to the grid cap of the 6J8G tube, through a .1 mfd. condenser, leaving the tube's grid clip in place.
  - (b) Connect output meter across plates of 6N7G tube.
  - (c) Set Signal Generator to exactly 262.5 kilocycles and turn volume control on full.
  - (d) Turn condenser gang to a position where no squeals or beat notes can be noticed, also so that when the tuning condenser is rotated within narrow limits there is no appreciable change in output.
  - (e) Adjust trimmers A, B, C & D through the cut-outs on the side of the chassis (illus. 12 & 13, Fig. 5) carefully for maximum output.
  - (f) Repeat adjustments of I-F trimmers A, B, C & D with as low an output from the Signal Generator as possible, for more accurate alignment.
2. Aligning at 5000 Kilocycles
  - (a) Turn band switch to police band (clockwise).
  - (b) Leave Signal Generator leads connected the same as for I-F adjustments.
  - (c) Turn tuning condenser plates all the way out and against high frequency stop.
  - (d) Set Signal Generator to exactly 5000 kilocycles and adjust oscillator trimmer "G" (Fig. 4) carefully for maximum output, being careful to peak the signal received with trimmer screw out at minimum capacity.
3. Aligning at 1550 Kilocycles
  - (a) Turn band switch to broadcast band (counter clockwise).
  - (b) Set Signal Generator to 1550 kilocycles and leave the tuning condenser against high frequency stop.
  - (c) Adjust oscillator trimmer "I" (Fig. 4) for maximum output.
4. Aligning at 600 Kilocycles
  - (a) Connect Signal Generator leads to 6K7G, R-F grid, leaving the grid clip in place.
  - (b) Set Signal Generator to 600 kilocycles and tune the receiver to this signal.
  - (c) Adjust oscillator padder condenser "K" (Fig. 5) rocking gang con-
5. Aligning at 1400 Kilocycles
  - (a) Set Signal Generator at 1400 kilocycles.
  - (b) Tune set to this signal and adjust R-F trimmer "H" (Fig. 4) and antenna trimmer "M" (Fig. 4) to maximum output.
6. Aligning at 4000 Kilocycles
  - (a) Turn band switch to police band.
  - (b) Set Signal Generator to 4000 kilocycles and tune receiver to this signal.
  - (c) Adjust police band antenna trimmer "F" (Fig. 4) for maximum output.
7. Aligning at 1800 Kilocycles
  - (a) Set Signal Generator at 1800 kilocycles and tune receiver to this signal.
  - (b) Adjust oscillator padder condenser "J" (Fig. 5) rocking gang condenser plates back and forth through the signal until maximum output is obtained.
  - (c) Close gang and check to see if tuning range extends to 1600 kilocycles.
8. Realigning at 1400 Kilocycles
  - (a) Turn band switch to broadcast band.
  - (b) Set Signal Generator to 1400 kilocycles.
  - (c) Tune set to this signal and adjust R-F trimmer "H" and antenna trimmer "M" to maximum output (Fig. 4).
9. Realigning at 600 Kilocycles
  - (a) Check alignment of antenna series condenser "E" (Fig. 5) for maximum output.
10. Checking I-F Band Spread

The Model 165 Cathode Ray Oscilloscope should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustment of the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Connect Cathode Ray from connection "I" (Fig. 3) to ground.

denser plates back and forth through the signal until maximum output is obtained.

(d) Remove signal generator lead from 6K7G tube clip and connect to the antenna terminal through a .0002 mfd. condenser.

(e) Adjust antenna series condenser "E" (Fig. 5) for maximum output.

5. Aligning at 1400 Kilocycles

(a) Set Signal Generator at 1400 kilocycles.

(b) Tune set to this signal and adjust R-F trimmer "H" (Fig. 4) and antenna trimmer "M" (Fig. 4) to maximum output.

6. Aligning at 4000 Kilocycles

(a) Turn band switch to police band.

(b) Set Signal Generator to 4000 kilocycles and tune receiver to this signal.

(c) Adjust police band antenna trimmer "F" (Fig. 4) for maximum output.

7. Aligning at 1800 Kilocycles

(a) Set Signal Generator at 1800 kilocycles and tune receiver to this signal.

(b) Adjust oscillator padder condenser "J" (Fig. 5) rocking gang condenser plates back and forth through the signal until maximum output is obtained.

(c) Close gang and check to see if tuning range extends to 1600 kilocycles.

8. Realigning at 1400 Kilocycles

(a) Turn band switch to broadcast band.

(b) Set Signal Generator to 1400 kilocycles.

(c) Tune set to this signal and adjust R-F trimmer "H" and antenna trimmer "M" to maximum output (Fig. 4).

9. Realigning at 600 Kilocycles

(a) Check alignment of antenna series condenser "E" (Fig. 5) for maximum output.

10. Checking I-F Band Spread

The Model 165 Cathode Ray Oscilloscope should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustment of the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Connect Cathode Ray from connection "I" (Fig. 3) to ground.

SETTING UP AUTOMATIC TUNING DELCO MODELS R-1134-35-39 HOME RADIO

1. Loosen RESET LOCK SCREW in center of tuning knob.
2. Press any one of the automatic tuner levers all the way down. Stations may be set up in any sequence desired.
3. Hold the lever down firmly and tune set to station desired. When desired station is clearly tuned in, release the lever and follow same procedure until all levers have been set up.
4. Rotate the tuning knob to the right (clockwise) as far as it will turn and firmly tighten RESET LOCK SCREW.

DELCO MODELS R-1134-35-39 CIRCUIT ALIGNMENT

1. Aligning I-F Stages at 465 Kilocycles

- (a) Connect the ground lead of the signal generator in series with a .1 mfd. condenser to B- (pin #8 on 25L6G tube). Connect the signal lead of the signal generator to the grid cap of the 6AG6 tube, leaving grid clip in place.
- (b) Connect the output meter across the plate (pin 3) and screen (pin 4) of the 25L6G output tube.
- (c) Set signal generator to exactly 465 kilocycles and turn volume control on full.
- (d) Turn the rotor plates of the condenser gang all the way out of mesh and against the high frequency stop.
- (e) Adjust the trimmers (E-F) on the second I-F coil and then the trimmers on the first I-F coil (C-D Fig. 3) carefully for maximum output.
- (f) Repeat adjustments of the four I-F trimmers with as low an output from the signal generator as possible, for more accurate alignment.

2. Aligning at 1720 Kilocycles

- (a) Leave ground lead of signal generator connected to B- through a .1 mfd. condenser as before. Connect the signal lead of signal generator through a .0001 mfd. condenser to the antenna terminal.
- (b) Turn tuning condenser plates all the way out and against high frequency stop.
- (c) Set signal generator to exactly 1720 kilocycles and adjust oscillator trimmer (7B Fig. 3) carefully for maximum output, being careful to peak the signal with trimmer screw out or at minimum capacity.

3. Aligning at 1400 Kilocycles

- (a) Set signal generator to 1400 kilocycles and turn condenser gang plates until this signal is tuned in with maximum output.
- (b) Adjust the antenna trimmer (7A Fig. 3) for maximum output. Do not disturb the 1720 kilocycle adjustment of the oscillator trimmer.

DELCO MODEL R-3215 CIRCUIT ALIGNMENT

1. Aligning I-F Stages at 455 Kilocycles

- (a) Attach the ground lead of the signal generator to the chassis ground post. Connect the other lead to the grid cap of the 6K8 tube through a .02 mfd. series condenser. DO NOT REMOVE GRID CLIP.
- (b) Set the signal generator to EXACTLY 455 kilocycles and turn receiver volume control on full.
- (c) Peak each of the 2nd I-F coil trimmers, 2A & 2B, (Illus. 2, Fig. 3).
- (d) Peak each of the 1st I-F coil trimmers, 1A & 1B, (Illus. 1, Fig. 3).
- (e) To assure most accurate trimmer setting repeat above adjustments several times always using lowest possible signal generator output consistent with readable output meter scale deflection.

2. Aligning "American Broadcast" 1730-540 Kilocycle Band

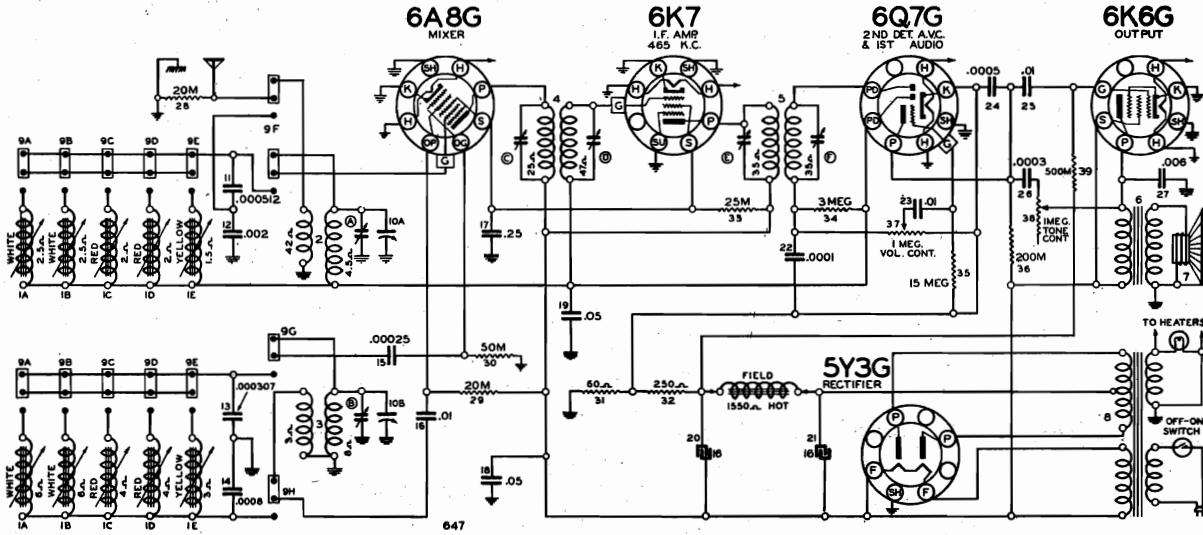

- (a) Connect signal generator antenna lead to receiver antenna terminal through a .00025 mfd. condenser, and the other signal generator lead to ground terminal.
- (b) Adjust band selector switch for operation on 1730-540 kilocycle band.
- (c) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the needle does not point exactly to the last line move needle to correct position.
- (d) Set signal generator frequency and receiver dial to EXACTLY 1730 kilocycles, and bring in 1730 kilocycle signal generator signal to maximum output by adjusting 1730 kilocycle oscillator trimmer, (Illus. 7C Fig. 4).
- (e) Set signal generator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 kilocycle oscillator padder (Illus. 6, Fig. 3) for maximum output.
- (f) Padder (Illus. 8, Fig. 3) for maximum signal response.

3. Aligning "Foreign Short Wave" 5.8-18.1 Megacycle Band

- (a) Place band selector switch for operation on 5.8-18.1 megacycle band, tune receiver dial and set signal generator frequency to EXACTLY 18.1 megacycles.
- (b) Adjust 18.1 megacycle oscillator trimmer (Illus. 7B, Fig. 4) to bring in 18.1 megacycle test signal to maximum output. If more than one peak is noticed, back off trimmer to minimum capacity, then screw down the trimmer (add capacity) until the second peak is tuned in.
- (c) Tune receiver dial and set signal generator frequency to EXACTLY 15 megacycles.
- (d) While rocking gang condenser slightly to right and left, adjust 15 megacycle antenna trimmer (Illus. 7A, Fig. 4) for maximum 15 megacycle test signal response.

- (f) Adjust the trimmers on the second I-F coil (Illus. 5, Fig. 3) and then the trimmers on the first I-F coil (Illus. 4, Fig. 3) carefully for maximum output.
- (g) Repeat adjustments of the four I-F trimmers with as low an output from the signal generator as possible, for more accurate alignment.
2. Aligning at 1400 Kilocycles
- (a) Connect the signal lead of signal generator through a .0001 mfd. condenser to the antenna terminal. Connect ground lead of signal generator to chassis.
- (b) Set signal generator to 1400 kilocycles.
- (c) Turn tuning condenser plates until test scale dial is at the 1400 kilocycles position as noted from the reference mark you made on the front support bracket.
- (d) Adjust oscillator trimmer (Illus. 10B, Fig. 3) carefully for maximum output, being careful to peak the signal received with trimmer screw out at minimum capacity.
- (e) Adjust the antenna trimmer (Illus. 10A, Fig. 3) for maximum output with as low an output from the signal generator as possible, for more accurate alignment.
- (f) After completing the alignment procedure, the alignment should be checked with the cathode ray oscillograph. Connect the oscillograph across the volume control.

**GENERAL:** The Delco Model R-1140 is a 5 tube, 110 volt A.C. superheterodyne automatic electric tuning receiver with a 6" dynamic speaker. Tuning is accomplished by means of the conventional manual control or by push button switches which control adjustable permeability tuned coils. Tuning range is from 530 to 1720 kilocycles. Five push buttons are used for automatic tuning, a sixth for switching from automatic to manual tuning.

The function of each button is, left to right:

1. Automatic tuning 530-800 K.C.
2. Automatic tuning 800-1100 K.C.
3. Automatic tuning 1100-1400 K.C.
4. Automatic tuning 1400-1720 K.C.
5. Automatic tuning 975-1560 K.C.
6. Switch-Manual to automatic tuning

SETTING UP AUTOMATIC ELECTRIC TUNING

Setting up the stations is accomplished by means of a single adjustment for each button, accessible from the rear of the chassis.

1. Turn on the set, and allow 15 minutes for the set to "warm up" before setting the station adjustment screws for the push buttons.
2. Press button #6 and tune in the desired station by means of the manual tuning control.
3. Press one of the buttons #1 to #5 which range corresponds to the station frequency and, with a small screw driver adjust screw on back of chassis corresponding to button pressed until the same station is accurately tuned in.
4. Press button #6, changing from "Push Button" to "Dial Tuning" to ascertain that the same program is heard for both.
5. Moistens and insert the call letters of the station on the front of the button.
6. Repeat the operation for the other buttons.

CIRCUIT ALIGNMENT

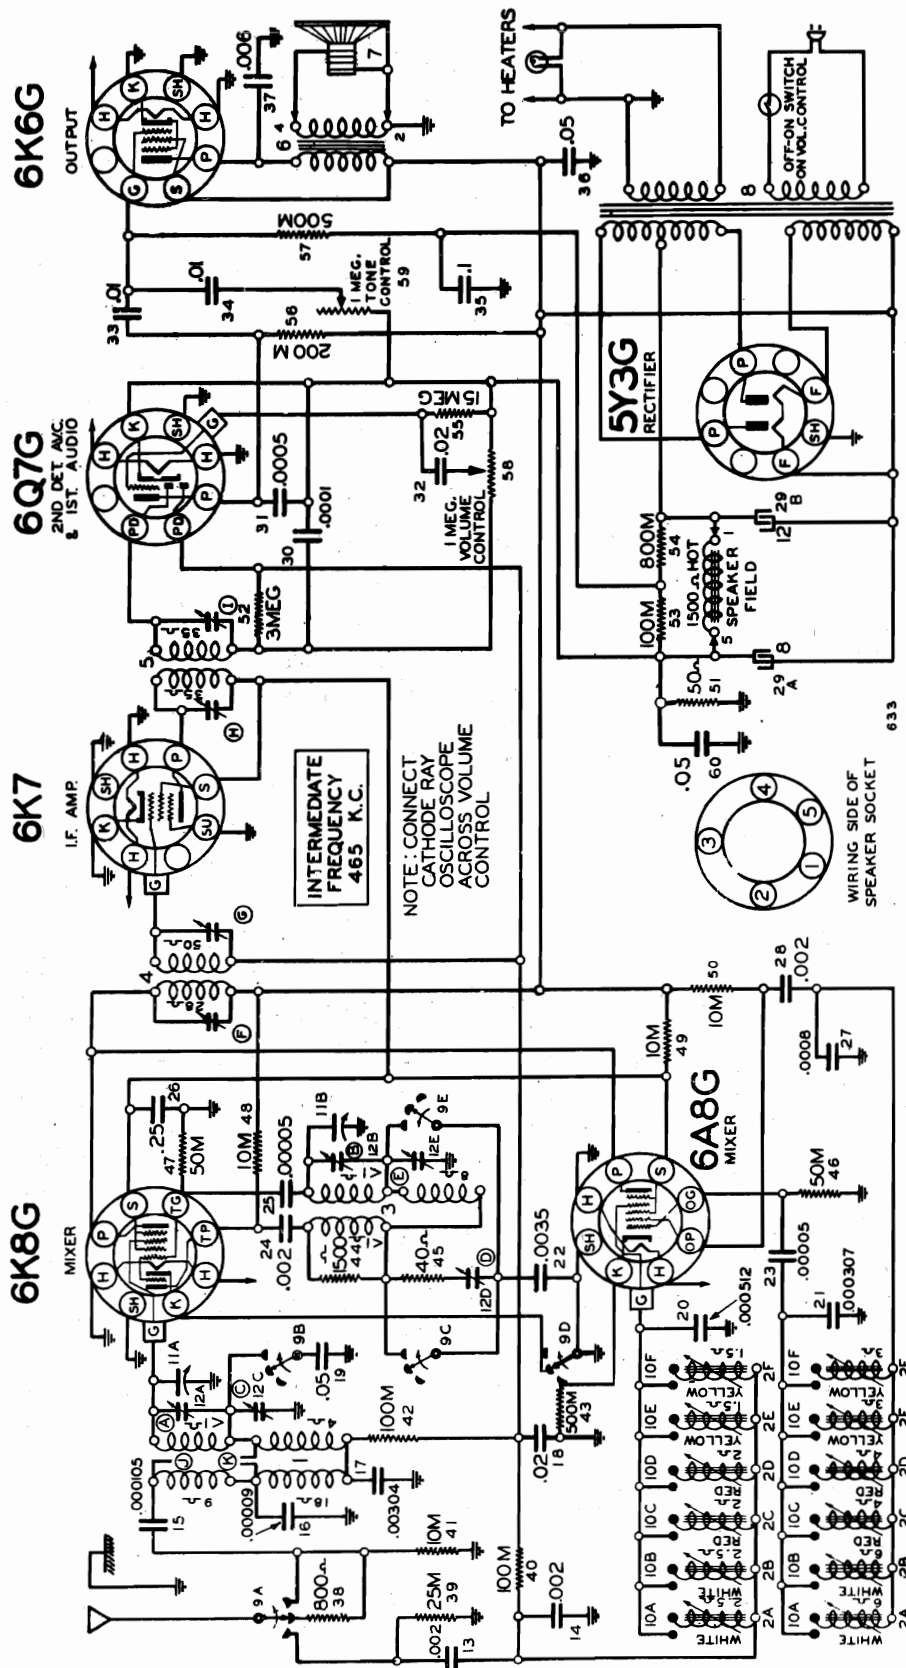

For alignment purposes, a test scale is stamped on the inside of the dial drum on the condenser shaft. Before starting alignment procedure, turn the rotor plates of the condenser gang all the way out of mesh and against the high frequency stop and make an indicating mark on the front support bracket in line with the high frequency mark on test scale for future reference.

1. Aligning I-F Stages at 465 Kilocycles
  - (a) Connect the ground lead of the signal generator to the chassis frame.
  - (b) Connect the signal lead of the signal generator to the grid cap of the 6A8G tube through a .1 mfd. condenser, leaving grid clip in place.
  - (c) Connect the output meter across the plate (pin 3) and screen (pin 4) of the 6K6G output tube.
  - (d) Press #5 button (Dial Tuning), turn the volume control on full and the tone control to extreme clockwise (treble) position.
  - (e) Set the signal generator to exactly 465 kilocycles and turn the rotor plates of the condenser gang all the way out of mesh and against the high frequency stop.

3. 720 to 1120 K.C.
4. 720 to 1120 K.C.
5. 1000 to 1560 K.C.
6. 1000 to 1560 K.C.

GENERAL: The Delco Model R-1141 is a six tube, two band superheterodyne receiver with a 6" dynamic speaker. Tuning is accomplished by means of the conventional manual control, or by push button switches which control adjustable permeability tuned coils. The frequency ranges of the push buttons are, left to right:

SETTING UP AUTOMATIC ELECTRIC TUNING

Setting up the push buttons for pre-selected stations is accomplished by means of a single adjustment for each button, accessible from the front of the cabinet. These screw driver adjustments are made through the small openings in the escutcheon, in which the call letter tabs are placed.

1. Turn the set "on" and set the band change switch to the broadcast manual (center) position and allow about 15 minutes to warm up.
2. Tune in the desired station by means of the manual tuning control.
3. Press one of the buttons which most conveniently covers the frequency of the stations, turn the band change switch to the automatic (left hand) position and, with a small screw driver, adjust the screw directly above the button, until the station is tuned in accurately.
4. Turn the band change switch back to the center position to check the accuracy of the adjustment.
5. Insert the call letters of the station in the opening and cover with the celluloid tab provided.
6. Repeat the operation for the other buttons.

ALIGNMENT FOR MODELS R1141, R1142, and R1143.

NOTE FIGURE REFERENCES IN THE TEXT REFER TO FIGURES SHOWN WITH EACH MODEL.

1. Aligning I-F Stages at 465 Kilocycles

- (a) Connect the ground lead of the signal generator to the chassis frame.
- (b) Connect the signal lead of the signal generator to the grid cap of the 6AG6 tube through a 1.0 mfd. condenser, leaving the grid clip in place. *6K8G (R1143)*
- (c) Connect the output meter across the plate and screen of the 6F6G tube.
- (d) Press a button, turn the band change switch to the automatic (left hand) position, volume control on full, and the tone control in the treble position. *R1143 Use #10 Button; Variable Fully Open*
- (e) Set the signal generator to exactly 465 kilocycles and adjust the trimmers on the second I-F coil (illus. 5, Fig. 3) and the first I-F coil (illus. 4, Fig. 3) for maximum output. Use as low a signal from the signal generator as will give a readable indication on the output meter. DO NOT REALIGN THE I-F COILS IN THE MANUAL (CENTER) POSITION (MODEL R1144 ONLY)
- (f) After completing the Alignment Procedure, the alignment should be checked with the Model 165 Cathode Ray Oscillograph. Connect the oscillograph across the volume control. *FOR R1143 Across #40 Cond. Pkt.*

2. Aligning at 17 Megacycles

- (a) Remove the signal lead of the signal generator from the grid of the 6AG6 and connect to the antenna terminal of the receiver through a 400 ohm resistor. *R1143 (6K8G)*
- (b) Turn the band change switch to the short wave (right hand) position. *FOR R1143 - Press #8 Button (Auto-Manual Tuning)*
- (c) Set the signal generator to exactly 17 megacycles and rotate the variable section of the condenser gang to indicate 17 megacycles on the test scale. *R1142 (ILLUS. 12D, FIG. 4)*
- (d) Adjust the oscillator trimmer condenser (illus. B, Fig. 4) for maximum output. *R1141, R1143 (ILLUS. B, FIG. 3) - R1143*
- (e) Adjust the antenna trimmer (illus. K, Fig. 4) while rocking the condenser gang back and forth through the signal, until maximum output is obtained. *FOR MODEL 1142 SEE (ILLUS. 12A, FIG. 4)*
- (f) Increase the signal from the signal generator and check for image frequency response. If the image does not fall at approximately 1630 megacycles, repeat section 2.

3. Aligning at 1735 Kilocycles (MODELS R1141, R1142 ONLY)

- (a) Remove the 400 ohm resistor and connect the signal lead of the signal generator to the antenna terminal of the receiver through a .0002 mfd. mica condenser.

3. Aligning at 5 Megacycles MODEL R1143 ONLY

- (a) Press #9 button (Intermediate wave--manual tuning).
- (b) Set the signal generator to exactly 5 megacycles and rotate the variable section of the condenser gang to indicate 5 megacycles on the test scale.
- (c) Adjust the oscillator trimmer condenser (illus. G, Fig. 3) for maximum output.
- (d) Adjust the antenna trimmer condenser (illus. C, Fig. 3) for maximum output.

4. Aligning at 1690 Kilocycles MODEL R1143 ONLY

- (a) Remove the 400 ohm resistor and connect the signal lead of the signal generator to the antenna terminal of the receiver through a .0002 mfd. mica condenser.
- (b) Press #10 button (Broadcast--manual tuning).
- (c) Turn the variable plates of the condenser gang completely out of mesh and against the high frequency stop.
- (d) Adjust image trimmer (illus. E, Fig. 3) two turns up from tight.
- (e) Set the signal generator to exactly 1690 kilocycles.
- (f) Adjust the oscillator trimmer condenser (illus. H, Fig. 3) for maximum output.
- (b) Turn the band change switch to the broadcast Manual (center) position.

- (c) Turn the variable plates of the condenser gang completely out of mesh and against the high frequency stop.
- (d) Set the signal generator to exactly 1735 kilocycles.
- (e) Adjust the oscillator trimmer condenser (illus. E, Fig. 4) for maximum output. *MODEL R1141 ONLY FOR MODEL R1142 SEE (ILLUS. 12E, FIG. 4)*

4. Aligning at 1400 Kilocycles

- (a) Set the signal generator to approximately 1400 kilocycles.
- (b) Rotate the variable plates of the condenser gang until the signal is tuned in with maximum output.
- (c) Adjust the antenna trimmer (illus. C, Fig. 4) for maximum output.

5. Aligning at 600 Kilocycles

- (a) Set the signal generator to approximately 600 kilocycles.
- (b) Rotate the variable plates of the condenser gang until the signal is tuned in. *MODEL R1141 ONLY FOR MODEL R1142 (ILLUS. 12B, FIG. 4) FOR MODEL R1143 (ILLUS. D, FIG. 3)*
- (c) Adjust the oscillator series condenser (illus. D, Fig. 4) while rocking the condenser gang back and forth through the signal until maximum output is obtained.

6. Aligning for Image Frequency Response

- (a) Set the signal generator at 2100 kilocycles. *FOR R1143 AT 1930KC.*
- (b) Rotate the variable plates of the condenser gang until the image of this signal is tuned in at 1170 kilocycles. *FOR R1143 AT 1000KC.*
- (c) Adjust the two-wire capacitor (illus. K, Fig. 4) by twisting, until a minimum output is obtained. *FOR R1143 - SEE (ILLUS. 12E, FIG. 3) FOR R1142 - SEE (ILLUS. 12C, FIG. 4)*
- (d) Set the signal generator at 2630 kilocycles.
- (e) Rotate the variable plates of the condenser gang until the image of this signal is tuned in at 1700 kilocycles.
- (f) Adjust the single wire capacitor (illus. J, Fig. 4) by moving it either toward or away from the coil winding until a minimum output is obtained.

7. Repeat Sections 4 and 5 for Maximum Output

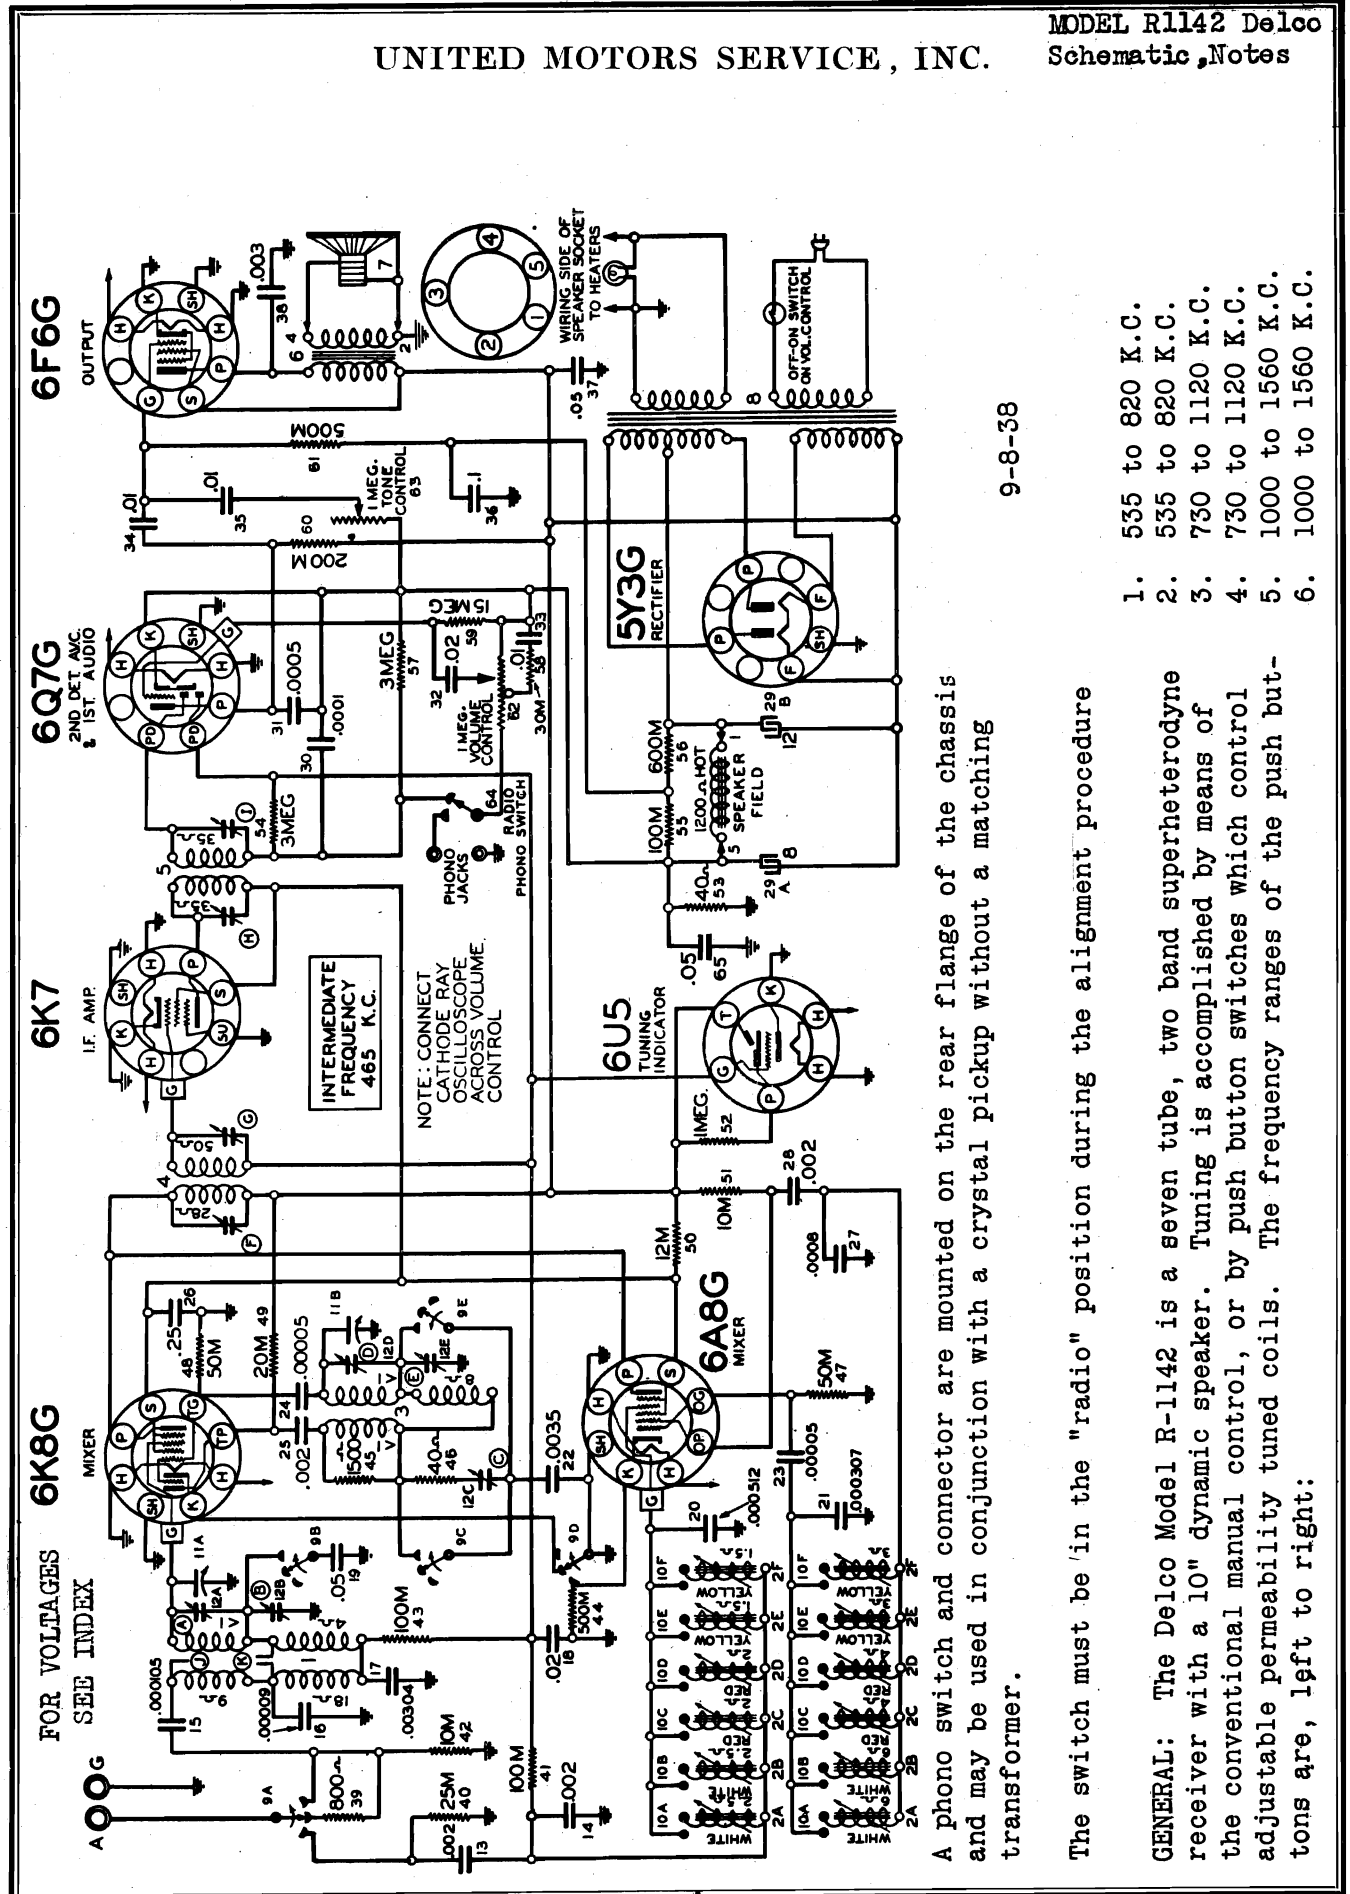

8. Repeat Section 6 for Minimum Output

9. Repeat Section 2 (e) for Maximum Output

9. Repeat Section 2 (e) for Maximum Output

UNITED MOTORS SERVICE, INC.

MODEL R1142 Delco  
Schematic, Notes

9-8-38

A phono switch and connector are mounted on the rear flange of the chassis and may be used in conjunction with a crystal pickup without a matching transformer.

The switch must be in the "radio" position during the alignment procedure

1. 535 to 820 K.C.
2. 535 to 820 K.C.
3. 730 to 1120 K.C.
4. 730 to 1120 K.C.
5. 1000 to 1560 K.C.
6. 1000 to 1560 K.C.

**GENERAL:** The Delco Model R-1142 is a seven tube, two band superheterodyne receiver with a 10" dynamic speaker. Tuning is accomplished by means of the conventional manual control, or by push button switches which control adjustable permeability tuned coils. The frequency ranges of the push buttons are, left to right:

MODEL R1145 Delco  
Alignment

ALIGNMENT MODEL R1144

1. Aligning I-F Stages at 465 Kilocycles

- (a) Connect the ground lead of the signal generator to the chassis frame.
- (b) Connect the signal lead of the signal generator to the grid cap of the 6K8 tube through a .1 mfd. condenser, leaving the grid clip in place.
- (c) Connect the output meter across the plates of the 6K6G tube.
- (d) Press #2 button (Broadcast:Manual), turn the volume control on full and the tone control on treble and turn the variable plates of the condenser gang completely out of mesh and against the high frequency stop.
- (e) Set the signal generator to exactly 465 kilocycles and adjust the trimmers on the second I-F coil (Illus. N&M, Fig. 3) and the first I-F coil (Illus. K&L, Fig. 3) for maximum output. Use as low a signal from the signal generator as will give a readable indication on the output meter.
- (f) After completing the Alignment Procedure, the alignment should be checked with the Model 165 Cathode Ray Oscilloscope. Connect the oscilloscope from point (Fig. 4) to ground.

2. Aligning at 1690 Kilocycles

- (a) Disconnect the signal lead of the signal generator from the grid of the 6K8 and connect to the antenna terminal of the receiver through a .002 mfd. mica condenser.
- (b) With the controls set as before, adjust the broadcast oscillator trimmer for maximum output (Illus. I, Fig. 4).

3. Aligning at 1400 Kilocycles

- (a) Set the signal generator to approximately 1400 kilocycles.
- (b) Rotate the variable section of the condenser gang until the signal is tuned in with maximum output.
- (c) Adjust the antenna trimmer (Illus. E, Fig. 4) and R-F trimmer (Illus. F, Fig. 4) for maximum output.

4. Aligning at 600 Kilocycles

- (a) Set the signal generator to approximately 600 kilocycles.
- (b) Rotate the variable section of the condenser gang until this signal is tuned in with maximum output.
- (c) Adjust the oscillator series condenser (Illus. J, Fig. 4) while rocking the condenser gang back and forth through the signal, until maximum output is obtained.

5. Aligning at 17. Megacycles

- (a) Remove the .0002 mfd. condenser and connect the signal lead of the signal generator to the antenna trimmer of the receiver through a 400 ohm resistor.
- (b) Press #4 button (Short Wave Band:Manual).
- (c) Set the signal generator to exactly 17. megacycles and rotate the variable section of the condenser gang to indicate 17. megacycles on the test scale.
- (d) Adjust the oscillator trimmer condenser (Illus. C, Fig. 4) for maximum output.
- (e) Adjust the R-F trimmer condenser (Illus. B, Fig. 4) and antenna trimmer (Illus. A, Fig. 4) while rocking the condenser gang back and forth through the signal, until maximum output is obtained.
- (f) Increase the signal output from the signal generator and check for image frequency. If the image does not fall at approximately 1630 megacycles, repeat section 5.

6. Aligning at 5. Megacycles

- (a) Press #3 button (Medium Wave Band:Manual).
- (b) Set the signal generator to exactly 5. megacycles and rotate the variable section of the condenser gang to indicate 5. megacycles on the test scale.
- (c) Adjust the oscillator trimmer condenser (Illus. H, Fig. 4) R-F trimmer (Illus. G, Fig. 4) and antenna trimmer (Illus. D, Fig. 4) for maximum output.

7. Repeat Sections 2, 3 and 4.

ALIGNMENT MODEL R1145

1. Aligning I-F Stages at 465 Kilocycles

- (a) Connect the ground lead of the signal generator to the chassis frame.
- (b) Connect the signal lead of the signal generator to the grid cap of the 6K8G tube through a .1 mfd. condenser, leaving the grid cap clip in place.
- (c) Connect the output meter from the plate of the 6AC5G tube to B plus.
- (d) Turn the rotor plates of the gang condenser to a point where no whistles or beat notes are heard.
- (e) Set the signal generator to exactly 465 kilocycles.
- (f) Adjust the trimmers on the first I-F coil (Illus. G & H, Fig. 3) and the second I-F coil (Illus. I & J, Fig. 3) for maximum output.
- (g) After completing the alignment procedure, the alignment should be checked with a cathode ray oscilloscope. Connect the oscilloscope from the high side of the volume control to ground.

2. Aligning at 1750 Kilocycles.

- (a) Remove the signal lead of the signal generator from the grid of the 6K8G and connect to the antenna terminal of the receiver through a .0002 mfd. mica condenser.
- (b) Set the signal generator to exactly 1750 kilocycles.
- (c) Turn the rotor plates of the gang condenser completely out of mesh and against the high frequency stop.
- (d) With the band change switch in the Broadcast position, adjust the oscillator trimmer condenser (Illus. F, Fig. 3) for maximum output.

3. Aligning at 1500 Kilocycles

- (a) Leave the signal generator leads connected as before.
- (b) Set the signal generator to 1500 kilocycles.
- (c) Rotate the variable plates of the gang condenser until this signal is tuned in with maximum output.
- (d) Adjust the antenna trimmer (Illus. A, Fig. 3) for maximum output.

4. Aligning at 600 Kilocycles

- (a) Set the signal generator to 600 kilocycles.
- (b) Rotate the variable plates of the gang condenser until this signal is tuned in with maximum output.
- (c) Adjust the oscillator padder condenser (Illus. C, Fig. 3) while rocking the rotor plates back and forth through the signal until maximum output is obtained.

5. Aligning at 17 Megacycles

- (a) Remove the .0002 mfd. mica condenser coupling the signal generator lead to the antenna terminal of the receiver and replace with a 400 ohm resistor.
- (b) Turn the band change switch to short wave position.
- (c) Set the signal generator to 17 megacycles.
- (d) Turn the rotor plates of the gang condenser until this signal is tuned in with maximum output.
- (e) Adjust the oscillator trimmer (Illus. E, Fig. 3) and the antenna trimmer (Illus. B, Fig. 3) for maximum output.

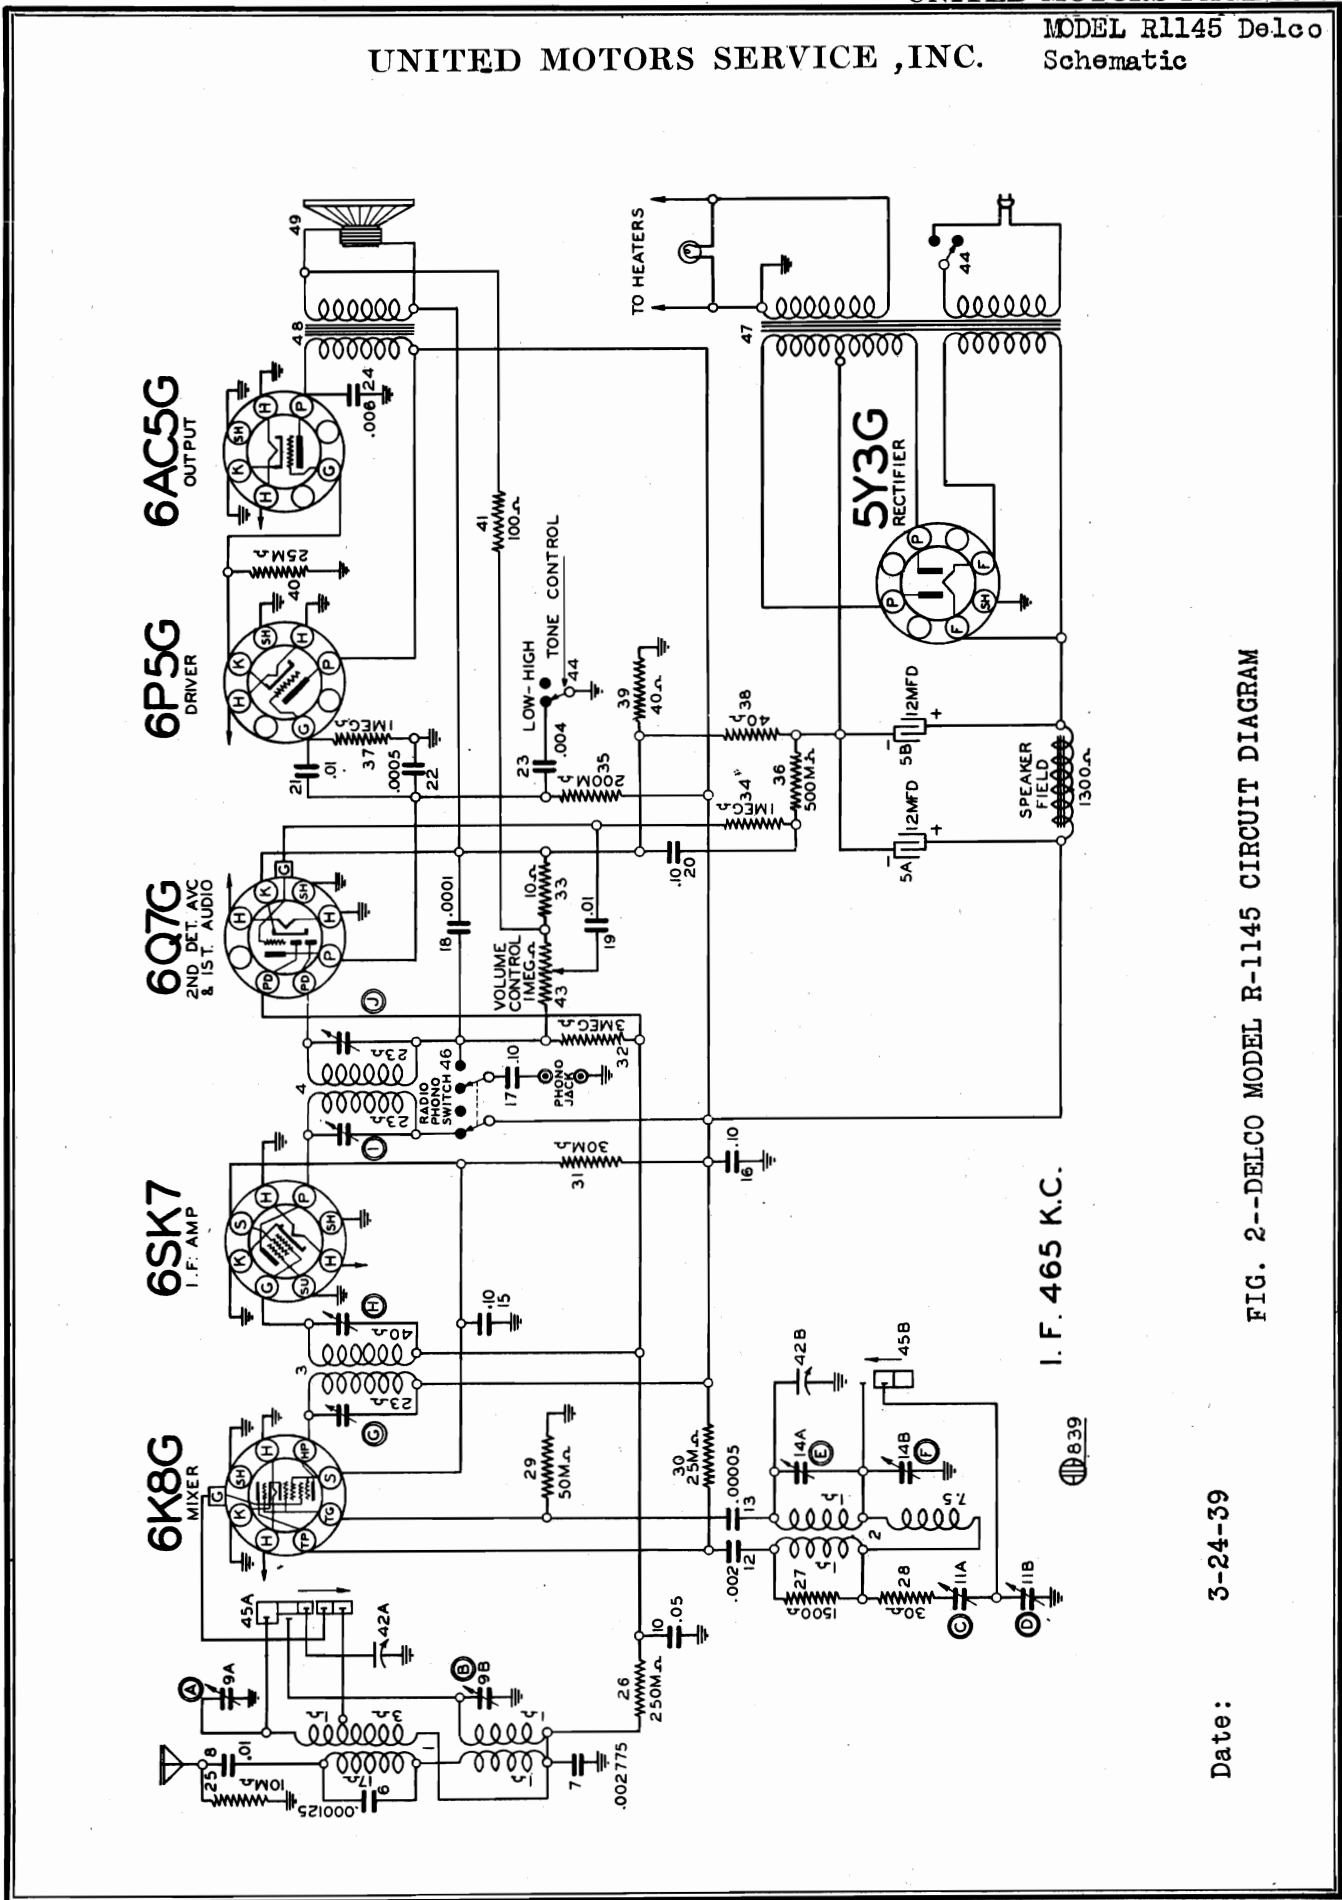

6. Aligning at 6 Megacycles

- (a) Set the signal generator to 6 megacycles.
- (b) Turn the rotor plates of the gang condenser until this signal is tuned in with maximum output.
- (c) Adjust the oscillator padding condenser (Illus. D, Fig. 3) while rocking the rotor plates back and forth through the signal until maximum output is obtained.

IF PEAK 456 KC

MODEL NO. 166 RIS

DESCRIPTION

This receiver is a 7 tube alternating current operated superheterodyne. The tubes used are a 76 as oscillator, a 6A7 as modulator, a 6D6 as I.F. amplifier, a 75 as A.V.C. and audio rectifier and audio voltage amplifier, a 42 as power audio amplifier, an 80 as a power rectifier and a 655 as tuning indicator. This receiver is made to cover 3 tuning bands, the broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.6 M.C. to 1.7 M.C. and the high frequency or foreign band which is from 20 M.C. to 5.4 M.C.

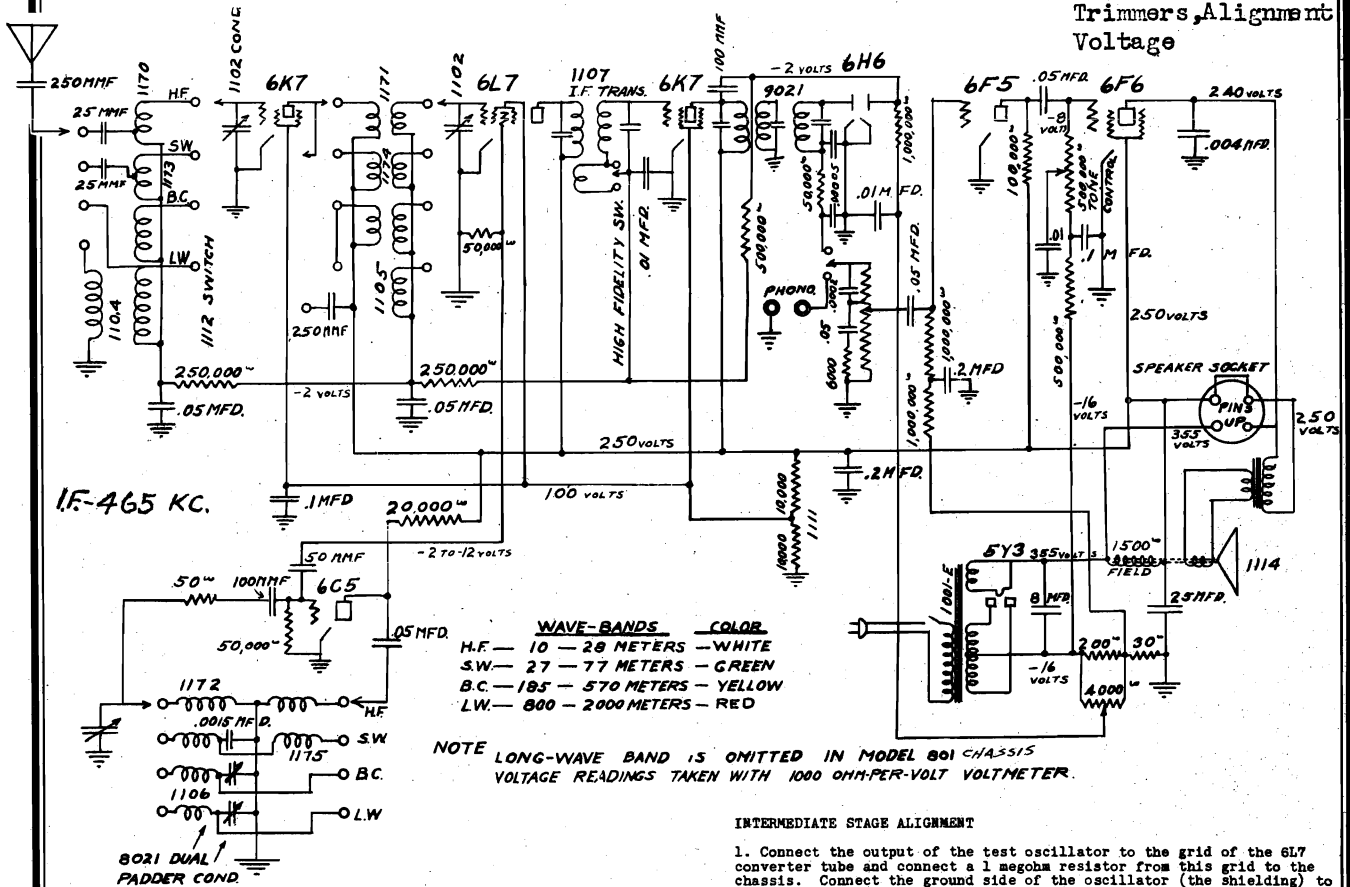

ALIGNMENT PROCEDURE

The following alignment procedure is for use only by competent service men having the proper equipment. Re-alignment is very seldom needed and is usually only required after some major part has been replaced because of damage to the receiver. The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or micro-volter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output. All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter. Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure. Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground post of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F. Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1680 K.C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer and the 1500 K.C. broadcast preselector trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output while tuning the receiver back and forth across the signal from the generator. This completes the alignment of the broadcast band. The police band is aligned by feeding 4.0 M.C. signal to the receiver antenna lead through the .00025 condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output. The short wave band is aligned in the same way using a 15 M.C. signal and

LW	800 - 2000 METERS	RED

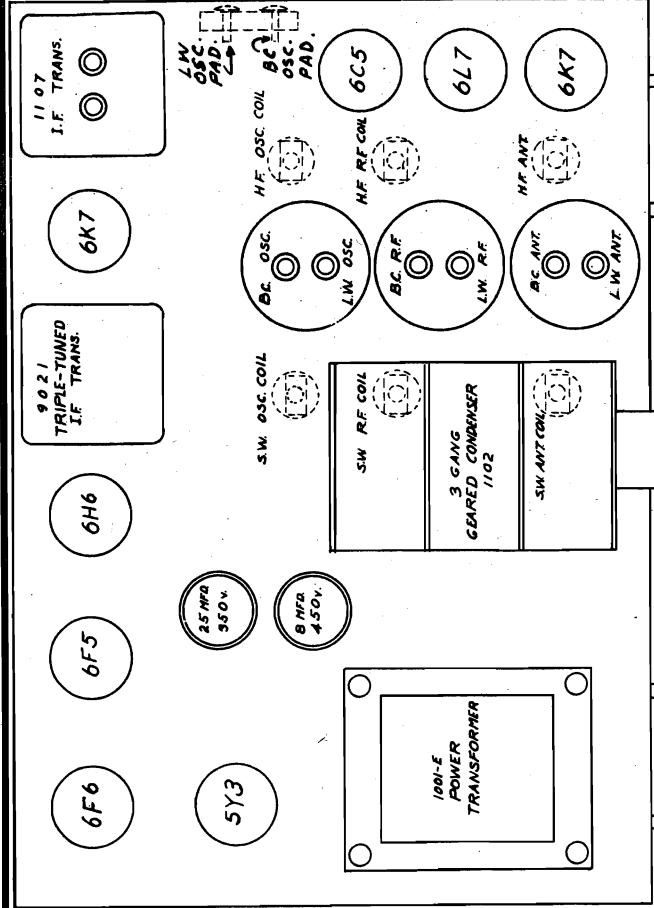

NOTE LONG-WAVE BAND IS OMITTED IN MODEL 801 CHASSIS  
VOLTAGE READINGS TAKEN WITH 1000 OHM-PER-VOLT VOLTMETER.

INTERMEDIATE STAGE ALIGNMENT

1. Connect the output of the test oscillator to the grid of the 6L7 converter tube and connect a 1 megohm resistor from this grid to the chassis. Connect the ground side of the oscillator (the shielding) to the receiver chassis.
2. Set the test oscillator to 465 K.C. Refer to Curve B on the Calibration chart to obtain the proper setting of the test oscillator.
3. Set the tone control to the left. Align the output intermediate frequency transformer by turning the top screw at the rear of the output I.F. transformer until maximum response is obtained on the output meter. Adjust the other trimmer screws in the same manner.
4. Adjust the input intermediate frequency transformer in the same manner.

ALIGNMENT OF TUNING CIRCUITS

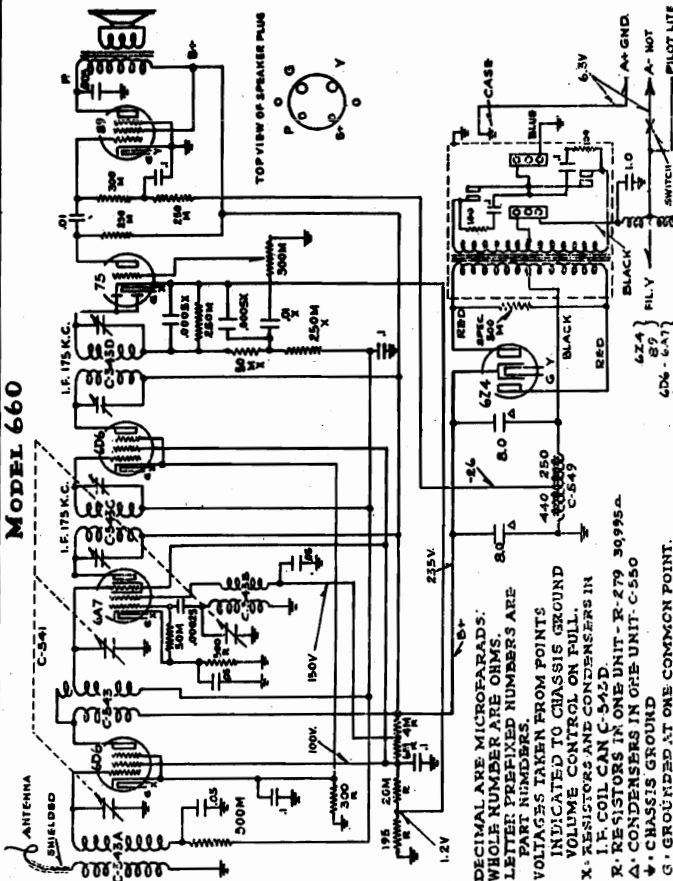

5. Connect the output of the test oscillator to the antenna lead of the receiver through a .00025 M.F.D. condenser and connect the ground side (shielding) to the chassis.
  6. Set the wave change switch to the long-wave position (Red). Set the dial and test oscillator to 900 meters. Adjust the long-wave oscillator trimmer until the signal is brought in. If no signal is heard, then adjust the long-wave padder. See diagram of chassis for location of trimmer and padder condensers.
  7. Then adjust the long-wave antenna and R.F. trimmers for maximum response. Set the dial and test oscillator to 1800 meters and adjust the long-wave padder for maximum response while rocking the gang condenser. By rocking the gang is meant tuning to a point just above and just below the test oscillator frequency while making some other adjustment. Return to 900 meters and repeat the entire procedure.
  8. Set the wave change switch to the broadcast position (Yellow). Set the dial and test oscillator to 214 meters (1400 K.C.) and adjust the B.C. oscillator, R.F. and antenna trimmers till maximum response is obtained. Set the dial and test oscillator to 600 K.C. and adjust the B.C. padder condenser while rocking the gang till maximum response is obtained.
  9. Set the wave change switch to the high frequency band (Short-wave Green). Substitute a 400 ohm resistor for the .00025 M.F.D. condenser in the antenna circuit. Set the dial and test oscillator to 30 meters (10 megacycles). Stand the receiver on end and adjust the 30 meter oscillator coil (located to the right of switch when viewed from bottom) till the signal is brought in. Stop at the first peak. Screwing the trimmer down still more will give another peak which is the image and must not be used. To make certain the set is not tuned to the image, set the test oscillator to 11 megacycles and if another signal is received, then the set is correctly tuned. Reset the test oscillator to 30 meters and adjust the R.F. and antenna trimmers for maximum response, while rocking the gang. Set the dial and test oscillator to 75 meters and check for sensitivity.
  10. Set the wave-change switch to the ultra-high frequency band (White). Set the test oscillator and dial to 11 meters (27.3 megacycles). Adjust the oscillator trimmer till the signal is brought in. Continue on through to the second peak. The image signal will now be found at 26.3 megacycles if the oscillator trimmer adjustment is correct. Reset the dial to 11 meters and adjust the R.F. and antenna trimmers for maximum response while rocking the gang.
- Set the dial and test oscillator to 26 meters and check for sensitivity.

105 to 125 volts, 50-60 cycles, A.C. power supply.  
The four tubes used in this set are as follows: 1—No. 280 Full Wave Rectifier; 1—No. 77 Radio Audio Amplifier; 1—No. 78 Detector; 1—No. 42 Audio Amplifier.  
Set band switch  
In the left-hand position, broadcast stations on frequencies between 550 and 1500 Kilocycles will be received. When the band switch is thrown to the right, stations operating on frequencies ranging from 1500 to 4800 Kilocycles will be heard.

**SERVICE SUGGESTIONS**  
In changing tubes always remove the plug from light socket. Make sure all tubes are pushed firmly into their proper sockets and that clips are always fastened to caps on tops of tubes. Be sure that aerial and ground are properly connected. A thirty to fifty-foot aerial is recommended for best operation. To remove chassis from cabinet, first remove knobs. Then remove four screws from bottom of cabinet holding base. Re- move screws holding speaker in cabinet and remove speaker and chassis as a unit.

READ ALL VOLTAGES FROM SOCKET PRONG TO GROUND UNLESS OTHERWISE SPECIFIED. (EXCEPT FILAMENT)  
\*\* READ FROM 375 OHM RESISTOR #1267 TO GROUND.  
\* COMPARATIVE VOLTAGE IS NOT TRUE VOLTAGE APPLIED.

TO ALIGN THE VARIABLE CONDENSER: IT IS IMPORTANT WHEN ALIGNING TO FOLLOW THE PROCEDURE CAREFULLY, OTHERWISE THE RECEIVER WILL LACK SENSITIVITY AND THE DIAL CALIBRATION WILL BE INCORRECT.  
1. CONNECT THE HIGH OUTPUT SIDE OF THE OSCILLATOR TO THE RECEIVER ANTENNA LEAD AND THE GROUND TO THE CHASSIS.  
2. PLACE THE BAND SELECTOR SWITCH FOR OPERATION ON THE BROADCAST BAND, TUNE THE RECEIVER TO EXACTLY 1100 KILOCYCLES ON THE DIAL AND SET THE TEST OSCILLATOR FREQUENCY TO 1100 KILOCYCLES. THEN BRING IN THE 1100 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSERS LOCATED ON TOP OF THE GANG CONDENSER.  
3. SET THE BAND SELECTOR SWITCH FOR OPERATION ON THE SHORT WAVE BAND, TUNE THE RECEIVER DIAL TO EXACTLY 4 MEGACYCLES AND SET THE TEST OSCILLATOR TO THIS FREQUENCY. THEN ADJUST THE TRIMMER CONDENSER MOUNTED ON THE COIL LOCATED UNDERNEATH THE CHASSIS FOR MAXIMUM SENSITIVITY. ROCK GANG CONDENSER WHEN MAKING THIS ADJUSTMENT.

AETNA MODEL 500-3 BAND

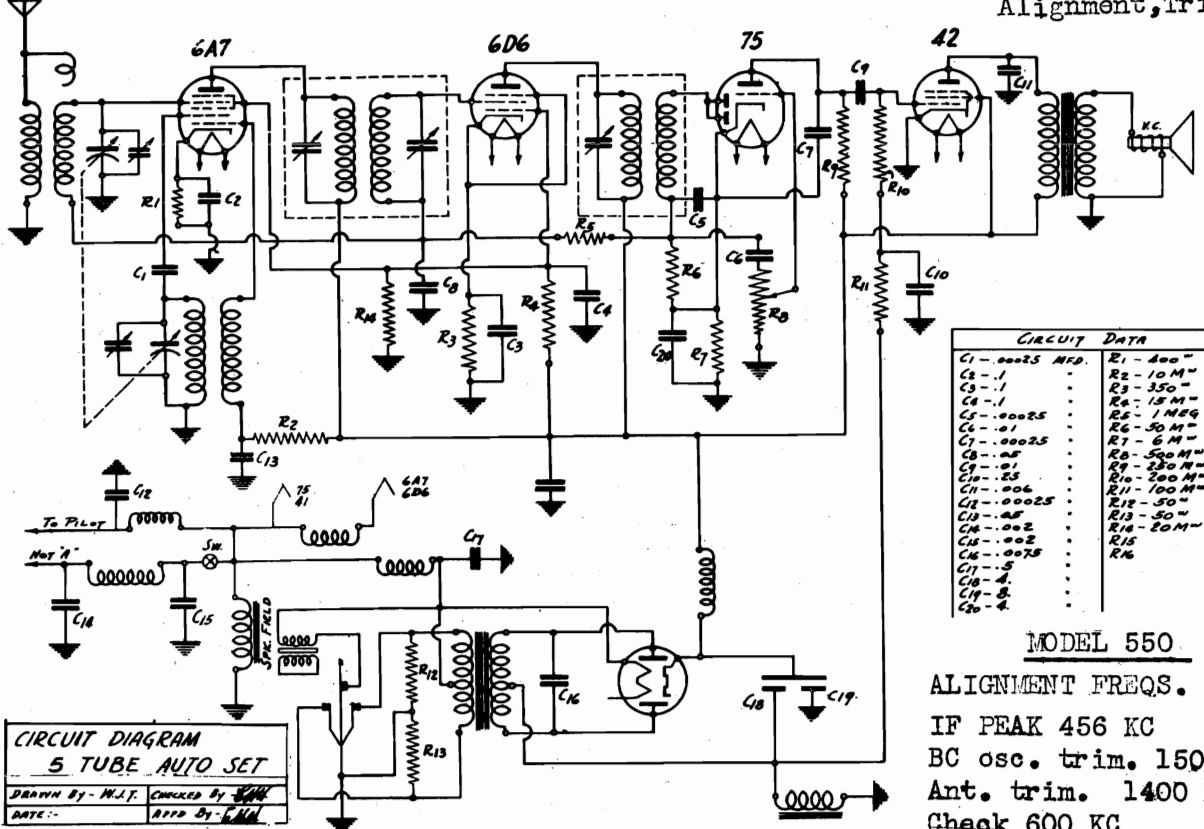

To adjust the R. F. circuits: (1) Set pointer on tuning chart to 1400 K. C. with band switch in the broadcasting position. (2) Adjust test oscillator to 1400 K. C. and connect to antenna lead on chassis. (3) Adjust test oscillator on oscillator section of the tuning condenser for maximum reading. (4) Reset dial pointer on receiver and test oscillator to 600 K. C. (5) Adjust 600 K. C. padding condenser for maximum reading moving tuning condenser back and forth slowly while making adjustment (the 600 K. C. padding condenser is mounted on the base at the left of the tuning condenser). (6) Reset oscillator and tuning pointer on the receiver to 1400 K. C. and readjust trimmer on oscillator section of tuning condenser for maximum reading. (7) Reset dial pointer on receiver and test oscillator to 15 megacycles. (8) Set band change switch in the right hand position. (9) Adjust trimmer on first section of tuning condenser for maximum reading. (10) Reset dial pointer on receiver and test oscillator to 3.6 megacycles. (11) Set band change switch in left hand position. (12) Adjust 3.6 megacycle trimmer condenser for maximum reading (the 3.6 megacycle trimmer is mounted under the chassis and directly in front of the band change switch. (13) Reset dial pointer on receiver and test oscillator to 1400 K. C. (14) Set band change switch in broadcasting position and adjust 1400 K. C. trimmer for maximum reading (the 1400 K. C. trimmer is mounted under the chassis directly over the antenna coil).

WALGREEN CO.

105-115 volts alternating current 50-60 cycles - 60 watts.  
GREEN (Broadcast band) 530 - 1550 Kilocycles  
RED (Short wave band) 1550 - 14,000 Kilocycles

IF PEAK 456 KC

- \* R.2, R.4, R.5, R.6, R.7 & R.8 IN ONE UNIT P-1012
- \* C.16 & C.17 IN ONE UNIT P-1003
- X.R.9, R.10, R.11, C.8, C.9 & C.10 IN I.F. CAN P-1005

To peak I.F. transformers connect oscillator (set at 456 KC) to grid of 2A7 tube and (Black) ground wire. With variable condenser set at minimum capacity, (extreme left of its rotation) adjust four trimmers (one nut and one screw on each transformer trimmer) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).

To align Broadcast band, set wave changing switch to Green (right turn) and with variable condenser at minimum capacity disconnect antenna wire and connect 1550 KC oscillator to antenna coil in series with a 75 MMFD condenser. Adjust oscillator (front) section trimmer to resonance. Set oscillator to 1400 KC, rotate variable condenser until signal is tuned in, then adjust R.F. (rear) section trimmer to resonance. Check output at 1200, 1000, 800, and 600 Kilocycles if necessary bend plates (of rear R.F. section of variable only).

To align Short wave band, set wave changing switch to RED (left turn) and with input oscillator connected as above and set at 1720 KC, tune in signal, adjust padding condenser on rear of chassis to resonance. Check for output at 1550 KC and at harmonics of 1000 KC (2000 KC), of 1200 KC (2400 KC), of 1400 KC (2800 KC), and of 1720 KC (3440 KC). **DO NOT BEND PLATES.**

For failure to operate over both bands check 2A7 tube and connections to and contacts of wave changing switch.

WALGREEN CO.

MODEL 575  
Schematic, Socket  
Alignment, Trimmers

# Service Notes

Voltages taken from different points of circuit to chassis are measured with volume control full on, using a voltmeter having a resistance of 1000 ohms per volt. These voltages are indicated on the schematic circuit diagram.

### Part No. 145-2

Common Black to Brown	—.003	x 600 Volts
Common Black to Green	—.1	x 200 Volts
Common Black to Red	—.1	x 200 Volts
Common Black to Orange	—.25	x 200 Volts
Blue to Blue	—.05	x 400 Volts

### Part No. 145-3

Common Black to Brown	—.1	x 200 Volts
Common Black to Green	—.05	x 200 Volts
Common Black to Orange	—.05	x 200 Volts
Common Black to Yellow	—.05	x 200 Volts

## Aligning I. F. Transformer Voltage

1. With volume control full on, at extreme right of its rotation, and with variable condenser at its maximum capacity position (extreme right of its rotation) make the following adjustments:

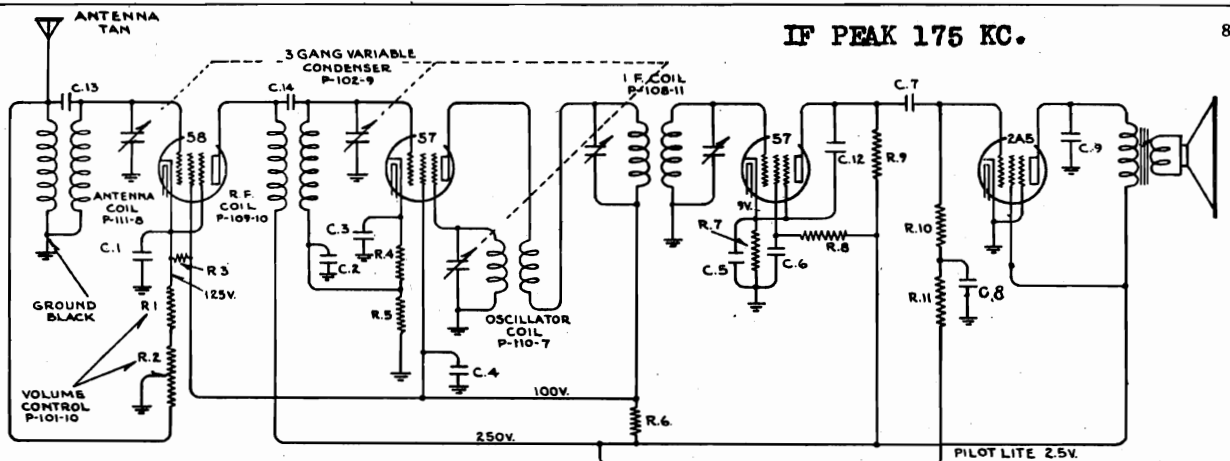

- Connect an external oscillator adjusted to 175 kilocycles, in series with a .1 mfd. condenser, to the control grid cap of the type 57 tube located between the R. F. coil (part numbers 109-10) and the I. F. transformer (part number 108-11) and chassis.
- Adjust trimming condensers of I. F. transformer (part number 108-11) to resonance. See top view of chassis. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or between the plate and screen terminals of the type 2A5 tube, by means of an adapter. Maximum deflection of the meter indicates resonance. Care must be taken to use only enough signal to give a readily readable output, as excessive input will result in overload and a false resonance point.

NOTE: The two trimmer condensers which tune the primary and secondary of the I. F. transformer are adjusted by set screws accessible from the back of the chassis.

## Aligning R. F. and Oscillator Circuits

1. Connect the external oscillator set at 1720 kilocycles and in series with a 200 Mfd. condenser, between the antenna (tan) and ground (black) leads.

- With volume control full on and variable condenser plates in minimum capacity position, plates entirely out of mesh (extreme left of its rotation), adjust trimmer of rear oscillator section of variable condenser to resonance.
- Shift external oscillator frequency from 1720 to 1400 kilocycles, pick up signal by rotating variable condenser and peak R. F. (center) and antenna (front) section trimmers of variable condenser to resonance.
- Check tracking at 1500, 1200, 1000, 800, 600 and 530 kilocycles by changing external oscillator frequency and rotating variable condenser to pick up signal. Adjust slotted end plates of R. F. (center) and antenna (front) sections to increase output, if necessary. DO NOT BEND OSCILLATOR PLATES.

**ALIGNING INSTRUCTIONS—**

Descriptions of various dummy antennas used and referred to in these instructions:  
 (1) I.F. Dummy—Consists of a .1 mfd. condenser connected in series with the external oscillator.  
 (2) Broadcast Dummy—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.  
 (3) Intermediate and Short Wave Dummy—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

**Resonance Indicator:**  
 Use as a resonance indicator an output meter connected across the primary of its rotation, or by means of an adapter between the plate and screen terminals of the type 42 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range volt meter should be used.

**SERIES A**

**Alignment**  
 No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as poor installations, open or grounded antenna systems, low line voltages, defective tubes, condensers and resistors. In order to properly align this chassis, an oscillator (generator) is absolutely necessary. No aligning adjustments should be attempted with the chassis in the cabinet. To remove the knobs, pull them off and to take the chassis out of the cabinet, remove the three bolts by which it is fastened and the speaker plug which you will find on the front flange of the chassis.

**Aligning I. F. Transformers**

1. With volume control full on, the extreme right of its rotation, and with wave changing switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, plates entirely out of mesh, adjust the I.F. transformers (adjustments at the top of parts number 108-26 and 108-27—see top view).  
 (a) Connect external oscillator in series with I.F. dummy antenna. With external oscillator adjusted to 370 kilocycles, in series with I.F. dummy antenna to the control grid cap of the type 6D6 tube and chassis ground, adjust output I.F. transformer, part number 108-27, to resonance.  
**Note:** Output I.F. transformer, part number 108-27, has only one adjustment.  
 (b) Move generator output clip from grid of 6D6 to grid cap of type 6F7 tube and align input I.F. transformer, part number 108-26, to resonance. **NOTE: IT IS EXTREMELY NECESSARY TO ALIGN BOTH I.F. STAGES SEPARATELY.**

**Broadcast Band Alignment—**

(540 - 1720 Kilocycles)  
 1. With wave changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with broadcast dummy antenna to an antenna lead and black ground lead, make the following adjustments:  
 (a) Set external oscillator to 1720 kilocycles and adjust oscillator trimmer to resonance. This adjustment is the rear adjustment of a group of three located next to the variable condenser.  
 (b) Readjust external oscillator to 600 kilocycles and adjust broadcast series pad to resonance by rotating condenser to approximately 600 kilocycles, rocking it slowly to and fro until by adjusting pad maximum output is attained. This adjustment is located at the front of the chassis next to the variable condenser and wave changing switch.  
 (c) Check for tracking and sensitivity at 1400 and 1000 kilocycles. **NOTE:** It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

**Short Wave Band Alignment—**

(7.5 - 23.0 Megacycles)  
 1. This band is aligned after the I.F. adjustments have been completed. Set wave selector switch in the short wave position, extreme right of its rotation, set pointer of dial to 21 megacycles.  
 (a) With external oscillator set at 21 megacycles, and connected to the tan antenna lead in series with the short wave dummy and to the black ground lead, adjust the oscillator short wave trimmer until generator signal is picked up. This trimmer is the one closest to the front of the chassis of the group of three trimmers located next to the gang condenser (see top view of chassis).  
 (b) Adjust short wave antenna trimmer to resonance. This adjustment is to the right of the 6F7 tube and is the one closest to the front of the chassis (see top view).  
 (c) Re-set external oscillator to 9 megacycles and pick up oscillator signal by rotating variable condenser, moving dial pointer. Check for tracking and sensitivity and do not bend plates. **NOTE:** It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

**Intermediate Band Alignment—**

(2.3 - 7.6 Megacycles)  
 1. With wave selector switch in the center position and with dial pointer set to 7 megacycles, makes the following adjustments:  
 (a) With external oscillator set at 7 megacycles and connected in series with the short wave dummy antenna to the tan antenna lead and black ground lead, same as for short wave adjustments, adjust center trimmer of oscillator coil, part number 110-13, until 7 megacycle signal is picked up. This is the center adjustment of a group of three located next to the gang condenser (see top view).  
 (b) Adjust antenna trimmer to resonance, this adjustment is the rear of a group of two located at the right of the chassis next to the 6F7 tube (see top view).  
 (c) Re-set external oscillator to 2.5 megacycles (2500 kilocycles), pick up signal by rotating condenser and moving dial pointer. Check for tracking and sensitivity. Do not bend plates. **NOTE:** It is extremely necessary in making all of the above adjustments that the fundamental signal of the oscillator be tuned in and not the image frequency, which will fall below the fundamental.

**Service Notes**

To check for open by-pass condensers, shunt each condenser with another of similar capacity and of the same voltage rating, which is known to be good, until the defective unit is located. Open by-pass condensers frequently cause oscillation and distorted tone. Defective and shorted electrolytic filter condensers cause excessive hum, motor-boating, low volume and a reduction in all D.C. voltages. Open or shorted electrolytic and by-pass condensers (across bias resistor of type 42 tube) will cause low volume and distorted tone.  
 Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. The drive may be disassembled to replace the compression spring (part number 112-31) by removing the two screws which fasten it to the dial bracket. Before reassembling all parts should be carefully cleaned and a small amount of vaseline applied to the ball bearings. All other dial parts are hardened and should cause no trouble.

**Notes**

25 Cycle chassis differ from regular 60 cycle and 40 cycle chassis in that a larger electrolytic filter condenser is used. The regular condenser is part number 119-11 and the larger unit for the 25 cycle chassis is part number 119-12.  
 Part number 106-18, a metal clad resistor, consists of the following sections with resistances and wattages as noted: one, 500 ohms; one, 35 ohms, one, 200 ohms, all 1/3 watt, plus or minus 10%.

Read from cathode to negative side of filter choke.

NOTE:  
1. DOTTED LINES DENOTE SHIELDING.  
2. ALL NOS. SHOWN RELATIVE TO PARTS ARE OUR PART NUMBERS.  
3. NUMBERS SHOWN WITH PREFIX 'A' ARE COMPLETE ASSEMBLIES.

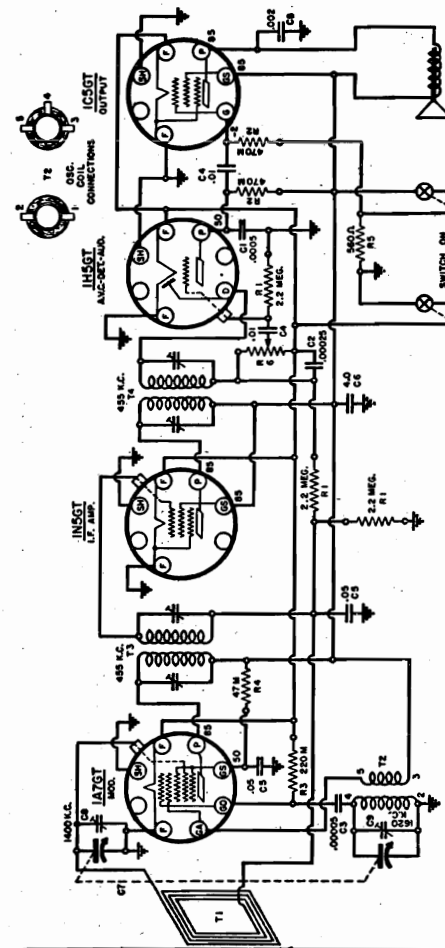

TO ALIGN THE VARIABLE CONDENSER:  
1. Connect the high output side of the oscillator to the receiver antenna lead and the ground to the chassis.  
2. Place the band selector switch for operation on the broadcast band, tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSERS LOCATED ON TOP OF THE GANG CONDENSER.

If the R.F. and antenna coils are not defective, and if the rotor and stator plates of the gang condenser have not been bent so as to destroy proper spacing, the receiver will correctly track over the entire tuning range.

**DESCRIPTION**

This receiver is a portable, four (4) tube, battery operated superheterodyne with self-contained loop antenna and batteries.

The tubes used are a 1A7GT as an oscillator converter; a 1N5GT as an I. F. amplifier; a 1H5GT as an A.V.C. detector and audio amplifier; and a 1C5GT as a power output.

This receiver is made to cover the standard broadcast band from 1620 K.C. to 535 K.C.

**BATTERIES**

Listed below are various manufacturers of batteries and their part numbers that may be used to make up the combination of batteries to be used with this receiver.

Wireless Record Player  
Schematic Data

WARWICK MFG. CORP.

ATTACHMENT

There is incorporated in this Phono-Oscillator unit a tip jack terminal strip microphone connection. The microphone is supplied as an attachment and can be purchased under the part No. 79-263 from your dealer. In its attachment to the receiver, plug in the ends of the microphone cord into the tip jacks (see pictorial) and have switch in the first position. That is, in the position to operate the oscillator but not the phono-motor.

Note:—Be sure to shut off the record player completely when it is not in use by turning the switch to the "off position".

PHONO-OSCILLATOR

DESCRIPTION

This unit is a Two Tube Phono-Oscillator. The tubes used are a 12SA7 as an oscillator and a 3524GT as a power rectifier.

This unit should be operated between 1500 K.C. and 1700 K.C. and is so designed that the playing of a record on the unit makes it possible that you receive this same recording from any radio set within a nearby vicinity.

INSTALLATION

This Phono-Oscillator is designed to operate from a 105-180 volt 60 cycle A.C. current supply only; do not connect this to any other source unless so specified. If in doubt about your power supply, your local power company will give you this information.

There are no connections needed between the Radio Receiver and the Phono-Oscillator. The only needed connection is the power supply line cord to an electric outlet.

For best results it would be advisable to use medium or soft needles. They will assure you longer record life and are not as severe on the tone arm as other types of needles.

The tone arm is a sensitive unit and precaution should be taken in handling. It would be injurious to drop or rest the tone arm on the point of the needle. Always use arm rest when the Phono-Oscillator is not in use.

OPERATION

Place the Phono-Oscillator near an electric outlet and within a distance of about 80 feet of the Radio Receiver which you intend to use. Do not set this unit near a radiator or other heater since the cabinet may be damaged.

Attach line cord plug to the nearest outlet.

Adjust your radio receiver to maximum volume and set tuning dial to a point at the high frequency end between 1600 K.C. and 1700 K.C. where minimum interference from outside stations is noticed.

Allowing the Radio Receiver to remain at that adjustment, turn switch knob on the Phono-Oscillator (see pictorial diagram) in a clockwise direction until the first click is noticed. This will turn the oscillator section of the unit on, and about 1/2 minute should be allowed for tubes to heat up. With a record in the proper position on the turn table turn the same switch knob further toward the right (in a clockwise direction) until another click is heard. This will turn the Phono-Motor on and when the record has reached its proper speed of rotation, set the pick-up arm with its needle lightly upon the record.

The Phono-Oscillator is now operating and if it is not being heard over the radio it will indicate that it is oscillating at a different frequency than that set up on the Radio Receiver. In order to set the oscillator to the same position as the radio receiver there is incorporated a tuning condenser, (see pictorial layout). Turn this condenser with a screw driver in a clockwise rotation, slowly and carefully until the response of the record is picked up by the Radio Receiver. If when turning the tuning condenser as mentioned above you do not get a response after 3 or 4 turns it will indicate that you have gone past the point. It will be necessary to turn in the opposite direction (counter clockwise) until the response is obtained.

In order to get maximum volume and clarity it would be advisable to tune your radio a few degrees one way or the other until the best result is obtained.

MODEL 9-58  
Alignment, Tuner Data

WARWICK MFG. CORP. MODEL 9-46  
Alignment, Wave Trap Notes  
Tuner Data

**WAVE TRAP:** Model 9-46  
In localities where particular interference is noticed from odd transmitters it would be advisable to attach to the receiver an antenna wave trap. Connect the antenna wire from the receiver (this lead) and the antenna lead-in from your antenna to the binding post marked "A" on the wave trap. Connect the binding post of your receiver (this lead) and the ground lead coming from your ground connection to the binding post of your wave trap. This antenna wave trap can be obtained under the part No. 1016310255 as a service part.

This wave trap is supplied tuned to a frequency of 455 K.C. If there is only one interfering station it would be advisable to tune the wave trap to the frequency of the interference. Where there are more than one interference it would be advisable to have the wave trap tuned to a frequency of 455 K.C. to keep the interference at a minimum.

**HOW THE AUTOMATIC PUSH-BUTTON TUNER FUNCTIONS:** Model 9-46  
This unit is mechanically operated by means of a proven cam and lever action, designed to rotate a shaft 90 degrees. Since the variable gang condenser must rotate 180 degrees, a 2 to 1 step up mechanical lever action is incorporated to give full rotation to the gang condenser. Three links are used to transmit the motion of the push-button to the variable gang condenser: first, a driver lever or link connected to the tuner shaft, second, a driven lever connected to the gang condenser shaft and third a connecting link, connecting the two levers together mechanically.

The plunger bar that retains the screw type push-buttons also holds a cam to itself by a shoulder that this cam fits on the rivet proper and is locked in position with a small square plate, fitting in the plunger bar. To lock on into position, screw the push-button knob toward the right (clockwise). The end of the push-button screw will then force a small square plate known as a brake shoe against the periphery of the cam. To disengage the cam, the push-button knob must be loosened by rotating it toward the left (counter-clockwise). When this push-button screw is loosened, it will automatically release the brake shoe from the cam, leaving the cam free to rotate and set its new position to the setting of the lever bar.

If it becomes necessary to realign the tuner in relation to the gang condenser, the following procedure should be followed to assure perfect tuning operation:

1. Slip driver arm on to the tuner shaft and the driven arm on to the variable condenser shaft. Do not tighten set screws.
  2. Connect these two lever arms by slipping the connecting link over the heads of the shoulder rivets. This link has a slight offset and precaution should be taken when assembling to see that it is installed in the proper manner as illustrated in the Pictorial. It will be necessary to tilt the link slightly in order to slip it over the head of the shoulder rivets. Then attach spring as shown.
  3. In making the final adjustment, that of setting the condenser in relation to the tuner, set the condenser to the station desired. Then the spring on the end of the lever arm should be raised as high as possible (see Pictorial). With the lever arm in a vertical position as shown, tighten set screws.
- It is essential that all set screws be tightened securely so as to prevent a variation from original setting. If for some reason, a replacement is necessary for some particular item on the tuner proper, such as a lever bar, cam, plunger bar or brake shoe, it would be advisable to return the complete tuner proper for replacement.

**HOW THE AUTOMATIC PUSH-BUTTON TUNER FUNCTIONS:** Model 9-58  
This unit is mechanically operated by means of a proven cam and lever action, designed to rotate a shaft 90 degrees. Since the variable gang condenser shaft must rotate 180 degrees, a 2 to 1 step up mechanical lever action is incorporated to give full rotation to the gang condenser. Three links are used to transmit the operation of the push-button to the variable gang condenser: first, a driver lever or link connected to the tuner shaft, second, a driven lever connected to the gang condenser shaft and third, a connecting link, connecting the two lever arms together mechanically.

If it becomes necessary to realign the tuner in relation to the gang condenser, the following procedure should be followed to assure perfect tuning operation:

1. Attach driver arm to the lever bar by means of two machine screws, making sure that they are assembled with lockwashers and tightened securely.
2. Slip the drum assembly, which consists of the drum, drum hub, and the driven arm, over the variable condenser shaft but do not tighten set screws.
3. Connect these two lever arms by slipping the connecting link over the heads of the shoulder rivets. This link has a slight bend (offset) about 1/3 of its length and is to be installed with the shorter end toward the top and the offset towards the rear when looking at it from the drum end. Attach the tension spring between the two shoulder rivets. This spring is incorporated to take up all the unnecessary slack in the drive.
4. In making the final adjustment, that of setting the condenser in relation to the tuner, place the condenser arm across gradually down to within 1/4 of an inch of the variable condenser shaft. When in this position, tighten set screws in the drum hub with the right hand.

**INDEX TAPS:** Model 9-46  
Cut the call letters of your four (4) selected stations from the list supplied with your receiver and slip them into the top of the Push-Buttons. Arrange the call letters in the buttons with the call letter of the highest frequency station, the one that comes in closest to the number 100 on the tuning knob, toward the rear of the receiver and work progressively toward the front so that the lowest frequency station, the one that comes closest to the number 90 on the tuning knob, would be toward the front.

**SETTING PUSH-BUTTONS:**  
1. By means of the Station Selector Knob, tune in WITH THE RIGHT HAND AS ACCURATELY AS POSSIBLE the station having the highest frequency—that is, your selected station which is tuned in nearest number 100 on the Station Selector Knob.

2. After the station has been tuned in accurately with the right hand, continue to hold it in its exact position firmly, and with the left hand turn the Push-Button to be set up for that station by uncreeping the Push-Button about one turn to the left (counter-clockwise).

3. Continuing to hold the Station Selector Knob in its exact position, PUSH THE PUSH-BUTTON IN ALL THE WAY with the left hand.

4. After the Push-Button has been depressed all the way, tighten it gently toward the right (clockwise). Release Push-Button slowly and when in normal position grip button and tighten firmly.

The Push-Button tuning system is now correctly set up for your first selected station of highest frequency and the Call Letter Tab for that station should be in the Push-Button nearest the rear of the receiver.

Follow through with this same procedure, setting up the other 3 stations in the order of their frequency—that is, the second station set up will be second highest in frequency and the third station set up will be third highest in frequency.

**INDEX TAPS:** Model 9-58  
Cut the call letters of your four (4) selected stations from the list supplied with your receiver and slip them into the Tab Holder from the front, with the clear celluloid in front of the call letters to protect them. Arrange the call letters in the Buttons from right to left. Have the call letters of the lowest frequency station, that is, the station that comes in nearest to the top of the dial scale, at the extreme right-hand button and work progressively to the left so that the highest frequency call letters will be in the extreme left-hand button.

**SETTING PUSH-BUTTONS:**  
1. By means of the Station Selector Knob, tune in WITH THE RIGHT HAND AS ACCURATELY AS POSSIBLE the station having the lowest frequency—that is, your selected station which is tuned in nearest the top of the dial scale.

2. After the station has been tuned in accurately with the right hand, continue to hold it in its exact position firmly, and with the left hand loosen the Push-Button to be set up for that station by uncreeping the Push-Button about one turn to the left (counter-clockwise).

3. Continuing to hold the Station Selector Knob in its exact position, PUSH THE PUSH-BUTTON IN ALL THE WAY with the left hand.

4. After the Push-Button has been depressed all the way, tighten it gently toward the right (clockwise). Release Push-Button slowly and when in normal position grip button and tighten firmly.

The Push-Button tuning system is now correctly set up for your first selected station of lowest frequency and the Call Letter Tab for that station should be at the extreme right of the Call Letter Holder.

Follow through with this same procedure, setting up the other 3 stations in the order of their frequency—that is, the second station set up will be second lowest in frequency and the third station set up will be third lowest in frequency.

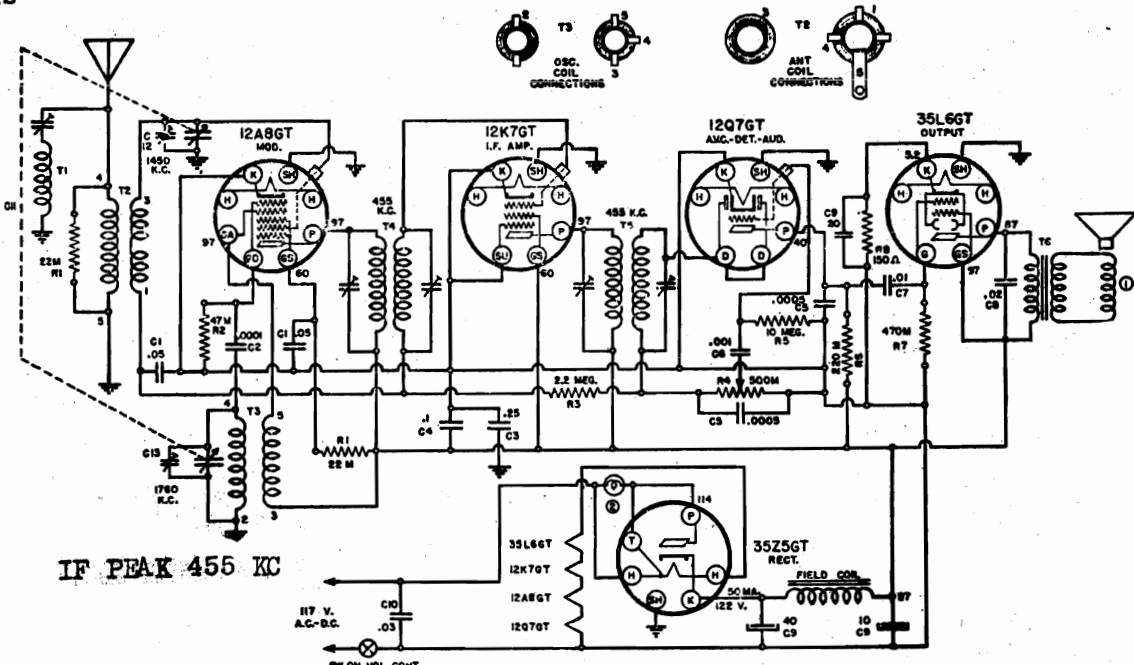

Carefully check each Push-Button for the accuracy of its setting. If, when tuning in any station with its automatic adjustment, you find that the station is not coming in as accurately as that obtained with manual tuning, this may indicate the automatic adjustment for that station was not set up correctly. This may be due to the fact that the Push-Button has been tuned in manually, or that the station was not set up correctly. See Chart Below. The Push-Button adjustments, correction can be made by repeating the above procedure for that button only. Do not reset those Push-Buttons that are accurately adjusted.

No further adjustments are necessary to operate your radio automatically or manually. To receive any one of your selected stations for automatic operation, merely push in ALL THE WAY the Button set up for that station.

To receive all other stations in the regular manner turn the tuning knob to the frequency of the station desired.

This receiver is a 6-tube AC/DC current operated Superheterodyne.  
The tubes used are: a 6A7 as an oscillator-converter; a 6D6 as an I. F. amplifier; a 75 as an A.V.C. detector and audio amplifier; a 25L6G as a beam output; a 25Z5 as a power rectifier; and a BK49B as a voltage divider.  
This receiver is made to cover from 1750 KC. to 535 KC., which covers the standard broadcast band and the first police band.

This receiver is a 5 tube AC/DC current operated T.R.F.  
This receiver is made to cover from 1750K.C. to 535K.C.

MODEL 542 (Late)

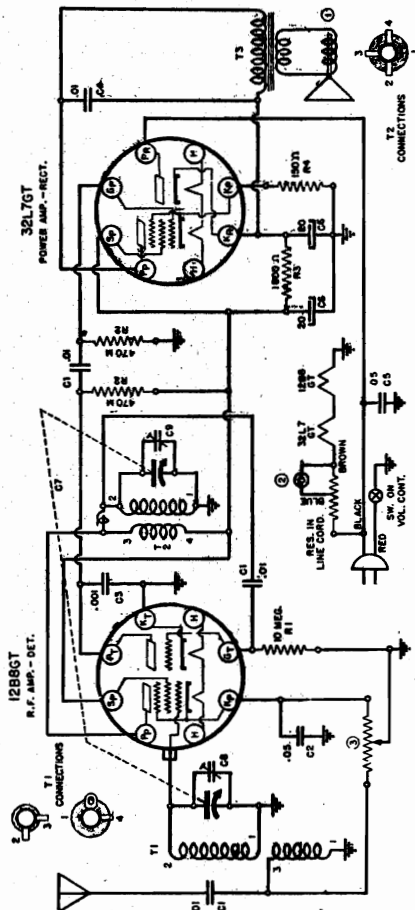

STANDARD BROADCAST RECEIVER

Model No. 9-22 is a 2-tube T.R.F. radio receiver for operation on a 117 Volt A.C. 60 cycle or 117 Volt D.C. supply. The tubes used are a 12B8GT as an R.F. Amplifier and Detector and a 35L7GT as a Power Amplifier and Rectifier.

This receiver covers a frequency range from 540 Kilocycles to 1760 Kilocycles (K.C.).

The scale is calibrated in kilocycles (less the final zero). Standard broadcast stations are listed in kilocycles in most station lists.

**DESCRIPTION**

This receiver is a 4 tube, 6 volt storage battery operated superheterodyne.

The tubes used are 6D86 as oscillator modulator, 6S7G as I.F. amplifier, a 6T7G as A. V. C. and audio rectifier and audio voltage amplifier and a 1F5G as power audio amplifier.

This receiver is made to cover the standard broadcast band, from 1730 K.C. to 535 K.C.

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 10,000 ohms, to the two plate and screen pins of the 1F5G tube.

Connect the signal generator to the grid cap of the 6D8G tube through a 1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. Set the dial to about 1000 K.C., feed in a 456 K.C. signal. Adjust the first and second I.F. trimmers until the maximum output is obtained. This aligns the I.F.

Turn the dial to the extreme high frequency end. Feed a 1740 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1740 K.C. oscillator trimmer until maximum output is shown. Set the generator to 1400 K.C. and tune in this signal on the receiver. Then adjust the 1400 K.C. antenna trimmer to maximum output. This completes the alignment.

LOCATIONS OF PARTS UNDER CHASSIS

LOCATIONS OF PARTS ON TOP OF CHASSIS

**FOR TUNER SEE INDEX**

TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS.  
VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO CHASSIS.  
VOLTAGES MUST BE MEASURED WITH NO SIGNAL.  
ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMER CONDENSERS.  
WHERE NO VOLTAGE READING IS SHOWN AT SOCKET PRONG, IT INDICATES ZERO VOLTAGE OR A VERY LOW READING.  
FIGURES AT CATHODES ARE CATHODE CURRENT IN MILLIAMPERES  
CAPACITY VALUES ARE IN MICROFARADS.

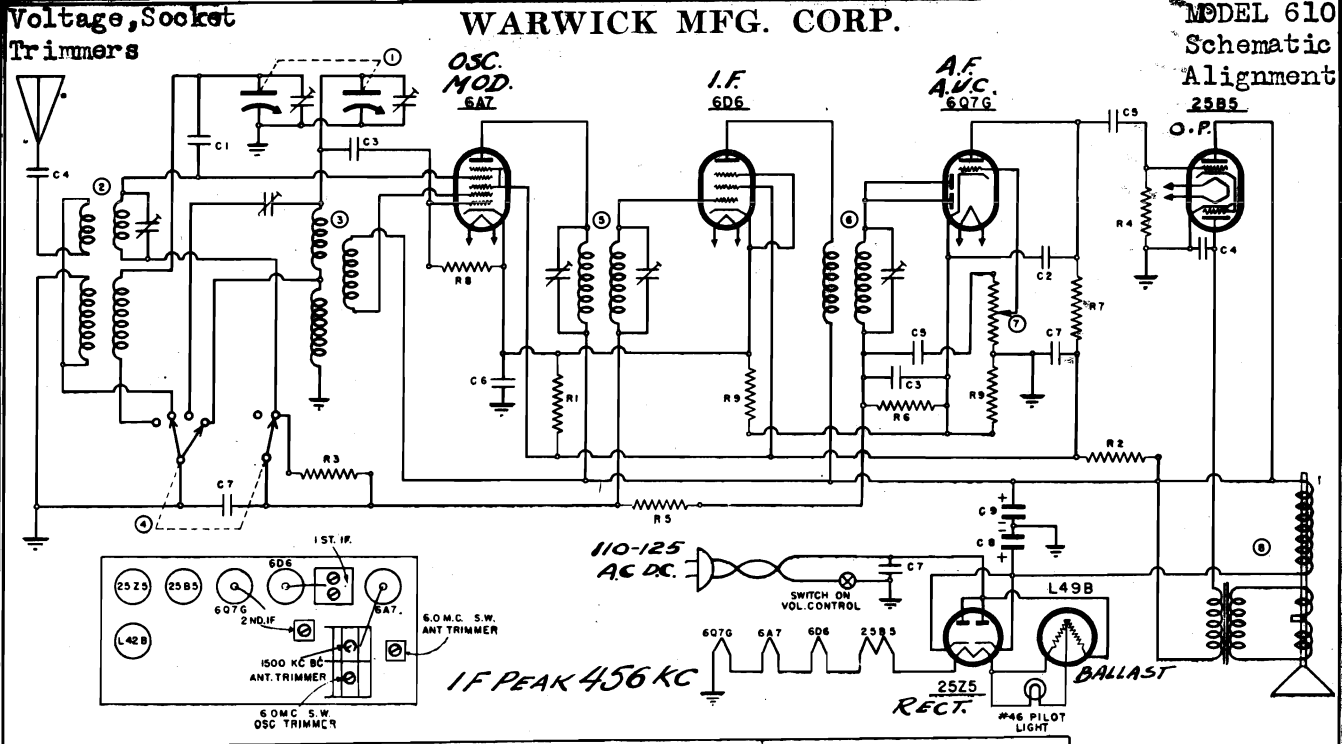

**ALIGNMENT PROCEDURE**

**PRELIMINARY**

- Output Meter Connections
- Output Meter Reading to Indicate 1 Watt
- Generator Ground Lead Connection
- Dummy Antenna Value to Be in Series with Generator Output
- Connection of Generator Output Lead
- Generator Modulation
- Position of Volume Control

Position of Variable	Generator Frequency	Dummy Antenna	Generator Connection	Adjustments (In Order Shown)	Trimmer Function
Closed	456 KC	1 mfd.	6A7 Grid	T2, T1	I. F.
Fully Open	1400 KC	.0002 mfd.	Antenna Conn.	C16	Oscillator Trimmer
600 KC	1580 KC	.0002 mfd.	Antenna Conn.	C15	Antenna Trimmer
	600 KC	.0002 mfd.	Antenna Conn.	C3	Antenna Padder

The variable condenser should be at 600 k.c. for antenna adjustment.  
The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy. A final adjustment of antenna padder condenser C3 is always made after the receiver is installed in the car, in order to match the car antenna.  
Always keep the output power from the generator at its lowest possible value to prevent the A.V.C. of the receiver from interfering with accurate alignment.

PART NO	DESCRIPTION	PART NO	DESCRIPTION	PART NO	DESCRIPTION	610	
R2	6104	5000 OHM 1/2 WATT CARBON RES	C1 15-105	00056 MFD. MICA CONDENSER 13%	1	19-114	2 GANG VARIABLE CONDENSER

R8	6056	200,000	C7 1622	35	7	24-106	VOL. CONTROL WITH SWITCH
R9	6025	50,000	C8 18-211	30	8	79-221	DYNAMIC SPEAKER
R10	6009B	50	C9 18-211	8			

The two tuning bands covered are  
 1720 K.C. to 540 K.C.  
 6.2 M.C. to 2.28 M.C.

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter. Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the receiver chassis through another .1 M.F. condenser. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Turn the wave switch to the short wave position and set the dial to 6.0 M.C. Feed a 6.0 M.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Tune the 6.0 M.C. Oscillator trimmer to give resonance. Two points may be found where this signal can be heard. The correct setting is the one where the trimmer is screwed the loosest. This may also be checked by turning the dial to about 5.0 M.C. where the signal should again be heard.

Then turn the wave switch to broadcast position and turn the dial to the extreme high frequency end. Feed in a 1720 K.C. signal and adjust the broadcast oscillator trimmer, which is located under the receiver at the wave switch, to resonance. Then set the signal generator to 1500 K.C. and tune in this signal on the receiver. Adjust the 1500 K.C. antenna trimmer for maximum output.

Again turn the wave switch to short wave position and tune in a 6.0 M.C. signal from the generator. Adjust the 6.0 M.C. antenna trimmer to maximum output.

This receiver is made to cover from 1740 K.C. to 535 K.C.

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to plate and screen pins of output tube, or a low voltage A.C. meter may be used connected across speaker voice coil. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. Set the dial to about 1000 K.C., feed in a 456 K.C. signal. Adjust first and second I.F. trimmers for maximum output. Refer to chassis lay-out for location of trimmers.

Turn the dial to the extreme high frequency end. Feed a 1740 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1740 K.C. oscillator trimmer until maximum output is shown. Set the generator to 1400 K.C. and tune in this signal on the receiver. Then adjust the 1400 K.C. antenna trimmer to maximum output. This completes the alignment.

VOLTAGES MEASURED WITH 1000 OHM PER VOLT VOLTMETER.

This receiver is made to cover  
from 1740 K.C. to 540 K.C.

FOR TUNER SEE INDEX

CHASSIS LAYOUT FOR MODEL 655B.

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to plate of output tube and B+, or a low voltage A. C. meter may be used connected across speaker voice coil. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. Set the dial to about 1000 K.C., feed in a 455 K.C. signal. Adjust first and second I.F. trimmers for maximum output. Refer to chassis lay-out for location of trimmers.

Turn the dial to the extreme high frequency end. Feed a 1760 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1760 K.C. oscillator trimmer until maximum output is shown. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. antenna trimmer to the maximum output. This completes the alignment.

MODEL 654

Schematic, Voltage, Socket

WARWICK MFG. CORP.

Trimmers, Alignment

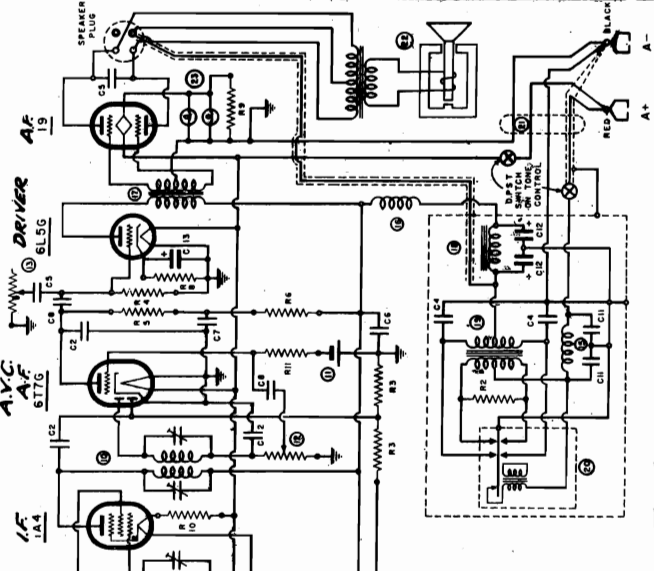

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.4 M.C. to 1.7 M.C. and high frequency or foreign band which is from 19 M. C. to 5.0 M.C.

This receiver is a 6 tube, 6 volt storage battery operated superheterodyne.

		12 24-105	VOLUME CONTROL		
		13 26-107	TONE CONT. WITH SWITCH		

The short wave band is aligned in the same way using a 15 M.C. signal and adjusting the 15 M.C. short wave antenna trimmer after having turned the wave switch to the right hand position.

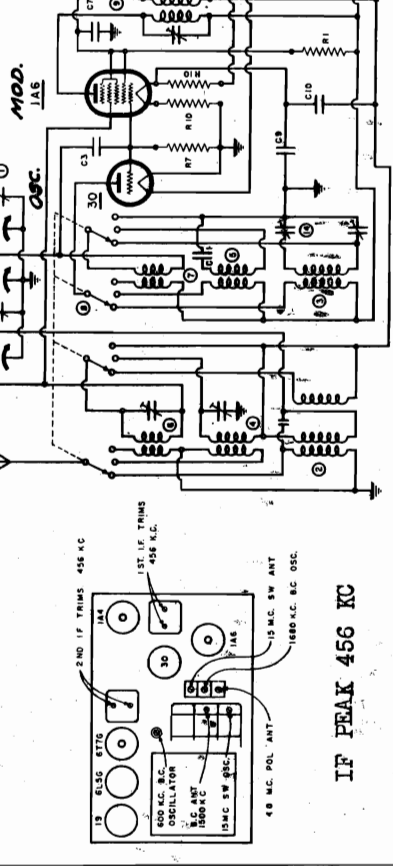

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 10,000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 1A6 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground post of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the signal generator connected to the grid cap of the 1A6, turn the wave switch to the right hand (short wave) position. Set the dial and the signal generator to 15.0 M.C. Tune in the signal by adjusting the 15.0 M.C. oscillator trimmer. The signal will be heard at two different settings of the trimmer. The proper setting is the one where the signal is heard when the trimmer is the loosest. Also when the dial of the receiver is turned the signal will be heard again at about 14.0 M.C. If the signal is heard at about 16.0 M.C. on the dial instead of 14.0 M.C. the wrong setting has been used and should be corrected.

Set the wave switch on broadcast position and turn the dial to the extreme high frequency end. Feed a 1680 K.C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output while tuning the receiver back and forth across the signal from the generator. This completes the alignment of the broadcast band.

The police band is aligned by feeding a 4.0 M.C. signal to the receiver antenna lead through the .00025 condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output.

LOCATIONS OF PARTS UNDER CHASSIS

**FOR TUNER SEE INDEX**

TUBE SOCKETS ARE VIEWED FROM UNDER SIDE OF CHASSIS.  
VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO CHASSIS.  
VOLTAGE READINGS MUST BE MEASURED WITH NO SIGNAL.  
ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMER CONDENSERS.  
WHERE NO VOLTAGE READING IS SHOWN AT SOCKET PRONG, IT INDICATES ZERO VOLTAGE OR A VERY LOW READING.  
FIGURES AT CATHODES ARE CATHODE CURRENT IN MILLIAMPERES.  
CAPACITY VALUES ARE IN MICROFARADS.

**ALIGNMENT PROCEDURE**

**PRELIMINARY**

- Output Meter Connections
- Output Meter Reading to Indicate 1 Watt
- Generator Ground Lead Connection
- Dummy Antenna Value to Be in Series with Generator Output
- Generator Modulation
- Position of Volume Control

Position of Variable	Generator Frequency	Dummy Antenna	Generator Connections	Trimmer Adjustment (In Order Shown)	Trimmer Function
Closed	262 KC	.1 mfd.	6A8 Grid	T5, T4	I.F.
Fully Open	1580 KC	.0002 mfd.	Antenna Conn.	C3	Oscillator Trimmer
1400 KC	1400 KC	.0002 mfd.	Antenna Conn.	C2, C6	Ant. & R.F. Trimmer
600 KC (Rock)	600 KC	.1 mfd.	6K7 R.F. Grid	C9	Padder Oscillator
600 KC	600 KC	.0002 mfd.	Antenna Conn.	C5	Padder Antenna

The variable condenser should be rocked back and forth a degree or two while making the 600 K.C. adjustment on oscillator padder only.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

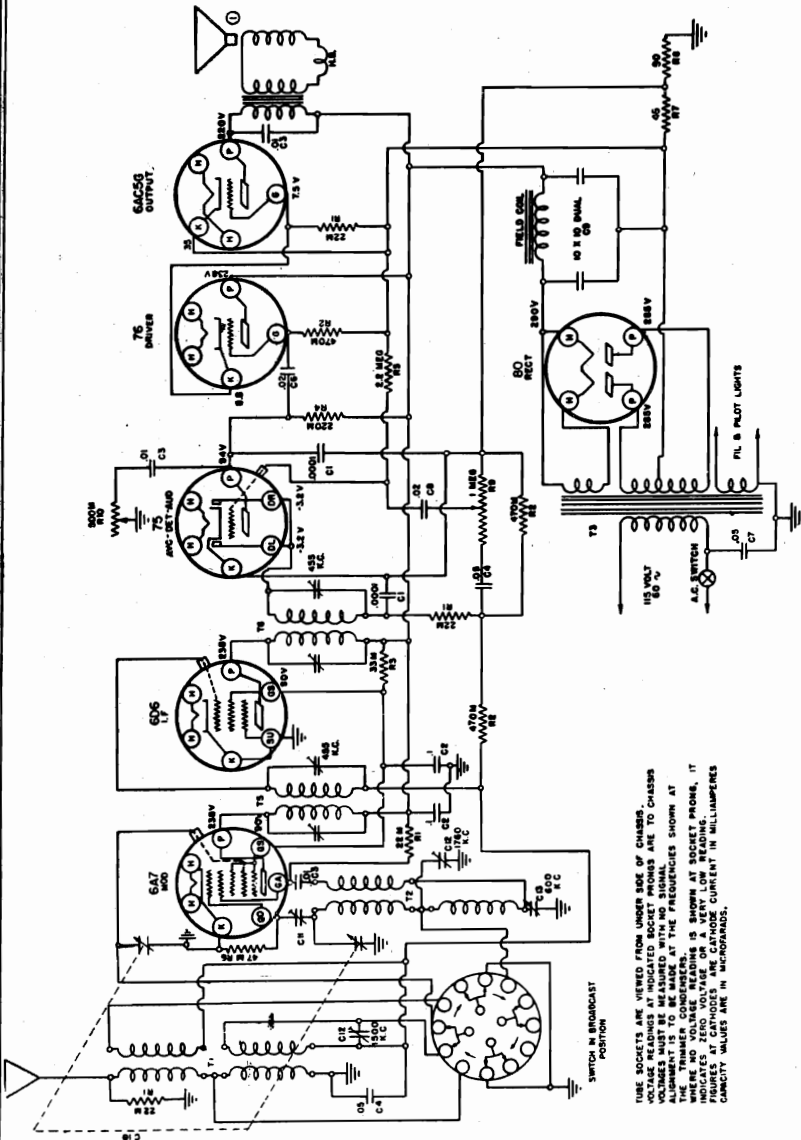

Across Loud Speaker Voice Coil  
1.85 Volts  
Receiver Chassis  
See Chart Below  
See Chart Below  
30%, 400 Cycles  
Fully On

A final adjustment of the antenna padder condenser C5 is always made after the receiver is installed in the car, in order to match the car antenna.

Always keep the output power from the generator at its lowest possible value to prevent the A.V.C. of the receiver from interfering with accurate alignment.

DESCRIPTION

This receiver is a 6-tube alternating current operated superheterodyne. The tubes used are—a 6A7 as oscillator modulator, a 6D6 as I. F. amplifier, a 75 as A. V. C. and audio rectifier and audio voltage amplifier, a 76 as a direct coupled driver, a 6AC5G as a power audio amplifier, and a 80 as a power rectifier.

This receiver is made to cover two tuning bands—the standard broadcast band which ranges from 1740 KC to 540 KC, and the short wave band which has a frequency range of from 24 MC to 5.9 MC.

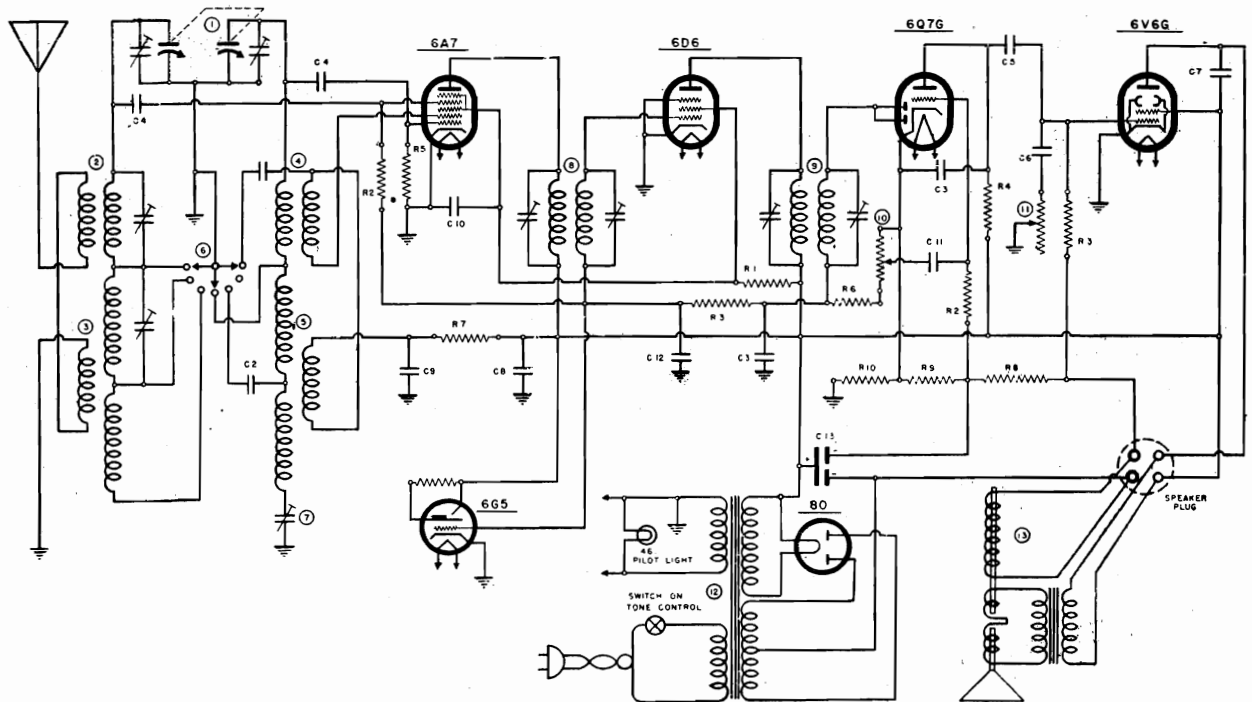

ALIGNMENT

FOLLOW PROCEDURE AS FOR MODEL 648 BUT ALIGN OSC-PAD, (C13 shown on chassis layout above) AT 600 KC as a final adjustment.

Schematic, Voltage, Socket  
Alignment, Trimmers WARWICK MFG. CORP.

This receiver is made to cover two tuning bands, the Standard broadcast band which ranges from 1740 K.C. to 540 K.C. and the short wave band which has a frequency range of from 24 M.C. to 5.9 M.C.

FOR TUNER SEE INDEX

TUBE SOCKETS ARE VIEWED FROM UNDERSIDE OF CHASSIS. VOLTAGE READINGS AT INDICATED SOCKET PRONGS ARE TO ZERO VOLTAGE REFERENCE POINT ON CIRCUIT. VOLTAGES MUST BE MEASURED WITH NO SIGNAL. ALIGNMENT IS TO BE MADE AT THE FREQUENCIES SHOWN AT THE TRIMMER CONDENSERS. WHERE NO VOLTAGE READING IS SHOWN AT SOCKET PRONG, IT INDICATES ZERO VOLTAGE OR A VERY LOW READING. CAPACITY VALUES ARE IN MICROFARADS.

**ALIGNMENT PROCEDURE**

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter. Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 10,000 ohms, to plate of output tube and B+, or a low voltage A. C. meter may be used connected across speaker voice coil. The output meter remains connected during the entire alignment procedure.

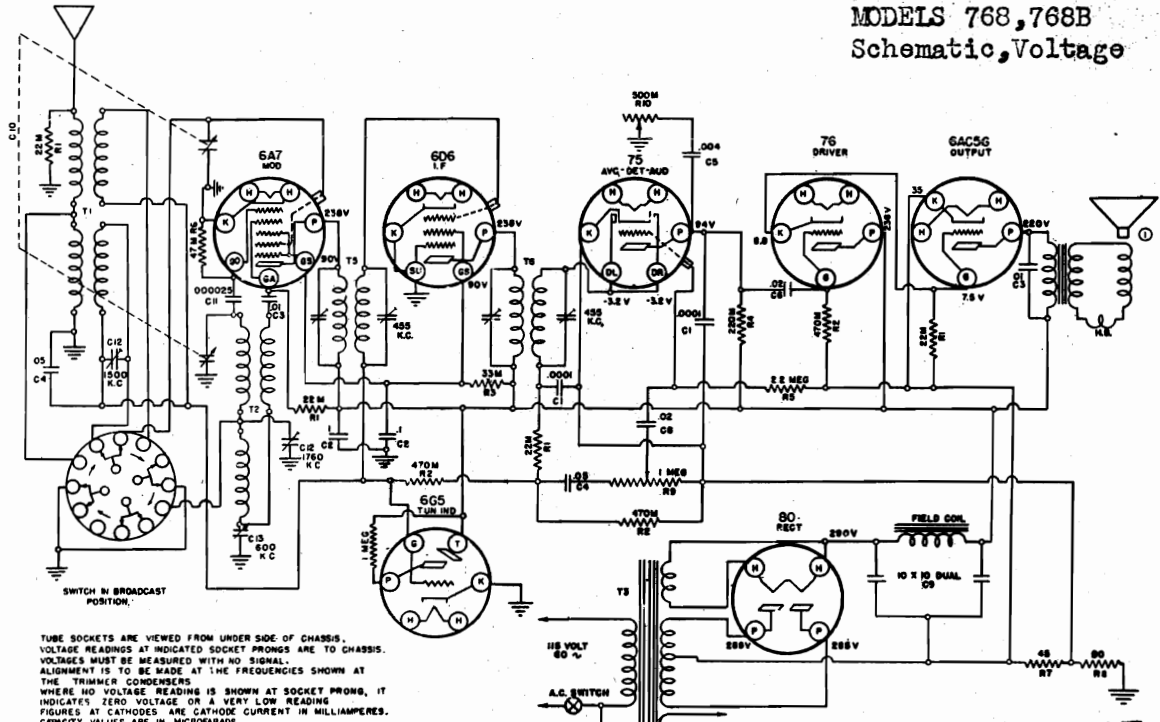

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. Set the dial to about 1000 K.C., feed in a 455 K.C. signal. Adjust first and second I.F. trimmers for maximum output. Refer to chassis lay-out for location of trimmers.

Turn the dial to the extreme high frequency end. Feed a 1760 K.C. signal to the receiver antenna lead through a .00025 MF mica condenser. Adjust the 1760 K.C. oscillator trimmer until maximum output is shown. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. antenna trimmer to the maximum output. Then impress a 600 K.C. signal into the receiver antenna lead and tune in this signal on the receiver. Adjust oscillator padding condenser to the maximum output. For the alignment of the short wave band open variable condenser to minimum capacity. With an impressed signal of 24 M.C. adjust trimmer designated as C14 in schematic diagram for maximum output. Follow through with this procedure several times in order to obtain the best alignment adjustment possible. This completes the alignment.

**FREQUENCY CALIBRATION ADJUSTMENT**

While a station of known frequency is tuned in, remove the pilot light socket. In the tuning control head, immediately in front of position from which the dial light socket has been removed, will be seen a small screw head. This is the calibration adjustment screw. By turning this screw with a small screw driver, the frequency indicated by the dial may be made to correspond to the frequency of the station tuned in. After adjusting calibration by this means the dial light socket is replaced.

After the receiver is installed the 600 K.C. antenna compensator condenser is adjusted to give best sensitivity while the receiver is tuned to as weak a station as can be heard near 600 K.C. The volume control should be turned full on while making this adjustment.

WARWICK MFG. CORP.

MODEL 872  
Schematic, Voltage, Socket  
Alignment, Trimmers

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.6 M.C. to 1.7 M.C. and high frequency or foreign band which is from 20 M.C. to 5.4 M.C.

**ALIGNMENT**

- IF** Adjust at 456 KC through a 0.1 mfd. condenser.
- SW** Proper adjustment is loose trimmer setting at 15 MC, as signal is heard at 2 settings. Signal must be heard only at about 14 MC dial setting and not at 16 MC.
- BC** Adjust oscillator trimmer at 1680 KC through 0.00025 mfd. condenser. Adjust antenna trimmer at 1500 KC. Adjust padder at 600 KC.
- Police** Adjust antenna trimmer at 4 MC., through 0.00025 condenser.

659, 768, 768B, 946, 749, 749B

After receiver is installed and antenna and ground properly connected, plug line cord into a convenient outlet. Then turn the volume control to about the center of rotation. This will turn the receiver on and put it in an operating condition. Time must be allowed for the tubes to heat up before stations can be tuned in. This time is approximately one-half minute.

The automatic tuning feature of your radio makes it possible to set up 6 favorite American broadcast stations and tune them in quickly with the automatic tuner. Choose stations for push-button operation heard with good volume at all times.

Cut the call letters of your 6 selected stations from the list supplied with your receiver and slip them into the Tab Holder from the top, with the clear celluloid in front of the call letters to protect them. Arrange the call letters in the Tab Holder from right to left. Have the call letters of the lowest frequency station at the extreme right and work progressively to the left so that the highest frequency call letters will be at the extreme left.

Follow the procedure outlined below, in order to adjust the push-buttons properly:

1. By means of the Station Selector Knob tune in WITH THE RIGHT HAND AS ACCURATELY AS POSSIBLE the station having the lowest frequency—that is, your selected station which is tuned in nearest the right-hand side of the dial.
2. After the station has been tuned in accurately with the right hand, continue to hold it in its exact position firmly, and with the left hand loosen the Push-Button to be set up for that station by unscrewing the Push-Button about one turn to the left (counter-clockwise).
3. Continuing to hold the Station Selector Knob in its exact position, PUSH THE PUSH-BUTTON IN ALL THE WAY with the left hand.
4. After the Push-Button has been depressed all the way, tighten it gently toward the right (clockwise). Release Push-Button slowly and when in normal position grip button and tighten firmly.

The Push-Button tuning system is now correctly set up for your first selected station of lowest frequency and the Call Letter Tab for this station should be at the extreme right of the Call Letter Holders.

Follow through with this same procedure, setting up the other 5 stations in the order of their frequency—that is, the second station set up will be second lowest in frequency and the third station set up will be third lowest in frequency.

Carefully check each Push-Button for the accuracy of the setting. If, when tuning in any station with its Automatic Push-Button it does not have equal volume or clarity to that obtained with manual tuning, this may indicate the automatic adjustment for that station was not made accurately. Should there be any inaccuracy in any one of the Push-Button adjustments, correction can be made by repeating the above procedure for that button only. Do not reset those Push-Buttons that are accurately adjusted.

No further adjustments are necessary to operate your radio automatically or manually. To receive any one of your four selected stations for automatic operation, merely push in ALL THE WAY the Button set up for that station.

Models 768, 768B

**ALIGNMENT PROCEDURE**

The following alignment procedure is for use only by competent service men having the proper equipment. Re-alignment is very seldom needed and is usually only required after some major part has been replaced because of damage to the receiver.

The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to plate of output tube and B+, or a low voltage A. C. meter may be used connected across speaker voice coil. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. Set the dial to about 1000 K.C., feed in a 455 K.C. signal. Adjust first and second I.F. trimmers for maximum output. Refer to chassis lay-out for location of trimmers.

Turn the dial to the extreme high frequency end. Feed a 1760 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1760 KC oscillator trimmer until maximum output is shown. Set the generator to 1500 KC and tune in this signal on the receiver. Then adjust the 1500 KC antenna trimmer to the maximum output. Then impress a 600 KC signal into the receiver antenna lead and tune in this signal on the receiver. Adjust oscillator padding condenser to the maximum output. Follow through with this procedure several times in order to obtain the best alignment adjustment possible. This completes the alignment.

MODEL 761

**ALIGNMENT PROCEDURE**

The following alignment procedure is for use only by competent service men having the proper equipment. Re-alignment is very seldom needed and is usually only required after some major part has been replaced because of damage to the receiver.

The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total resistance approximately 10,000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the 1A6 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground post of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1680 K.C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output while tuning the receiver back and forth across the signal from the generator. This completes the alignment of the broadcast band.

The police band is aligned by feeding 4.0 M.C. signal to the receiver antenna post through the .00025 condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output.

The short wave band is aligned in the same way using a 15 M.C. signal and adjusting the 15 M.C. short wave antenna trimmer after having turned the wave switch to the right hand position.

**DESCRIPTION**

This receiver is a 7 tube, 6 volt storage battery operated superheterodyne.

The tubes used are a 30 as oscillator, a 6D8G as modulator, two 1A4 tubes as I.F. amplifiers, a 6T7G as A.V.C. and audio rectifier and audio voltage amplifier, a 6L5G as audio driver and a 19 as power audio amplifier.

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.6 M.C. to 1.7 M.C. and high frequency or foreign band which is from 20 M.C. to 5.4 M.C.

While a ground is not always necessary with receivers which are made to use the lighting mains as a source of power, a battery operated receiver always requires a good ground if best performance and distance reception is expected. A ground may be made to a water supply system or to a galvanized pipe driven into ground that is moist most of the time. The use of a lightning arrester is very good insurance against damage by lightning. Several types are on the market and may be obtained very easily. Soldering of all antenna and ground lead joints will eliminate any noise which may be caused by loose connections.

The antenna and ground leads connect to the marked binding posts located on the back of the chassis.

A 6 volt storage battery is the only power supply required for this receiver. The yellow battery lead connects to the positive (+) terminal of the battery and the black lead connects to the negative (-) terminal. If these connections are reversed the receiver will not operate and may be seriously damaged if left this way for more than a short time. Never charge the battery while operating the receiver. Attempting to use any other source of power supply will cause serious damage to the receiver.

For MODELS A2, A3, A4, A5 Series  
Installation Data. Panel View, Details

# Instructions for Mounting the New 7 Station Automatic Tuning Panel on the 7, 9, 11 and 13 Tube Chassis (REPLACING MOTOR DRIVE PANEL)

## New 7 Station Automatic Tuning Panel

There are 8 push buttons. Buttons Nos. 1 to 3 and 5 to 8 are Automatic Tuning Station Buttons. Button No. 4 is the Manual Tuning Button - See Fig. 1. When this button is depressed, the radio is in the manual tuning position.

The small buttons above the push buttons are still used for setting the stations. However, with the new panel, this is done by turning the button clockwise or counter-clockwise until the desired station is tuned in.

The aligning screw, shown in Fig. 1, when turned, moves the iron core of the antenna coil for aligning purposes.

### Old Parts Used

Use the following parts of the old assembly:

- Escutcheon Plate,
- Station Buttons and Hairpin Springs,
- Setting Buttons,
- Glass Screen and Rubber Bands.

### The Following New Parts are Supplied

7 Station Automatic Tuning Panel Assembly.

The parts shown in the list at the end of these instructions.

### Removing Old Motor Drive Panel from Chassis

Remove the knobs. Two are set screw knobs and three are the push-on type.

Remove the station buttons by pushing down the lower end of the small hairpin spring at the back of the button and, at the same time, pulling the button off the shaft. Remove the setting buttons by pulling them off.

The screws in the wooden support behind the electric drive panel must be unscrewed and the support removed from the cabinet.

Remove the speaker plug from the socket at the back of the chassis and also the tuning eye tube from its clamp bracket. Loosen the screw holding the bottom shield connection to the back of the chassis. Unscrew and remove the shipping bolts and the "L" bolts from beneath the chassis shelf.

The chassis may then be removed.

Remove the old tuning eye tube bracket from the cabinet.

Turn the electric-manual lever to the electric position.

Unsolder the wire to the silencer switch at the back of the chassis and also the two motor leads at the A. C. terminal strip under the chassis. Early models used a metal shell condenser which was connected at the same terminal strip. Remove this condenser if one is installed.

Take off the collars from the volume and tone control shafts.

Remove the glass screen by taking out the two screws and removing the two brackets.

Remove the four red mounting screws.

The panel can then be pulled straight out from the chassis.

### Mounting New Automatic Tuning Panel on the Chassis

Put a piece of insulating tape on the surface of the support casting at the point shown in Fig. 2. This will prevent possible short circuiting of the switch contacts.

Before mounting the new panel on the chassis, cut off any leads not required as shown in the table - Fig. 7. Bring the tuner panel near the chassis and pass the white-blue tracer and white-red tracer leads through the hole in the chassis under the front section of the gang condenser. Turn the gang condenser until the spring clip on the drive drum is at its lowest position - See Fig. 2 lower left. Line up the drive arm on the large panel drive pulley with the spring clip on the gang condenser drive

drum. Since the drive arm will line up with the spring clip under two conditions, refer to Fig. 2 lower left for the correct relation of drive cord winding to drive arm.

Spread the spring clip SLIGHTLY with a small screw driver, bringing this screw driver up from beneath the chassis. Then push the panel toward the chassis, lowering it slightly so that the large drive pulley may be brought up in back of the bracket below the projector compartment. Insert the drive arm in the spring clip.

Mount the panel on the chassis using the four mounting screws at the four points shown in Fig. 1.

Secure the two braces to the back of the panel as shown in Fig. 2.

Remove the two screws at the top of the lens housing support bracket. Using the two 8-32 X 3/8" screws supplied, secure the back end of the braces in place. When attaching the brace to the tuner switch side of the lens housing bracket, ground the lug of the braided wire under the screw head as illustrated.

Replace the glass screen using clamps, nuts, and lock washers supplied.

Replace the collars on the volume control and tone control shafts.

Wire the panel in the circuit following Figs. 3, 4, 9, 10, 15, and 16.

Replace chassis in cabinet reversing procedure followed when removing the chassis. The wooden shipping support is not used.

The electric-manual lever is not used. A cover plate is supplied which covers the opening left by the removal of this lever. This plate is so made that the back portion should fit snugly into the opening in the cabinet. If it does not, file the cabinet until it fits snugly in place.

Then put the tuning knob on the shaft.

### Knobs and Cover Plate

The 5 control knobs formerly used with the motor drive panel are also used with the new automatic tuning panel.

The cover plate used under the tuning knob is described in the previous article.

### Alignment

After the new panel is installed, realign the chassis using as a guide the alignment procedure given in the service manual for each chassis.

### Parts Shipped With 7 Station Automatic Tuning Panel

QUANTITY	ITEM	APPLICATION
1.....	20,000 Ohm Resistor.....	To be used when installing panel on 9, 11, and 13 tube chassis only.
2.....	Braces.....	To secure the panel to top of projector assembly.
4.....	8-32 X 3/8" screws.....	2 used for front end of above brace. 2 used for back end of above brace.
2.....	#8 Shakeproof Lock Washers.....	To secure above brace to panel.
2.....	8-32 Hex Nuts.....	To secure above brace to panel.
2.....	Glass Retainer Clamps.....	To hold the glass screen in place.
2.....	6-32 X 1/4" Round Head Screws...	For above.
2.....	#6 Split Lock Washers.....	For above.
1.....	Circular Cardboard Tab with Words "Manual Tuning" on it.....	To be put into manual switch button (4th button from left).
1.....	Round Celluloid Tab.....	To be pushed into above mentioned button over the cardboard tab.
4.....	8-32 X 1/4" Mounting Screws..... (Heads Red)	To mount panel to chassis.
4.....	#8 Split Lock Washers.....	For above.
1.....	Round Cover Plate.....	To cover opening in front panel of cabinet left by removal of the electric-manual lever.

If a definite peak cannot be reached when making the 1830 KC adjustment on the B range, cut off the compensating condenser C16 in the 9 and 11 tube models, C14 in the 13 tube model, and C13 in the 7 tube model.

If a definite peak cannot be reached when making the 22,000 KC adjustment on the D range, simply back off this trimmer as far as it will go and proceed with the 20,000 KC adjustment.

Next align the automatic tuner. The automatic tuning system is aligned by turning the aligning screw which shifts the position of the iron core of the antenna coil while the coil remains stationary.

Depress station button No. 1 - See Fig. 1. Tune in a signal of the frequency shown below for button No. 1. Turn setting button No. 1 clockwise or counter-clockwise until this signal is accurately tuned in. Then turn the aligning screw of button No. 1 clockwise or counter-clockwise until maximum output is obtained.

Follow the same procedure with regard to the other station tuning buttons using the frequencies shown below.

- Button No. 1...Aligning Frequency 700 KC
- Button No. 2...Aligning Frequency 700 KC
- Button No. 3...Aligning Frequency 850 KC
- Button No. 5...Aligning Frequency 850 KC
- Button No. 6...Aligning Frequency 850 KC
- Button No. 7...Aligning Frequency 1100 KC
- Button No. 8...Aligning Frequency 1100 KC

### Mounting New Panel on Early Chassis Equipped with First Motor Drive Panels

Chassis equipped with the early type motor drive panel may be identified by the fact that when the chassis is removed from the cabinet and the electric-manual lever is in the electric position, all four red mounting screws can be seen - See Fig. 23. On late models, the two top red screws are behind the glass screen and cannot be seen unless this screen is removed - See Fig. 22.

To mount the new automatic tuning panel on the early chassis, first, using a hack saw, cut off the portion of the bracket assembly below the projector compartment as shown in Fig. 21.

Mount the new panel on the chassis using the two bottom mounting screws. Extend a pencil or pointed instrument through the center of the two upper panel mounting holes and place a mark on the bracket extending down from the projector compartment.

Remove the two lower mounting screws and take off the new panel. Drill and tap two holes for the two upper 8-32 mounting screws in the bracket. The new panel can then be mounted by means of the four mounting screws.

ALIGNMENT PROCEDURE

STEP (Follow Order at Given)	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE	ADJUSTMENT
I. F.	.1 mf.	456 KC	Grid of 1st Det.	2nd I. F. (C9) & (C10) 1st I. F. (C6) & (C7)	Turn rotor to full open	Adjust to Maximum Output
1730 KC Adj.	200 mmf.	1730 KC	Antenna Lead	Osc. (C4)	Turn Rotor to full open	Adjust to Maximum Output
1500 KC Adj.	200 mmf.	1500 KC	Antenna Lead	Ant. (C3)	Turn Rotor to Max. Output	Adjust to Maximum Output

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
NOTE—To obtain dial scale calibration, tune in an 800 KC signal. The pointer should be at the 800 KC mark on the dial. If it is not, note the position of the pointer and remove the chassis from the cabinet. Loosen the pointer screw and set the pointer so that it will be at the 800 KC mark. Tighten the pointer screw and replace the chassis in the cabinet. If the pointer is not at the 800 KC mark another adjustment will be necessary.

## ALIGNMENT PROCEDURE

## SERIES S1

Volume Control—Maximum All Adjustments.

Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.

Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:  
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
Output Indicating Meter—Non-Metallic Screwdriver.  
Dummy Antennas—.1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR		TRIMMERS ADJUSTED See Illustration	PROCEDURE	
			FREQUENCY SETTING	CONNECTION AT RADIO		INITIAL STEPS	ADJUSTMENT
I. F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C19) & (C20)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C16) & (C17)	Turn Rotor to Full Open	Adjust to Maximum Output
<b>RANGE D</b>							
22,000 KC	Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C7)	Turn Rotor to Full Open	Adjust to Maximum Output
20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Antenna Range D (C2)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
<b>RANGE C</b>							
6350 KC	Range C	400 Ohm	6350 KC	Antenna Lead	Oscillator Range C (C8)	Turn Rotor to Full Open	Adjust to Maximum Output
6000 KC	Range C	400 Ohm	6000 KC	Antenna Lead	Antenna Range C (C3)	Turn Rotor to Max. Output	Adjust to Maximum Output
<b>RANGE B</b>							
1830 KC	Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C9)	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	1st Ant. Range B (C5) 2nd Ant. Range B (C6)	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Adjust to Maximum Output
600 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C10)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

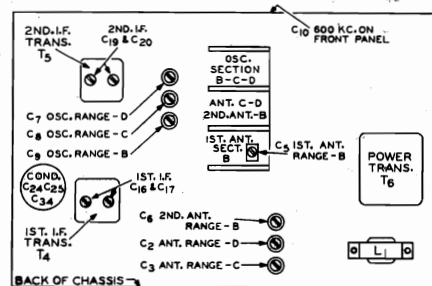

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—Loosen the pointer set screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

51-83

## ALIGNMENT PROCEDURE Series S2

Volume Control—Maximum All Adjustments.

Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.

Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:

An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.

Output Indicating Meter—Non-Metallic Screwdriver.  
Dummy Antennas—.1 mf., 200 mmf., and 400 ohms.

CAUTION—When aligning the short wave band, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

SIGNAL GENERATOR		DUMMY ANTENNA	BAND SWITCH	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM
FREQUENCY SETTING	CONNECTION AT RADIO				
I. F.					
456 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open	1st I.F. (C15) & (C16) 2nd I.F. (C21) & (C22)
<b>RANGE B</b>					
1730 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open	Oscillator Range B (C7)
1500 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Ant. Range B (C5)
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	600 KC (C8) Rock Rotor—See Note B
<b>RANGE D</b>					
18,300 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D (C6)
15,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	Ant. Range D (C3) Rock Rotor—See Note B
<b>PERMEABILITY TUNING UNIT</b>					
			BUTTON DEPRESSED (Band Switch in Push Button Position)	TURN SETTING SCREW TO MAXIMUM OUTPUT	ADJUST COIL POSITION TO MAXIMUM OUTPUT — See Note C
1100 KC	Antenna Lead	200 mmf.	No. 1	Setting Screw No. 1	Antenna Coil No. 1
1100 KC	Antenna Lead	200 mmf.	No. 2	Setting Screw No. 2	Antenna Coil No. 2
850 KC	Antenna Lead	200 mmf.	No. 3	Setting Screw No. 3	Antenna Coil No. 3
850 KC	Antenna Lead	200 mmf.	No. 4	Setting Screw No. 4	Antenna Coil No. 4
700 KC	Antenna Lead	200 mmf.	No. 5	Setting Screw No. 5	Antenna Coil No. 5
700 KC	Antenna Lead	200 mmf.	No. 6	Setting Screw No. 6	Antenna Coil No. 6

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

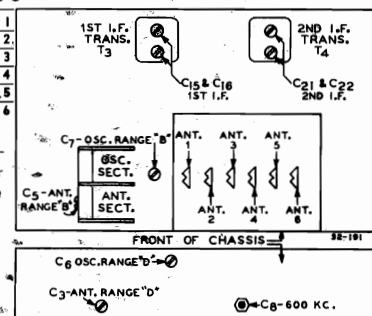

After each range is completed, repeat the procedure as a final check.

NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

NOTE C—At the top of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.

The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.  
These voltages are read under the following conditions:  
Battery Voltage—6.3.  
Volume Control—Maximum.  
Antenna Shorted to Ground.  
Readings taken with 1000 ohm-per-volt meter.

FOR DIAL AND DRIVE DATA, SEE INDEX

Fig. 3—Schematic Circuit Diagram

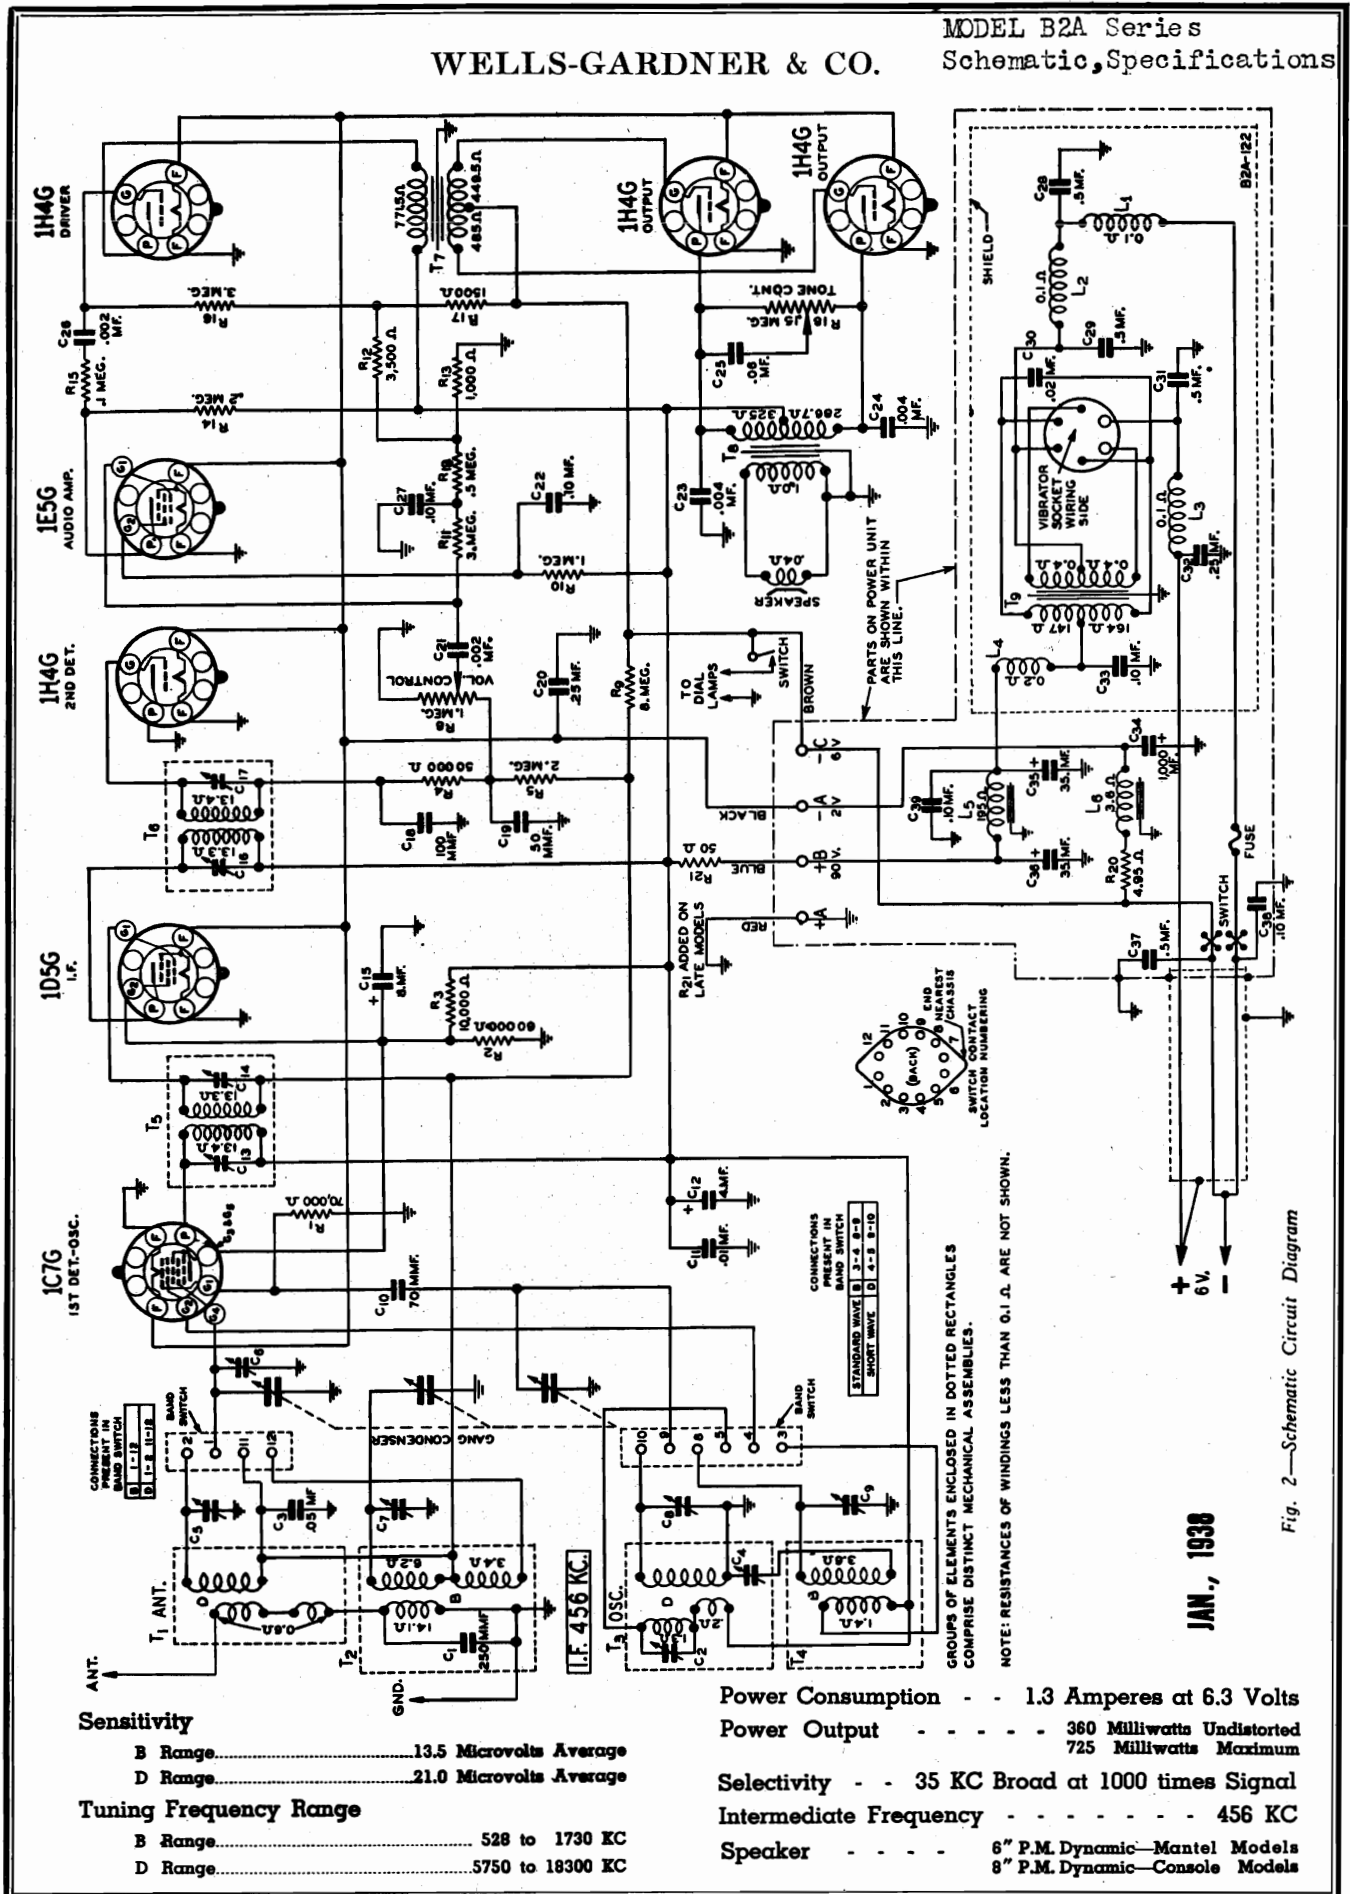

Tuning of the R.F. and oscillator fixed tuned circuits to the desired frequency is accomplished by varying the inductance of the tuning coils by changing the permeability of the magnetic circuit. This is done by moving an iron core in and out of the coil. The iron cores within the antenna and oscillator automatic tuning coil forms are secured to a brass rod. This rod is moved back and forth by a screw located at the front of the radio.

 Buttons 5 and 6 (Automatic Tuning) . . . . .520 to 980 KC

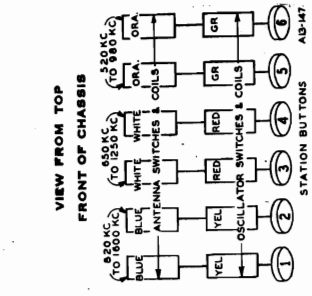

**Line Voltage Range**  
 The radio will operate satisfactorily within a line voltage range of 25 to 42 volts. If the line voltage is higher than 42, it will be necessary to use a series resistor to cut it down. If the voltage varies, a variable resistor may be required.

**Starting Current**  
 When first turned on, the drain for a few seconds is slightly higher than normal until the tubes heat up. Some automatic plants are adjusted to start under a load of 200 to 300 watts. If a number of devices such as lights or motors are being used and the radio set is turned on the total drain may be sufficient to start the plant.

**Caution**  
 If used on any other type of power supply than 32 volt DC, severe damage may be done to the receiver.  
 Do not turn the radio on unless all of the tubes and the dial lamps are in the proper sockets. Use only No. 51 dial lamps.

**Caution**  
 If used on any other type of power supply than 32 volt DC, severe damage may be done to the receiver.  
 Do not turn the radio on unless all of the tubes and the dial lamps are in the proper sockets. Use only No. 51 dial lamps.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each range is completed, repeat the procedure as a final check.  
NOTE A—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.  
NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.  
NOTE C—Leave condenser rotor at the 600 KC setting and adjust the signal generator until maximum output is obtained at or near 465 KC.  
NOTE D—At the top of the permeability tuning unit can be seen a pair of long coil springs. Turn the rotor back and forth and adjust the trimmer in the "W" opening of the antenna (rear) coil by twisting the plates or screwdriver until maximum output is obtained.  
CAUTION—When aligning the short wave band be sure that the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 KC on the dial of the radio. The longer signal, which is much weaker, will be heard at 15,000 KC. The signal will then be heard at 15,000 KC on the dial of the radio. It may be necessary to increase the input signal to hear the longer signal.

15,000 KC. The signal will then be heard at 15,000 KC on the dial of the radio. It may be necessary to increase the input signal to hear the longer signal.

MODEL A17

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.  
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
Allow Chassis and Signal Generator to "Heat Up" for several minutes.  
IMPORTANT—Follow procedure in the order shown.  
Dummy Antennas—1 mf., 200 mmf., and 400 ohms.

SIGNAL GENERATOR FREQUENCY SETTING	DUMMY ANTENNA	BAND SWITCH	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM
455 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open
<b>RANGE D</b>				
18300 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open
15,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output Ant. Range D (C2) Rock Rotor—See Note A
<b>RANGE C</b>				
9400 KC	Antenna Lead	400 Ohm	C Range	Turn Rotor to Full Open
9000 KC	Antenna Lead	400 Ohm	C Range	Turn Rotor to Max. Output Ant. Range C (C3) Int. Range C (C7)
<b>RANGE B</b>				
1600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open
1400 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Set Indicator to 1400 KC— See Note B
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Rock Rotor—See Note A

Phonograph Connections

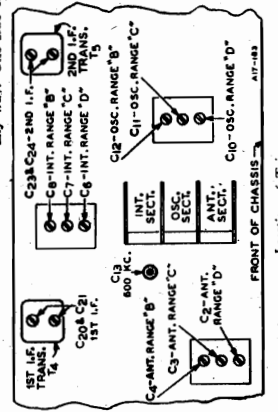

Phonograph connections are made as shown in the schematic circuit diagram—Fig. 3. On the top of the chassis base and between two of the 76 tube sockets is a round knockout 1 1/4 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.  
The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.  
These voltages are read under the following conditions:  
L. Volume Control—Maximum.  
Volume Control—Maximum.  
Antenna Shorted to Ground.  
Readings taken with 1000 ohm-per-volt meter.

Tone Control

There are 3 wiring lugs on the tone control. One of the end lugs connects to one end of the tone control resistor. The center lug connects to the slider. The other end lug on the tone control is used for external wiring purposes only and is not connected to the tone control resistor in any way. One side of the tone control condenser and a wire from the B+ line are connected at this lug.  
Twenty-Five Cycle Models  
The twenty-five cycle receiver differs only in the fact that a different power transformer is used.

Voltages at Sockets

The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.  
These voltages are read under the following conditions:  
L. Volume Control—Maximum.  
Volume Control—Maximum.  
Antenna Shorted to Ground.  
Readings taken with 1000 ohm-per-volt meter.

rack and panel assembly,  
see index.**

The following equipment is required for aligning:  
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
Output Indicating Meter--Non-Metallic Screwdriver.  
Dummy Antennas--1 mf., 200 mmf., and 400 ohms.

**ALIGNMENT PROCEDURE**

Volume Control--Maximum All Adjustments.  
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
Allow Chassis and Signal Generator to "Heat Up" for several minutes.  
**IMPORTANT**--Follow procedure in the order shown.

SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	DUMMY ANTENNA	BAND SWITCH SETTING	CONDENSER ON DIAL SETTING	ADJUST TRIMMERS TO MAXIMUM (Unless otherwise specified)
I. F.	485 KC Grid of 1st Det.	1 mf.	B Range	Turn Rotor to Full Open	2nd I.F. [C16] & [C17] 1st I.F. [C14] & [C15] Wave Top [C8] Adjust for MINIMUM Output
<b>WAVE TRAP</b>	455 KC Antenna Lead	200 mmf.	B Range	400 KC	Turn Rotor to Full Closed Position. Pointer should be at low frequency end mark on scale--See Note A.
<b>RANGE B</b>	1500 KC Antenna Lead	200 mmf.	B Range	1500 KC	Turn Rotor until dial pointer is at 1500 KC
	1500 KC Antenna Lead	200 mmf.	B Range	Leave Rotor at above setting	Oscillator Range B [C11] Ant. Range B [C3]
	400 KC Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	400 KC [C7] Rod Rotor--See Note B
<b>RANGE D</b>	18,300 KC Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D [C8] Ant. Range D [C1] Rod Rotor--See Note B
	15,000 KC Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	15,000 KC [C1] Rod Rotor--See Note B

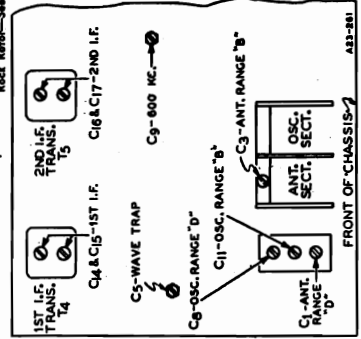

Fig. 2--Location of Trimmers

**Drive Cord Replacement**

Tie a knot with a small loop at one end of the new drive cord. Tie the free end of the drive cord to the tension spring. The distance between knots should be 49 3/4 inches. Arrange to keep the gang condenser in the completely closed position.

Place the looped end of the drive cord over hook A on condenser drive drum B (See Fig. 4). Pass the cord through slot C in the drum rim and wind one turn in a clockwise direction (from front of chassis) on condenser drive drum. Pass drive cord over pulleys D and E as shown. Continue cord down to shaft F and wind 4 turns clockwise, progressing towards the chassis. Bring cord over pulley G to bottom of condenser drive drum B as shown. Wind drive cord clockwise (from front of chassis) around condenser drive drum B to slot C. See that the drive cord does not cross in groove of condenser drive drum. Pass the remaining drive cord and tension spring through slot C and secure the free end of the spring on hook A.

Fig. 4--Drive Cord Replacement

**ALIGNMENT PROCEDURE**

Volume Control--Maximum All Adjustments.  
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
Allow Chassis and Signal Generator to "Heat Up" for several minutes.  
**IMPORTANT**--Follow procedure in the order shown.

SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	DUMMY ANTENNA	BAND SWITCH SETTING	CONDENSER ON DIAL SETTING	ADJUST TRIMMERS TO MAXIMUM (Unless otherwise specified)
I. F.	485 KC Grid of 1st Det.	1 mf.	B Range	Turn Rotor to Full Open	1st I.F. [C17] & [C18] 2nd I.F. [C20] & [C21] 3rd I.F. [C26]
<b>RANGE B</b>	1730 KC Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open	Oscillator Range B [C12] 1st Ant. Range B [C2] 2nd Ant. Range B [C1] See Note A
	1800 KC Antenna Lead	200 mmf.	B Range	400 KC [C11]	400 KC [C11] Rod Rotor--See Note B
<b>RANGE D</b>	18,300 KC Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D [C13] Ant. Range D [C3] Rod Rotor--See Note B
	15,000 KC Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	15,000 KC [C1] Rod Rotor--See Note B
	4000 KC Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	4000 KC [C7] Rod Rotor--See Note B

Align the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each range is completed, repeat the procedure as a final check.  
**CAUTION**--When aligning the short wave band, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

**Dial Pointer Attachment**--Tune in a station of known frequency. Move the pointer to the approximate frequency on the dial scale. Pass the cord through the slotted head--See Fig. 4. Hold the drive cord and slide the pointer to the exact frequency on the dial scale.

Intermediate Frequency - - - - - 456 KC.

Speaker - - - - - 6" P.M. Dynamic

Tuning Frequency Range - - - 540 to 1600 KC.

Sensitivity (For .05 Watt Output)

Table Model ..... 10.5 Microvolts Average  
Portable Model ..... 20 Microvolts Per Meter Average

JAN., 1939

Dummy Antennas—.1 mf. and 200 mmf.  
NOTE—Connect a loop approximately one foot in diameter across the antenna and ground posts of the signal generator. Secure the back in place on the cabinet. Connections for the output meter may be made through the opening for the outside antenna and ground connecting posts. This opening is at the bottom of the cabinet near the back. Place radio approximately 3 feet from loop so as to pick up signal. Radio should not be in proximity to any metal (metal bench, etc.).  
CALIBRATION—To obtain dial scale calibration, tune in an 800 KC signal. The pointer should be at the 800 KC mark on the dial. If it is not, loosen the pointer screw, set the pointer at the 800 KC mark and retighten the pointer screw.

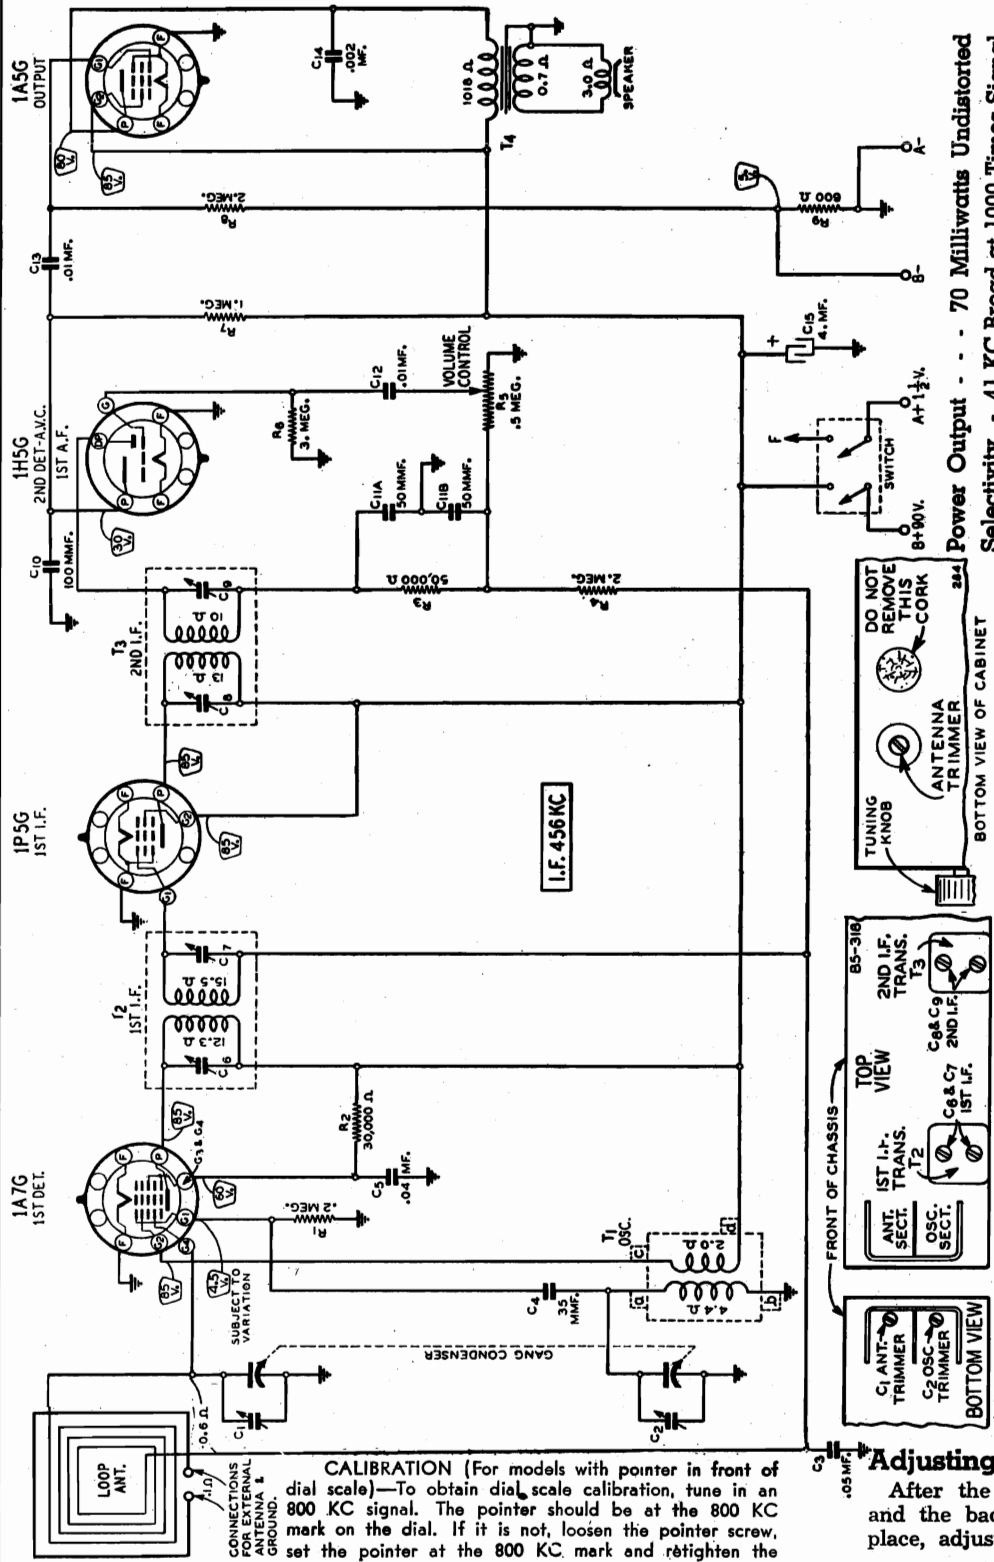

Volume Control—Maximum All Adjustments. Allow Chassis and Signal Generator to "Heat Up" for several Minutes

SIGNAL GENERATOR FREQUENCY SETTING	DUMMY ANTENNA	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM (See Fig. 3)
456 KC	.1 mf.	Turn rotor to full open	1st I.F. (C6) & (C7) 2nd I.F. (C11) & (C12)
1600 KC	.1 mf.	Turn rotor to full open	Oscillator (C2)
TABLE MODEL ONLY	200 mmf.	Turn rotor to max. output	Antenna (C1)
PORTABLE MODEL ONLY	1500 KC	None—See Note	Antenna (C1)

MODEL 4B5 Series  
Schematic, Voltage

WELLS-GARDNER & CO.

Socket, Trimmers  
Alignment

**ALIGNMENT PROCEDURE**

Volume Control—Maximum All Adjustments. Allow Chassis and Signal Generator to "Heat Up" for several minutes.

SIGNAL GENERATOR	DUMMY ANTENNA	CONDENSER SETTING
FREQUENCY SETTING	.1 mf.	Turn rotor to full open
456 KC	Grid of 1st Det.	Turn rotor to full open
1600 KC	Grid of 1st Det.	Oscillator (C2)
1500 KC	None—See Note	Antenna (C1)

ADJUST TRIMMERS TO MAXIMUM (See Trimmer Illustration)

1st I.F. (C6) & (C7)  
2nd I.F. (C8) & (C9)  
Oscillator (C2)  
Antenna (C1)

**Adjusting Antenna Trimmer**

After the batteries are installed and the back of the cabinet is in place, adjust the antenna trimmer.

Accurately tune in a weak station signal between 1400 and 1500 KC on the dial. With a screwdriver turn the adjusting screw of the antenna trimmer up or down until maximum output is obtained. This trimmer is reached through an opening in the bottom of the cabinet—see illustration. CAUTION: Do not remove the cork from the other opening at the bottom of the cabinet.

**CALIBRATION** (For models with pointer in front of dial scale)—To obtain dial scale calibration, tune in an 800 KC signal. The pointer should be at the 800 KC mark on the dial. If it is not, loosen the pointer screw, set the pointer at the 800 KC mark and retighten the pointer screw.

**CALIBRATION** (For model with pointer in back of celluloid dial scale)—To obtain dial scale calibration, tune in an 800 KC signal. The pointer should be at the 800 KC mark on the dial. IF THE POINTER IS AT A HIGHER KC MARK THAN 800 KC, grasp the drive cord below the tension spring. Hold the tuning control shaft motionless and slowly pull the drive cord down until the pointer is at the 800 KC mark. IF THE POINTER IS AT A LOWER KC MARK THAN 800 KC, grasp the drive cord above the tension spring. Hold the tuning control shaft motionless and slowly pull the drive cord up until the pointer is at the 800 KC mark.

Vibrator Location

FOR SETTING PUSH BUTTONS,  
SEE INDEX.

**IF ALIGNMENT**  
Adjust at 456 KC through 0.05 mfd. condenser.  
**BC ALIGNMENT**  
Adjust oscillator trimmer C8 at 1560 KC.  
Adjust C6 and C2 trimmers at 1000 KC.

FOR CONVENTIONAL ALIGNMENT, SEE SPECIAL SECTION  
OF VOLUME VIII

**Battery Cable and Fuse**

The battery connection is made at the ammeter. The end of the battery cable with the connecting lug is secured to one of the posts at the back of the ammeter in the instrument panel. The other end of the cable with the fuse receptacle connects to the battery cable from the radio after the fuse has been inserted.

A 9 ampere automobile fuse is used.

MODELS C5, 6CH5 Series  
Schematic, Socket, Trimmers.  
Alignment

WELLS-GARDNER & CO.

Location of Tubes and Vibrator.

Set the signal generator for 600 KC. Connect the output through a .05 mf. condenser to the control grid of the 6K7 R. F. tube. Rock the tuning condenser rotor and adjust the 600 KC oscillator padder (See Fig. 2) until the peak of greatest intensity is obtained. Leave the signal generator set for 600 KC and re-connect the output to the shielded antenna lead through a 120 mmf. condenser. Adjust the 600 KC antenna trimmer to maximum. (This trimmer is reached from outside of the case - See Fig. 1.) After the alignment procedure is completed, the antenna plug may be withdrawn and reinserted on the LG side if a low capacity (70 mmf.) car antenna is used.

**Adjusting Antenna 600 KC Trimmer** - After the radio is installed and the car antenna is connected, it will be necessary to readjust the antenna trimmer. Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained.

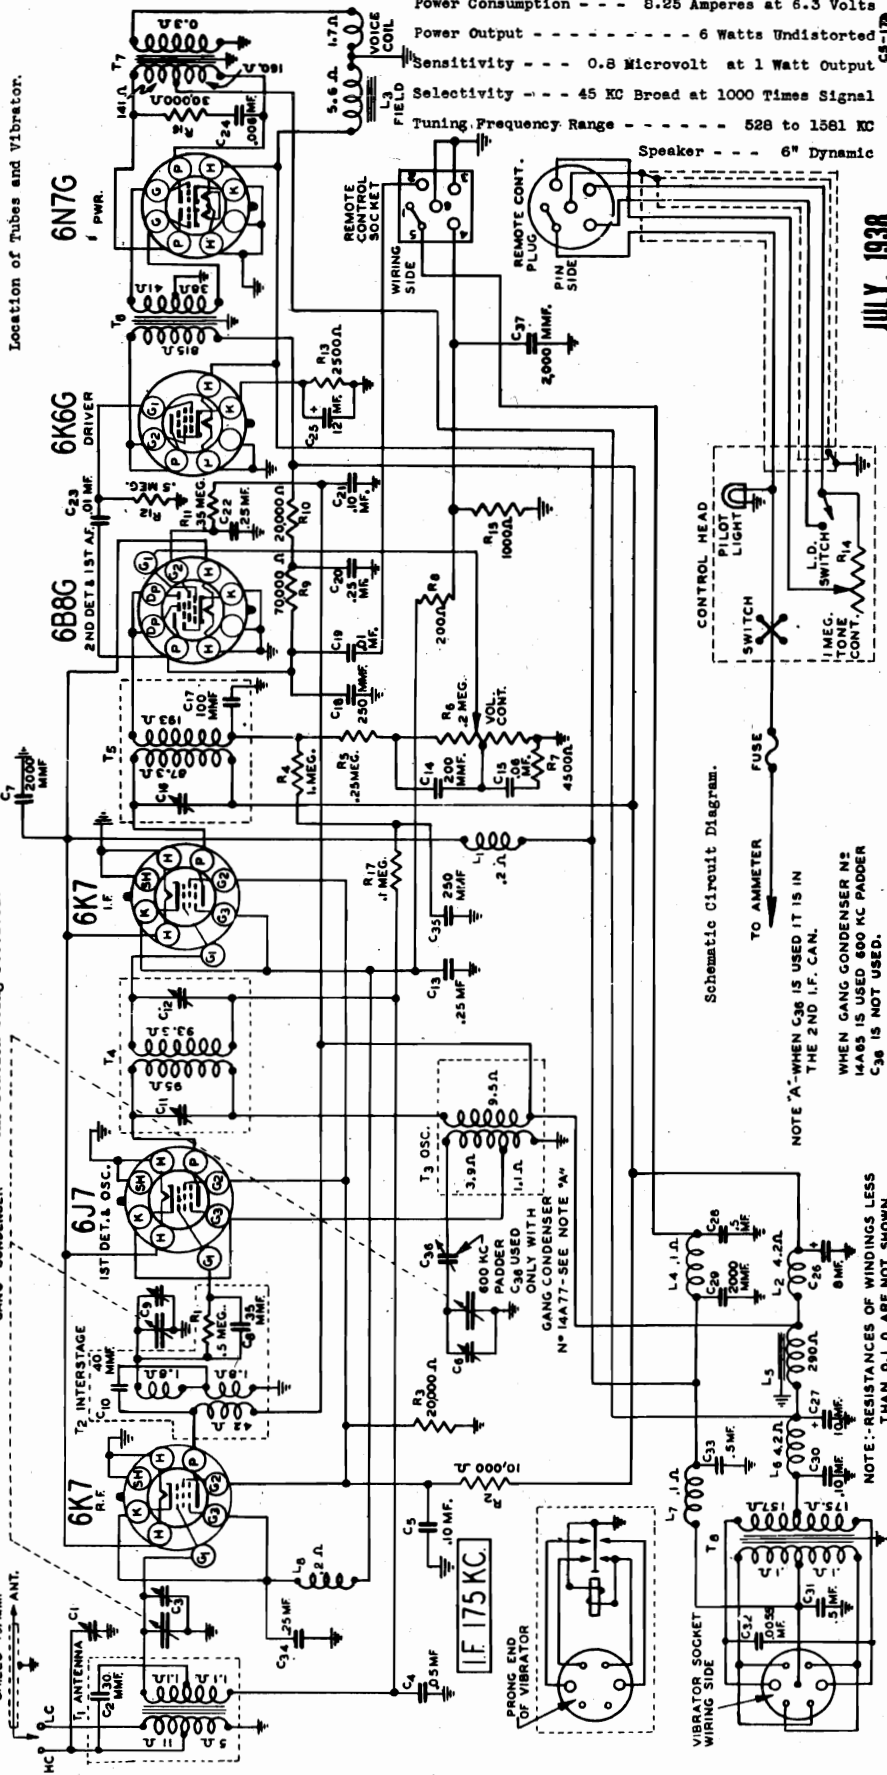

**Calibrating the Radio** - To calibrate the radio, tune in a station of known frequency. Remove the dial lamp assembly from the back of the dial unit. The calibration screw is at the bottom of the dial lamp tube. Hold the tuning knob. Insert a fine blade screwdriver and turn this screw so that the POLYMER travels in a clockwise direction until it is at the frequency of the station being received.

**Alignment and Calibration**

Set the signal generator for 175 KC and connect the output of the signal generator through a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. Connect the ground lead of the signal generator to the chassis. The chassis should be in the case. Set the volume control at maximum and the L-D switch in the distance position. Attenuate the signal from the signal generator to prevent the leveling off action of the AVC. Then adjust the three I.F. trimmers until maximum output is obtained - See Fig. 2.

Set the signal generator for 1581 KC. Turn the rotor of the tuning condenser to the full open position. Insert the antenna plug with the mark on the high capacity (40) side. Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator. Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained.

Set the signal generator for 1400 KC. Carefully turn the rotor of the tuning condenser until maximum output is obtained. Adjust the 1st detector and antenna 1400 KC trimmers for maximum output. Do not change the setting of the oscillator trimmer.

Schematic Circuit Diagram.

Power Consumption - - - 8.25 Amperes at 6.3 Volts  
Power Output - - - - - 6 Watts Undistorted  
Sensitivity - - - - - 0.8 Microvolt at 1 Watt Output  
Selectivity - - - - - 45 KC Broad at 1000 Times Signal  
Tuning Frequency Range - - - - - 528 to 1581 KC  
Speaker - - - - - 6" Dynamic

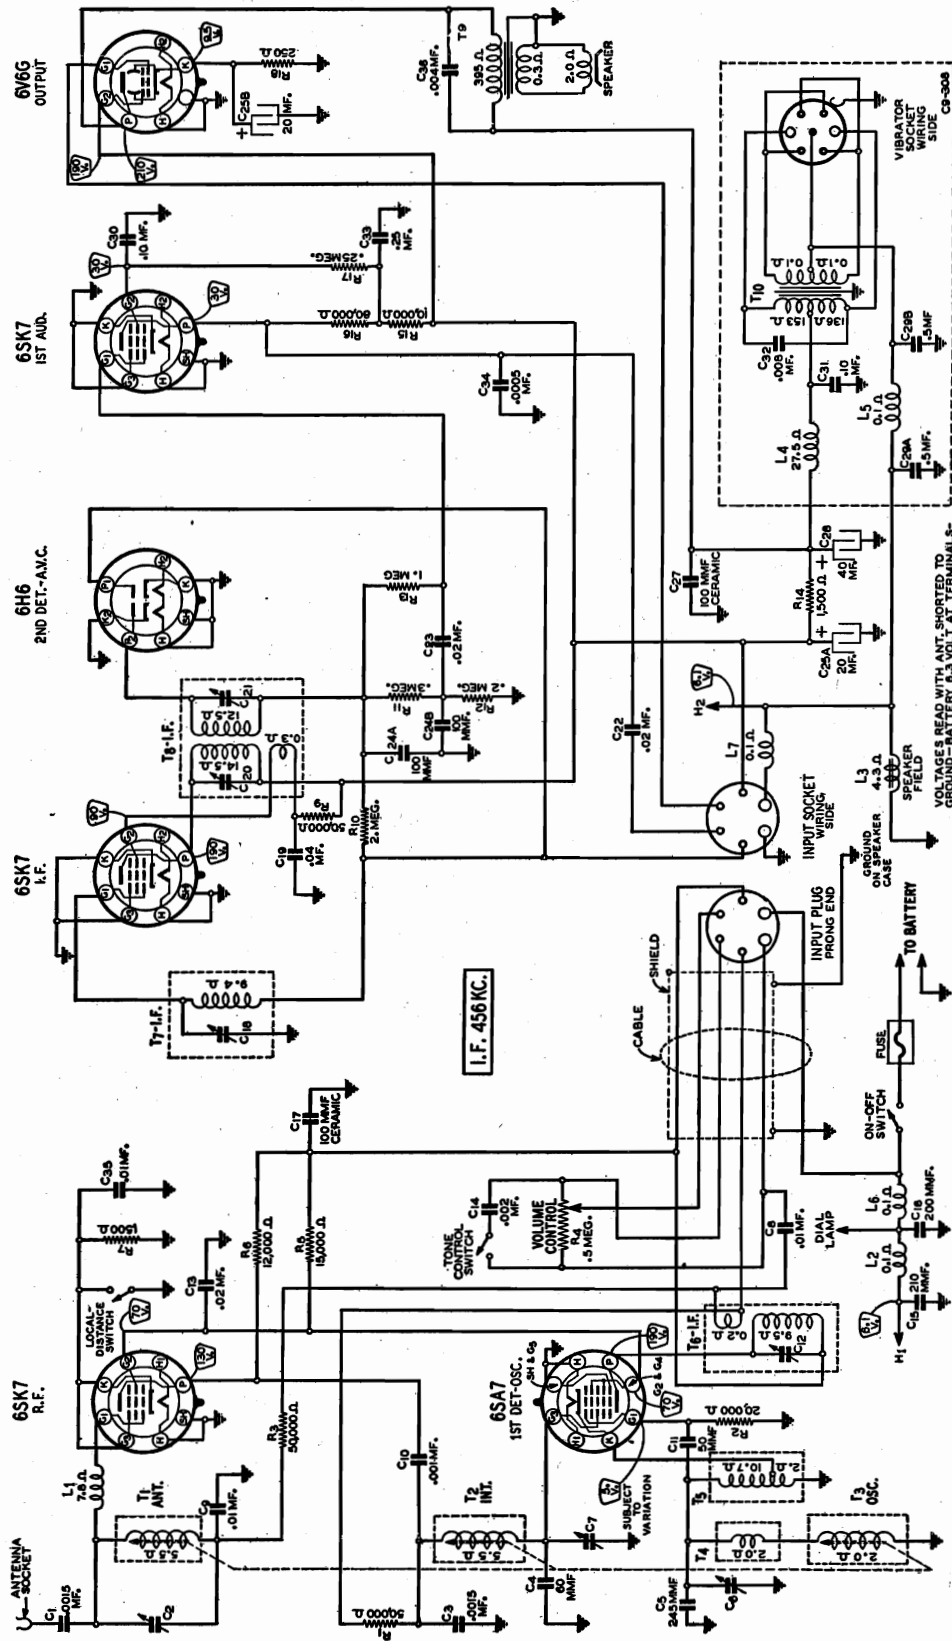

JULY, 1938

NOTE "A" - WHEN C38 IS USED IT IS IN THE 2ND I.F. CAN.  
WHEN GANG CONDENSER N2 14A85 IS USED 600 KC PADDER C38 IS NOT USED.

NOTE: - RESISTANCES OF WINDINGS LESS THAN 0.1 Ω ARE NOT SHOWN.

WELLS-GARDNER & CO.

MODEL 6C9 Series  
Schematic, Voltage  
Socket, Trimmers

- Power Consumption - 6.8 Amperes at 6.3 Volts
- Power Output - - - - 3 Watts Undistorted
- Sensitivity - - 1.5 Microvolts at .5 Watt Output  
(L-D Switch in Distance Position)
- Selectivity - 39 KC Broad at 1000 Times Signal
- Tuning Frequency Range - - - 540 to 1560 KC
- Intermediate Frequency - - - - 456 KC
- Speaker - - - - - 6" Electro-Dynamic

Tuner Data

WELLS-GARDNER & CO.

Antenna

**A shielded antenna cable with bayonet connector plug is required.**

The plug on the antenna cable is inserted in the socket at the bottom of the tuning unit case as shown in Fig. 1. The wire at the other end of the cable is connected to the antenna.

**LOW CAPACITY ANTENNA**

This radio is designed for a low capacity antenna.

1500 KC end of the dial, until the stop is reached.

**NOW LOCK THE TUNING MECHANISM** by inserting a screwdriver, as shown in Fig. 1, in the locking screw opening and turning the locking screw in a clockwise direction until it is tight.

Insert a celluloid reinforcement tab half-way in the slot at the front of station button No. 1.—See Fig. 3.

Remove the correct station call letter tab for button No. 1 from the sheet supplied by bending the sheet back and forth at the score line.

Place the call letter tab in front of the celluloid reinforcement tabs all the way in the button slot. Follow the same procedure for installing the station call letter tabs in any other buttons.

After the stations are set and the mechanism is locked, tune in each of them by depressing the proper button. If any of them does not appear to be properly tuned in after the button has been depressed, reset the station for that button following the procedure outlined above. Changing the setting of one button will not affect the setting of the others.

Fig. 3—Inserting the score line tab in front of the celluloid reinforcement tabs all the way in the button slot.

Procedure for Setting the Station Buttons

Turn the manual tuning knob carefully back and forth until the above mentioned station is accurately tuned in to the loudest point. This station is now set on button No. 1.

**CAUTION**—Do not touch this button again while the mechanism is unlocked as the setting may be altered.

Next keep the manual tuning button depressed with one hand and, with the other hand, depress the second station button firmly and gently. Then proceed to set the second station on your list in the same manner as described above.

Then continue to set any additional stations on your list on the remaining buttons.

After all desired stations have been set, release any station button which is depressed as follows: **KEEP THE MANUAL TUNING BUTTON DEPRESSED WITH ONE HAND** and, with the other hand, push in the OFF button a slight amount—only enough to release any station button which is depressed. Should the OFF button be pushed all the way in to the depressed position, no harm will be done except that the dial will not be illuminated.

Turn the manual tuning knob so that the indicator moves toward the speaker grille and speaker from the antenna socket on the tuning unit case in accordance with the article under "General Installation Items" in this manual.

Set the signal generator for 450 KC and connect the output of the signal generator through a .05 mfd. dummy antenna capacity to the output of the signal generator.

Set the signal generator for 1580 KC. Turn the tuning knob until the front cords are as far out of the chassis as they will go. Then adjust the oscillator trimmer C8 (Fig. 1) until maximum output is obtained.

Set the signal generator for 1000 KC. Turn the tuning knob until maximum output is obtained. Adjust the interstage trimmer C7 and antenna trimmer C2 for maximum output.—See Fig. 1.

Remove grille and speaker from speaker unit.

Remove the chassis from tuning unit case in accordance with the article under "General Installation Items" in this manual.

Use a 35 mmf. condenser for a dummy antenna. Connect the other end of the antenna cable through the dummy antenna capacity to the output of the signal generator.

Set the signal generator for 1580 KC. Turn the tuning knob until the front cords are as far out of the chassis as they will go. Then adjust the oscillator trimmer C8 (Fig. 1) until maximum output is obtained.

Set the signal generator for 1000 KC. Turn the tuning knob until maximum output is obtained. Adjust the interstage trimmer C7 and antenna trimmer C2 for maximum output.—See Fig. 1.

Remove grille and speaker from speaker unit.

Remove the chassis from tuning unit case in accordance with the article under "General Installation Items" in this manual.

Use a 35 mmf. condenser for a dummy antenna. Connect the other end of the antenna cable through the dummy antenna capacity to the output of the signal generator.

Set the signal generator for 1580 KC. Turn the tuning knob until the front cords are as far out of the chassis as they will go. Then adjust the oscillator trimmer C8 (Fig. 1) until maximum output is obtained.

Set the signal generator for 1000 KC. Turn the tuning knob until maximum output is obtained. Adjust the interstage trimmer C7 and antenna trimmer C2 for maximum output.—See Fig. 1.

Remove grille and speaker from speaker unit.

Remove the chassis from tuning unit case in accordance with the article under "General Installation Items" in this manual.

Use a 35 mmf. condenser for a dummy antenna. Connect the other end of the antenna cable through the dummy antenna capacity to the output of the signal generator.

Set the signal generator for 1580 KC. Turn the tuning knob until the front cords are as far out of the chassis as they will go. Then adjust the oscillator trimmer C8 (Fig. 1) until maximum output is obtained.

Set the signal generator for 1000 KC. Turn the tuning knob until maximum output is obtained. Adjust the interstage trimmer C7 and antenna trimmer C2 for maximum output.—See Fig. 1.

**HIGH CAPACITY ANTENNA**

If this radio is to be installed with a high capacity car antenna (200 mmf. total capacity of antenna and shielded cable) an adapter must be used. The adapter is inserted in the socket at the bottom of the tuning unit case. Then the antenna plug is inserted in the adapter.

The antenna should be mounted on the same side of the car as the tuning unit.

Fig. 1 MODEL 5C10

Fig. 1—Details of Mounting Tuning and Speaker Units

It is better to list the station with the lowest kilocycle number first, the station with the next higher kilocycle number next, and so on.

Depress the manual tuning button and keep it depressed during the entire setting operation as described below. See Fig. 1 for location of buttons. Turn the manual tuning knob so that the indicator moves toward the 1500 KC end of the dial until the stop is reached.

**UNLOCK THE TUNING MECHANISM** by inserting a screwdriver, as shown in Fig. 1, in the locking screw opening at the bottom of the tuning unit. Loosen the locking screw by turning it counter-clockwise as far as it will go.

**TO SET STATIONS ACCURATELY, DO NOT JAR THE RADIO OR BUTTONS WHILE THE MECHANISM IS UNLOCKED.**

**KEEP THE MANUAL TUNING BUTTON DEPRESSED WITH ONE HAND** and, with the other hand, depress the first (left hand) station button. Both will remain depressed.

Select the first station from the list you have made and tune in this station.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

Reassemble the radio and install it in the automobile. Insert the car antenna cable. Tune in a weak signal near 1000 KC and readjust the antenna trimmer C2 for maximum output.

Calibration—If it is necessary to calibrate the radio, remove the chassis from the tuning unit case. See article on that subject in this manual. Accurately tune in a signal of known frequency near 1000 KC. Loosen the set screw of the large gear that drives the dial drum. Turn the dial drum until the indicator line is at the frequency of the station tuned in. Tighten the set screw and reassemble.

**Adjusting Antenna Trimmer**  
After the antenna is connected, tune in a weak signal at approximately 1000 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna trimmer (C2) up or down until maximum output is obtained. See Fig. 1 for location of this trimmer.

The total capacity of antenna and shielded cable should be 35 to 60 mmf.

Types of Low Capacity Antennas  
—Door hinge; fishpole; over-the-roof types which are mounted quite a distance from the metal-roof of the car.

The antenna should be mounted on the same side of the car as the tuning unit.

When the antenna cable is connected to an antenna lead coming down the pillar post, the shielded cable should be pushed several inches up into the pillar post.

For the door hinge and over-the-roof type antennas, the antenna lead must be shielded the entire distance from the radio to the point where the lead goes through the car body to the antenna lead coming down the pillar post, the shielded cable should be pushed several inches up into the pillar post.

When the antenna cable is as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end, otherwise ignition noise may be picked up. The length of the pigtail from the grounding point to the end of the antenna cable should be kept as short as possible, preferably not over one inch.

DIAL AND DRIVE ASSEMBLY

Part No.	Description	List Price	
11A132	Dial Assembly complete with Gang Condenser, less Dial Lamps and Dial Lamp Sockets	4.60	
15A120	Dial Scale and Bracket Assembly	.35	
25X472	Bracket only for Dial Scale	.30	
58X243	Celluloid Dial Scale only	.50	
15X117	Dialer	.20	
	Dial Lamp—No. 51 Mazda		
7A40	Dial Lamp Socket	.10	
4X219	Dial Crystal and Escutcheon Assembly	1.50	
25X428	Dial Support Bracket ("L" Shaped)	.10	
25X427	Bracket and Bushing for Drive Shaft	.30	
2A41	Drive Shaft only	.10	
19X21	Horseshoe Washers for above Shaft	Doz.	.10
24X317	Drive Drum and Pointer Shaft	ea.	.50
31X21	Drive Cord for Tuning Condenser	ea.	.45
28X227	Tension Spring for Drive Cord	ea.	.20

TRANSFORMERS AND COILS

Part No.	Description	List Price
9A482	T1 Antenna Transformer and Can Assembly	\$2.20
9A493	T2 Oscillator Coil and Can Assembly	1.30
9A494	T3 1st I.F. Transformer and Can Assembly	1.50
9A495	T4 2nd I.F. Transformer and Can Assembly	1.45
53X134	T5 115 Volt, 40 Cycle Power Transformer	3.70
53X136	T6 115-230 Volt, 40-60 Cycle Power Transformer	4.70
9A714	T4 Output Transformer (Part of Speaker Assembly)	2.70
	L1 Wave Trap (456 KC)	.45

ALIGNMENT PROCEDURE

The following equipment is required for aligning:  
 An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
 Output indicating Meter—Non-Metallic Screwdriver.  
 Dummy Antennas—1 mf., 200 mmf., and 400 ohms.

PROCEDURE

Volume Control—Maximum All Adjustments.  
 Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
 Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY CONNECTION AT RADIO SETTING	TRIMMERS ADJUSTED	INITIAL STEPS	ADJUSTMENT
I. F.						
2nd I.F. Adj.	Range B	.1 mf.	456 KC	2nd I.F. [C19] & [C20]	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Def. [C17] & [C18]	Turn Rotor to Full Open	Adjust to Maximum Output
I.F. Wave Trap	Range B	200 mmf.	456 KC	Antenna Lead	Turn Rotor to Full Open	Adjust to Minimum Output
RANGE D						
18,300 KC	Range D	400 Ohm	18,300 KC	Oscillator Range D [C8]	Turn Rotor to Full Open	Adjust to Maximum Output
15,000 KC	Range D	400 Ohm	15,000 KC	Antenna Lead	Turn Rotor to Max. Output	Adjust to Maximum Output
5000 KC	Range C	400 Ohm	5000 KC	Oscillator Range C [C9]	Turn Rotor to Full Open	Adjust to Maximum Output
5000 KC	Range C	400 Ohm	5000 KC	Antenna Lead	Turn Rotor to Max. Output	Adjust to Maximum Output
RANGE B						
1730 KC	Range B	200 mmf.	1730 KC	Oscillator Range B [C10]	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Ant. Range B [C5]	Turn Rotor to Max. Output	Adjust to Maximum Output
600 KC	Range B	200 mmf.	600 KC	Antenna Lead	Turn Rotor to Max. Output	Adjust to Maximum Output

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
 After each range is completed, repeat the procedure as a final check.  
 NOTE A—Loosen the pointer set screw and set the pointer at the 1500 KC mark on the standard wave generator. Realign the set screw.  
 NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.  
 CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image frequency, which is 9500 KC, will be heard at 5000 KC on the dial. If the signal at 9500 KC is necessary to increase the input signal to hear the image.

MISCELLANEOUS SOCKETS

Part No.	Description	List Price
3A258	Tube Socket—Octal (7 prong)	.15
3A259	Tube Socket—Octal (5 prong)	.10
3A260	Tube Socket—Octal (6 prong)	.10
3A58	Speaker Socket, 5 Prong	.10
13X255	6G5 Tube Socket and Cable Assembly	.65

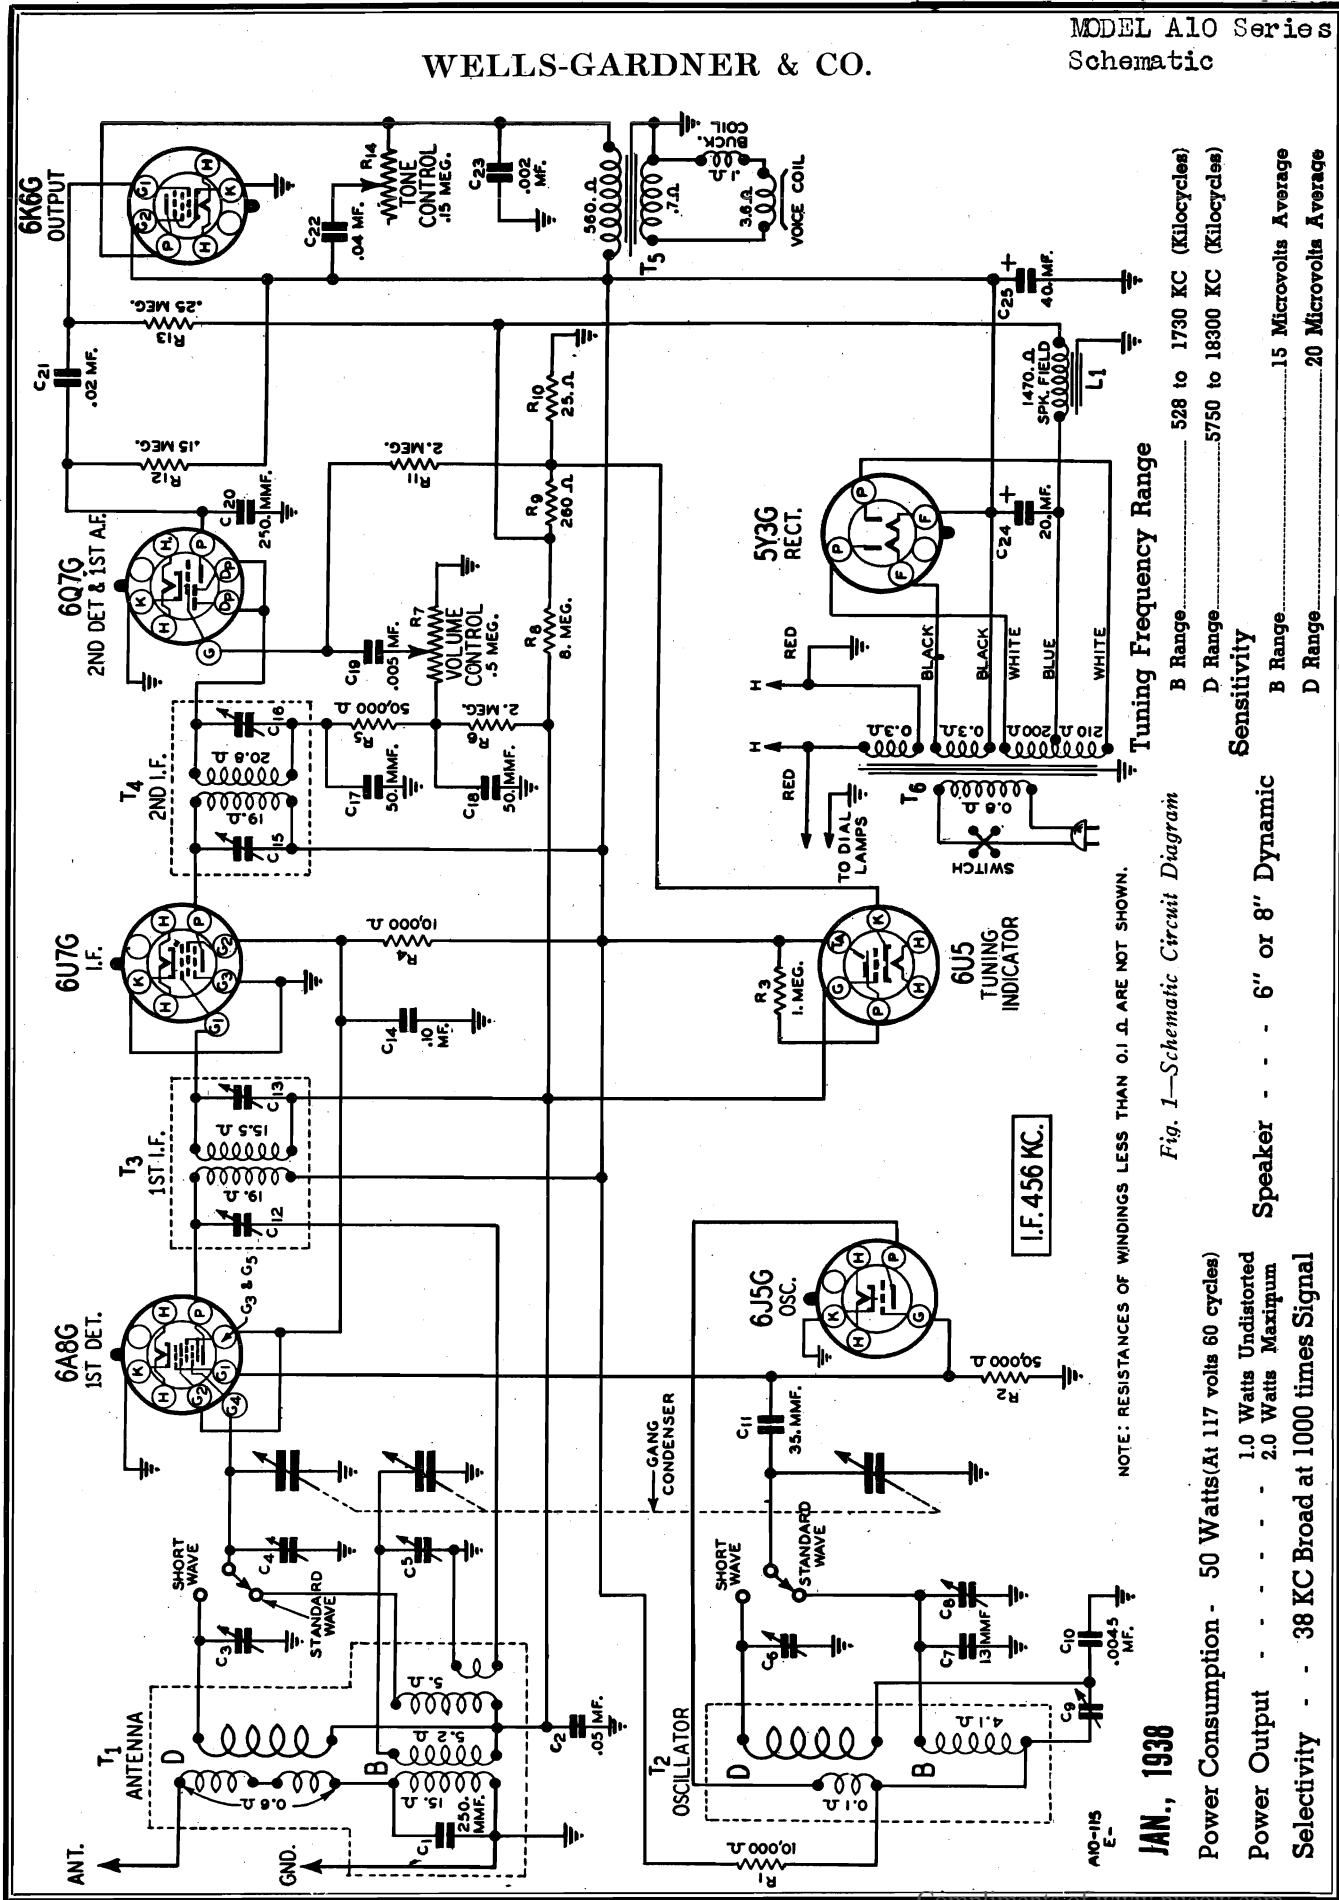

Series A8 - Replacement Parts

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

**ALIGNMENT PROCEDURE**

Volume Control—Maximum All Adjustments.  
 Connect Radio Chassis to Ground Post of Signal Generator With a Short Heavy Lead.  
 Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:  
 An all Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
 Output Indicating Meter; Non-Metallic Screwdriver.  
 Dummy Antennas—1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR		TRIMMERS ADJUSTED See Illustration	PROCEDURE		
			FREQUENCY SETTING	CONNECTION AT RADIO		INITIAL STEPS	ADJUSTMENT	
I.F.	456 KC	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C12) & (C13) 2nd I.F. (C15) & (C16)	Turn Rotor to Full Open Adjust to Maximum Output	
<b>RANGE B</b>	1730 KC	Range B	200 mmf.	1730 KC	Antenna Lead	Oscillator Range B (C8)	Turn Rotor to Full Open Turn Rotor to Max. Output Set Indicator to 1800 KC— See Note A	Adjust to Maximum Output
	1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	1st Ant. Range B (C5) 2nd Ant. Range B (C4)	Adjust to Maximum Output Turn Rotor to Max. Output Rock Rotor— See Note B	Adjust to Maximum Output
<b>RANGE D</b>	400 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C9)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor— See Note B
	18300 KC	Range D	400 Ohm	18300 KC	Antenna Lead	Oscillator Range D (C6)	Turn Rotor to Full Open	Adjust to Maximum Output Rock Rotor— See Note B
	15000 KC	Range D	400 Ohm	15000 KC	Antenna Lead	Ant. Range D (C3)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor— See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
 After each range is completed, repeat the procedure as a final check.  
 After alignment of Range D has been completed, do not make any adjustments of the Range B trimmers. If this is done, it will be necessary to realign Range D.

**NOTE A**—After the 1500 KC adjustment is made, the dial indicator should be at the 1500 KC mark on the dial scale. If it is not, the position of the indicator on the drive cord must be changed. This procedure, however, should not be followed unless it is absolutely necessary as there is danger of breaking the clamp which holds the indicator in place.

If the indicator must be moved, loosen the clamp at the back which holds it in place, move the indicator to the correct position, and bend the clamp back into place again.

**NOTE B**—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

at 15,000 on the dial of the radio. The image signal which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

**VOLTAGES AT SOCKETS**

Line Voltage: 117—Volume Control: Maximum. Antenna Shorted to Ground.  
 Readings taken with a 1000 Ohm-per-volt meter. Position of Band Switch: Standard Wave.

- (5) A.C. voltage as read across terminals 4 and 6.

Fig. 2—Location of Trimmers

**Replacing Drive Cords**

Three drive cords, Nos. 1, 2, and 3, as shown in Fig. 5, are used. To replace any of these cords, proceed as follows:

**Cord No. 1**

Turn the gang condenser to full open position.  
 Turn the drive shaft so that the holes for the cord are vertical. The positions of the drive shaft and drive drum are shown in Fig. 5.

Tie a double knot in one end of the cord. From the bottom of hole (A) in the drive shaft, thread the other end of the cord through the hole.

Slide a 1/2 inch length of fabric tubing on the cord, placing it near the free end. Fasten the shorter of the two springs used to the free end of the cord, making the distance between the two knots 22 3/4 inches.

Starting at the point where the cord leaves hole (A), wind it around the shaft 3/4 of a turn as shown in Fig. 5. Bring the end up to the wide groove (B) in the drive drum and wind on 2 1/4 turns, progressing toward the edge of the groove. Pass the cord through the slot at (C), placing the fabric tube (F) in position to protect the cord from being cut, and hook the spring to the pin at (D).

**Cord No. 2**

The gang condenser and tuning shaft should be in the same position as explained for Cord No. 1.  
 Tie a double knot in one end of the cord. From the top of hole (E) in the drive shaft, thread the other end of the cord through the hole.

Slide a 1/2 inch length of fabric tubing on the cord, placing it near the free end. Tie a slip knot with a small loop in the free end of the cord so that the length of the cord is 12 inches between the knots.

Starting at the point where the cord leaves hole (E), wind it around the shaft 3/4 turns as shown in Fig. 5. Do not attempt to wind the cord on the drive drum, but put the loop in the slip knot over pin (G). Rotate the drive drum clockwise about 1/2 a turn. This will unwind the cord on the drive shaft at (E).

Pass the cord through the slot at (C), placing the fabric tube (F) in position to protect the cord from being cut. While holding the cord on the wide flange, rotate the drive drum counterclockwise. The cord will be pulled into position in the groove.

The gang condenser and drive drum should be in the same position as explained for Cord No. 1.

Tie one end of the cord on hook (H).

Slide a 1/2 inch length of fabric tubing over the cord. Place this tubing approximately 1 3/4 inches from the end of the cord to be attached to the spring.

Tie the other end of the cord to the longer of the two springs used. The length of the cord between the knots should be 34 3/4 inches.

Pass the cord through slot (J) in groove (P) of the drive drum. Bring the cord up to pulley (K), around the other pulleys as shown in Fig. 5, and down to groove (P). After passing the cord around the drive drum 1/2 turn in groove (P), fasten the spring to hook (Q).

**Attaching Dial Pointer**—Tune in a station of known frequency. Move the pointer to this frequency on the dial scale. After the pointer has been moved to the correct position, clamp it tightly over the fabric tubing on the cord—See Fig. 5.

**Lever Tuning Assembly Adjustments**

**Pressure of Spacers on Heart Cams**—The heart cams must rotate freely relative to the shaft spacers when the tightening lever is in the "loose" position and must not rotate relative to the shaft spacers when this lever is in the "tight" position.

Pressure of the spacers against the heart cams is determined by the position of nut (R) on the threaded shaft—See Fig. 5. If, after the tightening lever is turned to the "tight" position, the cams can turn relative to the shaft, this nut must be tightened.

Bend back the ears of washer (S)—See Fig. 5, and tighten nut (R) about 1/2 turn. Bend the ears of the washer down again on nut (R). Tighten the tightening lever and see if the cams are sufficiently tight.

In general, nut (R) should be at such a position on the threaded shaft that the stop on the tightening lever moves to about 1/4 inch from the end of the slot in the tightening washers when a reasonable amount of pressure is exerted on this lever.

**Connection between Gang Condenser and Cam Shaft**—One screw only should be used in the universal joint connection between the condenser shaft and the cam shaft. If 2 screws are used, considerably more pressure must be exerted on the station levers to rotate the cam shaft.

Fig. 4—Location of Tubes

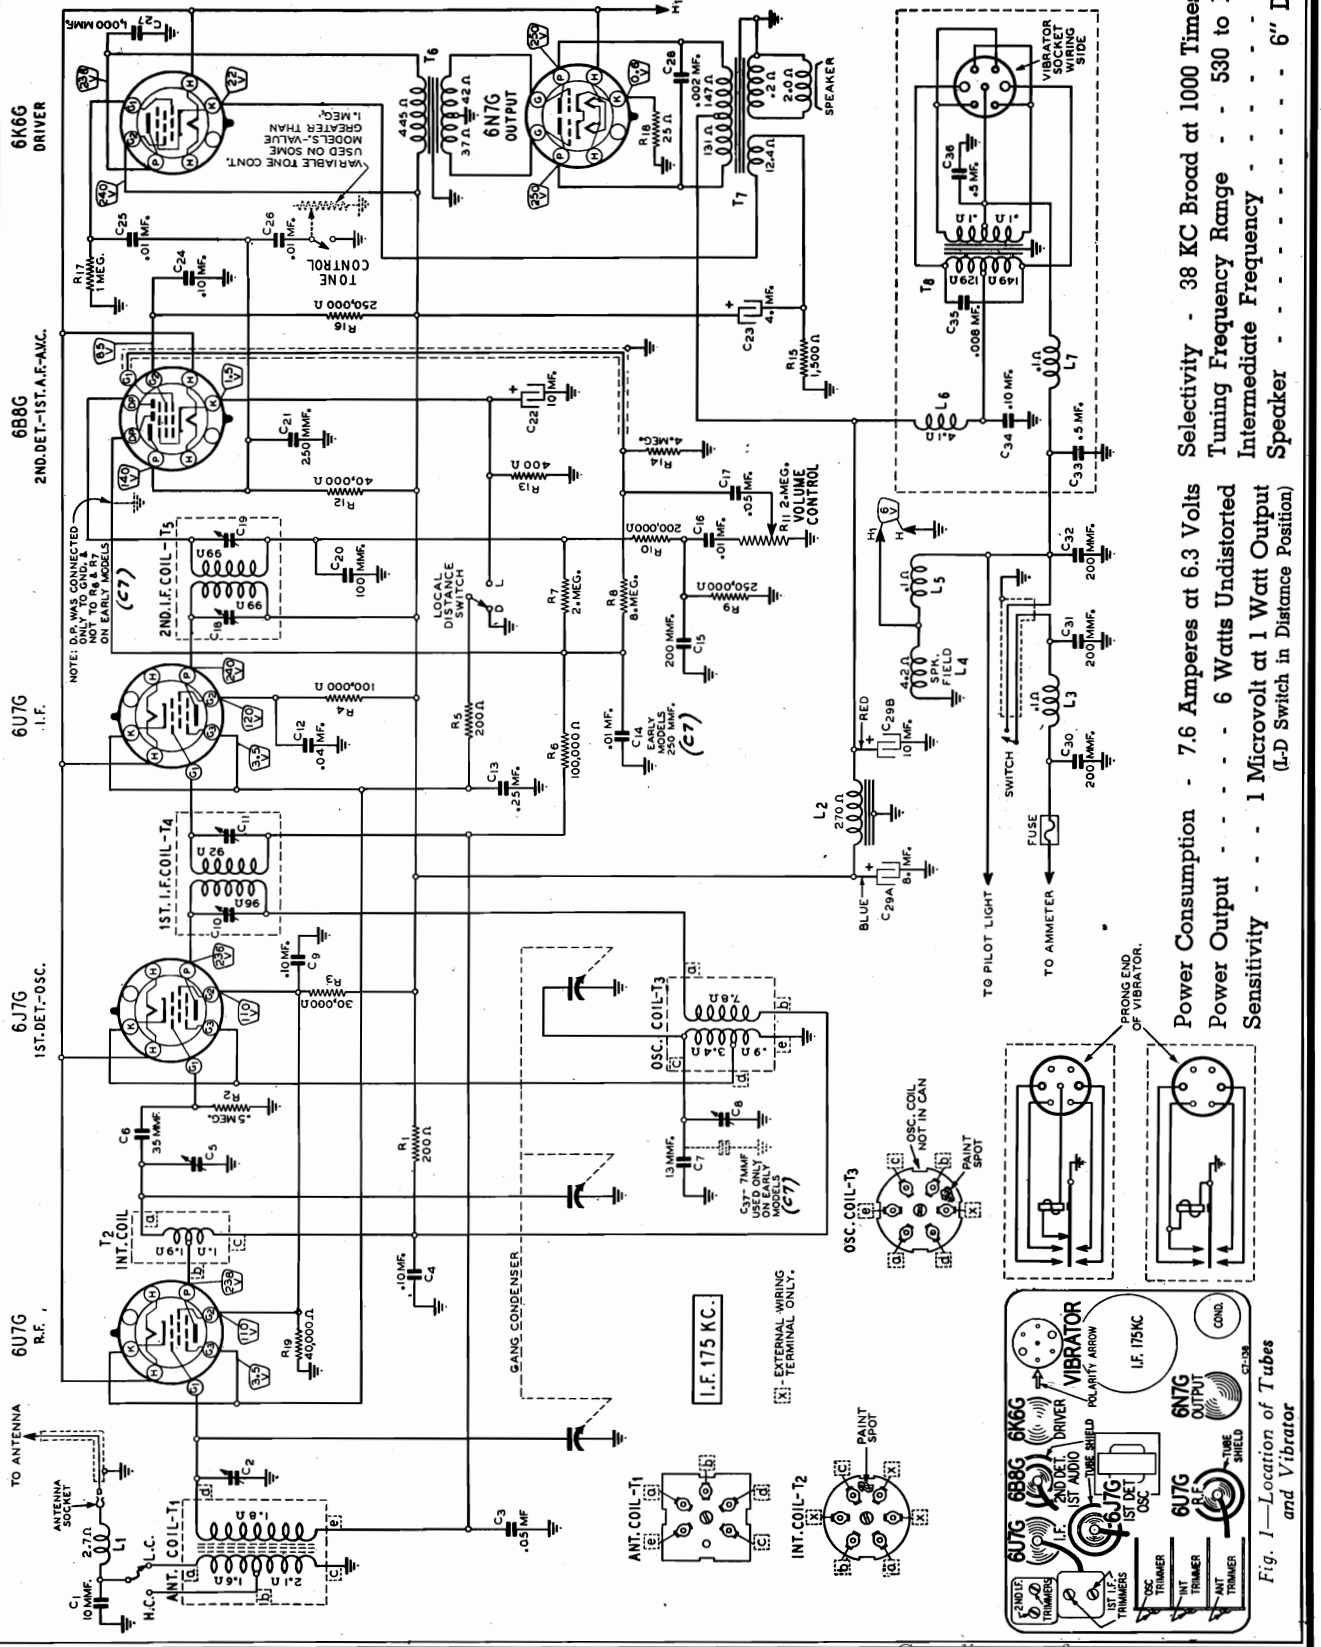

Fig. 5—Replacement of Drive Cords

**CAUTION**—When aligning the short wave band, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard

WELLS-GARDNER & CO.

MODELS C7,C11 Series  
Schematic, Voltage, Socket  
Alignment, Trimmers

**ALIGNMENT** Adjust IF trimmers at 175 KC thru .05 mf dummy. Adjust Osc. trimmer at 1581 KC thru 120 mmf dummy if 60 inch cable 70 mmf is used - or thru 25 mmf dummy if 30 inch cable 35 mmf dummy is used. Adjust Interstage and Antenna trimmers at 1400 KC. Readjust Antenna trimmer C2 at 1400 KC.

Selectivity - 38 KC Broad at 1000 Times Signal  
Tuning Frequency Range - 530 to 1581 KC  
Intermediate Frequency - 175 KC  
Speaker - 6" Dynamic  
Power Consumption - 7.6 Amperes at 6.3 Volts  
Power Output - 6 Watts Undistorted  
Sensitivity - 1 Microvolt at 1 Watt Output (L-D Switch in Distance Position)

**MODEL All Series**  
Schematic, Voltage  
Alignment, Socket

**DC OPERATION**—Filament and ballast tube voltages will be the same as AC (for 117 volt line). The plate, screen and bias voltages will be slightly lower than those shown above. When operated on DC, the rectifier tube acts as a low resistance series resistor with a drop of approximately 6 volts between plate and cathode.

**CAUTION**—In any service work on the AC-DC chassis, keep it on a wood or other insulated surface to avoid contacts with ground.

**MAY, 1938**

Power Consumption - 48 Watts (At 117 volts AC Supply)  
 Power Output - .8 Watts Undistorted  
 Selectivity - 30 KC Broad at 100 times Signal.  
 Tuning Frequency Range - 530 to 1730 KC  
 Sensitivity - 180 Microvolts Average

**ALIGNMENT PROCEDURE**

Volume Control—Maximum All Adjustments. Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

SIGNAL GENERATOR	DUMMY ANTENNA	CONDENSER SETTING
456 KC	.1 mf.	Turn rotor to full open
1730 KC	200 mmf.	Turn rotor to full open
1500 KC	200 mmf.	Turn rotor to max. output

ADJUST TRIMMERS TO MAXIMUM (See illustration)

TRIMMERS	SETTING
I.F. (C6) & (C7)	Oscillator (C3)
Antenna (C2)	Antenna (C2)

The following equipment is required for aligning:  
 Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
 Output Indicating Meter; Non-Metallic Screwdriver.  
 Dummy Antennas—.1 mf. and 200 mmf.

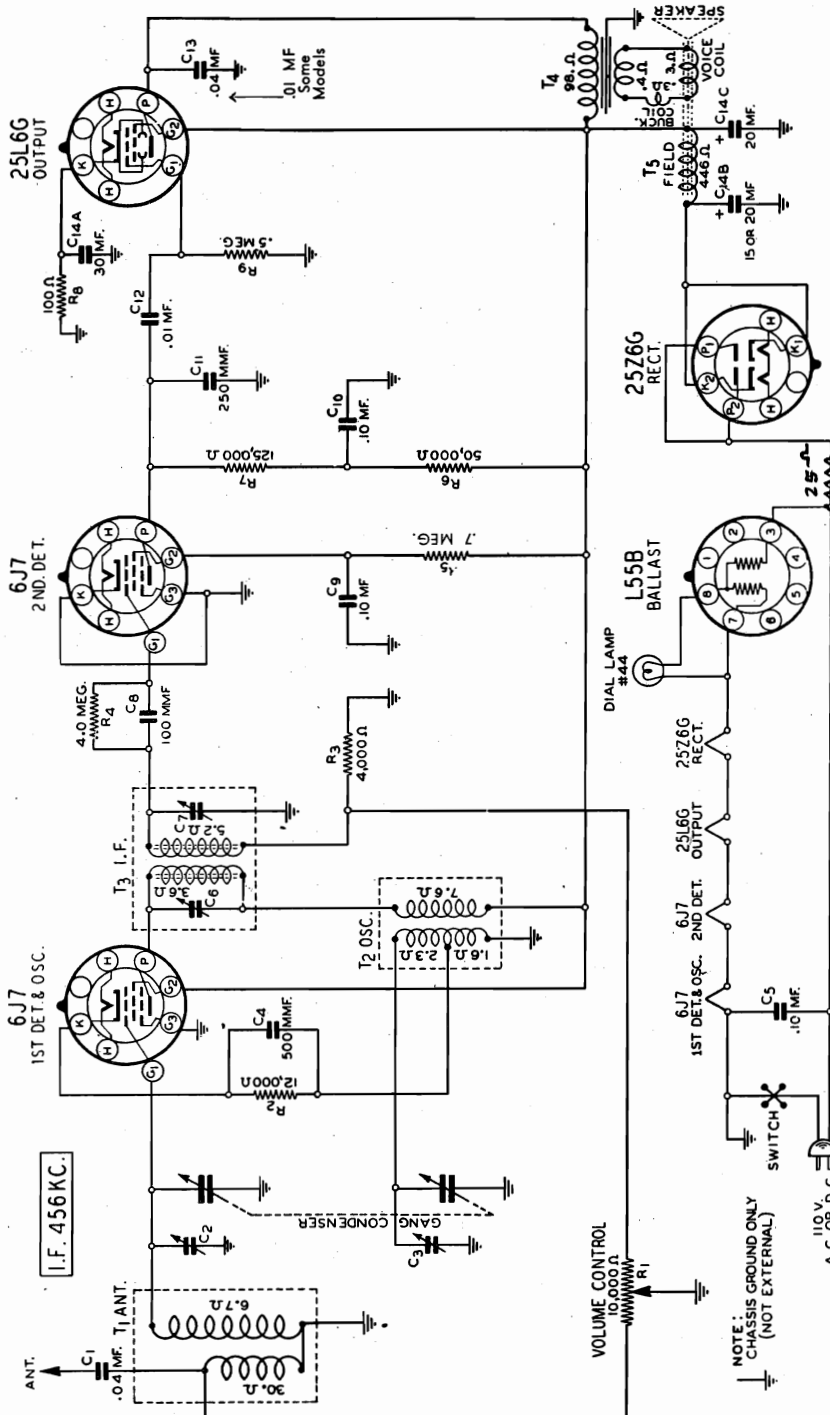

**NOTE**—To obtain dial scale calibration, tune in an 800 KC signal. The pointer should be at the 800 KC mark on the dial. If it is not, loosen the pointer screw, set the pointer at the 800 KC mark and retighten the pointer screw.

MODEL A12 Series Late Schematic, Voltage, Socket Trimmers, Changes Tuner Switches

ISSUE NUMBER CHANGES

The last digit of the number on the chassis number label identifies the radio as to the issue number.

**ISSUE NO. 1**

The information contained in the Series A12 Service Manual, with the exception of the Replacement Parts List and Schematic Circuit Diagram, applies with minor changes to all chassis issues, 1 through 6. The Replacement Parts List and Schematic Circuit Diagram, however, apply only to No. 1 issue chassis.

**ISSUE NOS. 2 and 3**

**MECHANICAL CHANGES** -- The station button plunger has a length of 7-3/16 inches.

The locking plate for the station button plungers has been redesigned and now employs two side arms mounted in rubber cushioned hinge brackets which are attached to the rear bracket of the tuner assembly by two screws.

**ELECTRICAL CHANGES** -- The Schematic Circuit Diagram (Fig. 3) is that of Issue Nos. 2 through 6. The AVC voltage is fed to the grid of the R.F. tube through the manual and automatic tuning coils. Formerly, it was applied directly to the grid of the R.F. tube through a 1 Megohm resistor.

The operating voltages of several of the tubes have been changed. Correct values are shown on the schematic in this supplement.

**ISSUE NOS. 4 and 5**

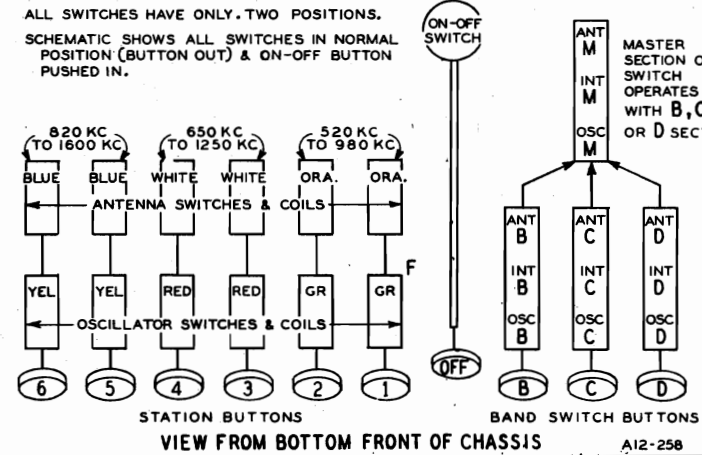

**MECHANICAL CHANGES** -- The antenna coil (T1) and Wave Trap Coil (L1) have been moved from the top of the chassis base to a position just in back of the band switch underneath the chassis base.

The Wave Trap Trimmer (C1) has been moved from its former position near the 1st I.F. Transformer (T6) to a position near the 6U7G R.F. tube.

**ELECTRICAL CHANGES** -- The Wave Trap Coil (L1) and Trimmer Condenser (C1) have been removed from the antenna circuit and are now connected in the interstage circuit - See Fig. 3.

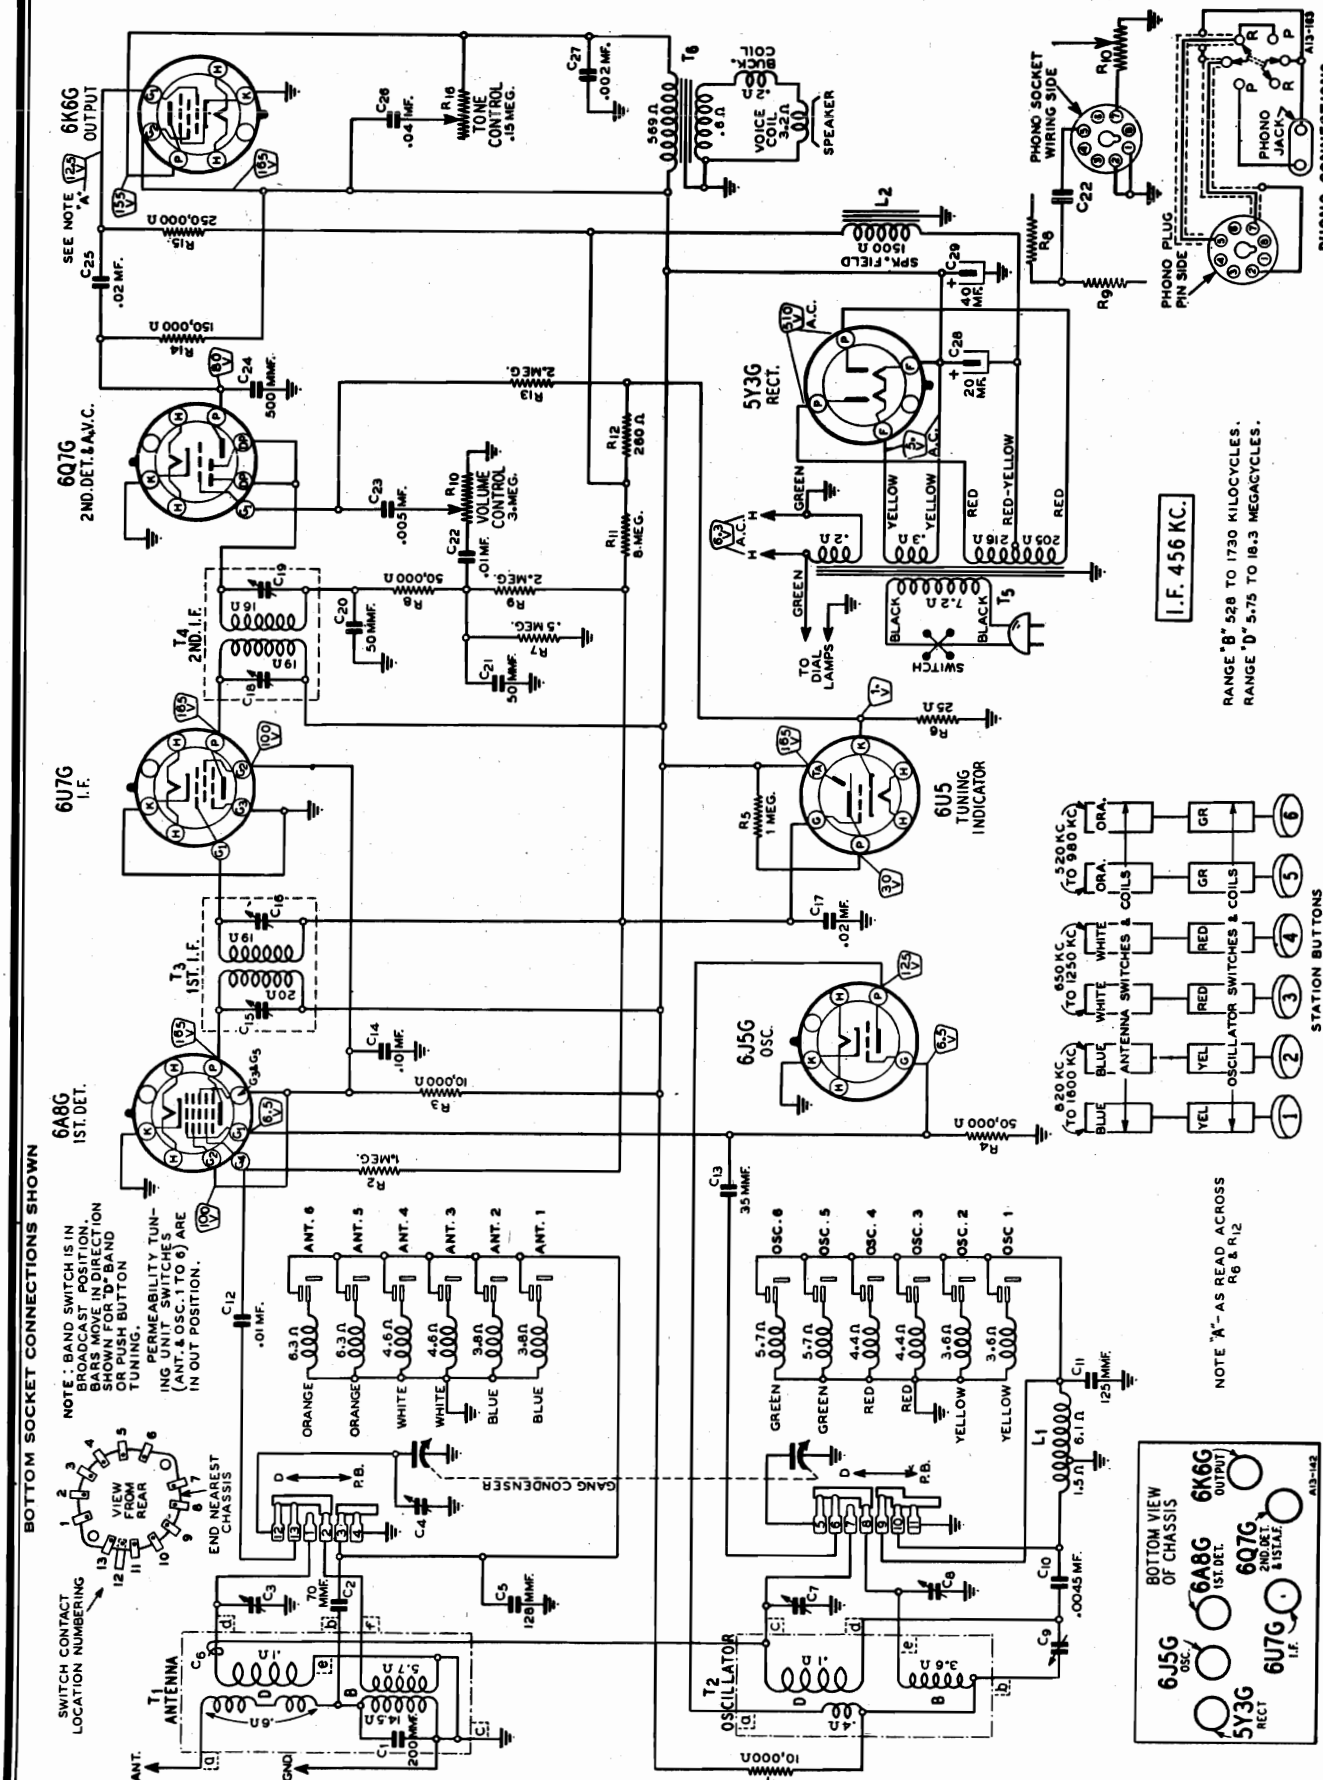

**ISSUE NO. 6**

**ELECTRICAL CHANGES** -- The Tone Control, formerly in the 1st audio plate has been put in the diode circuit - See Fig. 3. A 1 Megohm Tone Control (R22) and a .02 mf. (C37) condenser were used in the audio plate. A 3 Megohm Tone Control (R32) and a .001 mf. (C49) condenser are used in the diode circuit.

D Range (Manual Tuning) 5750 to 18300 KC (Kilocycles)

Buttons 1 and 2 (Automatic Tuning) 820 to 1600 KC

Buttons 3 and 4 (Automatic Tuning) 650 to 1250 KC

Buttons 5 and 6 (Automatic Tuning) 520 to 980 KC

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.

Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.

Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:

An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.

Output Indicating Meter—Non-Metallic Screwdriver. Dummy Antennas—:1 mf., 200 mmf., and 400 ohms.

SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	DUMMY ANTENNA	BAND SWITCH	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM
<b>I. F.</b>					
456 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open	1st I.F. (C15) & (C16) 2nd I.F. (C18) & (C19)
<b>RANGE B</b>					
1730 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open	Oscillator Range B (C8)
1500 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Ant. Range B (C4)
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	600 KC (C9) Rock Rotor—See Note B
<b>RANGE D</b>					
18,300 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D (C7)
15,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	Ant. Range D (C3) Rock Rotor—See Note B
<b>PERMEABILITY TUNING UNIT</b>					
			<b>BUTTON DEPRESSED</b> (Band Switch in Push Button Position)	<b>TURN SETTING SCREW TO MAXIMUM OUTPUT</b> —See Instruction Book	<b>ADJUST COIL POSITION TO MAXIMUM OUTPUT</b> —See Note C
1100 KC	Antenna Lead	200 mmf.	No. 1	Setting Screw No. 1	Antenna Coil No. 1
1100 KC	Antenna Lead	200 mmf.	No. 2	Setting Screw No. 2	Antenna Coil No. 2
850 KC	Antenna Lead	200 mmf.	No. 3	Setting Screw No. 3	Antenna Coil No. 3
850 KC	Antenna Lead	200 mmf.	No. 4	Setting Screw No. 4	Antenna Coil No. 4
700 KC	Antenna Lead	200 mmf.	No. 5	Setting Screw No. 5	Antenna Coil No. 5
700 KC	Antenna Lead	200 mmf.	No. 6	Setting Screw No. 6	Antenna Coil No. 6

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

NOTE C—At the top of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.

CAUTION—When aligning the short wave band be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for

15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at

15,000 less 912 KC; or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

**NOTE A**—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

**NOTE B**—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

**NOTE C**—Leave condenser rotor at the 600 KC setting and adjust the signal generator until maximum output is obtained at or near 456 KC.

**NOTE D**—At the top of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.

**CAUTION**—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for

15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at

15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

Fig. 2—Location of Trimmers

WELLS-GARDNER & CO.

ALIGNMENT

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

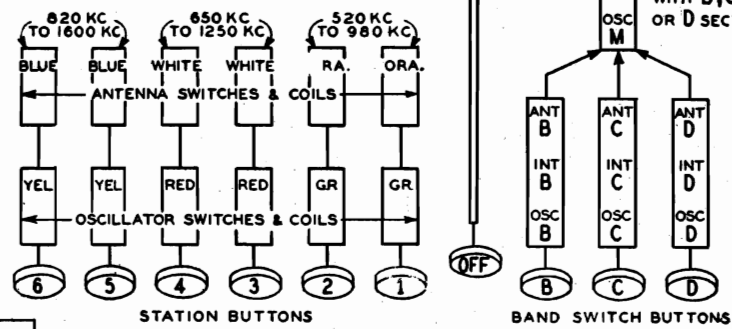

NOTE A—Hold the tuning knob and turn the film drum until it is at the 1500 KC mark on the dial.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

NOTE C—At the bottom of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows:

ALL SWITCHES HAVE ONLY TWO POSITIONS. SCHEMATIC SHOWS ALL SWITCHES IN NORMAL POSITION (BUTTON OUT) & ON-OFF BUTTON PUSHED IN.

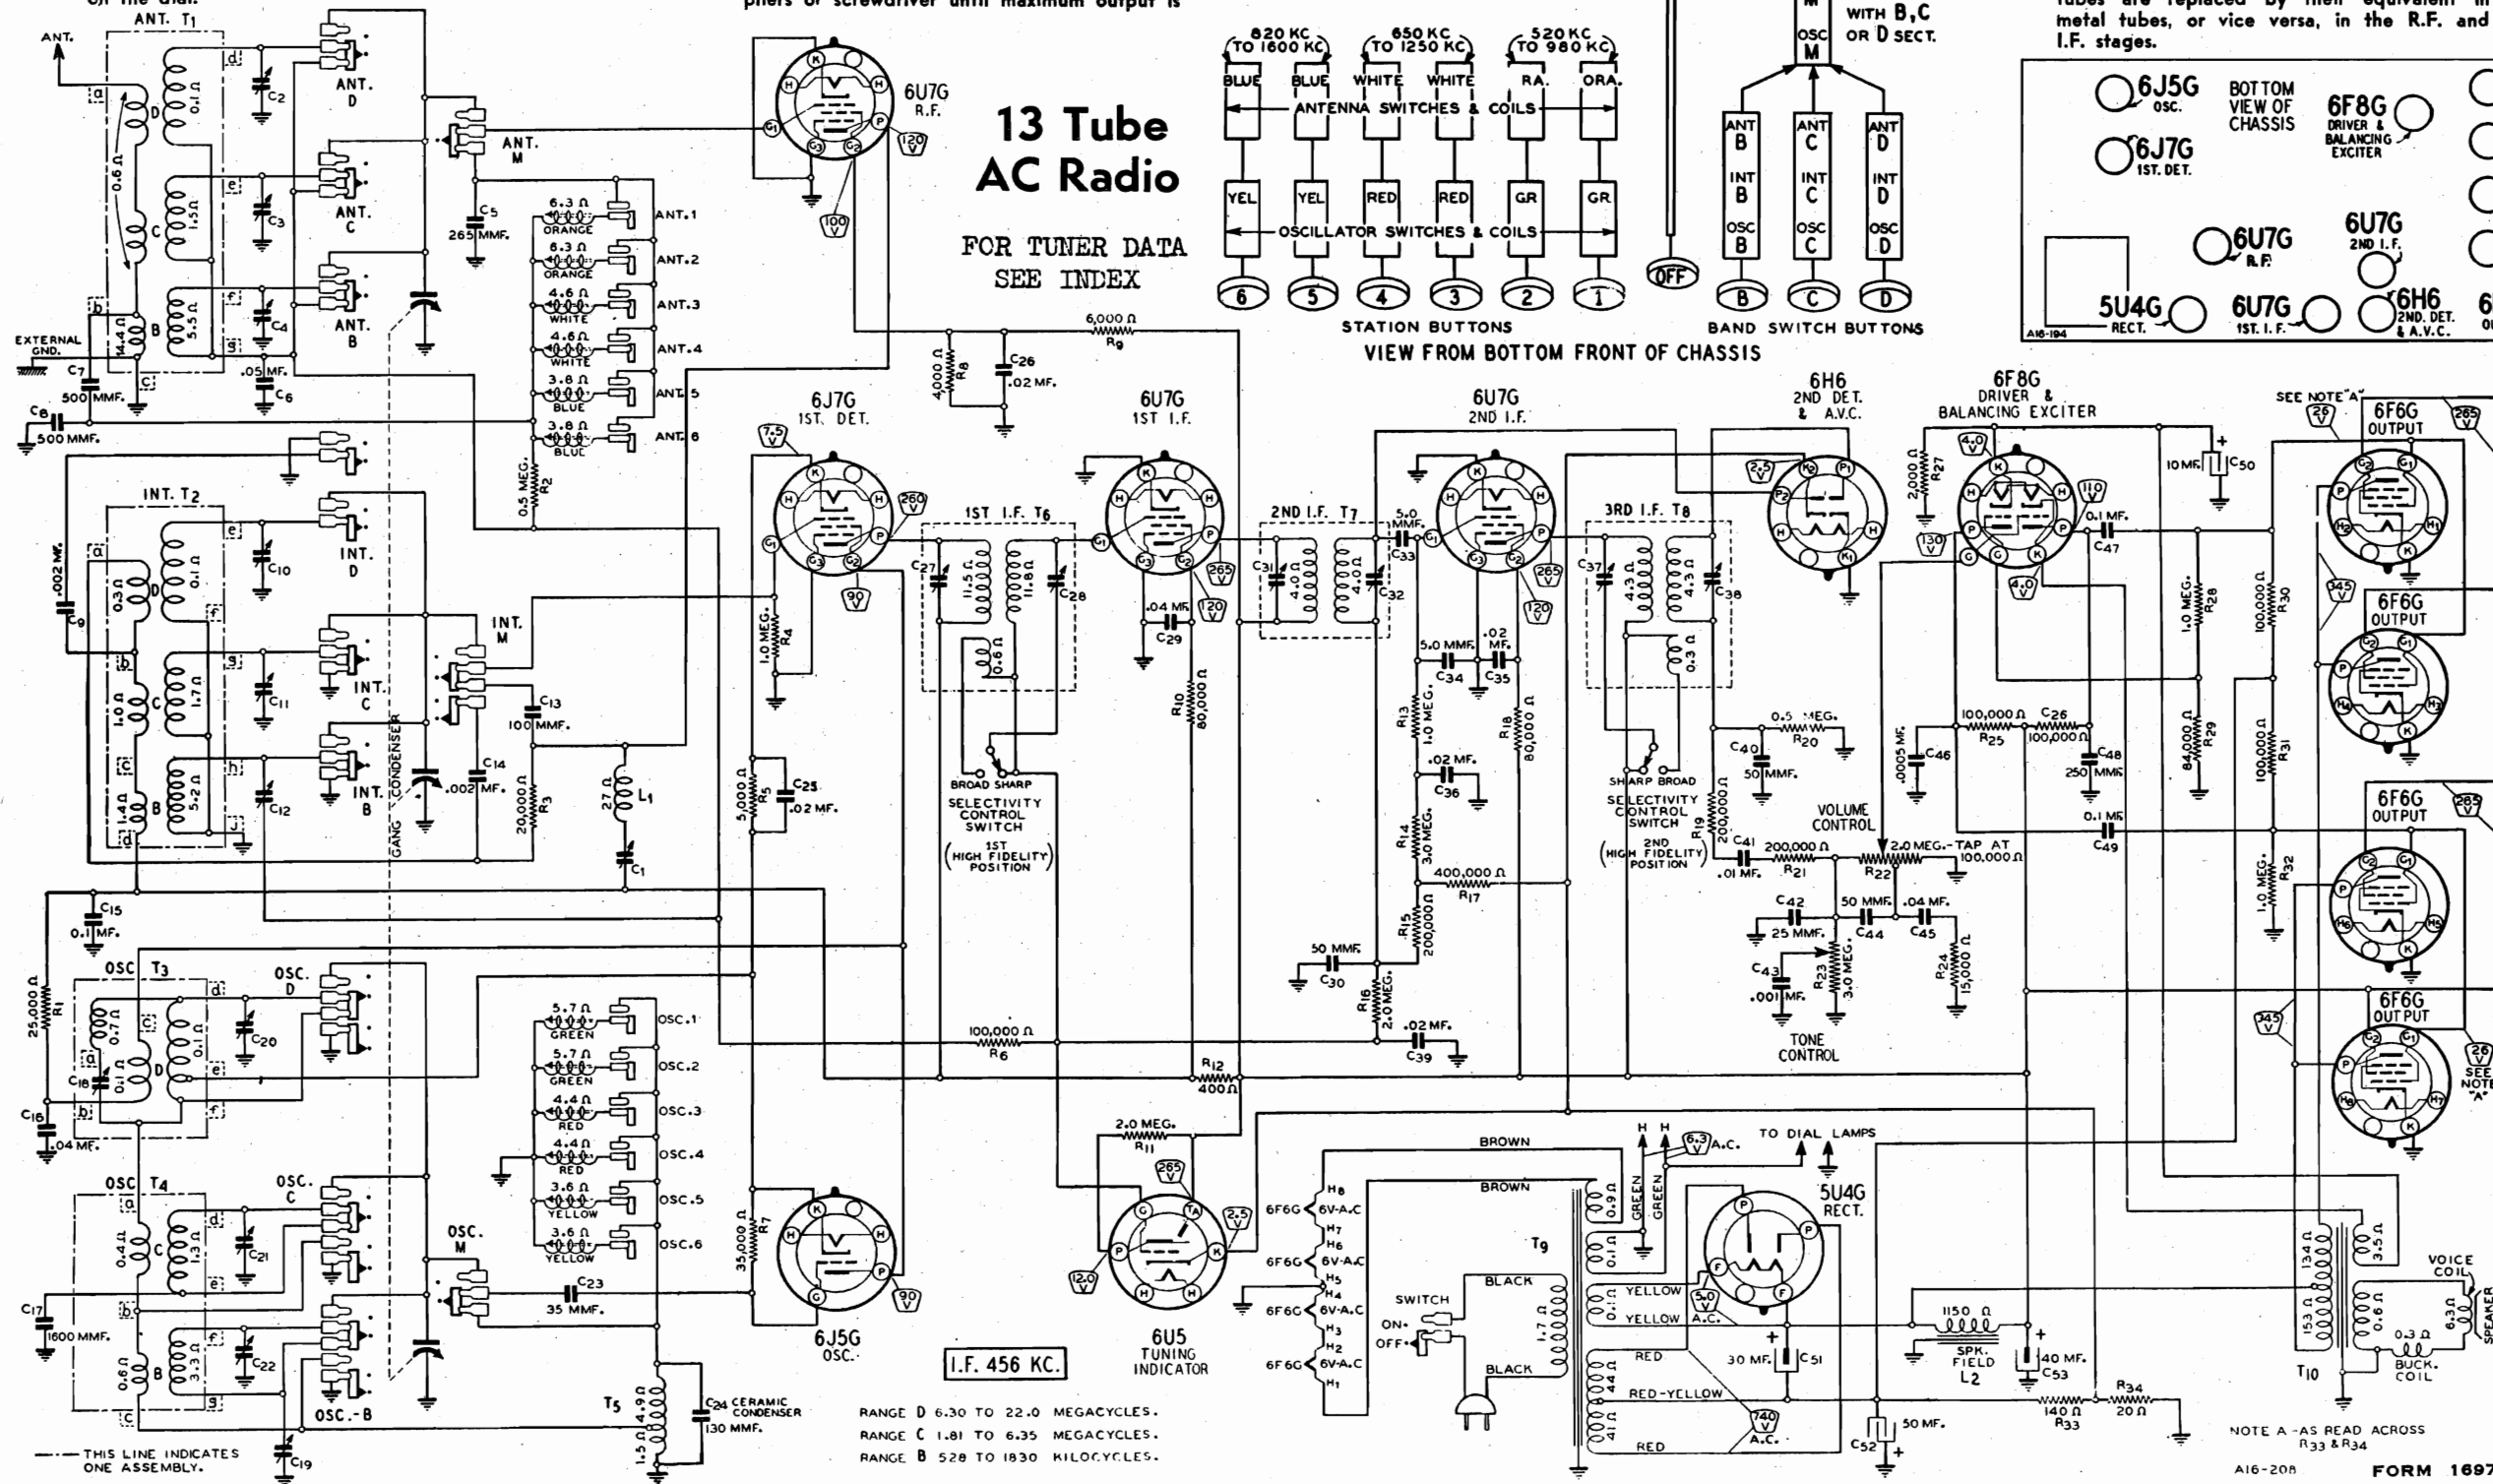

Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Volume Control—Maximum All Adjustments. Selectivity Control—Sharp Position All Adjustments. Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead. Allow Chassis and Signal Generator to "Heat Up" for several minutes.

Table with columns for Frequency Setting, Dummy Antenna, Button Depressed, and Adjuster Setting. It lists various frequency ranges (B, C, D) and their corresponding adjustments for maximum and minimum output.

Fig. 2—Location of Trimmers. CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Turn the dial to 5000 KC. The signal will then be heard at 5000 KC.

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency between 800 and 1,000 KC on the Broadcast band. Hold the tuning knob in position and turn the film drum until it is at the correct kilocycle mark on the dial scale. There should be a dot at the bottom of the film drum which will permit the drum to be rotated a small distance.

If the drum must be rotated an additional amount in order to calibrate, loosen the film drum pulley set screw (Fig. 6) and turn the film drum until it is at the correct position. Then tighten this set screw. EARLY MODELS—Some of the early production models employed a film drum pulley bushing with a small set screw hole—See Fig. 6. Two types of film drum pulleys were used with this bushing: one employed a 3/16 inch brass set screw, the other a 1/8 inch steel set screw. In calibrating, the latter screw should not be passed through the set screw hole in the bushing, but should be tightened against the outer wall of the bushing. If calibration cannot be made without passing the set screw through the hole, loosen the 6 screws around the edge of the film drum, and carefully rotate the film a slight amount

Tuner Data

SETTING PUSH BUTTONS WG SERIES A15, A22, A23, A24.

Selecting the Stations to be Set

There are 6 buttons on the push button tuning dial by means of which 6 stations may be set for quick tuning. They are numbered 1 to 6 in Fig. 2.

Make a list of your favorite stations, those which you tune in regularly. There may be any number up to and including 6 in this list.

It is better to list the station with the highest kilocycle number first, the station with the next lower kilocycle number next, and so on.

Frequencies Covered by Each Button

The frequency range of each station button is shown in Fig. 2. Any station within the range of a button may be set. Although, in some cases, it may be possible to set a certain station on several buttons, it is better to set the stations so that the kilocycle numbers decrease from buttons 1 to 6.

Setting a Station Button

Select a station from the list you have prepared, preferably the station with the highest kilocycle number, and tune in this station with the tuning knob in the usual way. Determine what program is being broadcast.

At each side of the escutcheon plate is an escutcheon screw—See Fig. 2. Remove the escutcheon plate by unscrewing these two screws. Be careful to avoid scratching the plate.

When this is done, the setting screws above the six buttons will be exposed.

Turn the band switch knob to the PUSH BUTTON TUNING position—See Fig. 2. The station tuned in previously will probably disappear.

If the kilocycle number of the station tuned in is within the range of button No. 1, push this button in. The same station or a different station may be heard.

With a small screw driver, slowly turn the setting screw above button No. 1 in or out until the desired station (the one previously tuned in) is heard. Turning the screw in (clock-

wise) will tune in stations with higher kilocycle numbers while turning the screw out (counter-clockwise) will tune in stations with lower kilocycle numbers. Be sure not to tune in some other station broadcasting the same program. Using the tuning eye as a guide, accurately tune in this station. The station is now set on this button.

To determine whether the correct station has been set, turn the band switch knob back to the BROADCAST position. The same station should be heard (provided the tuning knob has not been turned). If it is not, turn the band switch knob to the PUSH BUTTON TUNING position again and retune with the setting screw.

Remove the station call letter tab from the sheets provided and push the tab all the way to the bottom of

the rectangular space above the correct station button opening in the escutcheon plate. Then cover the call letter tab with one of the clear celluloid tabs.

Proceed in the same manner to set stations on any of the remaining buttons. Use blank tabs above buttons on which stations are not set.

After all of the stations have been set, carefully replace the escutcheon plate.

If at any time you wish to change the setting of a button from one station to another, repeat the above procedure. Changing the setting of one button will not affect the setting of any of the other buttons. The old call letter tab may be removed by sticking a pin through the notch in the celluloid tab and through the call letter tab.

WG SERIES A20 ALIGNMENT, DRIVE CORD DATA, PHONOGRAPH NOTES.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.

Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.

Allow Chassis and Signal Generator to "Heat Up" for several minutes.

IMPORTANT—Follow procedure in the order shown.

The following equipment is required for aligning:

An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.

Output Indicating Meter—Non-Metallic Screwdriver.

Dummy Antennas—.1 mf., 200 mmf., and 400 ohms.

SIGNAL GENERATOR FREQUENCY SETTING	CONNECTION AT RADIO	DUMMY ANTENNA	BAND SWITCH SETTING	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM (Unless otherwise specified)
I. F. 456 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open	2nd I.F. (C16) & (C17) 1st I.F. (C14) & (C15)
WAVE TRAP 456 KC	Antenna Lead	200 mmf.	B Range	600 KC	Wave Trap (C5) Adjust for MINIMUM Output
RANGE B 1730 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open	Oscillator Range B (C11)
1500 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Ant. Range B (C3)
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	400 KC (C9) Rock Rotor—See Note B
RANGE D 18,300 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D (C8)
15,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	Ant. Range D (C1) Rock Rotor—See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

Fig. 4—Drive Cord

Voltagess at Sockets

The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.

These voltages are read under the following conditions:

- Line Voltage—117.
- Volume Control—Maximum.
- Antenna Shorted to Ground.
- Readings taken with 1000 ohm-per-volt meter.

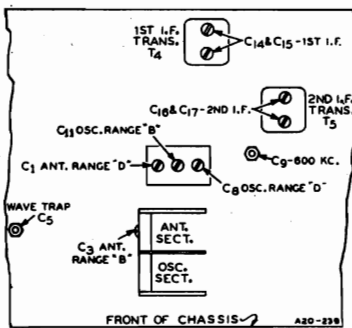

Fig. 2—Location of Trimmers

Drive Cord Replacement

Tie a knot with a small loop at one end of the new drive cord. Slide a 1 3/4 inch length of fabric tubing on the cord. Tie the free end of the drive cord to the tension spring. The distance between knots should be 48 1/2 inches.

Arrange to keep the gang condenser in the completely closed position.

Place the looped end of the drive cord over hook A on condenser drive drum B (See Fig. 4). Pass the cord through slot C in the drum rim and wind one turn in a clockwise direction (from front of chassis) on condenser drive drum. Pass drive cord over pulleys D and E as shown. See that the fabric tubing is now between pulleys D and E. Continue cord down to shaft F and wind 2 1/4 turns clockwise, progressing towards the chassis. Bring cord over pulley G to bottom of condenser drive drum B as shown. Wind drive cord clockwise (from front of chassis) around condenser drive drum B to slot C. See that the drive cord does not cross in groove of condenser drive drum. Pass the remaining drive cord and tension spring through slot C and secure the free end of the spring on hook A.

DIAL POINTER ATTACHMENT

Tune in a station of known frequency. Move the pointer to this frequency on the dial scale. Clamp pointer tightly over the fabric tubing on the cord—See Fig. 4.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram—Fig. 3. On the back panel of the chassis base is a round knockout 1-9/64 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (See parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.  
 Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.

Allow Chassis and Signal Generator to "Heat Up" for several minutes.

IMPORTANT—Follow procedure in the order shown.

SIGNAL GENERATOR		DUMMY ANTENNA	BAND SWITCH SETTING	CONDENSER OR DIAL SETTING	ADJUST TRIMMERS TO MAXIMUM (Unless otherwise specified)
FREQUENCY SETTING	CONNECTION AT RADIO				
I. F. 456 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open	2nd I.F. (C16) & (C17) 1st I.F. (C14) & (C15)
WAVE TRAP 456 KC	Antenna Lead	200 mmf.	B Range	600 KC	Wave Trap (C5) Adjust for MINIMUM Output
RANGE B				Turn Rotor to Full Closed Position. Pointer should be at low frequency end mark on scale—See Note A.	
1500 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor until dial pointer is at 1500 KC	Oscillator Range B (C11)
1500 KC	Antenna Lead	200 mmf.	B Range	Leave Rotor at above setting	Ant. Range B (C3)
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	600 KC (C9) Rock Rotor—See Note B
RANGE D					
18,300 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D (C8)
15,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	Ant. Range D (C1) Rock Rotor—See Note B

NOTE A—The low frequency end mark is a small dot at the left side of the short wave scale under the "5." of the number 5.8 and to the right of the "C" of the letters MC. If the pointer is not at this mark on the dial, move the pointer to this mark.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

General Service Data

Drive Cord Replacement

Tie a knot with a small loop at one end of the new drive cord. Tie the other end to the tension spring, leaving a distance of 64 1/2 inches between the knots.

Turn the gang condenser to the full open position. Secure the free end of the spring over hook A—See Fig. 4. Turn the gang condenser to the completely closed position.

Pass the cord through slot B and, around the drive shaft—spool, progressing away from the chassis. Pass cord up and over the drive drum. Guiding the cord in the groove of the drive drum, turn the gang condenser to the full open position. If necessary, stretch the tension spring and pull the drive cord taut. Pass drive cord through slot B and secure the loop to the tension spring at point G.

EARLY MODELS—In the early models using a larger drive shaft spool (See Fig. 4), there should be a distance of 65 1/2 inches between the knots.

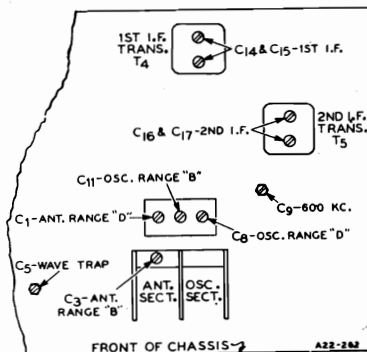

DIAL POINTER ATTACHMENT—Tune in a station of known frequency. Move the pointer to the approximate frequency on the dial scale. Pass the cord through the slotted head—See Fig. 4. Hold the drive cord and slide the pointer to the exact frequency on the dial scale

Rack and Pinion Assembly

If it is ever necessary to re-assemble the automatic tuning unit, proceed as follows: The pinion gear shaft should be held in such a position that the flat portion is vertical or turned slightly counter-clockwise from the vertical as shown in Fig. 5.

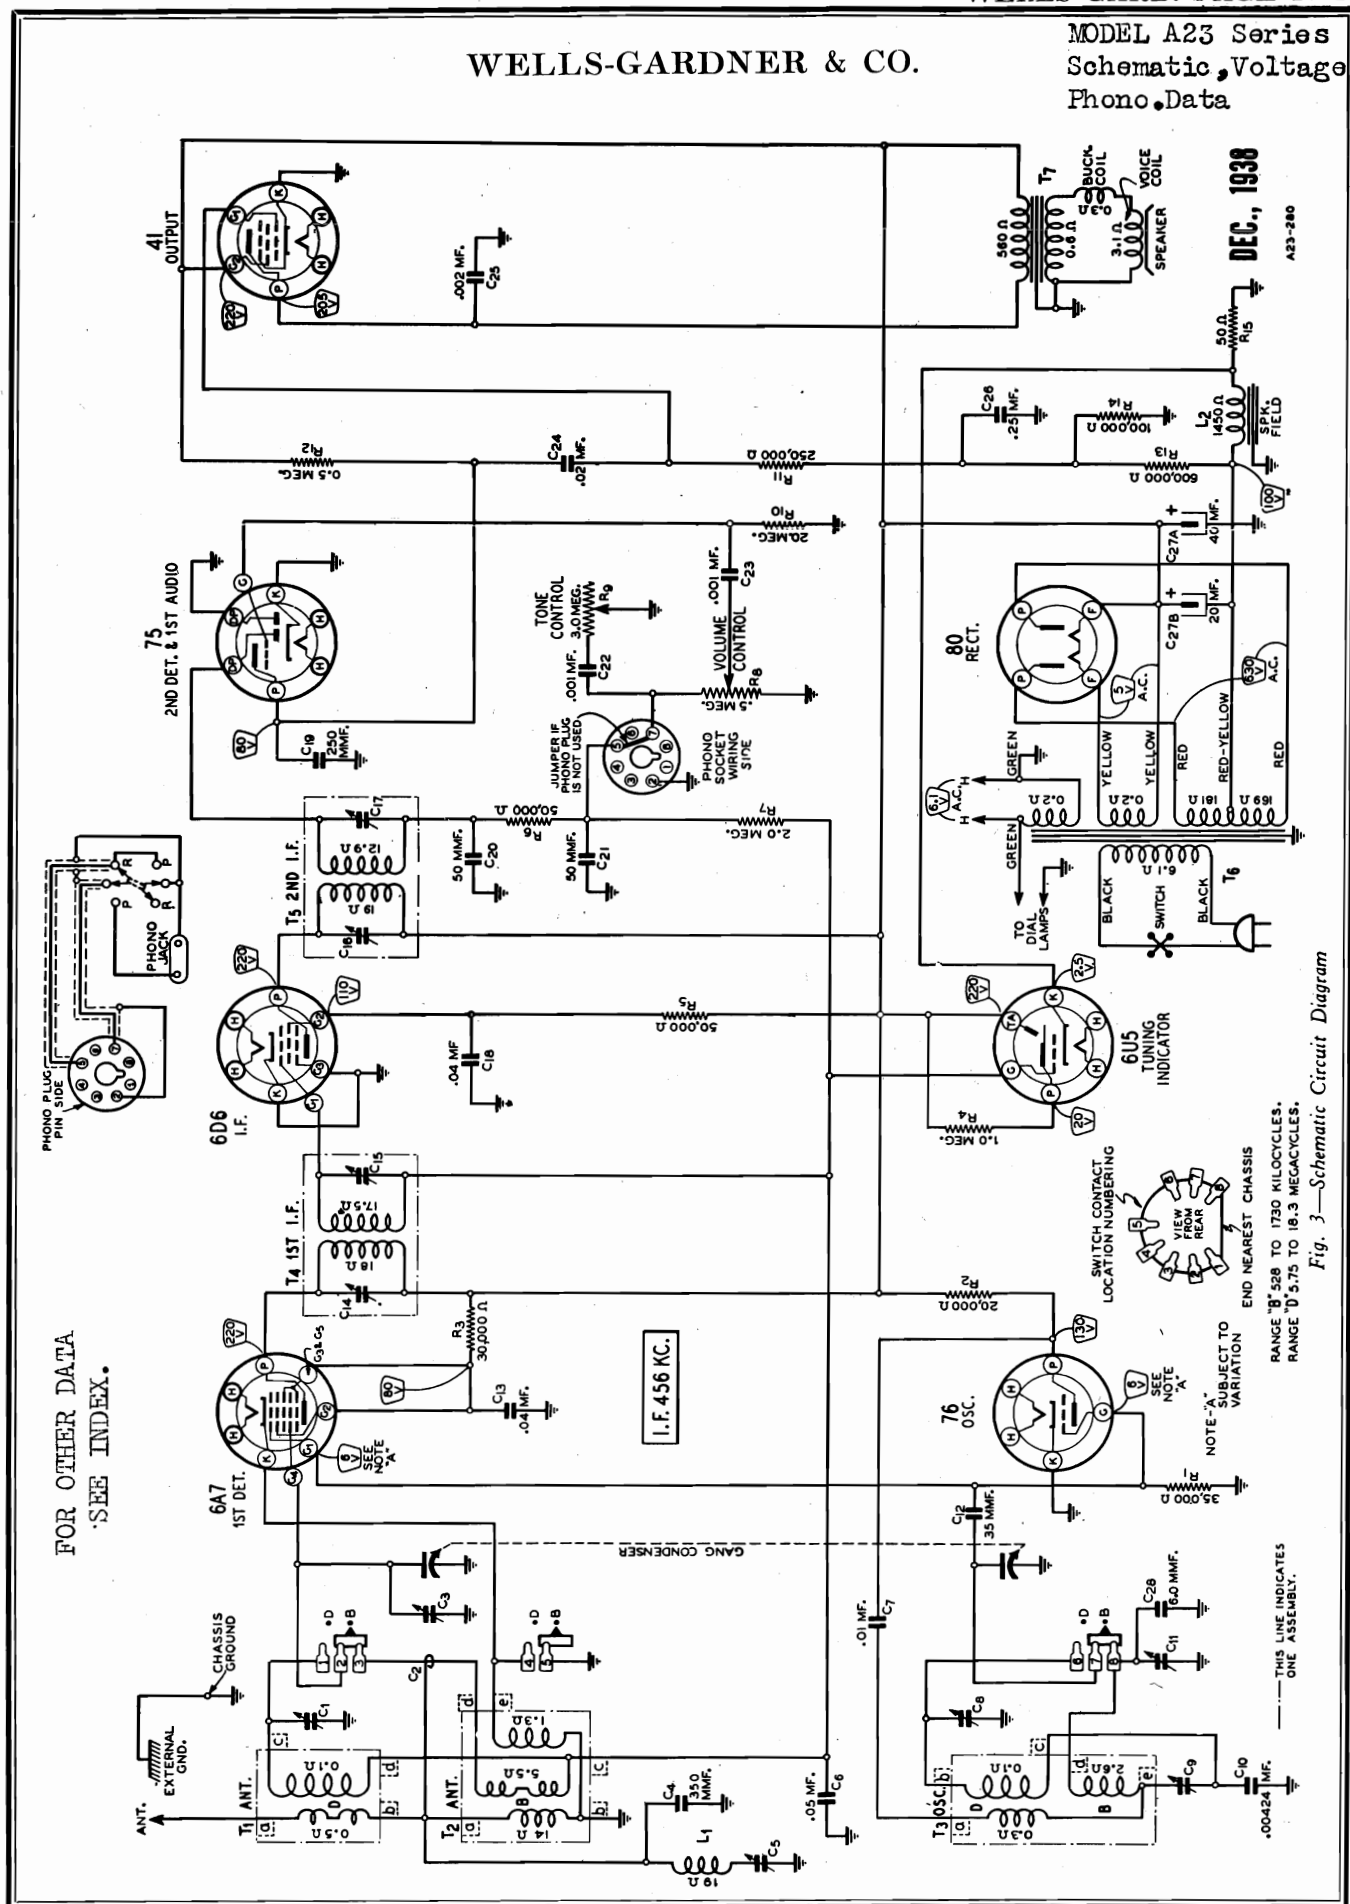

The lower rack should be meshed with the pinion gear so that the 8th tooth from the front on each side of the rack is in line with the axis of the pinion gear shaft—See Fig. 5. The upper rack should then be lined up with the lower rack and meshed with the pinion gear. The 8th tooth from the front on each side of the upper rack will then line up with the axis of the pinion gear shaft.

The rear and side brackets can then be mounted on the rack and pinion assembly.

MODEL A24 Series  
Schematic, Voltage  
Phono, Data

WELLS-GARDNER & CO.

The chassis used in this model is almost identical to the chassis used in WG Series A22. The differences are in the re-mounting of the electrolytic condensers in order to keep them upright when the chassis is mounted in the cabinet, the addition of a phono motor socket to the back panel of the chassis, and the phono attachment parts. The alignment procedure and other service data given for Series A22 also applies to this model.

Tuner Data

WESTERN AUTO SUPPLY CO.

INSTRUCTIONS FOR ADJUSTMENT AND OPERATION OF THE  
ELECTRIC AUTOMATIC TUNING SYSTEM

Before attempting to adjust the automatic tuner, read the following instructions carefully and proceed exactly as directed. Setting up the *Master Selector* requires no tools, and is very easily accomplished when the proper procedure is followed.

The tuning unit consists essentially of three parts, which may be described briefly as follows:

**Master Selector:** This includes the *Selector Drum*, the *Selector Pins*, and the *Selector Light*. These parts are mounted on the rear of the variable condenser, together with their associated brackets and wiring.

**Motor and Drive:** This assembly consists of an induction motor having a mechanical drive clutch with magnetic throw-out, and a train of gears operating directly onto the *Manual Station Selector* drive shaft. No oiling is necessary.

**Push Button Assembly:** These buttons are located on the front of the chassis, and extend through the escutcheon above the dial. Stations are tuned in automatically when the button with the call letters of the desired station is depressed and held down until the motor stops and the station is heard. When the button is pushed down, an automatic silencer mutes the receiver until the desired station is exactly on tune.

SETTING UP THE MASTER SELECTOR

As a means of simplifying these operations, list ten of your favorite local or strong near-by stations according to frequency or position on the dial. Setting up weak or distant stations is not recommended. Call the station nearest the left-hand end of the dial (nearest 600 kc) the No. 1 station, and number the other stations similarly going from left to right across the dial. For example, assume that your favorite stations operate on frequencies of 600 kc, 700 kc, 800 kc, 900 kc, 1000 kc, 1100 kc, 1200 kc, 1300 kc, 1400 kc, and 1500 kc. Then the 600 kc station would be No. 1, the 700 kc station would be No. 2, and so on down the list with the 1500 kc station being designated No. 10. Reference to the push buttons is not necessary since they are not used until After the Master Selector has been set up.

On the back of the receiver will be found the *Selector Drum* and the ten *Contact Pins* which determine the points at which the tuner will stop when the buttons are pressed. Referring to the diagrams, Fig. 1 shows the general layout and relation of the drum and contacts. Fig. 2 shows one of the contact pins in detail: note that while the position of the contact may be varied at will by sliding it along the slot in the bracket, it is held securely by a strong spring which will not allow it to move when the selector drum turns under it. Fig. 3 shows the arrangement of the *Contact Pins*, each pin being numbered according to the system suggested for numbering the stations, thus pin No. 1 will be used for Station No. 1, pin No. 2 will be used for Station No. 2, and so on down the list.

On the *Selector Drum* are two pairs of *Contact Ribbons*. Note that there is a *Paint Dot* on the edge of the drum directly opposite the break in the ribbons on the upper half of the drum. This *Paint Dot* is for the purpose of locating the approximate position at which a given *Contact Pin* should be set in order to have the *Drum* stop for a particular station.

It is very important that the following steps be followed exactly as outlined; any deviation may necessitate re-setting some of the stations:

1. Set the receiver for reception of Standard Broadcast Stations as outlined previously under "Operation." Turn the Master Control Switch to the extreme right-hand position and wait about ten minutes to allow the tubes to reach their final operating temperature.
2. Using the Manual Station Selector (upper right) knob, tune in the No. 1 station, that is, the one nearest the 600 kc end of the dial. Watch the tuning eye closely, making certain that the station is tuned in perfectly.

3. Face the rear of the chassis. Attach the lead from the *Selector Light* to the No. 1 *Contact Pin*; unless the pin happens to be set exactly, the lamp will glow when the lead is touched to the pin.

4. Observe the position of the *Paint Dot* on the edge of the *Drum*. Grasp the No. 1 pin firmly and slide it toward the *Paint Dot*, being careful not to break the connection between the *Selector Light* lead and the pin. When the pin is directly opposite the *Paint Dot*, the light will go out, indicating that the contact is properly set. To insure greatest accuracy in making the setting, slide the pin back and forth across the break between the ribbons, leaving it set half way between the points where the lamp lights. **Be very careful not to move the Selector Drum while the pin is being set.** When the pin is definitely in its proper position, **Disconnect the Selector Light Lead from the Pin.**

5. Repeat the above procedure for the No. 2 station; tune in the station, connect the *Selector Light* lead to the No. 2 contact pin, move this pin opposite the *Paint Dot* so that the light goes out, then **Disconnect the Selector Light Lead.**
6. Using similar procedure, set up the other eight stations, in each case using the *Contact Pin* bearing the same number as that assigned to the station being set up. Always **Disconnect the**

ALIGNMENT PROCEDURE

The Master Control Switch must be turned to the extreme right hand position for all alignment.

IF. Connect generator ground to receiver chassis. Using 1 mfd. condenser in series with the high side of this generator, apply 45 kc signal to grid of the 6D6 second IF amplifier tube and tune the PRIMARY only of the third IF transformer. See above diagram. Connect generator to grid of 6D6 first IF tube and align the second IF transformer. Repeat for transformer No. 1 applying signal to grid of 6A7 transformer.

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then align the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc., and align the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrewed to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

AFC. Connect a high resistance DC voltmeter between the cathode of the 6D6 AFC control tube and the ground. Turn the Master Control Switch to the CENTER position and the Band Selector Switch to the extreme left hand position. Apply a strong 456 kc. signal to the grid of the 6A7 transformer and adjust the secondary of the third IF transformer until the voltage is the same as with no signal.

FOR OPERATING  
SUGGESTIONS  
SEE MODEL D691.

- Tubes required are:
- 1-6D6 Radio Frequency Amplifier
  - 1-6A7 Oscillator-transmitter
  - 1-76 Driver
  - 2-6D6 Intermediate Frequency Amplifiers
  - 1-6H6G Detector AVC-Discriminator
  - 1-42 Power Output
  - 1-6G5 Cathode Ray Tuning Tube
  - 1-80 Rectifier

*Selector Light Lead* as soon as a station has been set up; failure to do so will cause the receiver to hum, and may result in the lamp being burned out.

7. After all the stations have been set up, located the Call Letters of your stations on the printed sheets supplied with the receiver. Remove the desired call letter discs from the sheets. Remove the metal ferrules from the buttons, place the call letter discs behind the celluloid and press the ferrules back on the proper buttons.

8. The only operations necessary to receive any of the ten stations set up as outlined above are: Turn the Master Control Switch to the Center position, allow about one minute for the tubes to heat, press the button with the call letters of the desired station Holding the Button Down Until the Pointer Stops Moving and the Station is Heard, then adjust the tone and volume. Be sure that the Band Selector switch is in the proper position for reception of Standard Broadcast stations.

Master Control Switch: The extreme left position turns the power off. The center position connects the motor and the automatic frequency control for automatic tuning. The right hand position disconnects the motor and automatic frequency control, and increases sensitivity for manual tuning of weak stations. (The right hand position is also used for setting up stations for automatic tuning.)

Unless specifically stated otherwise, these receivers are designed to operate on 115 volts 60 cycles alternating current only.

MODEL D691  
Tuner Data  
Alignment

WESTERN AUTO SUPPLY CO.

ALIGNMENT OF SHORT-WAVE BANDS

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 5400 kc., then align the antenna trimmer at about 5000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency band to 16,000 kc., and align the antenna trimmer at about 15,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmed down tight, then unscrew to the second peak. The antenna trimmer should be screwed down tight, then unscrewed to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

Tubes required are:

- 1-6A7 Oscillator-translator
- 1-6D6 Intermediate Frequency Amplifier
- 1-6Q7G Detector AVC—First Audio Amplifier
- 1-76 Driver—Phase Inverter
- 1-76 Silencer
- 4-42 Power Output
- 1-80 Rectifier
- 1-6G5 Cathode Ray, Tuning Tube (on models equipped with "eye" tuning indicator)

3. Face the rear of the chassis. Attach the lead from the Selector Light to the No. 1 Contact Pin; unless the pin happens to be set exactly, the lamp will glow when the lead is touched to the pin.
4. Observe the position of the Paint Dot on the edge of the Drum. Grasp the No. 1 pin firmly and slide it toward the Paint Dot, being careful not to break the connection between the Selector Light lead and the pin. When the pin is directly opposite the Paint Dot, the light will go out, indicating that the contact is properly set. To insure greatest accuracy in making this setting, slide the pin back and forth across the break between the ribbons, leaving it set half way between the points where the lamp lights. Be very careful not to move the Selector Drum while the pin is being set. When the pin is definitely in its proper position, Disconnect the Selector Light Lead from the Pin.
5. Repeat the above procedure for the No. 2 station; tune in the station, connect the Selector Light lead to the No. 2 contact pin, move this pin opposite the Paint Dot so that the light goes out, then Disconnect the Selector Light Lead.
6. Using similar procedure, set up the other six stations, in each case using the Contact Pin bearing the same number as that assigned to the station being set up. Always Disconnect the Selector Light Lead as soon as a station has been set up; failure to do so will cause the receiver to hum, and may result in the lamp being burned out.
7. After all the stations have been set up, locate the Call Letters of your stations on the printed sheets supplied with the receiver. Remove the desired call letter blocks from the sheets, and insert them in the proper pockets above the push buttons.
8. The only operation necessary to receive any of the eight stations set up as outlined above are: Turn the power switch on by rotating the lower left knob to the right—turn the control a few degrees beyond the point at which the switch snaps on—allow about one minute for the tubes to heat, press the button under the call letters of the desired station Holding the Button Down Until the Pointer Stops Moving and the Station is Heard, then adjust the tone and volume. Be sure that the Band Selector switch is in the proper position for reception of Standard Broadcast Stations.

Be sure that your stations are listed in the proper order according to frequency or position on the dial. Do not confuse frequency (kilocycles) with wave length (meters). Do not set up weak stations, or distant stations too weak to afford clear reception at all times. Do not press more than one button at a time. Hold down more than one button will cause inaccurate tuning, or the motor may not turn at all. Do not leave the Selector Light Lead connected after pins are set up. Do not run the motor for excessively long periods of time. While no damage will result, a protective cut-out will shut off the power to the motor after four to five minutes of continuous operation, and the automatic tuner will not function again until the motor has been allowed to cool for several minutes. When tuning stations, do not release the button until the pointer stops moving. Do not attempt to set adjacent pins in the same slot too close together. Do not expect good results unless a good outdoor antenna is used. Do not change the relative positions of the contact pins; keep them in the same order as shown on the diagram (Figure 3).

OPERATING SUGGESTIONS

INSTRUCTIONS FOR ADJUSTMENT AND OPERATION OF THE D691 ELECTRIC AUTOMATIC TUNING SYSTEM

Before attempting to adjust the automatic tuner, read the following instructions carefully and proceed exactly as directed. Setting up the Master Selector requires no tools, and is very easily accomplished when the proper procedure is followed. The tuning unit consists essentially of three parts, which may be described briefly as follows: Master Selector: This includes the Selector Drum, the Selector Pins, and the Selector Lights. These parts are mounted on the rear of the variable condenser, together with their associated brackets and wiring. Motor and Drive: This assembly consists of an induction motor having a mechanical drive clutch with magnetic throw-out, and a train of gears operating directly onto the Manual Station Selector drive shaft. No oiling is necessary. Push Button Assembly: These buttons are located on the front of the chassis, and extend through the cutout on the dial. They are automatically depressed when the tuning knob is turned to the left of the station in question, and depressed again when the station is heard. When the button is pushed down, an automatic silencer mutes the receiver until the desired station is exactly on tune.

SETTING UP THE MASTER SELECTOR

As a means of simplifying these operations, list eight of your favorite local or strong near-by stations according to frequency or position on the dial. Setting up weak or distant stations is not recommended. Call the station nearest the left-hand end of the dial (nearest 1600 kc) the No. 1 station, and number the other stations similarly going from left to right across the dial. For example, assume that you favorite stations operate on frequencies of 1500 kc, 1400 kc, 1300 kc, 1200 kc, 1000 kc, 900 kc, 700 kc, and 600 kc. Then the 1500 kc station would be No. 1, the 1400 kc station would be No. 2, and so on down the list with the 600 kc station being designated No. 8. Reference to the push buttons is not necessary since they are used until After the Master Selector has been set up.

On the back of the receiver will be found the Selector Drum and the eight Contact Pins which determine the points at which the tuner will stop when the buttons are pressed. Referring to the diagrams, Fig. 1 shows the general layout and relation of the drum and contacts. Fig. 2 shows one of the contact pins in detail; it is held securely by a strong spring which will not allow it to move when the selector drum turns under it. Fig. 3 shows the arrangement of the Contact Pins, each pin being numbered according to the system suggested for numbering the stations, thus #1 No. 1 will be used for Station No. 1, #2 No. 2 will be used for Station No. 2, and so on down the list. Note that there is a Paint Dot on the edge of the drum directly opposite the break in the ribbons. This Paint Dot is for the purpose of locating the approximate position at which a given Contact Pin should be set in order to have the Drum stop for a particular station. It is very important that the following steps be followed exactly as outlined: any deviation may necessitate re-setting some of the stations: 1. Set the receiver for reception of Standard Broadcast Stations, as outlined previously under "Operations." Turn the receiver "On," let it run for at Least Ten Minutes to allow the tubes to reach their final operating temperature. 2. Using the Manual Station Selector (upper right) knob, tune in the No. 1 station, that is, the one nearest the 1600 kc end of the dial. Watch the tuning eye closely, making certain that the station is tuned in perfectly.

MODEL D692, Early  
 MODEL D694  
 Alignment, Socket  
 Trimmers

WESTERN AUTO SUPPLY CO.

MODEL D-694

Connect a high impedance AC voltmeter across the loudspeaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from the generator, strong signals tend to cause improper adjustments.

Be sure that the fidelity control is NOT in the HIGH FIDELITY position. It will not be possible to properly align the receiver unless this control is turned part way toward its "bass" position.

IF. Connect the generator ground to receiver chassis. Using .1 mfd. condenser in series with high side of generator, apply 456 kc. signal to grid of 6K7G second IF amplifier and align transformer No. 3. Repeat for transformer No. 2, applying signal to grid of 6K7G first IF amplifier. Repeat for transformer No. 1, applying signal to grid of 6A7 translator. (See above diagram for location of tubes and transformers.)

RF. (See circuit diagram for location of trimmers.) Using a 200 mmf. condenser in series with the high side of the generator, turn band selector switch all the way to the left, tuning condenser to minimum capacity, feed 1810 kc. signal to antenna terminal and adjust broadcast oscillator trimmer for top frequency. Set generator frequency at some point around 1500-1600 kc., and adjust broadcast antenna and RF trimmers. Set generator for 600 kc., tune receiver to signal and adjust the paddler. The tuning condenser should be rocked back and forth through the signal while varying the paddler in order to assure perfect alignment.

A 400 ohm resistor must be used in series with the generator as a "dummy" antenna for proper alignment of the two short wave bands. Set the band selector switch in the center position, adjust the oscillator top frequency for 6250 kc., then align the antenna and RF trimmers at about 6000 kc. With the band selector in the extreme right position, adjust the top frequency of the high frequency to 18,100 kc. and align the antenna and RF trimmers at about 16,000 kc. In order to make sure that the top end of the last band is set properly, it is best to screw the oscillator trimmer down tight, then unscrew to the second peak. The antenna and RF trimmers should be screwed down tight, then unscrew to the first peak. This procedure must be followed in order that the oscillator and RF circuits will be set in the correct relation to each other, otherwise a "dead" spot at a lower frequency will result, and the dial calibration will not be correct. Usually, it is best to rock the tuning condenser back and forth slightly while making these adjustments at high frequencies.

 Antenna Data

WESTERN AUTO SUPPLY CO.

Tubes must be in proper position and connected as shown.

- |   |  |
|---|--|
| Tubes required are:                     | 1—76 Driver—Phase Inverter   |
| 1—6D6 Radio Frequency Amplifier         | 2—42 Power Output  |
| 1—6A7 Oscillator-translator             | 1—80 Rectifier   |
| 2—6D6 Intermediate Frequency Amplifiers | 1—6G5 Cathode Ray Tuning Tube (on models equipped with "eye" tuning indicator) |
| 1—76 Automatic Bias Control             |  |
| 1—75 Detector AVC—First Audio Amplifier |  |

Do not use tubes of types different from those shown above. When replacing tubes or checking connections, refer to the TUBE LAYOUT CHART.

Connections

Turn the lower right knob to the left as far as it will go. This turns the power switch "off."

Connect the antenna and ground leads to the receiver as shown on the diagrams below. For use with a single wire antenna, connect as shown on Figure 1. If used with a doublet antenna, connect according to Figure 2.

MODELS WITH SINGLE SPEAKER ARE WIRED AS SHOWN ABOVE. FOLLOWING ADDITIONAL PARTS ARE USED: TRANS. T1, NO. 3 SPEAKER SOCKET, NO. 1 SPEAKER, RES. R31 & R32.

THE FOLLOWING PARTS IN THE OUTLINE ARE OMITTED: TRANS. T1, NO. 2 SPEAKER SOCKET, NO. 1 & NO. 2 SPEAKER, NO. 2.

NOTE: RESISTANCES OF WINDINGS LESS THAN 1 Ω. ARE NOT SHOWN.

For replacement purposes use a 5Y3G Rectifier tube in place of the 574MG rectifier. September, 1936

MODEL D695(1936)  
Voltage, Alignment  
Phono. Data, Notes

WESTERN AUTO SUPPLY CO.

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch should be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the diode return circuit at the volume control. This is done by removing the wire connecting condenser C42 to resistors R15, R19 and R22, at the terminal strip located near the back of the planetary drive. Cut this wire to correct length and solder it to the proper terminal on the phono switch—See Fig. 7, keeping the wire close to the back of the chassis base.

A wire is then connected from the lug on the above mentioned terminal strip to which C42 was connected, to the correct terminal on the phono switch—See Fig. 7. This wire should be brought directly to the back of the chassis at a point close to the phono jack pin tip nearest the channel provided for a chassis mounting bolt, and then routed over to the switch.

Complete the other connections as illustrated in Fig. 7.

It will be necessary to re-route the AC line cord away from the 6CY 1st audio grid lead by running it between the volume control and the filter choke and then straight back to the hole provided for it in the chassis base.

If a hum is heard when the phono pickup is touched, reverse the two pickup leads.

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Do not change the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Trimmer Replacement

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the coil side (side not grounded) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect it to the side of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire or a solder lug. The trimmer adjustment is replaced as usual, but be sure to keep the lead as short as possible and keep the ungrounded lead as far from ground as possible.

Planetary Drive Assembly

The planetary assembly is the unit that is integral with the tuning shaft.

If the nut on the back end of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back off this nut one or two turns and note the effect.

If this nut is too loose, the drive will slip in slow speed. The remedy in this case, of course, is to tighten the nut.

Should the condenser drive cord slip when the planetary pulley is turning, inspect the tuning condenser, drive drum and gears to see if they are turning properly or if they are being obstructed in some way.

If the drive turns unevenly (rough in spots), this may mean that the planetary assembly is defective or damaged internally and a new unit will be required.

Range C Alignment

CAUTION—When aligning the short wave bands be sure NOT to adjust the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

5800 KC Adjustment

Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range C position (first short wave band).

Adjust the oscillator Range C trimmer (C18) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C7 and C10) and antenna Range C trimmer (C2) to maximum.

Do not change the setting of the oscillator Range C trimmer.

1800 KC Adjustment

Set the signal generator for 1800 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 1800 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC. Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band switch to the Range D position (second short wave band).

Adjust the oscillator Range D trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C6 and C9) and antenna Range D trimmer (C1) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

I. F. Adjustment

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band switch to the Range B position (standard wave band). Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and the location is shown in Fig. 3.

Range B Alignment

After the procedure for the alignment of each range as explained below, is completed, it is advisable to repeat the procedure as a final check.

1730 KC Adjustment

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position.

Keep the band switch in the standard wave position.

Connect the antenna lead of the receiver through a 200 ohm. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

Adjust the oscillator Range B trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

In sets using pointers, loosen the screw of the large pointer and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the screw.

In sets using the moving beam of light, there is moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until it is at the 1500 KC mark on the dial. Retighten the screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C11) and antenna Range B trimmer (C3) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained.

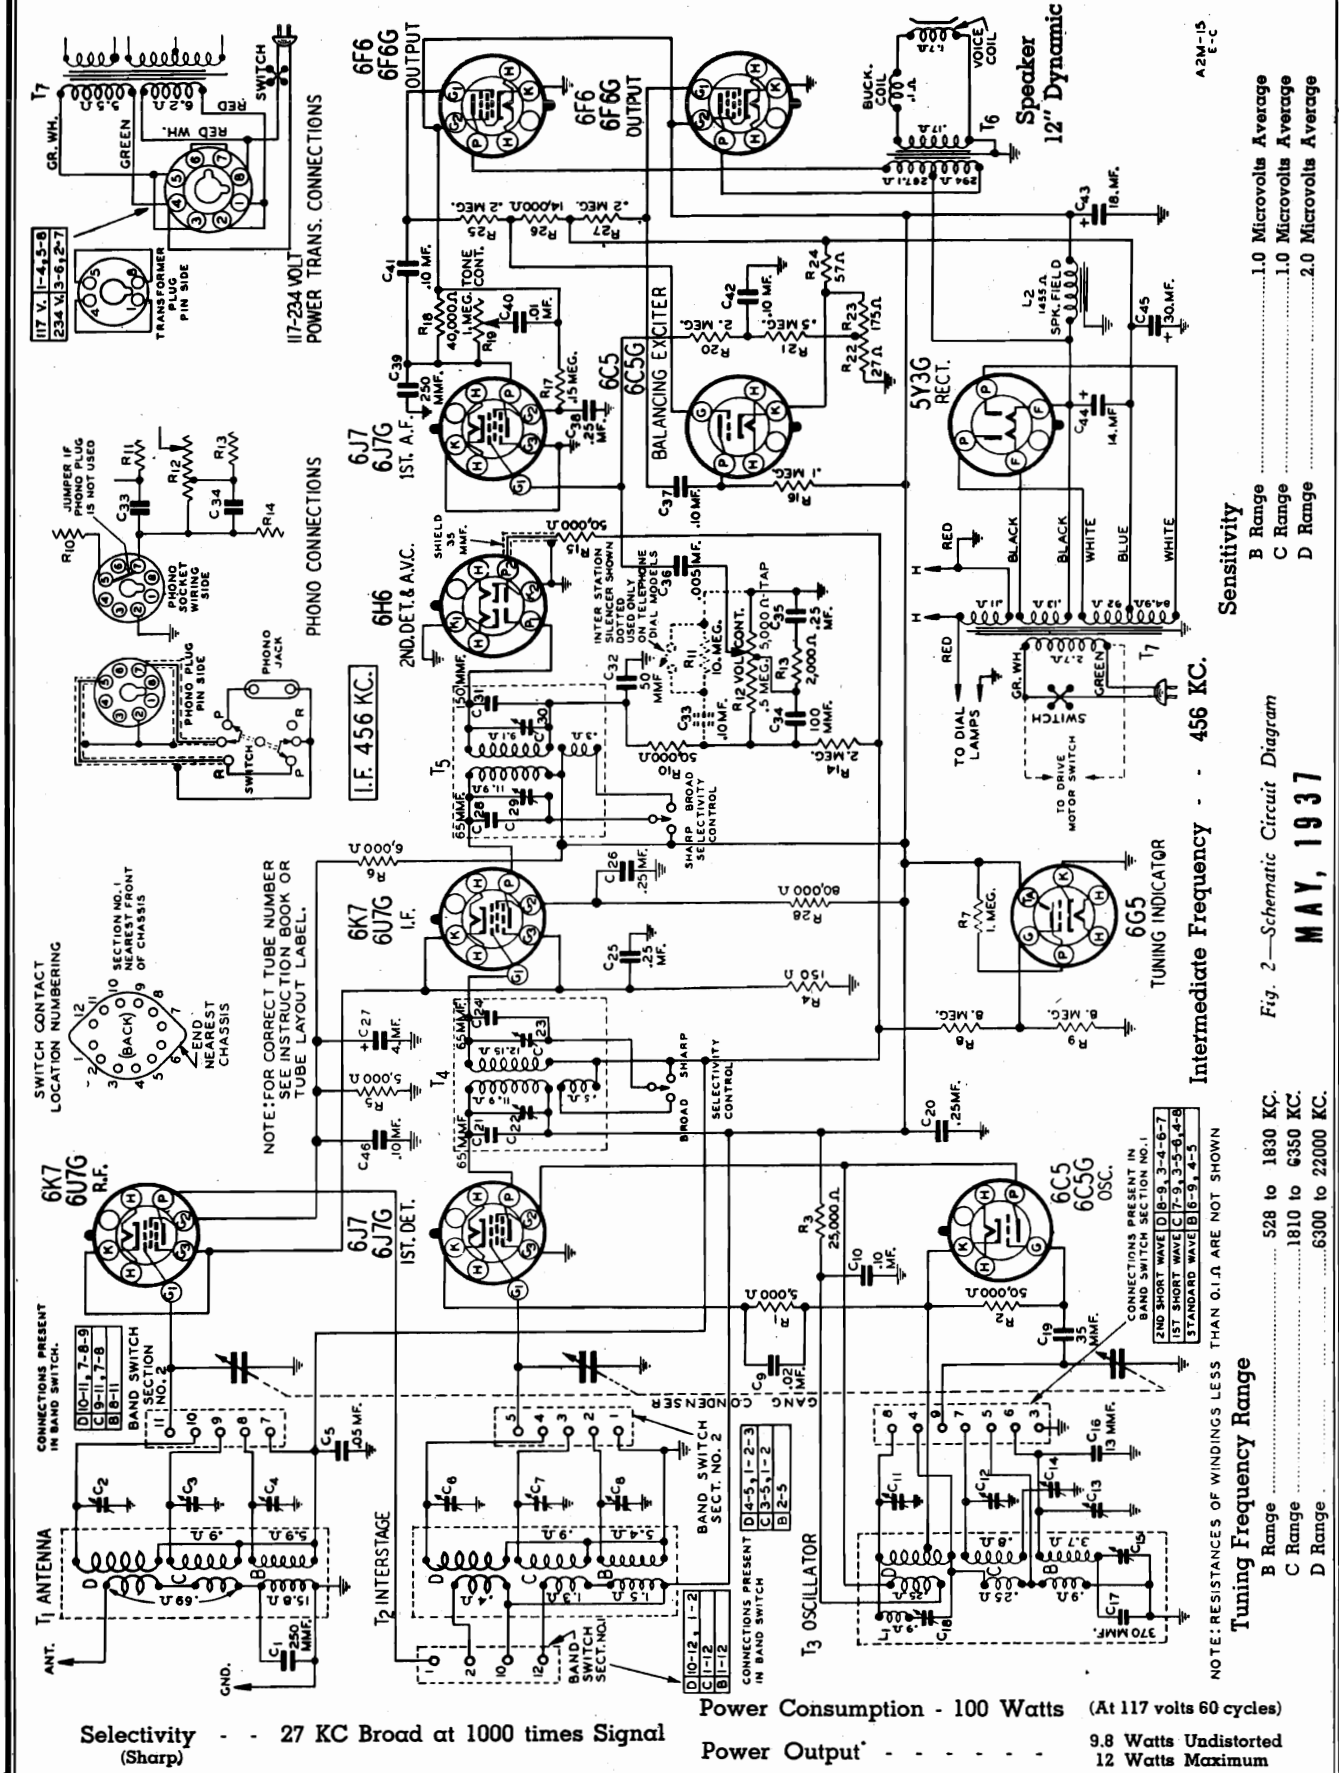

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

11 TUBE • 3 BAND • ALL WAVE

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.  
Selectivity Control—Sharp Position All Adjustments.  
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:  
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
Output Indicating Meter — Non-Metallic Screwdriver.  
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR		TRIMMERS ADJUSTED See Illustration	PROCEDURE	
			FREQUENCY SETTING	CONNECTION AT RADIO		INITIAL STEPS	ADJUSTMENT
<b>I. F.</b>							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output

7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C18)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial turning an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An embossed edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this

screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust of the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Fig. 3—Location of Trimmers

When the selectivity control is in the broad position, the coupling winding which is wound under the primary in the case of T4 is connected in series with the secondary. In the case of T5, the coupling winding which is wound under the secondary is in series with the primary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R.F. and I.F. tubes.

Across the volume control resistor R12 is a filter composed of condensers C34 and C35 and resistor R13. At high volume settings, the filter is not effective. At low volume settings, the action of the filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

The output of the 2nd detector is applied to the 6J7 1st A. F. tube. The output of this tube is fed thru resistance coupling into the 6F6 output tube shown nearest to it in the schematic.

A portion of the voltage developed across the output tube grid resistor is applied to the control grid of the 6C5 balancing exciter tube. This tube functions as a phase inverter and applies the audio voltage of proper phase and amplitude to the other 6F6 output tube. The two output tubes operate as a stage of Class A push-pull amplification. The balancing exciter tube thus replaces a push-pull input transformer. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6C5 tuning indicator tube is employed.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6C5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R.F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. The band switch sections are designated in the schematic as section 1 and section 2.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed through the interstage R.F. transformer with tuned secondary into a 6J7 tube which functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the

Fig. 1—Arrangement of Controls

1st and 2nd I.F. transformers are tuned by small trimmer condensers.

Referring to the 1st and 2nd I.F. transformers T4 and T5 in Fig. 2, it will be noted that there is a coupling winding shown below the primary of T4 and below the secondary of T5.

When the selectivity control is in the sharp position, the coupling windings are open circuited and the loose coupling which exists between the primary and secondary of these transformers results in high selectivity.

Fig. 6—Coil Terminal Arrangement and DC Resistance of Windings

WESTERN AUTO SUPPLY CO.

MODEL D697 Voltage, Socket Changes, Phono Data Parts List

Fig. 7—Octal Tube Terminal Numbering (bottom of socket).

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true—the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the front panel of the chassis base is a round knockout 1 1/2 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

Fig. 4—Location of Tubes

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—see Fig. 2.

117-234 Volt Power Transformers

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Notes issued for this chassis. (see index)

Changes in Later Models

Later models of this series have the following changes incorporated in them.

On the first models, the 2nd I.F. coil was not expanded. In other words, the extra selectivity coupling winding was not incorporated in the early type coil. Models with the letter "C" or any later issue stamped on the chassis use the new type coil with the selectivity coupling winding.

When ordering parts, therefore, it is important that the issue letter on the chassis be noted and the correct part number as shown in the parts list be specified.

VOLTAGES AT SOCKETS

Table with columns: TUBE, FUNCTION, Prong No. 1, Prong No. 2, Prong No. 3, Prong No. 4, Prong No. 5, Prong No. 6, Prong No. 7, Prong No. 8. Lists voltage readings for various tubes like 6K7, 6J7, 6C5, etc.

(1) A.C. voltage as read across heater terminals 2 and 7. (2) Subject to variation. (3) Bias (2.5 volts) as read across resistor R22. (4) Bias (24 volts) as read across resistors R22, R23, & R24. (5) A.C. voltage as read across filament terminals 2 and 8. (6) A.C. voltage as read across terminals 4 and 6.

The R.F. circuit of early models was slightly different from that used in later models. The screen grids of the R.F. and I.F. tubes now supplied by separate voltage sources were formerly connected together and supplied from a single source. On the latter models, resistor R 28 and condenser C 46 were not used.

Replacement Parts

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

MODEL D697

MODEL D698

Telephone Dial Data

WESTERN AUTO SUPPLY CO.

NOS. 9, 10, & 11 — 17 BUTTON TELEPHONE DIAL

NOS. 3 & 7 — PHANTOM LIGHT DIAL

APRIL, 1937

**Identification of Dial and Chassis**

The following description will identify the different dials:

No. 9 Dial—17 Button Telephone Dial—Station call letters in black push buttons.

No. 11 Dial—Same as No. 9 Dial except push buttons are brown.

No. 10 Dial—17 Button Telephone Dial—Station call letters are rectangular in shape and are mounted in rectangular openings in escutcheon ring. Equipped with visible tone and volume indicators.

No. 3 Dial—Glass dial—Moving beam of light indicators—Tone and volume indicated by series of circles.

No. 7 Dial—Glass dial—Moving beam of light indicators—Tone and volume indicated by slanting lines.

The following description will identify the chassis used with the above dials:

8 Tube—D698

11 Tube—D697

**Telephone Dial Assembly**

The telephone dial assembly provides a means of pre-setting a number of broadcasting stations and tuning in these stations at any time by depressing a button and rotating the dial to a stop position.

The apparatus is mounted on an assembly attached at the front of the chassis. An examination of this assembly will clearly show the method of operation.

**Silencer Circuit**—A silencer circuit is provided which results in silent tuning between stations when using the telephone dial buttons.

When a telephone dial button is depressed, a circuit is established between the ungrounded end of the volume control and the chassis ground. Referring to Fig. 1 it will be noted that contact is made between the line from the volume control, contact ring, contact washer arm (when button is depressed), spring and pulley ring stud. Since the pulley ring is at ground potential, this grounds the audio voltage and no signal will be heard until the button is released to break the contact.

It should be noted that the contact ring is part of the pulley ring assembly, but is insulated from it.

In the case of powerful local stations a slight amount of signal may be heard when the button is depressed.

**Telephone Dial Adjustments**

**Noise When Tuning in a Signal with a Telephone Dial Button**

As explained in the article on "Silencer Circuit" in this manual, no noise or signal should be heard when tuning in a signal with a telephone dial button until the button is released. If noise is heard while tuning in a signal with one of these buttons, it can be corrected as follows:

**If Noise Occurs on All Buttons**—This is probably due to a poor contact between the flat contact spring and the contact ring—See Fig. 1. Clean the flat contact spring and contact ring to insure a good electrical connection. Ordinary cleaning fluid may be used and will be effective in most cases in cleaning the surface without affecting the plating. If the contact is still not satisfactory, a piece of fine emery cloth may be used.

**If Noise Occurs on One Button Only**—This is due to a poor contact between the pulley ring stud, spring, contact washer, and contact ring—See Fig. 1. Clean all of these items of the particular button, in the same manner as mentioned previously, so as to provide a good electrical connection.

**Telephone Dial Drive Cord Slipping**

If the telephone dial drive cord slips on the tuning shaft pulley, this may be remedied by adjusting the drive cord tension pulley. Loosen the tension pulley bracket screw and adjust pulley assembly until the desired tension is obtained.

**Position of Stop Pin**

When the telephone dial assembly is on the chassis, the gang condenser rotor should not com-

Fig. 1—Silencer Assembly

pletely open or close. The travel of the rotor in this respect is controlled by the gang stop pin on the pulley ring—See Fig. 4. This is necessary to protect the gang condenser in case the telephone dial is swung rapidly to either of the extreme positions. When the gang stop pin is properly set, it will serve as the stop at both extreme positions. If the rotor is seen to open completely or close completely, the stop pin should be pulled back and re-set to overcome this condition.

**Greasing and Oiling**

After a period of time, put some light grease on the pulley ring shaft and on the teeth of the pulley ring. Use light oil on the drive shaft assembly bearing, care being taken not to get any on the drive cord.

**Telephone Dial Replacements**

**Replacing Complete Dial and Condenser Assembly**

Remove the grid lead clip from tube grid cap. Remove silencer cable from the contact spring assembly. Unsolder dial lamp lead from terminal of tube socket.

Unsolder the three stator section connections of the gang condenser. Unsolder the three braided shield leads which ground the gang condenser frame to the chassis, taking care not to loosen the connections of any other units which are grounded at these common points.

At the back of the gang condenser is a stud which secures the assembly to an "L" bracket which is secured to the chassis.

Through this stud is a cotter pin. Remove only the cotter pin, metal washer, and rubber washer.

Viewing the assembly from the back, on the left is a brass bolt which holds the dial support bracket to the chassis—remove this bolt from underneath the chassis.

Grasp the dial support brace and move entire assembly toward the front of the chassis. When the support casting rubber cushions slip clear of the slot in front of chassis, lift entire assembly clear of chassis.

To replace this assembly, reverse the procedure as given above.

**Replacing Pulley and Button Ring Assembly Only**

Remove drive cord.

From underneath the chassis, unsolder the dial lamp lead from prong of the tube socket. Pull this lead through and out to the front of the assembly.

Remove the four escutcheon screws which hold the escutcheon ring and glass crystal in place. The dial scale pointer is removed by unhooking it from the center stud. Unscrew and remove center stud, washers, and dial scale. Slide pulley ring assembly off the center shaft.

On the No. 10 dial, two strips of celluloid between the escutcheon ring and the glass crystal will have to be removed.

To replace the pulley ring assembly, proceed as follows: Lay the assembly face down and adjust the stop pin (Fig. 2) is directly in back of the wide spacer on the dial button ring. Pull this pin back and adjust it to the center position—See Fig. 2.

Rotate tuning condenser rotor counter-clockwise (from front) as far as possible—See Fig. 2.

Fig. 2—Replacing Pulley Ring Assembly

Place the pulley ring assembly on the shaft with the knot of the dial lamp lead at the top—do not engage the gears.

Pull the dial lamp lead through the slot in the dial support casting. Then place this lead through the clip under the dial support brace and out through the opening in the back of this brace.

With the gears still disengaged, rotate the pulley ring clockwise (from front) 1/2 revolution until the stop pin passes over the right gate and comes to rest against the left gate—See Fig. 2.

With the condenser rotor fully closed, push the pulley ring on the shaft until the pulley ring gear engages the fixed gear only (front) of the condenser drive gear assembly. Hold the pulley ring assembly and with a fine blade screw driver, move the movable (back) gear clockwise one tooth relative to the fixed gear—See Fig. 2. Then push the pulley ring all of the way on, engaging the movable gear.

Now lay the chassis on its back. Replace in the order given the large washer with rectangular hole, dial scale, washers, center stud, dial pointer, glass crystal, and escutcheon. Resolder the lamp lead.

For the No. 10 dial, before putting the escutcheon on, lay the two celluloid strips on the glass crystal with the inside flange facing away from the glass. Then lay the escutcheon on top of the celluloid strips. The section not cut out for station call letters should be at the wide spacer in the button spacer ring. Center the small holes in the celluloid discs in the station call letter openings and then tighten the escutcheon screws.

The stop pin must now be adjusted, as explained in article "Position of Stop Pin," until the condenser does not open or close fully. Injury to the condenser will result if allowed to open or close fully.

Replace the drive cord as explained in the article "Replacing Drive Cord."

**Replacing Gates**

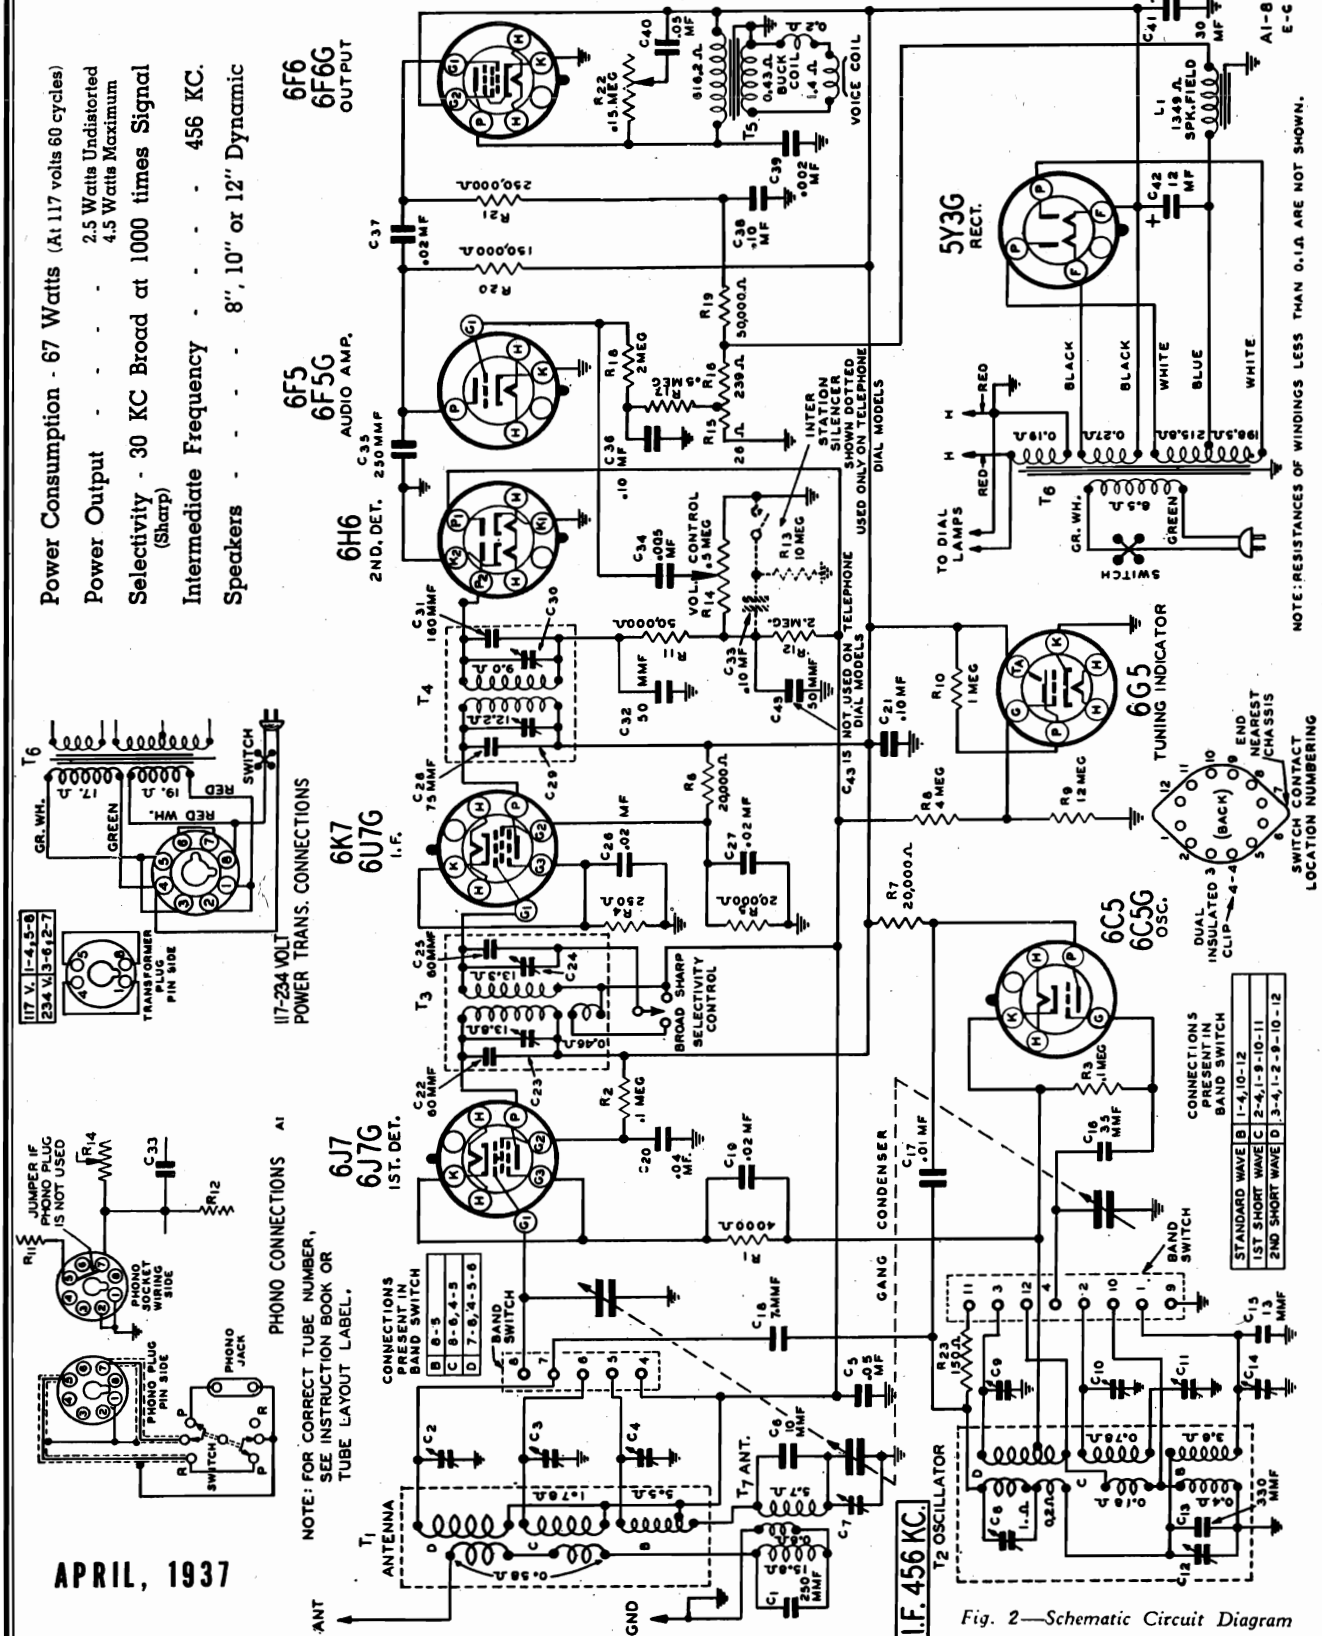

After a great amount of use, one or both of the stop gates may wear, making it necessary to replace the stop gate assembly. This is done by first removing the pulley ring assembly as explained in the article "Replacing Pulley and Button Ring Assembly."

The stop gate assembly is then removed by taking out the two screws at the bottom of the assembly.

WESTERN AUTO SUPPLY CO.

MODEL D698  
Schematic, Phono.  
Transformer Data

Power Consumption - 67 Watts (At 117 volts 60 cycles)  
Power Output - 2.5 Watts Undistorted

Alignment, Voltage  
Socket, Trimmers, Coils

WESTERN AUTO SUPPLY CO.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.  
Selectivity Control—Sharp Position All Adjustments.  
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.  
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:  
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.  
Output Indicating Meter — Non-Metallic Screwdriver.  
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR		TRIMMERS ADJUSTED See Illustration	PROCEDURE	
			FREQUENCY SETTING	CONNECTION AT RADIO		INITIAL STEPS	ADJUSTMENT
I. F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C23) & (C24)	Turn Rotor to Full Open	Adjust to Maximum Output
RANGE B							
1830 KC	Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C14)	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	1st Ant. Range B (C7) 2nd Ant. Range B (C4)	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Adjust to Maximum Output
400 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C12)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE C							
6350 KC	Range C	400 Ohm	6350 KC	Antenna Lead	Oscillator Range C (C10)	Turn Rotor to Full Open	Adjust to Maximum Output
6000 KC	Range C	400 Ohm	6000 KC	Antenna Lead	Antenna Range C (C3)	Turn Rotor to Max. Output	Adjust to Maximum Output
2000 KC	Range C	400 Ohm	2000 KC	Antenna Lead	2000 KC (C11)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE D							
22,000 KC	Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C9)	Turn Rotor to Full Open	Adjust to Maximum Output
20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Antenna Range D (C2)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C8)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

8 TUBE • 3 BAND • ALL WAVE

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial buttoning an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. [Do not tighten these screws too much.]

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

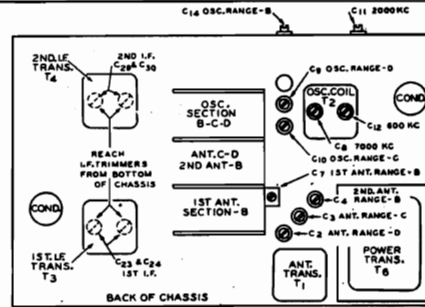

Fig. 3—Location of Trimmers

NOTE: RESISTANCES OF WINDINGS LESS THAN .10 ARE NOT SHOWN.  
Fig. 7—Coil Terminal Arrangement and D.C. Resistance of Windings in early models, write the factory for detailed instructions.  
Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the side panel of the chassis base is a round knockout 1 1/4 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

MODELS D701, D721

S721 (1936)

WESTERN AUTO SUPPLY CO.

Circuit Data, Alignment

Turn the rotor slowly back and forth, at the same time adjusting the 1800 KC trimmer, until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

**Range D Alignment**

**18,300 KC Adjustment**

Set the signal generator for 18,300 KC. Keep the antenna lead of the oscillator connected through the 400 ohm resistor to the output of the signal generator. Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range D position (2nd short wave band). Adjust the oscillator Range D trimmer (C12) until maximum output is obtained. See Fig. 3 for location of this trimmer.

**15,000 KC Adjustment**

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the interstage Range D trimmer (C8) and antenna Range D trimmer (C2) to maximum. When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor back and forth until the peak of greatest intensity is obtained. Do not change the setting of the oscillator Range D trimmer.

**6000 KC Adjustment**

Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

**Twenty-five Cycle Receivers**

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

**Trimmer Replacement**

If one trimmer of the gang trimmer strip should become defective, it is not necessary to replace the entire strip. A single trimmer P-17A36, as shown in the replacement parts list, may be used. Disconnect the lead from the defective trimmer (side the ground) of the defective trimmer in the strip. This connection is then made to the single trimmer. Connect the lead of the trimmer not in contact with the adjusting screw. The other side of the single trimmer is then connected to a good ground, using a piece of heavy wire in order to support the trimmer adequately. In replacing a trimmer, be sure to keep both leads as short as possible and keep the ungrounded lead as far from ground as possible.

**Voltage Chart**

The voltage readings are taken with a voltmeter having a resistance of 1000 ohms per volt. The standard metal tube socket terminal numbering system (bottom of socket) is shown in Fig. 5. On the schematic circuit diagram, Fig. 2 is a list giving the complete names of the tube elements and the corresponding symbols as used on the sockets on the schematic.

After the procedure for the alignment of each range, as explained above, is completed, it is advisable to repeat the procedure as a final check.

**Range B Alignment**

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position. Keep the band selector in the standard wave position. Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator. For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent AVC action.

**1730 KC Adjustment**

Adjust the oscillator Range B trimmer (C18) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

**1500 KC Adjustment**

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Readjust the set screw. Adjust Range B trimmer (C10) and antenna Range B trimmer (C4) to maximum. Do not change the setting of the oscillator Range B trimmer.

**600 KC Adjustment**

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth, at the same time adjusting the 600 KC trimmer, until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

**Range C Alignment**

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC. It may be necessary to increase the input signal to hear the image.

**5800 KC Adjustment**

Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator. Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range C position (1st long wave band). Adjust the oscillator Range C trimmer (C17) until maximum output is obtained. See Fig. 3 for location of this trimmer.

**5000 KC Adjustment**

Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the antenna Range C trimmer (C9) and antenna Range C trimmer (C5) to maximum. Do not change the setting of the oscillator Range C trimmer.

**1800 KC Adjustment**

Set the signal generator for 1800 KC. Turn the tuning condenser rotor until maximum output is obtained.

Resistance coupling is used between the first audio stage and the output stage which uses the 6X4 (or 6X6 output pentode tube). A type 5Z4MG (full wave glass tube) full wave rectifier is used in the power unit.

The models with the tuning indicator tube are wired as shown in the schematic. This tube contains a triode and cathode ray section in one envelope.

The cathode ray is produced by the attraction of the electrons from the upper end of the cathode to the coated target or anode, which is operated at a high positive potential. When this electron stream strikes the target the coating glows. The electron stream is controlled by an additional element, or control electrode, in the tube.

As a signal is tuned in, the control grid of the triode section of the 6E5 cathode ray tube becomes increasingly negative, the negative bias voltage being taken from the AVC line. The AVC voltage is regulated to a suitable value by the potentiometer arrangement of the 10 and 1.5 megohm resistors. The increased bias voltage reduces the triode plate current. This reduces the voltage drop across the 1 megohm plate resistor and raises the triode plate voltage. The triode plate is connected to the control electrode of the cathode ray section of the tube.

The shape and size of the area on the target struck by the cathode ray is governed by the voltage of the control electrode. When the signal is tuned to resonance, practically no plate current flows and the voltage of the control electrode is the same as that of the target. There is no opposition to the flow of electrons to the target. Tuning off resonance decreases the control electrode voltage, because of the opposing action of the target to widen, because of the opposing action of the flow of electrons in the direction of the control electrode.

**Alignment and Calibration**

Correct alignment is extremely important in connection with all wave radios. The receivers are all properly aligned at the factory with precision instruments and readjustment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 1800, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

**I. F. Adjustment**

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator. Turn the band selector to the Range B position (standard wave band).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments. Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

Then adjust the four I. F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 3.

This model is a three band radio with a tuning range in each band as shown in the specifications above. Three band coverage is accomplished by means of three sets of R. F. and oscillator coils and a two-section triple throw switch.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R. F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively. The band switch sections are designed as section one and section two.

The band switch completes connections to the coils in use. It also short circuits the R. F. transformer secondary and oscillator coil of lower frequency not in use.

The antenna transformer with tuned secondary feeds into a type 6K7 R. F. amplifier tube. The output of this tube is fed through the interstage R. F. transformer with tuned secondary into another 6K7 tube which functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R. F. amplifier is tuned. The oscillator potential is fed into the cathode circuit of the 6K7 1st detector tube. This results in the intermediate or beat frequency of 456 KC being present in the plate circuit of this tube.

Two stages of I. F. amplification are employed using 6K7 tubes. The primary windings of the first and second I. F. transformers and the primary of the 3rd I. F. transformer are tuned by small trimmer condensers.

Referring to the 1st and 2nd I. F. transformers T4 and T5 in Fig. 2, it will be noted that there is a coupling winding shown in the illustration below the primary of T4 and below the secondary of T5.

When the selectivity control is in the sharp position, the coupling windings are open, circuited and the loose coupling which exists between the primary and secondary of these transformers results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary in the case of T4 is connected in series with the secondary. In the case of T5, the coupling winding which is wound under the secondary is in series with the primary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A type 6Q7 duo-diode triode tube functions as the second detector and a one stage amplifier. The two diode plates are connected together. AVC voltage is applied through isolating resistors to the control grid circuits of the R. F. and I. F. tubes. The audio voltage developed across volume control resistor R13 is applied through the movable arm to the control grid of the 6Q7 tube.

Across the volume control resistor R13 is a filter composed of condensers C28 and C29 and resistor R14. A tap connection near the low potential end of the volume control is connected between the two condensers. At high volume settings, the filter is not effective. At the low volume settings, as the pointer approaches the tap, the higher frequencies are bypassed through condenser C28. At high frequencies are transmitted through condenser C29. At low volume settings the low frequency amplitudes are increased as a result.

Coils, Phono Connections

loose and a new one will be required. In the sets with the flat belt type of drive, there is an idler pulley which can be positioned, and by means of which the belt tension can be increased. In this type, therefore, the belt tension should be increased before attempting to put on a new one.

The replacement parts list shows the parts used in each type of drive and the parts common to both types.

Switch Contact Location Numbering

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 2. In contact locations not used, the number applying to that particular location is not employed.

Phonograph Connections

connected to the switch terminals nearest the chassis base. Before connecting the cable leads to the phono switch, it will be necessary to slip a piece of varnished tubing over the portion of the cable that passes near the 6K7 1st I.F. tube socket.

Now ground the shielding by soldering it to the lugs on the chassis base. One of these lugs is located just below the planetary drive; the other is near the rear mounting foot of the gang condenser.

Complete the other connections as illustrated in Fig. 7. The lead between the tone control and the .01 mf. tubular condenser C36 mounted on the back of the chassis base, should be covered with a piece of varnished tubing.

The tin plate shield is soldered to the tone control mounting bracket in such a way that when it is bent down toward the bottom and back of the chassis it will shield the lower leads of the phono switch and the lead between the tone control and tubular condenser C36.

After making the phono connections, the I.F. stages should be realigned.

Fig. 8—Location of Phono Knockouts

cord belt. This is a bronze cable with a black fabric covering. It is about 3/8 inch in diameter.

The belt type also has an idler pulley which the cord type does not have.

The planetary assembly is the unit that is integral with the tuning shaft. It is at the bottom of the belt. If the nut of this assembly is too tight, the drive will be jerky and will turn hard in high speed. If this condition exists, back off this nut one or two turns and note the effect. If the nut is too loose, the drive will slip in slow speed. The remedy in this case is, of course, to tighten up the nut.

Should the drive belt slip when the planetary pulley is turning, first inspect the drive drum assembly. This is the assembly which is mounted on the tuning condenser shaft. If this assembly and the tuning condenser rotor turn satisfactorily, the belt is probably too

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch—See Fig. 8.

The phono switch must be mounted with one set of terminals nearest the bottom of the chassis base.

The connections are made by opening the diode return circuit at the volume control. Unsolder the .01 mf. condenser C27 from the volume control.

Strip about 3/4 inches of the shielding from each end of the cable furnished with the phono attachment parts. Connect one lead of the cable to the terminal on the volume control from which condenser C27 was removed. The other end of this lead is connected to the phono switch as shown in Fig. 7. The second cable lead is connected to the open end of condenser C27. Then connect the other end of this lead to the phono switch as shown in Fig. 7. Both of the shielded cable leads connected to the phono switch are con-

MODEL D705  
Issues 1 to 6

WESTERN AUTO SUPPLY CO.

Drive Cord Data  
Switch Data, Phono.

### Drive Cord Replacement

**LATE MODELS**—Tie a knot with a small loop at one end of the new drive cord. Slide a 1¼ inch length of fabric tubing on the cord. The free end of the drive cord should be tied to the tension spring in such a manner that there is a distance of 56⅞ inches between the knots.

Turn the gang condenser to full open position.

Place the looped end of the drive cord over the hook on condenser drive drum A—See Fig. 2. Bring the cord up through the slot in the drum rim and pass to the right (from back of chassis) and around pulley B. Then bring the cord to the left and over pulley C. See that the fabric tubing is now between pulleys B and C. Continue cord down to control shaft D and wind 3½ turns counter-clockwise (from back of chassis) on shaft D. Bring cord up to and over pulley E. Bring cord down to top of drive drum A and wind one turn clockwise around the drum rim.

Pass the remaining drive cord and tension spring through the slot in the drum. Place free end of spring over the hook on the condenser drive drum.

**EARLY MODELS**—The procedure is the same as for the late models with the following exceptions:

The distance between the knots on the drive cord should be 49¼ inches.

Leaving shaft D (Fig. 3), the drive cord is brought directly to the top of drive drum A and then continued as in late models.

### Permeability Tuning and Band Switch Assemblies—Differences in Early Models

A few of the first models used a station button plunger 6⅞ inches long. These models may be identified by a red paint mark on the front bracket of the tuning unit at the upper right corner. On later models, this length was changed to 6⅞ inches. These models have an orange paint mark in place of the red mark. It is important, therefore, that the length be noted when ordering this part and the correct part number, as shown in the parts list, be specified.

ALL SWITCHES HAVE ONLY TWO POSITIONS.

SCHEMATIC SHOWS ALL SWITCHES IN NORMAL POSITION (BUTTON OUT) & ON-OFF BUTTON PUSHED IN.

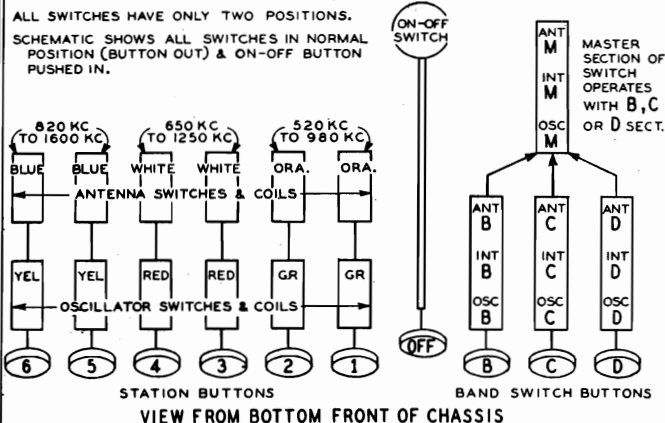

Fig. 5—Permeability Tuning Unit and Band Switch Arrangement.

The plungers are replaceable only on the permeability (6 button) tuning unit. In the case of the band switch unit, if any parts require replacing, the entire assembly must be ordered. Two of these assemblies are listed, one using the early short shaft and the other using the later long shaft. The short shaft (early unit) has no paint mark on it. The long shaft (late unit) has an orange paint mark on it.

A change was also made on the tuning rod assembly (Rod on which 2 iron cores are mounted). The rod used on early models was 3¼ inches long and the back end of the rod rested in a small cup in the end of the compression spring. The rod used on late models is 4¼ inches long, extends through the compression spring and projects beyond the rear bracket of the tuning assembly. Only the later type rod complete with the compression spring and a small washer is being furnished for replacement. This complete assembly is interchangeable with the early type.

**ATTACHING DIAL POINTER**—Tune in a 1500 KC signal. Move the pointer to the 1500 KC mark on the dial and clamp it tightly over the fabric tubing on the cord.

### Phonograph Connections

early models a 1¼ inch hole must be drilled in the back panel. A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug 1¼ inches in diameter. An octal and on the other end is a phono-base socket is then mounted in this graph-radio switch and double tip knockout opening. In the case of the jack.

ISSUE NUMBER CHANGES

The last digit of the number on the chassis number label identifies the radio as to the issue number.

ISSUE NO. 1

The information on the Replacement Parts List and Schematic Circuit Diagrams and now employs the side arms mounted in rubber cushioned hinge brackets which are attached to the rear bracket of the tuner assembly by the screws.

ISSUE NOS. 2 and 3

MECHANICAL CHANGES -- The station button plunger has a length of 7-5/16 inches.

The locking plate for the station button plungers has been redesigned and now employs the side arms mounted in rubber cushioned hinge brackets which are attached to the rear bracket of the tuner assembly by the screws.

FOR THE FOLLOWING ELECTRICAL CHANGES REFER TO SCHEMATIC ON THIS PAGE.

ELECTRICAL CHANGES -- The AVC voltage is fed to the grid of the R.F. tube through the manual and automatic tuning coils. Formerly, it was applied directly to the grid of the R.F. tube through a 1 megohm resistor.

The operating voltages of several of the tubes have been changed. Correct values are shown on the schematic in this supplement.

ISSUE NOS. 4 and 5

MECHANICAL CHANGES -- The antenna coil (T1) and Wave Trap Coil (T2) have been moved from the top of the chassis base to a position just in back of the band switch underneath the chassis base.

The Wave Trap Trimmer (C1) has been moved from its former position near the 1st I.F. Transformer (T6) to a position near the 6U7G R.F. tube.

ELECTRICAL CHANGES -- The Wave Trap Coil (T2) and Trimmer Condenser (C1) have been removed from the antenna circuit and are now connected in the interstage circuit.

ISSUE NO. 6

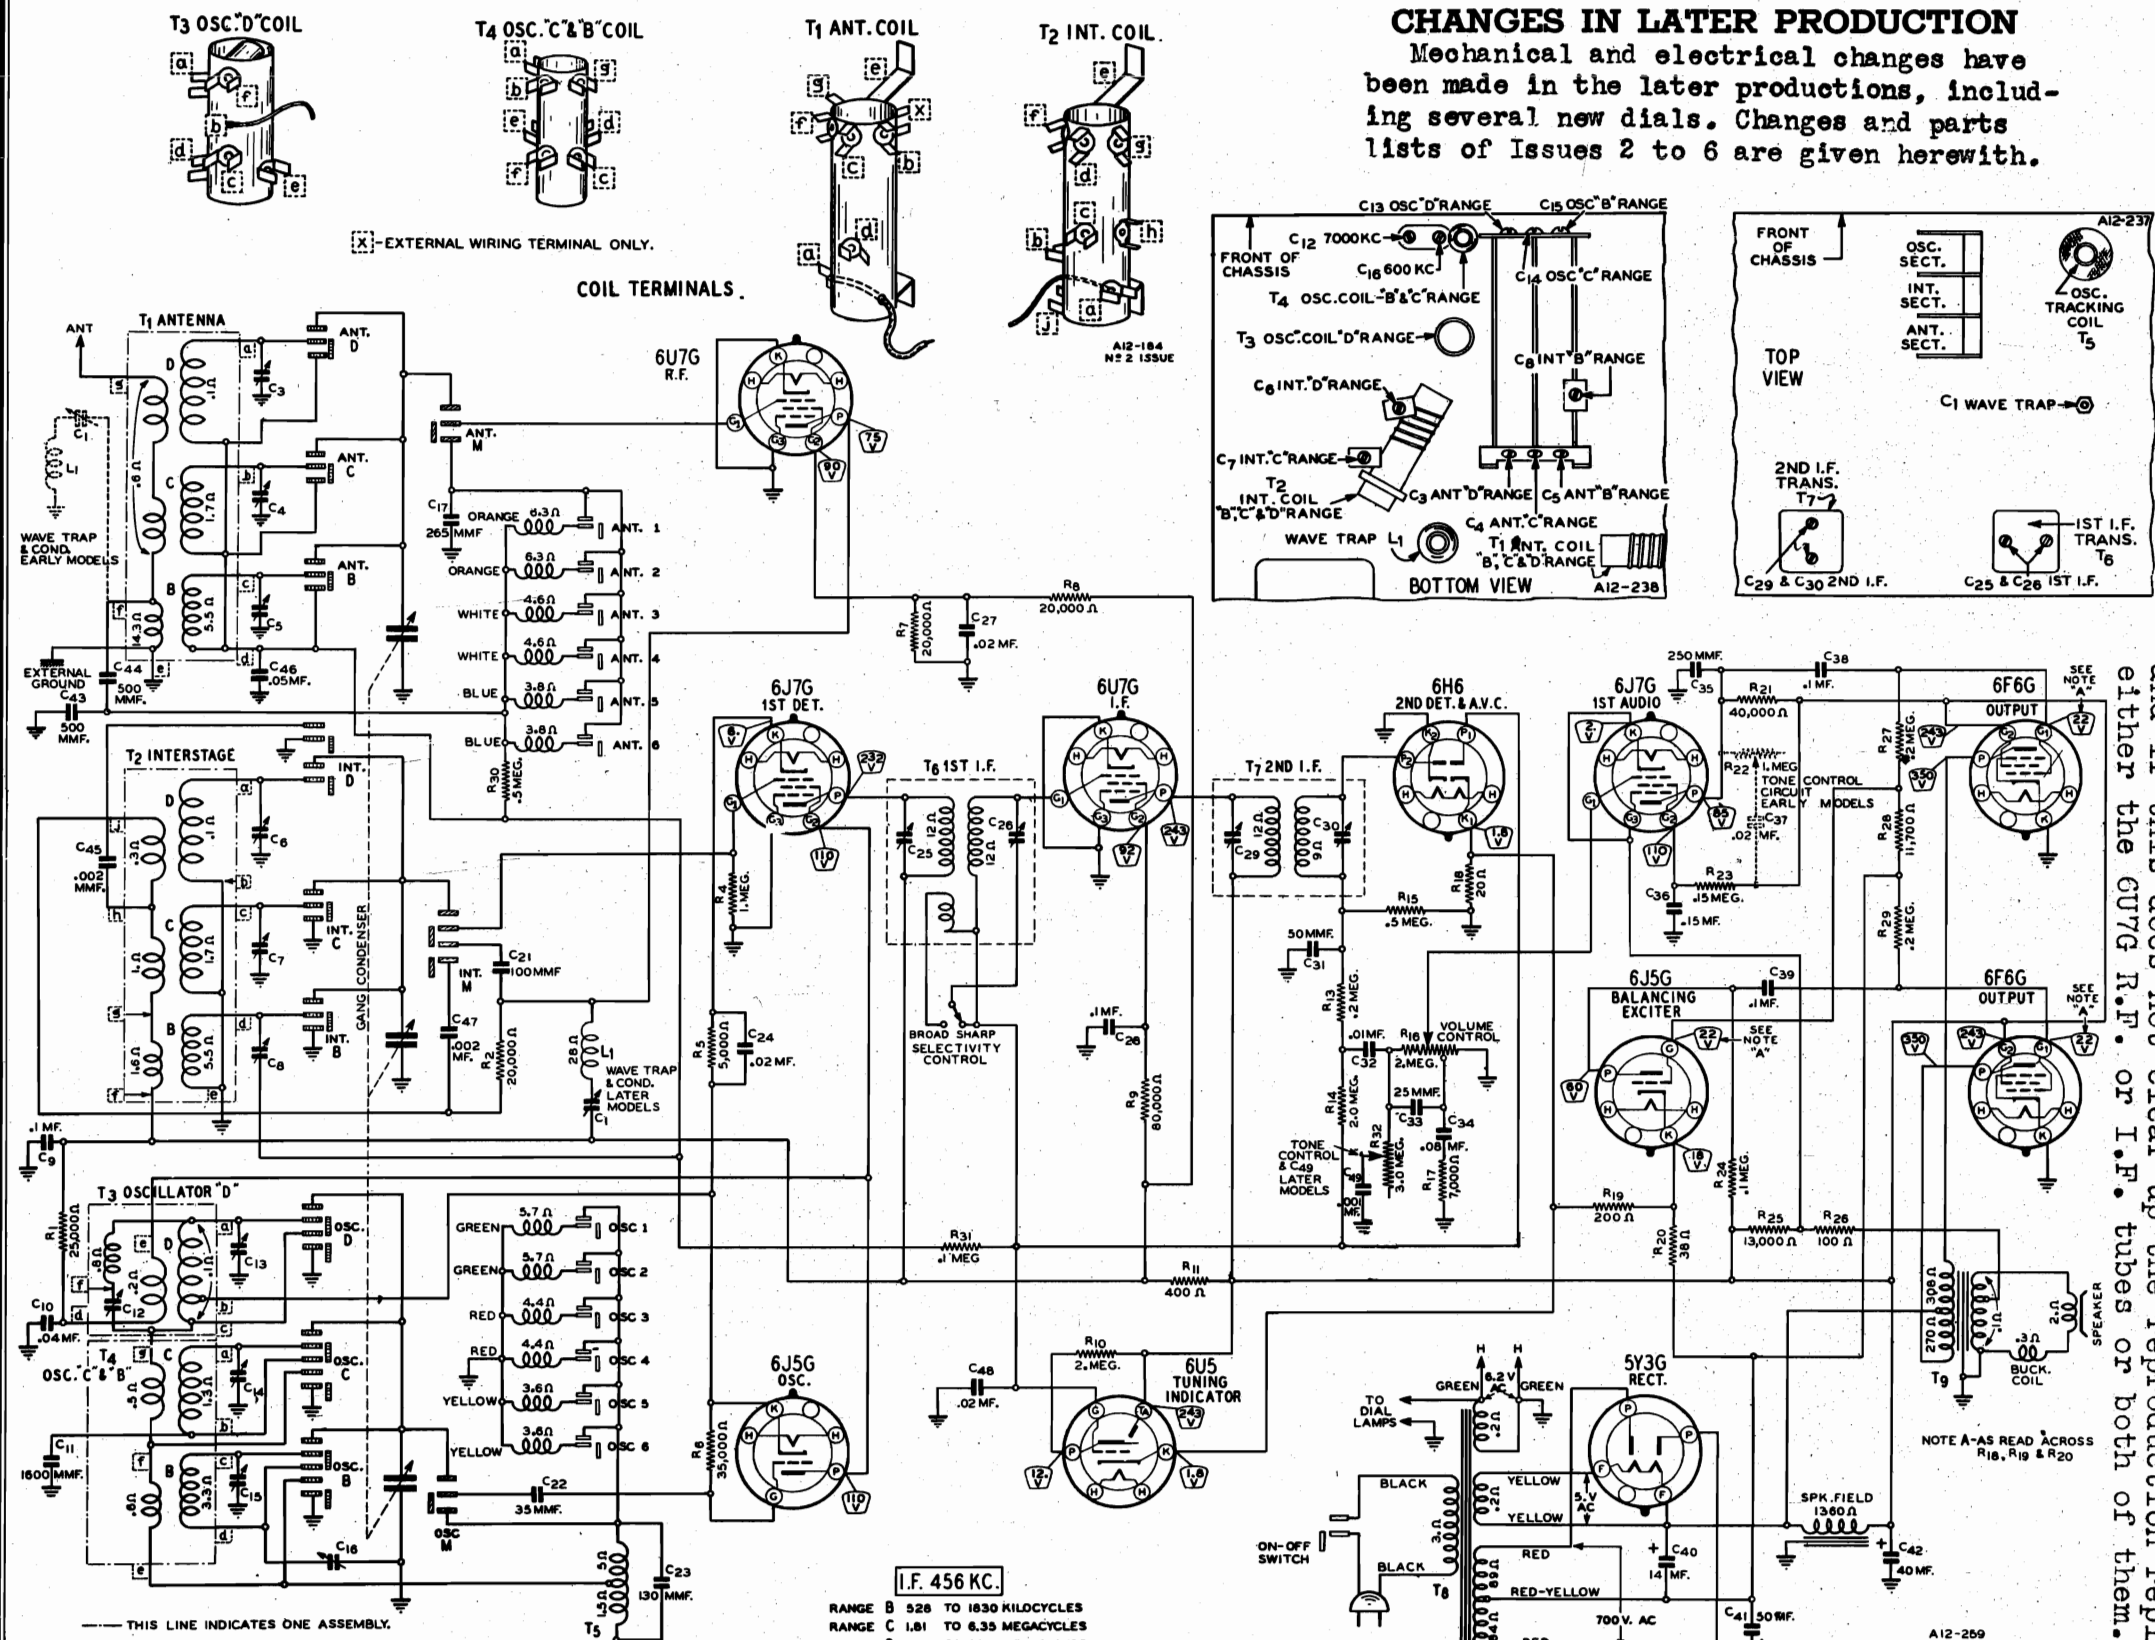

ELECTRICAL CHANGES -- The Tone Control, formerly in the 1st audio plate has been put in the diode circuit. A 1 megohm Tone Control (R22) and a .02 m.f. (.027) condenser were used in the audio plate. A 3 megohm Tone Control (R23) and a .001 m.f. (.049) condenser are used in the diode circuit.

DISORTION (ALL ISSUES NOS. 1 THROUGH 6)

If mushy reproduction is encountered on a medium or strong signal after the radio has been turned on for about ten minutes, it probably is due to grid current in the 6U7G R.F. and I.F. tubes.

Change the 4 megohm resistor R14 to a 2 megohm resistor and if this does not clear up the reproduction replace either the 6U7G R.F. or I.F. tubes or both of them.

CHANGES IN LATER PRODUCTION  
Mechanical and electrical changes have been made in the later productions, including several new dials. Changes and parts lists of Issues 2 to 6 are given herewith.

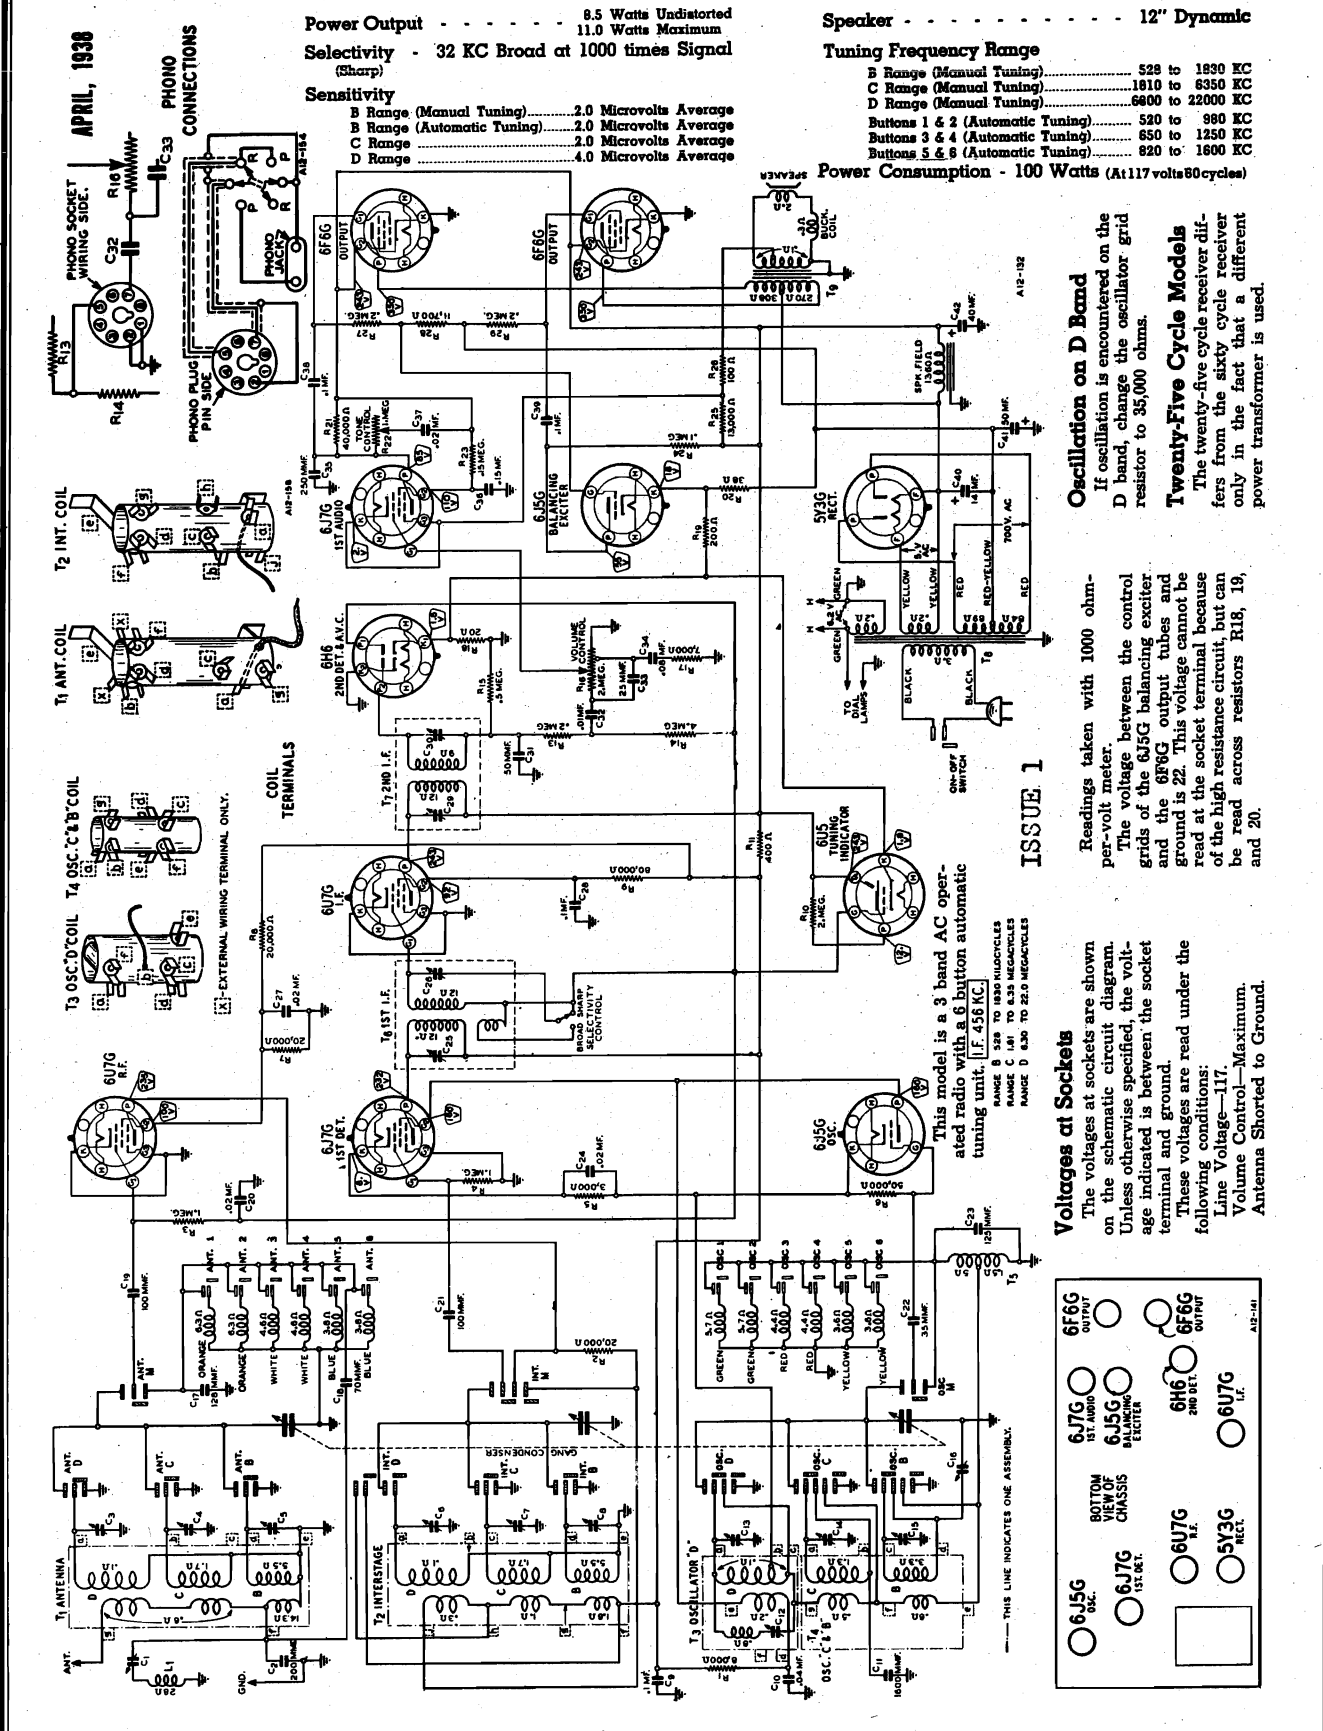

SCHEMATIC CIRCUIT DIAGRAM FOR ISSUE NOS. 2 THROUGH 6.

**Oscillation on D Band**  
If oscillation is encountered on the D band, change the oscillator grid resistor to 35,000 ohms.  
**Twenty-Five Cycle Models**  
The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

**Readings taken with 1000 ohm-per-volt meter.**  
The voltage between the control grids of the 6J5G balancing exciter and the 6F6G output tubes and ground is 22. This voltage cannot be read at the socket terminal because of the high resistance circuit, but can be read across resistors R18, 19, and 20.

**Alignments at Sockets**  
The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.  
These voltages are read under the following conditions:  
Line Voltage—117  
Volume Control—Maximum.  
Antenna Shorted to Ground.

MODEL D705, Issues 1 to 6  
Alignment, Trimmers WESTERN AUTO SUPPLY CO.

**Circuit**

Ten buttons are provided on the front panel. Three buttons actuate linear band switches for a broadcast and 2 short wave manual tuning ranges. Six buttons actuate switches which connect fixed tuned circuits for automatic tuning. Depressing any of the 9 band and automatic tuning buttons also turns on the radio. Depressing the 10th button will turn the radio to the off position.  
The band switch has 4 arms as shown in Fig. 5, one each for the B, C, and D bands (broadcast, 1st and 2nd short wave, respectively) and one called the "Master" arm. The master arm switches from manual to automatic tuning and vice versa. This arm is actually over the other 3 arms rather than in back of them, as shown in the illustration. Depressing any of the B, C, or D band buttons actuates the arm for that band and also the master arm. The latter is in only when one of the 3 band switch buttons is depressed.

In manual tuning, an R. F. antenna transformer with tuned secondary is used before the 6U7G R.F. tube. The output of this tube is fed through another R. F. transformer with tuned secondary into the 6J7G 1st detector tube. A 6J5G tube functions as a separate oscillator. The antenna, interstage, and oscillator circuits are tuned by sections of the gang condenser.  
In automatic tuning, the gang condenser is not used. A single tuned circuit is used before the R. F. tube while a stage of resistance coupling is employed between this tube and the 1st detector. The other automatic tuned circuit is the oscillator grid circuit. Tuning of the R. F. and oscillator fixed tuned circuits to the desired frequency is accomplished by varying the inductance of tuning coils by changing the permeability of the magnetic circuit. This is done by moving an iron core in and out of the coil.

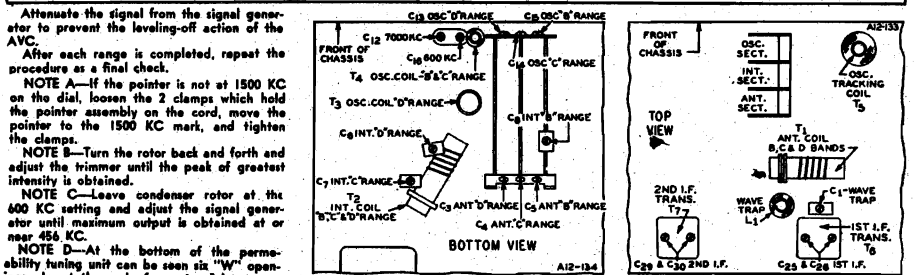

The iron cores within the automatic tuning antenna and oscillator coil forms are secured to a brass rod. This rod is moved back and forth by a screw at the front of the radio.  
Alignment between the oscillator and antenna automatic tuning coils is obtained by changing the antenna (rear) coil position while the iron core is held in place on the shaft.  
In the schematic, the band switch and the automatic tuning switch are broken into sections each of which is given a name that is, to some extent, descriptive of its location in the circuit. Ant. D, for example, completes the antenna coil D band connections when the D range button is depressed. The location of the Ant. D connections on the band switch is shown in Fig. 5. All of the switches have only 2 positions. In the schematic, they are in the normal or button out position.

Now, to describe the connections for one manual tuning range: Let us assume that the B band button is depressed. The antenna transformer B band secondary is connected to the R. F. tube grid circuit through the Ant. B and Ant. M sections of the B band and master switch arms. The antenna transformer C and D band secondaries are short circuited.  
The interstage transformer B band secondary is connected to the 1st detector tube grid circuit through the Int. B and Int. M sections of the switch arms mentioned above. The interstage transformer C band secondary is short circuited and the D band secondary is open circuited.  
The oscillator B band grid coil is

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each range is completed, repeat the procedure as a final check.  
NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.  
NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.  
NOTE C—Leave condenser rotor at the 600 KC setting and adjust the signal generator until maximum output is obtained at or near 456 KC.  
NOTE D—At the bottom of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.  
connected through the grid circuit of the oscillator tube through the Osc. B and Osc. M sections of the same switch arms as mentioned above. The oscillator B band cathode coil is connected to ground through the Osc. B section. The oscillator C and D band grid coils are short circuited.  
The permeability tuning coils are open circuited.  
In like manner, to describe the connections for one automatic tuning circuit, assume that button number 1 is depressed.  
The antenna circuit is connected to the R. F. tube grid circuit through the Ant. M section of the master switch arm. The antenna circuit is also connected to the antenna No. 1 permeability coil through Ant. 1 switch. The antenna No. 1 coil is shunted by fixed condenser C17. The connections from the antenna and interstage transformer secondaries are open circuited.  
The plate of the R. F. tube is connected in series with resistor R2 to the B+ line. It is also connected through coupling condenser C21 to the grid of the 1st detector. The latter is connected through grid leak R4 to ground.  
The oscillator cathode circuit is connected through the tap on tracking coil T5 to ground. This tracking coil T5 is connected through the Osc. M switch section to the control grid circuit of the oscillator tube. It is also connected to oscillator No. 1 coil through the Osc. 1 switch section. The tracking or oscillator grid coil is tuned by fixed condenser C23 and the inductance of oscillator coil No. 1.  
One stage of I. F. amplification is employed using a 6U7G tube. An expander is used in the 1st I. F. transformer for high fidelity reception.  
A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R. F. and I. F. tubes.  
Across the volume control resistor R16 is a filter composed of condensers C33 and C34 and resistor R17. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.  
The output of the 2nd detector is applied to the 6J7G 1st A. F. tube. The output of this tube is fed through

**CAUTION**—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.  
**NOTICE**—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.  
resistance coupling into the 6F6G output tube immediately to the right of it in the schematic.  
A portion of the voltage developed across the output tube grid resistor is applied to the control grid of the 6J5G balancing exciter tube. This tube functions as a phase inverter and applies the audio voltage of proper phase and amplitude to the other 6F6G output tube. The two output tubes operate as a stage of Class A push-pull amplification. The balancing exciter tube thus replaces a push-pull input transformer. A dynamic reproducer is employed.  
Degeneration or negative feedback is used in the audio amplifier. A portion of the voltage developed across the secondary of the output transformer is fed back into the cathode circuit of the 1st audio tube. The voltage fed back is of the proper phase to reduce the amplitude of certain frequencies. This results in a reduction in distortion.  
The power unit uses a 5Y3G full wave rectifier. A 6U5 tuning indicator tube is employed.

Replacing Drive Cord

Remove chassis from cabinet. Take off the pointer by removing the screw at the center of the dial. Remove the dial by taking out the six rivets from the dial assembly. Remove the on-off indicator dial by pulling it forward.

With the condenser plates in a completely open position, slip the new drive cord thru hole "A" (from the front) in the drive drum. See Fig. 9. Pull the cord thru this hole far enough to tie a knot near the end. Make this knot large enough so that it will not pull back thru the hole.

Slip the opposite end of the drive cord thru hole "B" of the drive drum. Now dip the piece of fine tubing (about 3/4" long) over the drive cord and insert about half of this tubing into hole "B" as shown in the illustration. This is important to prevent the cord from being cut.

Bring the drive cord down to the drive shaft and wrap the cord in a clockwise direction about two and one-half times around this shaft, progressing toward the front.

Bring the cord up from the drive shaft and wrap it around the drive drum approximately one and one-half times in a clockwise direction, progressing toward the front until the cord is up to the turned-in portion of the flange "C". See Fig. 9.

Pull the cord tight and tie the end of the cord to the tension spring as shown in the illustration. The knot should be at the bend in the flange so that the spring will be under sufficient tension to prevent the drive cord from slipping.

Now, by applying a little tension on the spring, hook the other end of the spring into hole "D" on the opposite side of the drum. Hook the spring from the inside (in later models hole "D" is replaced by a hook on the inside of the drive drum). Turn the drive shaft back and forth several times to take out the slack and see if the drive is operating properly. If the cord slips on the drive shaft, remove the spring from the drive drum and add an additional knot in the cord at the spring in order to put greater tension on the spring.

Replace the on-off indicator dial, care being taken that the indicator is so placed that it will properly show the on and off positions. Re-assemble the pointer and dial to the drive assembly. If the rivets are broken use No. 2 by 3/4" long round head machine screws and nuts.

Testing Batteries

If the receiver does not operate satisfactorily test the batteries under load. A high resistance meter is required for the "B" and "C" voltages. If any of the batteries are considerably below their rated voltage, new ones should be used. When the "B" batteries are replaced the "C" batteries should also be replaced. The reason for this is that the "C" drain is such that the "C" batteries are run down in about the same time as the "B" batteries.

"A" Battery and Regulator

This receiver is designed to operate with a 2 volt storage cell, but may be operated with a 3 volt dry "A" battery if used with a voltage regulator. The receiver may also be used with an air cell "A" battery provided a series resistor is used.

3 Volt "A" Battery—The voltage regulator required with this type of battery as illustrated in Fig. 4 is not supplied with the receiver unless specified. This device consists of a rheostat which controls the voltage, a voltmeter for measuring its value as supplied to the receiver and a small push button switch for cutting the voltmeter in and out of the circuit. It has two prongs at the bottom which plug into the socket in the platform at the rear left corner of the chassis. The circuit diagram of the regulator is shown in Fig. 5.

Fig. 5—Schematic Diagram of Voltage Regulator

The receiver is shipped from the factory with a jumper between the two socket connections and a fiber strip over the socket. This strip must be removed and the jumper taken out as illustrated in Figs. 6 and 7 before the regulator can be inserted as shown in Fig. 4. The jumper is in the "A+" line.

Fig. 6—Prying off Fiber Cover

When a new 3 volt "A" battery is inserted, the adjusting knob must be turned to the left hand position and then turned up until the voltmeter indicated 1.9 to 2 volts. The push button must be held in until the adjustment is completed. Caution the user never to operate the receiver with the adjustment beyond 2 volts.

Air Cell "A" Battery—If an air cell "A" battery is used, a series resistor will be required to reduce the voltage to the proper level of 2 volts for the tube filaments. Although the voltage regulator mentioned above can be used, the series resistor is cheaper and is satisfactory as the voltage of one of these batteries drops very little during the useful life of the battery.

Fig. 7—Removing Jumper Wire

Fig. 9—Replacing Drive Cord

Alignment Procedure and Dial Calibration

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide accurately calibrated signals over the standard wave band and at the intermediate frequency and an output meter are required for indicating the effect of adjustments. Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 175 KC. Connect the antenna lead of the signal generator thru a 1 MΩ condenser to the coil end of the grid leak resistor R1. There is a lead which runs from the center tuning condenser stator to a lug at the bottom of the R. F. coil assembly. This connection can be made at the lug on the coil to which this lead is connected.

Connect the ground lead of the receiver to the ground post of the signal generator. Turn the volume control to the maximum position. Then adjust the three I. F. trimmers until maximum output is obtained. The adjusting screws for these

condensers are reached from the top of the chassis, and the location is shown in Fig. 8.

As stated above, use a non-metallic screwdriver to make the adjustment.

1750 KC Adjustment

Set the signal generator for 1750 KC. Turn the rotor of the tuning condenser to the full open position.

Connect the antenna lead of the receiver thru a 250 mmf. condenser to the output of the signal generator. Keep the volume control at the maximum position. Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained. The location of this trimmer is shown in Fig. 8.

1500 KC Adjustment

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st detector and antenna trimmers for maximum output. Do not change the setting of the oscillator trimmer.

Dial Calibration

To obtain dial scale calibration tune in an 800 KC signal and set the dial pointer at that mark on the dial scale. When calibrated in this manner, the setting will be approximately correct at both ends of the scale.

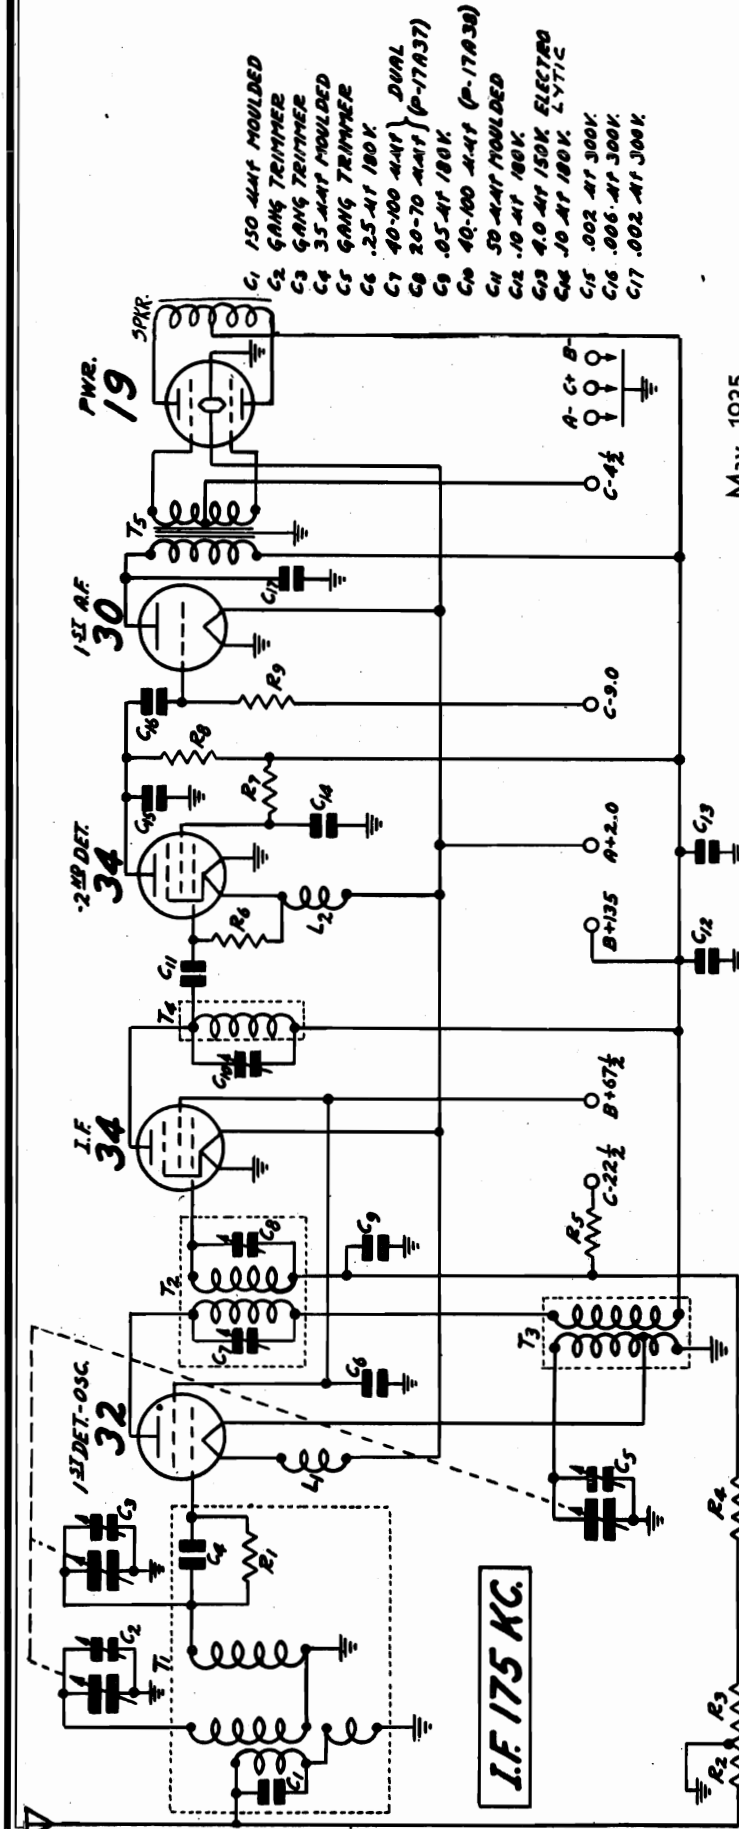

SPECIFICATIONS

Sensitivity	15 Microvolts Absolute
Tuning Range	530 to 1750 KC

**CORRECT ALIGNMENT PROCEDURE**  
The intermediate frequency I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, the Short Wave Band may be aligned.

**I.F. ALIGNMENT**  
With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test oscillator to 456 KC and connect the oscillator to the grid of the first detector tube (6A8G) through a .05 or .1 mfd. capacitor. The ground on the oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

**BROADCAST BAND ALIGNMENT**  
Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica capacitor. Set the Broadcast "oscillator trimmer" to minimum and the oscillator to 1730 KC and check at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding elements become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

**SHORT WAVE BAND ALIGNMENT**  
The short wave band is adjusted by setting the generator to 16,000 KC and tuning in the signal. Adjust the "short wave antenna" to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding elements become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

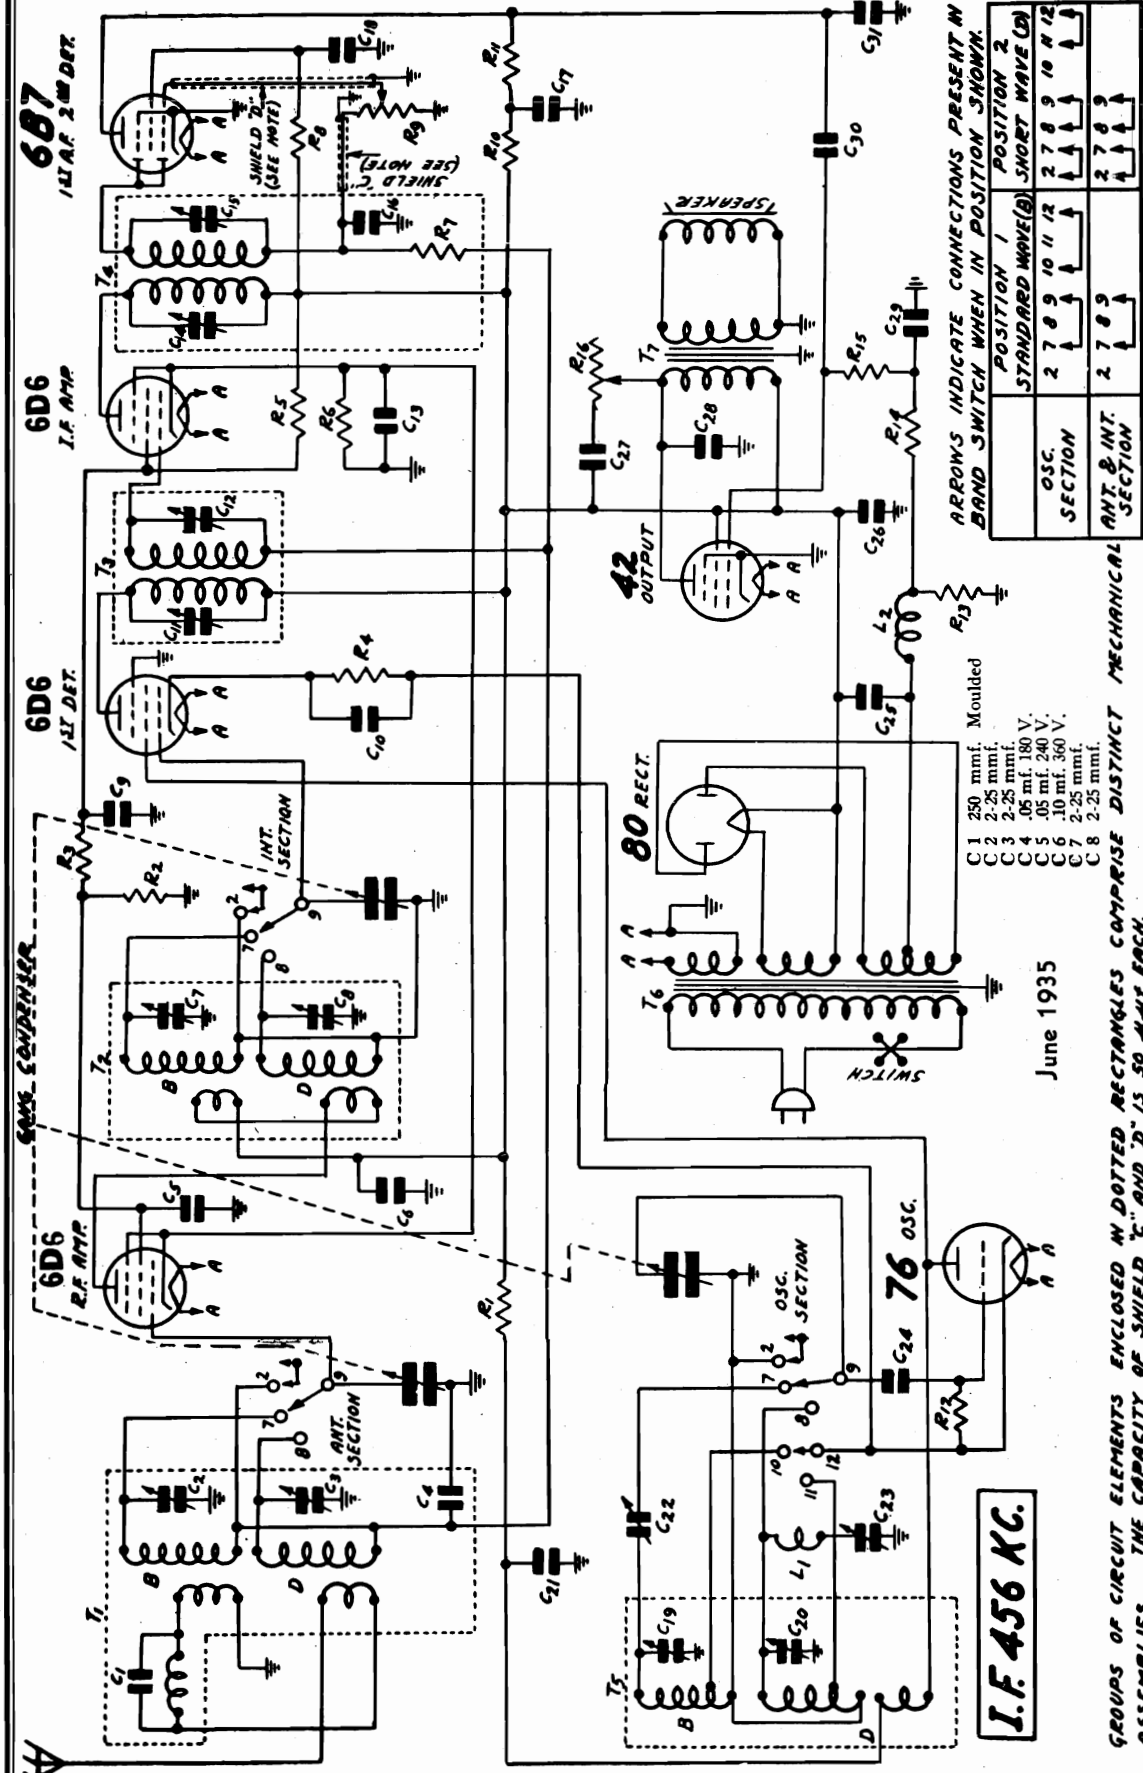

**SPREADCAST POSITION**  
This receiver requires a good ground.

This receiver requires a good ground.

S710, S711

WESTERN AUTO SUPPLY CO.

Alignment, Trimmers  
Voltage, Socket, Coils  
Resistances, Changes

**D. C. Resistance of Coil Wires and D. C. Resistance of Windings**

Part No.	Item	D. C. Resistance in Ohms
53591	115 volt 60 cycle Power Transformer	1.1
	Tube Filament Secondary (A-A)	1.1
	Tube Filament Secondary (A-A)	1.1
	High Imp. Center tap to Input	1.1
	High Imp. Center tap to Output	1.1
9A381	High Tracking Coil	1.1

**Changes in Early Models**  
In the early models of this receiver the oscillator standard wave trimmer C19 was in the oscillator coil can—see Fig. 4.  
In the early models the antenna transformer had two B primary windings as shown in Fig. 5. In later models only one winding was used as shown in Fig. 3.

Fig. 5—Antenna Transformer on Early Models

Fig. 6—Location of Tubes

Loosen the pointer set screw and set the pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.  
Adjust the interstage standard wave trimmer (C7) and antenna standard wave trimmer (C2) until maximum output is obtained.  
Do not change the setting of the oscillator standard wave trimmer.  
**6000 KC Adjustment**  
Set the signal generator for 6000 KC.  
Turn the tuning condenser rotor until maximum output is obtained.  
Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 4 for location of this trimmer.  
Be sure to use a non-metallic screw driver for this adjustment.  
**18,300 KC Adjustment**  
Set the signal generator for 18,300 KC.  
Turn the rotor of the tuning condenser to the full open position.  
Turn the band switch to the short wave position.  
As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.  
Adjust the oscillator short wave trimmer (C20) until maximum output is obtained. See Fig. 4 for location of this trimmer.  
If a maximum output peak cannot be reached, it may be due to the fact that the antenna and interstage short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum output.

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.  
A signal generator that will provide an accurately calibrated signal at 450, 1730, 1500, 600, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.  
Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:  
**I. F. Adjustment**  
Set the signal generator for a signal of 450 KC.  
Connect the antenna lead of the signal generator thru a .1 MF condenser to the grid of the 1st detector.  
Connect the ground lead of the signal generator to the chassis ground.  
Turn the band switch to the standard wave position.  
Turn the volume control to the maximum position.  
Attenuate the signal from the signal generator to prevent the leveling-off action of the A.V.C.  
Then adjust the four I. F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 6.  
**1730 KC Adjustment**  
Set the signal generator for 1730 KC.  
Turn the rotor of the tuning condenser to the full open position.  
Keep the band switch in the standard wave position.  
Connect the antenna lead of the receiver through a 250 mmf. condenser to the output of the signal generator.  
For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.  
Adjust the oscillator standard wave trimmer (C19) until maximum output is obtained. The location of this trimmer is shown in Fig. 4.  
**1500 KC Adjustment**  
Set the signal generator for 1500 KC.  
Turn the rotor of the tuning condenser carefully until maximum output is obtained.

**D. C. Resistance of Windings**  
Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets. Refer to Fig. 3.

Part No.	Item	D. C. Resistance in Ohms
9A388	Antenna Transformer	20.7
	Range B Primary Winding	6.1
	Range B Secondary Winding	1.1
	Range D Primary Winding	3.0
	Range D Secondary Winding	6.4
	Range D Tertiary Winding	2.2
	Range D Quaternary Winding	2.2
	Oscillator Grid Coil	7.5
	Red White to White	4.0
	Black White to Black	4.0
	Black White to Ground	4.0
	Black White to Grid	4.0
	Oscillator Plate Coil	11.1
1st I. F. Transformer	Primary Winding	12.0
	Secondary Winding	11.1
2nd I. F. Transformer	Primary Winding	12.0
	Secondary Winding	11.1
Output Transformer (Part of Speaker Assembly)	Primary Winding	50.0
	Secondary Winding	1.0
Dynamic Speaker	Coil	102.5
Speaker Voice Coil	Coil	4.1
Speaker Junction Coil	Coil	6.2

**VOLTAGES AT SOCKETS**  
Line Voltage - 112

Type of Tube	Function	Heater Volts	Plate Cathode Ground	Screen Cathode Ground	M. A.
6D6	R. F.	6.1	240	95	3
6D6	1st Det.	6.1	240	100	9
76	Osc.	6.1	100		5
6D6	I. F.	6.1	240	120	3
6B7	2nd Det.	6.1	55	40	0

80	Rectifier	4.6			32.0 per plate

**15,000 KC Adjustment**  
Set the signal generator for 15,000 KC.  
Turn the rotor of the tuning condenser carefully until maximum output is obtained.  
Adjust the interstage short wave trimmer (C8) and antenna short wave trimmer (C3) until maximum output is obtained.  
When adjusting the interstage short wave trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.  
Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator short wave trimmer, the 15,000 KC adjustment must be repeated.  
Do not make any further change in the setting of the oscillator short wave trimmer.

**6000 KC Adjustment**  
Set the signal generator for 6000 KC.  
Turn the tuning condenser rotor until maximum output is obtained.  
Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 4 for location of this trimmer.  
Use a non-metallic screw driver for this adjustment.

ground lug away from this terminal. Be sure to solder back to this ground lug any leads that were connected to it (not including cathode connection of socket). Connect one side of the 12 mfd. 25 volt electrolytic condenser to ground and the other side of the condenser to the cathode terminal of the 6B7 2nd detector and the phono switch as shown in Fig. 7. To this same terminal on the phono switch connect the 900 ohm .2 watt resistor. The other side of this resistor goes to ground. Complete the other connections as illustrated.

A high impedance pick-up should be used. If a low impedance pick-up is used a step-up transformer will be required for sufficient volume. The volume control and tone control of the set will regulate the phono volume and tone.

Servicing R. F. Coil Assemblies

The R. F. coil assemblies in this receiver are sold complete with can. This is due to the fact that the trimmers are soldered to the can, and cannot be easily disassembled.

The lead colors and resistances of the various windings in each assembly are shown in Fig. 3.

If it is ever necessary to remove one of coil assemblies from the can, proceed as follows: First remove the nuts from the screws at the top of the can. The outside lug on the trimmer condenser is inserted in a slot in the coil can, and this lug is soldered into position.

Apply a soldering iron to the can at the point of the soldered connection. Then with a screw driver lift up on the outside edge of the trimmer (edge soldered to can) until the trimmer is clear of the can. After the trimmers are all unsoldered, the coil can be taken out.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle chassis can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

MODELS D-710, D-711, S-710, S-711 (1935)

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch—see Fig. 8.

For mounting the 12 mfd. 25 volt dry electrolytic condenser, two No. 27 drill holes should be drilled in the side of the chassis base directly below the wet electrolytic condensers. These holes are 1/4" from

Fig. 7—Phonograph Connections

Fig. 8—Location of Phono Knockouts

the bottom, 7/8" and 3 3/4" from the front of the chassis.

The ground lug which extends out from the side of the chassis should be bent back into the chassis wall. The connections are made by opening the diode return circuit at the volume control. Unsolder the shielded lead which runs from the I. F. transformer to the volume control at the lug on the volume control. Cut this lead to length and connect it to the switch as shown in Fig. 7. The extra length of shielded lead which is provided, is connected from the volume control R9 to the phono switch as illustrated.

Remove the ground from the cathode terminal of the 6B7 2nd detector tube by bending the chassis

General Service Data

D. C. Resistance of Windings

MODEL D712M (1935)  
Alignment, Changes  
Resistances

WESTERN AUTO SUPPLY CO.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and readjustment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator through a .01 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 1.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position. Keep the band selector in the standard wave position. Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action. Adjust the oscillator Range B trimmer (C32) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C7) and antenna Range B trimmer (C2) to maximum. Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range C position (1st short wave band—green dial color).

Adjust the oscillator Range C trimmer (C30) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C8) and antenna Range C trimmer (C3) to maximum. Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC. Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position. Turn the band selector to the Range D position (2nd short wave band—red dial color). Adjust the oscillator Range D trimmer (C29) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated. Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained. Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

D. C. Resistance of Windings

Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets.

Part No.	Winding	Code	D. C. Resistance in Ohms
P-9A405	Antenna K. F. Transformer	T1	21.8
	Range A Primary Winding		0.3

	Tube Filament Secondary (B-B) (6Ω)		0.1
	High Voltage Secondary Winding		18
	Center Tap to Inside		18
	Center Tap to Outside		18
P-9A210	2nd I. F. Plate Oscillator Reactor	L1	36
P-9A201	High Frequency Oscillator Tracking Coil	L3	1.2

**Twenty-five Cycle Receivers.**  
The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Changes in Early Models

In the early models of this receiver the tone control resistor (R11) was connected as a series variable resistor connecting in series through the condenser C23 between the grids of the 45 tubes in the audio output stage. In the later models it is employed as a potentiometer in the manner shown in Fig. 2. The 100,000 ohm resistor (R18) was not used in the early models. Condenser C21 was connected directly to resistor R7.

The type 6K7 metal tubes replace the type 6D6 glass tubes which were used in the early models. Condenser C35 was added to the oscillator coil standard wave section in later models. It is not, however, used in all cases but only when this capacity is required in this circuit.

Fig. 8—Details of Panel Drilling for Phono Assembly

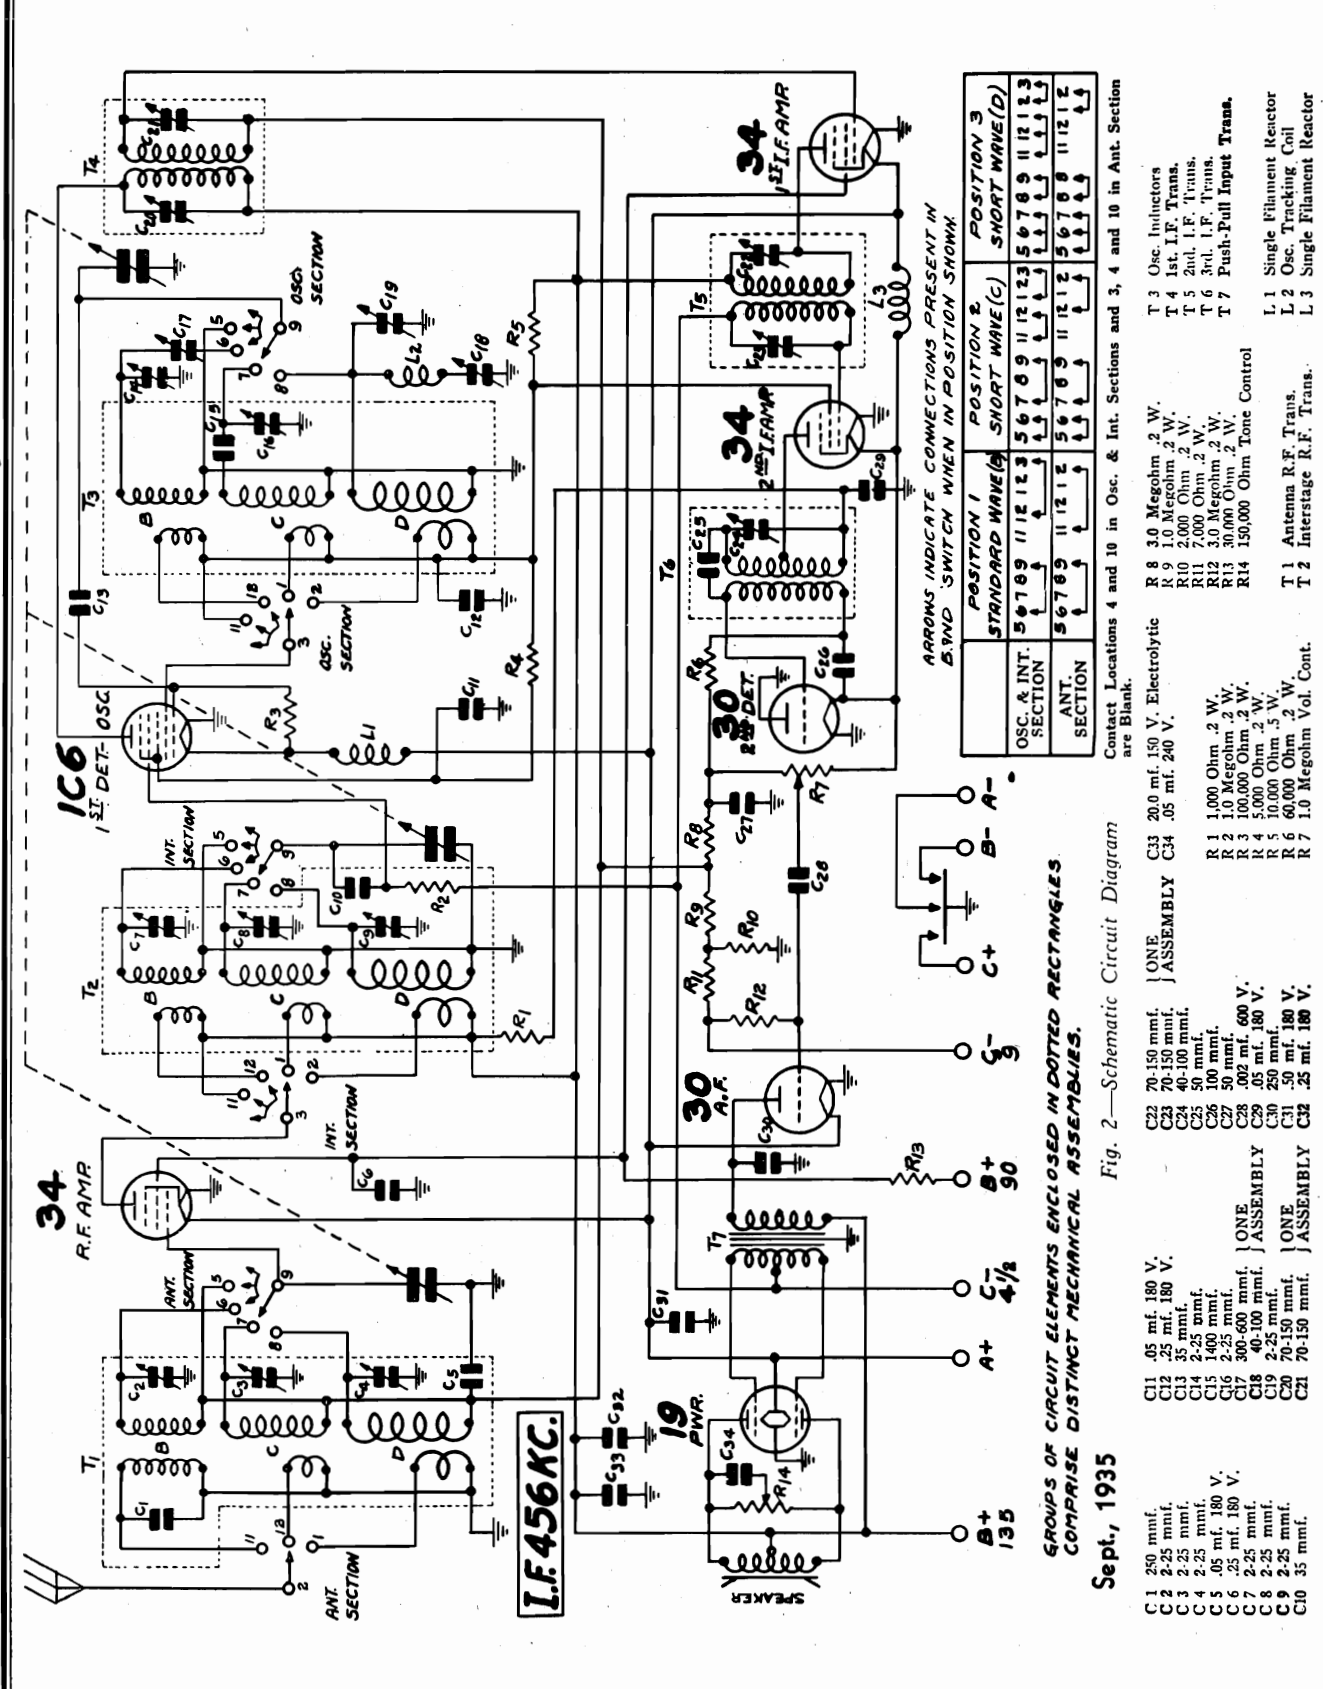

Phonograph Connections

Phonograph connections can be made as shown in Fig. 7. The parts required to make this installation are shown in the parts list.

To mount the phono switch and phono jack, drill holes of a size and in the position shown in Fig. 8 at the left hand side (from back) of the rear panel of the chassis.

**Alignment and Calibration**

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 4800, 4200, 16,000, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

**I. F. Adjustment**

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator through a 0.1 mf. condenser to the switch end of condenser C-10—see Fig. 2. There is a lead which goes to the lug on the top of the center stator section of the tuning condenser—see Fig. 10. The connection can be made at this lug.

Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the levelling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 10.

**Range B Alignment**

**1730 KC Adjustment**

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C14) until maximum output is obtained. The location of this trimmer is shown in Fig. 9.

**1500 KC Adjustment**

Set the signal generator for 1500 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the interstage Range B trimmer (C7) and antenna Range B trimmer (C2) to maximum.

**600 KC Adjustment**

Set the signal generator for 600 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

**Range C Alignment**

**4800 KC Adjustment**

Set the signal generator for 4800 KC.

Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C16) until maximum output is obtained. See Fig. 9 for location of this trimmer.

**4200 KC Adjustment**

Set the signal generator for 4200 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C8) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

**Range D Alignment**

**16,000 KC Adjustment**

Set the signal generator for 16,000 KC.

Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

Adjust the oscillator Range D trimmer (C19) until maximum output is obtained. See Fig. 9 for location of this trimmer.

**15,000 KC Adjustment**

Set the signal generator for 15,000 KC.

Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C9) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 16,000 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

**6000 KC Adjustment**

Set the signal generator for 6000 KC.

Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer (C18) until the peak of greatest intensity is obtained. See Fig. 9 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment.

**Voltages**

Check the voltages at the sockets to see if correct values are being delivered to the tubes. The antenna and ground should be disconnected and the antenna and ground leads from the set connected together. The volume control should be turned to the right or maximum position.

The voltage chart gives the voltages with all tubes in, the speaker connected and the set in operating condition. These voltages are typical of the sets but will vary slightly with variations in individual receivers, tubes, test equipment used and battery voltages.

**Changes in Early Models**

Condenser C35 7 mmf. (not shown in Fig. 2) was added to the oscillator coil assembly in parallel with oscillator Range B trimmer condenser C14. It is not, however, used in all cases but only when this capacity is required in this circuit.

MODEL D713 (1935)

Drive Cord Data

Resistances

WESTERN AUTO SUPPLY CO.

## Replacing Drive Cord

Take off the station pointer by removing the screw at the center of the dial.

Loosen the two set screws in the collar on the band selector shaft.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis and one screw at the top which secures this assembly to the bracket.

Pull the dial assembly forward until the collar is free of the band selector shaft; and lay the assembly face downward in front of the chassis.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 12.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 12. Insert one end of the new drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord, which has been inserted through the hole, to one end of the tension spring.

Wrap the cord in a counter clockwise direction (facing front of chassis) around the drive drum approximately one and one half turns, progressing toward the front.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one half times around this shaft as shown in Fig. 12, progressing toward the back of chassis.

Wrap the cord on directly under the drive drum above.

Then bring this cord up to the drive drum until it is up to the hole in the drive drum as shown in the illustration.

Now insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension

spring. The end of the spring when hanging free should be approximately  $\frac{3}{8}$ " from the flange of the drum as shown in Fig. 12. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Turn the drive shaft back and forth several times.

Replace the drive assembly and pointer.

Replace the chassis in the cabinet.

MODEL D714 (1939)  
Alignment, Tuner

WESTERN AUTO SUPPLY CO.

FIG. 4

**DIAL CALIBRATION:**  
To correct dial calibration, rotate the tuning knob to the right until the dial pointer reaches the tuning knob to the left until the pointer reaches the other extreme end of the dial scale.  
Stop clamps on the pointer slider bar make the pointer self aligning thereby correcting dial calibration.

To remove the chassis from the cabinet, remove the four bolts which are used to fasten the chassis to the cabinet bottom; pull the knobs off their shafts and detach the pointer from the drive string (see Fig. 1, top view).  
**NOTE:**—On the front of the string dial drum a calibrated scale is provided for aligning this chassis to the frequencies listed in the alignment procedure. Attach a pointer so that it will indicate proper dial setting in respect to the position of the variable condenser.

**ALIGNMENT PROCEDURE**

- The following equipment is required for aligning:
- An all wave signal generator which will provide an accurately calibrated signal at the test frequency.
  - Output indicating meter.
  - Non-metallic screwdriver.
  - Dummy antenna—1 mf., 200 mmf. and 400 ohms.

BAND	SIGNAL GENERATOR Frequency Setting	Dummy Antenna Connection to Radio	Pushbutton Indicated Below Pushbutton	Variable Condenser Setting	Trimmers Adjusted (In Order Shown)	Trimmer Function	Adjustment

	465 Kc.	.1 MFD. Grid of 6K8G	Broadcast	Rotor full open (Plates out of mesh)	Two trimmers on top (See Fig. 1)	Input I. F.	Adjust to maximum output
BROADCAST BAND	1750 Kc.	200 mmf. Antenna lead	Broadcast	Rotor full open (Plates out of mesh)	Trimmer (C16) at 17 MC	Broadcast oscillator	Adjust to maximum output
	1400 Kc.	200 mmf. Antenna lead	Broadcast	Set Dial at 1400 Kc.	Trimmer (C5) at 1400 Kc.	Broadcast antenna	Adjust to maximum output
	600 Kc.	200 mmf. Antenna lead	Broadcast	Set Dial at 600 Kc.	Trimmer (C14) at 600 Kc.	Broadcast oscillator series pad	Adjust to maximum rock dial. (See note "A")
	465 Kc.	200 mmf. Antenna lead	Broadcast	Set Dial at 465 Kc.	Trimmer (C4) at 465 Kc.	Broadcast oscillator I. Tap	Adjust to minimum output
SHORT WAVE BAND	17 Mc.	400 ohms Antenna lead	Short Wave	Set Dial at 17 MC	Trimmer (C15) at 17 MC	Short Wave oscillator	Adjust to maximum output
	17 Mc.	400 ohms Antenna lead	Short Wave	Dial Set at 17 MC	Trimmer (C9) at 17 MC	Short Wave oscillator	Adjust to maximum output
	6 Mc.	400 ohms Antenna lead	Short Wave	Set Dial at 6 MC	Trimmer (C13) at 6 MC	Short Wave oscillator series pad	Adjust to maximum rock dial. (See note "A")

**SERVICE NOTES:**

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected with a Volt meter having a resistance of 1000 ohms per volt.  
All voltages as indicated on the voltage chart are measured with 115 volts A. C. on the primary of the power transformer.  
Resistances of coil windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D. C. voltages is usually caused by a shorted electrolytic condenser; open by-pass condensers frequently cause oscillation and distorted tone.

**PROCEDURE FOR SETTING THE AUTOMATIC STATION PUSHBUTTONS:**

Important: Allow the radio to "warm up" for about 15 minutes before setting the station adjustment screws for the pushbuttons.  
After you have made up your list of stations, press button marked "Broadcast" and tune set manually until station selected having the highest frequency is tuned in and the program noted. Press button covering frequency range in which station is located (See Fig. 3). Adjust screw through station

**NOTE "A":** Turn the dial back and forth slightly (rock) and adjust trimmer until the peak of greatest intensity is obtained.  
Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.  
After each band is completed, repeat the procedure as a final check.

tab opening above button pressed until the same station is heard clearly and is correctly tuned.

Press pushbutton marked "Broadcast" and tune in next station selected. Press button covering frequency range in which station is located. Adjust screw through station tab opening above button pressed until the same station is heard clearly and with maximum volume.

Follow this procedure for each button until you have selected all of your stations. The automatic buttons are now set up for quick tuning and no further adjustment is necessary.

**NOTE:** In setting up the pushbuttons, station identification may require switching back and forth to button marked "Broadcast" until the same program is heard for both. If the same program is heard on more than one station, find the station on dial tuning and select the proper one on the pushbutton by comparing the order or sequence of programs with that on dial tuning.

Pinch out the station call letter tabs of the stations you have set for the automatic buttons. The set of call letters supplied and insert them into the rectangular slots in the escutcheon. One of the small, clear celluloid tabs supplied should be snapped into place over each of the station call letter tabs.

Fig. 4—Oscillator Trimmer Location

MODELS S712, D714M(1935)

Voltage, Socket, Coils WESTERN AUTO SUPPLY CO.  
Changes, Phono. Data

A standard arrangement for switch contact location numbering has been adopted. This numbering is illustrated in Fig. 5. In contact locations not used, the number applying to that particular location is not employed.

Changes in Early Models

In the early models of this receiver, the antenna transformer (T1) had two Range B Primary windings as shown in Fig. 8.

The oscillator Range B and C trimmer locations varied in the early and intermediate models of this receiver as shown in Figs. 3 and 4.

Referring to Fig. 2, in the early models of this receiver, contact No. 4 in the interstage section of the band selector was not used. The purpose of this contact arrangement is to short out variable resistor R2 in the second short wave position. In these models the relative positions of resistors R1 and R2 were reversed. The common connection from the suppressor grid and cathodes of the R. F. and I. F. amplifier tubes was connected to the control arm of variable resistor R2. The latter was connected to resistor R1 which was grounded at the other end. The by-pass condenser C6 remains connected as before, to the cathode and suppressor grid connection.

The type 6K7 and 6F6 metal tubes replace the types 6D7 and 42 glass tubes respectively which were used in the early models.

Fig. 8—Antenna Transformer in Early Models

Phonograph Connections

Replace the single lug insulated terminal strip (located on the rear panel, directly in back of the band selector switch) with (P-4A39) double lug insulated terminal strip with ground lug. Be sure to solder back to this new terminal strip any leads that were connected to the other terminal strip.

The connections are made by opening the diode return circuit at the volume control. Unsolder the 50,000 ohm resistor R9 (covered with saturated sleeving in early models) from the lug at the volume control and from the shielded lead which runs from the I. F. transformer. Cut this shielded lead to length and connect to the open lug on the new terminal strip. Connect one side of the 50,000 ohm resistor R9 to the same lug and the other side to the phono switch—see Fig. 9. Ground the shield to the ground lug of the terminal strip.

The extra shielded lead which is provided should be inserted into a piece of saturated sleeving.

Fig. 9—Phonograph Connections

Servicing R. F. Coil Assemblies

The R. F. transformers and oscillator coil assemblies in this receiver are sold complete with can. This is due to the fact that the trimmers are soldered to the can, and cannot be easily disassembled.

The lead colors and resistances of the various windings in each assembly are shown in Fig. 5.

If it is ever necessary to remove one of coil assemblies from the can, proceed as follows: First remove the nuts from the screws at the top of the can. The outside lug on the trimmer condenser is inserted in a slot in the coil can, and this lug is soldered into position.

Apply a soldering iron to the can at the point of the soldered connection. Then with a screw driver lift up on the outside edge of the trimmer (edge soldered to can) until the trimmer is clear of the can. After the trimmers are all unsoldered, the coil can be taken out.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

Phonograph connections can be made as shown in Fig. 9. The parts required are shown in the parts list. Knockouts are provided in the back panel of the chassis for mounting the phono jack and phono switch—See Fig. 10.

For mounting the 12 mfd. 25 volt dry electrolytic condenser, two No. 27 drill holes should be drilled in the side of the chassis directly below the wet electrolytic condensers. These holes are 1 1/4" from the bottom, 7/8" and 3/4" from the front of chassis. The ground lug which extends out from the side of the chassis should be bent back into the chassis wall.

WESTERN AUTO SUPPLY CO. **MODELS S712, D714M(1935)**  
Circuit Data, Alignment

**Circuit**

This model is a three band receiver with a tuning range in each band as shown in the specifications above. Three band coverage is accomplished by means of three sets of R. F. and oscillator coils and a three section triple throw switch.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R. F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively. The three sections of the band switch are designated in the schematic as the antenna, interstage and oscillator sections.

The band switch completes connections to the coils in use. It also short circuits the R. F. transformer secondary and oscillator coil of lower frequency not in use.

The antenna transformer with tuned secondary feeds into a type 6K7 R. F. amplifier tube. The output of this tube is fed through the interstage R. F. transformer with tuned secondary into another 6K7 tube which functions as the 1st detector.

A separate type 76 tube is employed in the oscillator circuit. Referring to the oscillator assembly T3, Fig. 2, B, C and D refer to the standard wave, 1st short wave and 2nd short wave oscillator coils respectively. The oscillating circuit is always resonant at 475 KC above the frequency to which the R. F. amplifier is tuned.

Fig. 1—Arrangement of Controls

The oscillator potential is fed into the cathode circuit of the 6K7 first detector tube. This results in the intermediate or beat frequency of 475 KC being present in the plate circuit of this tube.

One stage of I. F. amplification is employed using a 6K7 tube. The primaries and secondaries of the first and second I. F. transformers are tuned by small trimmer condensers.

**Selectivity Control**—Referring to the 1st I. F. transformer T3 in Fig. 2, it will be noted that there is a coupling winding shown in the illustration below the primary. Refer also to the by-pass arrangement in the pentode plate circuit of the 6B7.

When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity. High audio frequencies are by-passed to ground through condenser C35.

When the selectivity control is in the broad position,

the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

In order to allow passage of the higher audio frequencies in the broad position, the capacity of the by-pass condenser to ground is greatly reduced (C35 and the capacity of shield E in series).

**Dual Volume Control**—A dual manual volume control is employed. In one section the audio voltage applied to the 1st audio section of the 6B7 tube is varied (R10). In the other section the R. F. and I. F. bias is varied (R2). The purpose of the latter section is to reduce the sensitivity of the receiver at low volume settings in order to cut down noise pick-up between stations. The variable section R2 is shorted out through contact No. 4 of the interstage section of the band selector when in the 2nd short wave position.

A type 6B7 duo diode pentode tube functions as the second detector and a one stage audio amplifier. The two diode plates are connected together. AVC voltage is applied through isolating resistors to the control grid circuits of the R. F. and I. F. tubes. The audio voltage developed across volume control resistor R10 is applied through the movable arm to the control grid of the 6B7 tube. Resistance coupling is used between the first audio stage and the output stage which employs a type 6F6 output pentode tube. A type 80 full wave rectifier tube is used in the power unit.

**Alignment and Calibration**

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

**I. F. Adjustment**

Set the signal generator for a signal of 475 KC. Connect the output of the signal generator through a .1 mf. condenser to the grid of the 1st detector. Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color). Turn the selectivity switch to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the levelling-off action of the A. V. C.

Then adjust the four I. F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 6.

**Range B Alignment**

**1730 KC Adjustment**  
Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position. Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal

generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A. V. C. action.

Adjust the oscillator Range B trimmer (C21) until maximum output is obtained. The location of this trimmer is shown in Figs. 3 and 4.

**1500 KC Adjustment**

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

There is a lever arm in front of the large gear on the tuning condenser shaft by means of which the position of the station pointer may be adjusted. Set the station pointer at the 1500 KC mark on the dial scale by adjusting this lever arm.

Adjust the interstage Range B trimmer (C9) and antenna Range B trimmer (C2) to maximum.

**600 KC Adjustment**

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

**Range C Alignment**

**5800 KC Adjustment**

Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

Adjust the oscillator Range C trimmer (C23) until maximum output is obtained. See Figs. 3 and 4 for location of this trimmer.

**5000 KC Adjustment**

Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range C trimmer (C10) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

**Range D Alignment**

**18,300 KC Adjustment**

Set the signal generator for 18,300 KC. Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

Adjust the oscillator Range D trimmer (C24) until

maximum output is obtained. See Fig. 3 for location of this trimmer.

**15,000 KC Adjustment**

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the interstage Range D trimmer (C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

**6000 KC Adjustment**

Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

**Tuning-Frequency Range**

B Range	535 to 1730 KC
C Range	1715 to 5800 KC
D Range	5750 to 18300 KC

**Sensitivity**

B Range Average	0.5 Microvolts Absolute
C Range Average	1.0 Microvolts Absolute
D Range Average	2.0 Microvolts Absolute

Power Consumption - 68 Watts (At 115 volts 60 cycles)

Power Output - 3 Watts Unfiltered

Selectivity - 88 KC Broad at 1000 times Signal (Sharp)

Intermediate Frequency - 456 KC

Speaker - 6" and 8" Dynamic

MODEL D716 (1935)

Alignment, Resistances WESTERN AUTO SUPPLY CO.

Alignment and Calibration

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment.

A signal generator that will provide an accurately calibrated signal at 456, 1730, 1500, 600, 5800, 5000, 18,300, 15,000 and 6000 KC and an output indicating meter are required. It will be practically impossible to align the receiver if unsatisfactory apparatus is used. If a station is tuned in with the selectivity control in the broad position and this control is then turned to the sharp position, the station may disappear. This is not an indication that the receiver is out of alignment.

Use a non-metallic screwdriver for the adjustments. The complete procedure is as follows:

I. F. Adjustment

Set the signal generator for a signal of 456 KC. Connect the output of the signal generator to the grid of the 1st detector through a 0.1 MF condenser. Connect the ground lead of the receiver to the ground post of the signal generator.

Turn the band selector to the Range B position (standard wave band—purple dial color).

Turn the selectivity control to the sharp position and keep it in this position for all adjustments.

Turn the volume control to the maximum position. Attenuate the signal from the signal generator to prevent the leveling-off action of the A.V.C.

Then adjust the five I.F. trimmers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis, and the location is shown in Fig. 5.

Range B Alignment

1730 KC Adjustment

Set the signal generator for 1730 KC. Turn the rotor of the tuning condenser to the full open position.

Keep the band selector in the standard wave position.

Connect the antenna lead of the receiver through a 200 mmf. condenser to the output of the signal generator.

For this and all subsequent adjustments keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range B trimmer (C38) until maximum output is obtained. The location of this trimmer is shown in Fig. 3.

1500 KC Adjustment

Set the signal generator for 1500 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Loosen the pointer set screw and set the large pointer at the 1500 KC mark on the standard wave band scale. Retighten the set screw.

Adjust the 1st and 2nd interstage Range B trimmers (C8 and C13) and antenna Range B trimmer (C2) to maximum.

Do not change the setting of the oscillator Range B trimmer.

600 KC Adjustment

Set the signal generator for 600 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 600 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Be sure to use a non-metallic screwdriver for this adjustment.

Range C Alignment

5800 KC Adjustment

Set the signal generator for 5800 KC. Connect the antenna lead of the receiver through a 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range C position (1st short wave band—green dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range C trimmer (C40) until maximum output is obtained. See Fig. 3 for location of this trimmer.

5000 KC Adjustment

Set the signal generator for 5000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range C trimmers (C9 and C12) and antenna Range C trimmer (C3) to maximum.

Do not change the setting of the oscillator Range C trimmer.

Range D Alignment

18,300 KC Adjustment

Set the signal generator for 18,300 KC. Keep the antenna lead of the receiver connected through the 400 ohm resistor to the output of the signal generator.

Turn the rotor of the tuning condenser to the full open position.

Turn the band selector to the Range D position (2nd short wave band—red dial color).

As mentioned above, keep the volume control at the maximum position and attenuate the signal from the signal generator to prevent A.V.C. action.

Adjust the oscillator Range D trimmer (C41) until maximum output is obtained. See Fig. 3 for location of this trimmer.

15,000 KC Adjustment

Set the signal generator for 15,000 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained.

Adjust the 1st and 2nd interstage Range D trimmers (C10 and C11) and antenna Range D trimmer (C4) to maximum.

When adjusting the 2nd interstage Range D trimmer, it will be necessary at the same time to turn the tuning condenser rotor slowly back and forth until the peak of greatest intensity is obtained.

Then go back and repeat the procedure as given for the 18,300 KC adjustment. If it is found necessary to make any appreciable change in the setting of the oscillator Range D trimmer, the 15,000 KC adjustment must be repeated.

Do not make any further change in the setting of the oscillator Range D trimmer.

6000 KC Adjustment

Set the signal generator for 6000 KC. Turn the tuning condenser rotor until maximum output is obtained.

Turn the rotor slowly back and forth at the same time adjusting the 6000 KC trimmer until the peak of greatest intensity is obtained. See Fig. 3 for location of this trimmer.

Use a non-metallic screwdriver for this adjustment

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

A 115-230 Volt, 40 to 60 cycle as well as other power transformers with special power ratings are also available for this model.

IC 95114	Field coil 10" speaker SK 9578 & 10" speaker SK 9583
IC 95114	18 mfd., 400 V. electrolytic condenser
IC 95114	.001 mfd., 400 V. condenser, .25 cycle
IC 95114	.001 mfd., 400 V. condenser
IC 95114	.05 mfd., 400 V. condenser
IC 95114	10,000 ohm, 1/2 W. resistor
IC 95114	9 mfd., 400 V. electrolytic condenser
IC 95114	47,000 ohm, 1/2 W. resistor - part of IC 95114
IC 95114	.008 mfd. mica condenser

WAVE TRAP ADJUSTMENT

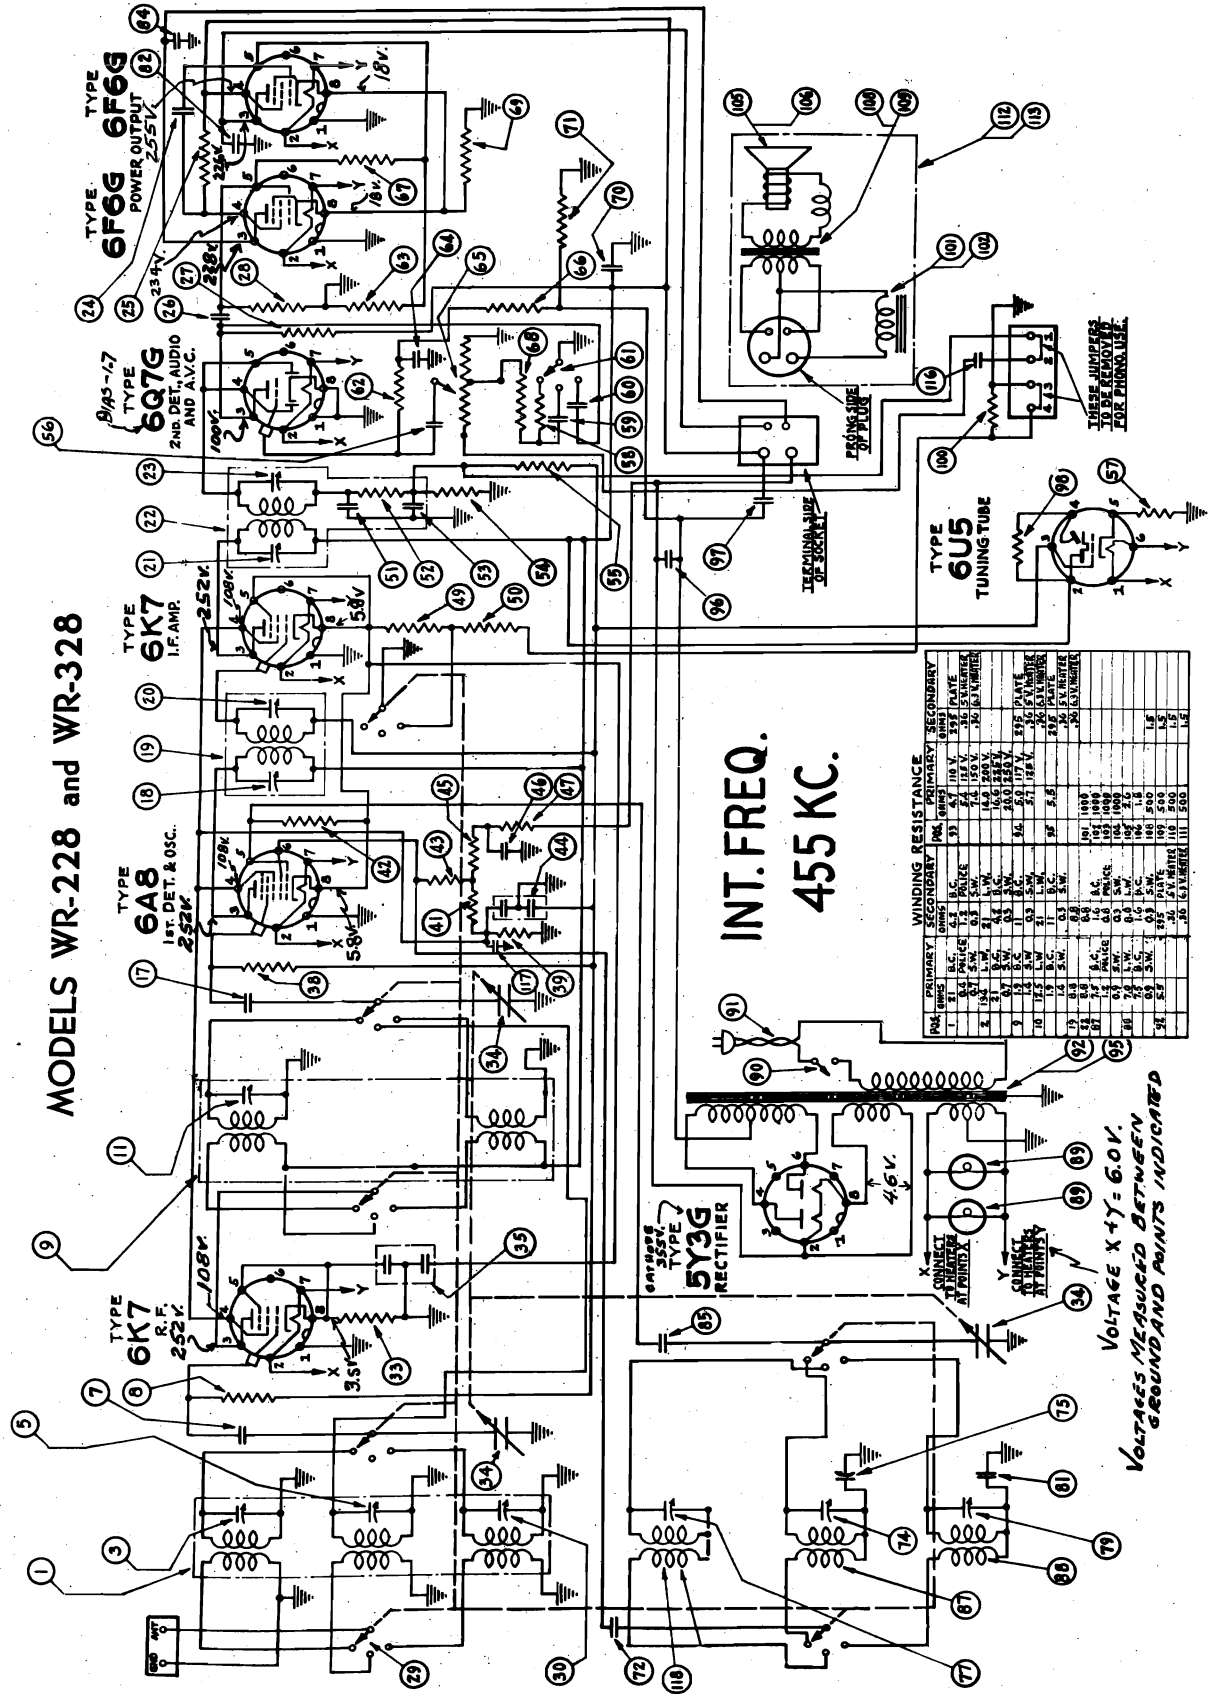

Under actual operating conditions this trimmer may be adjusted slightly to minimize an interfering signal known to be on or near the 455 K.C. channel.

Set the test oscillator to 455 K.C. and with the signal applied to the antenna adjust trimmer #3 to minimize the signal. Use 5 mfd dummy capacitor for I.F. align. Use .0002 mfd dummy capacitor for BC GREEN BANDS. Use .0002 mfd dummy capacitor for BC RED BANDS.

 "Standard Broadcast" (A)..... 540-1,770 kc  
 "Medium Wave" (B)..... 2.3-7 mc  
 "Short Wave" (C)..... 7-22 mc

**Calibration Scale on Indicator Drive - Cord Drum.**—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment, therefore, a calibration scale is provided on the front of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment chart. The position of the dial is marked on the drum scale with a 180° mark on the vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the drum to the center of the shaft is measured, which is used to set the dial by means of two set screws, which must be tightened accurately when the drum is in the correct position.

**Pointer for Calibration Scale.**—Improve a pointer for the indicator on the dial. The pointer should be made of brass, and fastened to the cabinet frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

**Dial-Indicator Adjustment.**—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with a screw. The indicator has a spring clip for attachment to the cable.

After completion of alignment, seal the I.F. core-adjusting screws with household cement.

The dial tuning (right-hand) push button must be pushed in for steps 1 to 5 inclusive.

Steps	Connect the high side of test-osc. to—	These test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap. in series with .01 mfd.	455 kc	"A" band, Quiet Point	L1 and L18 (Std. I.F. Transformer)
2	6A8 det. grid cap. in series with .01 mfd.	455 kc	between 550-750 kc	L10 and L11 (Std. I.F. Transformer)
3	Antenna Terminal, in series with 400 ohms	90 mc	90 mc (85° "C" band)	C18 (osc.) * C30 (ant.) **
4	Antenna Terminal, in series with 400 ohms	6.1 mc	6.1 mc (81° "B" band)	C26 (osc.) †
5	Antenna Terminal, in series with 200 mfd.	1,500 kc	1,500 kc (284° "A" band)	C35 (osc.)
6	Follow "Adjustments for Electric Tuning"			

\* Use minimum capacity peak if two peaks can be obtained.  
 † Use minimum capacity peak if two peaks can be obtained.  
 ‡ Use minimum capacity peak if two peaks can be obtained.  
 § Use minimum capacity peak if two peaks can be obtained.  
 ¶ Use minimum capacity peak if two peaks can be obtained.  
 NOTE: Oscillator tracks 455 kc above signal on all bands.

ADJUSTMENTS FOR ELECTRIC TUNING

This receiver has seven push buttons. The right-hand button connects the gang condenser for manual tuning. The other buttons connect the oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool for manual tuning. Turn the dial for five minutes before making adjustments.

1. Make a list of the desired six stations, arranged in order from low to high frequencies. See "Tune and Frequency" view for frequency coverage of each button.
2. Push in the dial-tuning button, and manually tune in the first station on the list.
3. Adjust the antenna trimmer (A) and adjust No. 1 oscillator (L17) to the station. Screw the antenna trimmer all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C16) for maximum volume. Check the adjustment of coil and trimmer using the circuit to lower frequencies.
5. Adjust for each of the remaining five stations in the same manner. Careful adjustment of the oscillator coils and antenna trimmers. Use the Precision Eye to ensure sharp peaking.

Phonograph Terminal Board.—A 3-terminal board is located on the rear of the chassis for connecting a phonograph pickup, or Record Player, into the audio amplifier of the receiver.

The above schematic shows connections for a high-impedance pickup with a switch for changing from radio to record. For low-impedance pickups, a suitable step-up transformer should be used to provide proper impedance matching, and should be connected between the pickup and phono switch. The volume control is optional.

**Loudspeaker.**—The loudspeaker voice-coil may be centered in the normal manner by using three narrow feelers to obtain equal spacing of the air-gap. The dust cover must be removed before centering, and may be done by gently cutting it free from the cone, being careful not to cut or damage the cone while doing so.

Precautionary Lead Dress—

1. Dress power leads against left apron to prevent hum pickup.
2. Dress R1 away from front of chassis.
3. Electric-tuning lamp leads must be dressed in front of range switch.
4. Range lead from L5 to range switch away from other leads.
5. Dress leads away from antenna coil.
6. Dress other parts and leads away from R14, as it becomes heated.
7. Leads across back of chassis should be dressed under electrolytic to prevent approaching phono board.
8. Keep leads of C27 as short as possible.

MODEL WR-472 PHONOGRAPH MOTOR SERVICE DATA

3. Motor not properly supported from motor board.
4. Burrs on poles of rotor or stator. Remove with fine emery cloth.

**Removing Rotor.**—The rotor and armature assembly simply rest on the ball bearing at bottom of vertical bearing. Remove by lifting up.

**Rotor Adjustment.**—Loosen the three screws that hold the rotor to the stator. Adjust the rotor so that the clearance between the gap between the rotor and stator, and then carefully tighten the three screws. The top of rotor must be flush with top of stator; add additional steel washers beneath the stator if necessary.

**Lubrication.**—Oiling points are indicated in figure 1.

TURNABLE HELD ON SHAFT BY RETAINING RING & WASHER

Figure 1—Motor Assembly

Alignment Procedure

Presenting dial.—With gang condenser in full mesh, move dial pointer to coincide with horizontal lines. This is a friction adjustment.

Re-setting I.F. Adjustment Screws.—After completion of alignment, seal the I.F. core adjusting screws with a few drops of household cement.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
No. 1	6K7 I-F grid cap. in series with .01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L18 (Std. I.F. Transformer)
No. 2	6A8 1st-det. grid cap. in series with .01 mfd.	455 kc	L5 and L6 (Std. I.F. Transformer)	
No. 3	Antenna lead, in series with 200 mfd.	1,500 kc	1,500 kc	C18* (osc.) C3 (antenna)

\* Trimmer C17 on gang condenser should be screwed clockwise for maximum capacity before adjusting C18

Loudspeakers

- Type..... 5 inch electrodynamic  
 V-C impedance..... 5 ohms at 400 cycles  
 Power Supply Ratings  
 Rating A-6..... 105-125 volts, 60 cycles, 80 watts  
 Rating A-5..... 105-125 volts, 50 cycles, 80 watts  
 Phonograph..... Synchronous (manual starting)  
 Records..... 10-inch and 12-inch, 78 r.p.m.  
 Pickup..... Crystal, 80,000 ohms at 1,000 cps.  
 Average Output of Pickup..... 1/2-volts, at 1,000 cps, across 1/4 meg. load

The synchronous motor used in this instrument is designed to operate on 110-120 volt a-c. It has many features of economy of need, low power consumption, ease of repair, and long life. The parts that may require attention are plainly shown in figure 1. The motor is started by turning "on" with the band. Smooth starting and running will be insured by keeping the bearings well cleaned and oiled.

1. Hum and Vibration.—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. Excessive vibration occurs if may be due to:  
 a. binding, or any feature that will cause binding.  
 b. leather washer not oiled. (Check to make certain that the leather washer is above the steel washer.)

**Turntable Alignment.**—The turntable should be aligned with the motor shaft. The turntable should be turned until the pointer is in the center of the scale. The turntable should be turned until the pointer is in the center of the scale. The turntable should be turned until the pointer is in the center of the scale.

**Output Motor Alignment.**—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

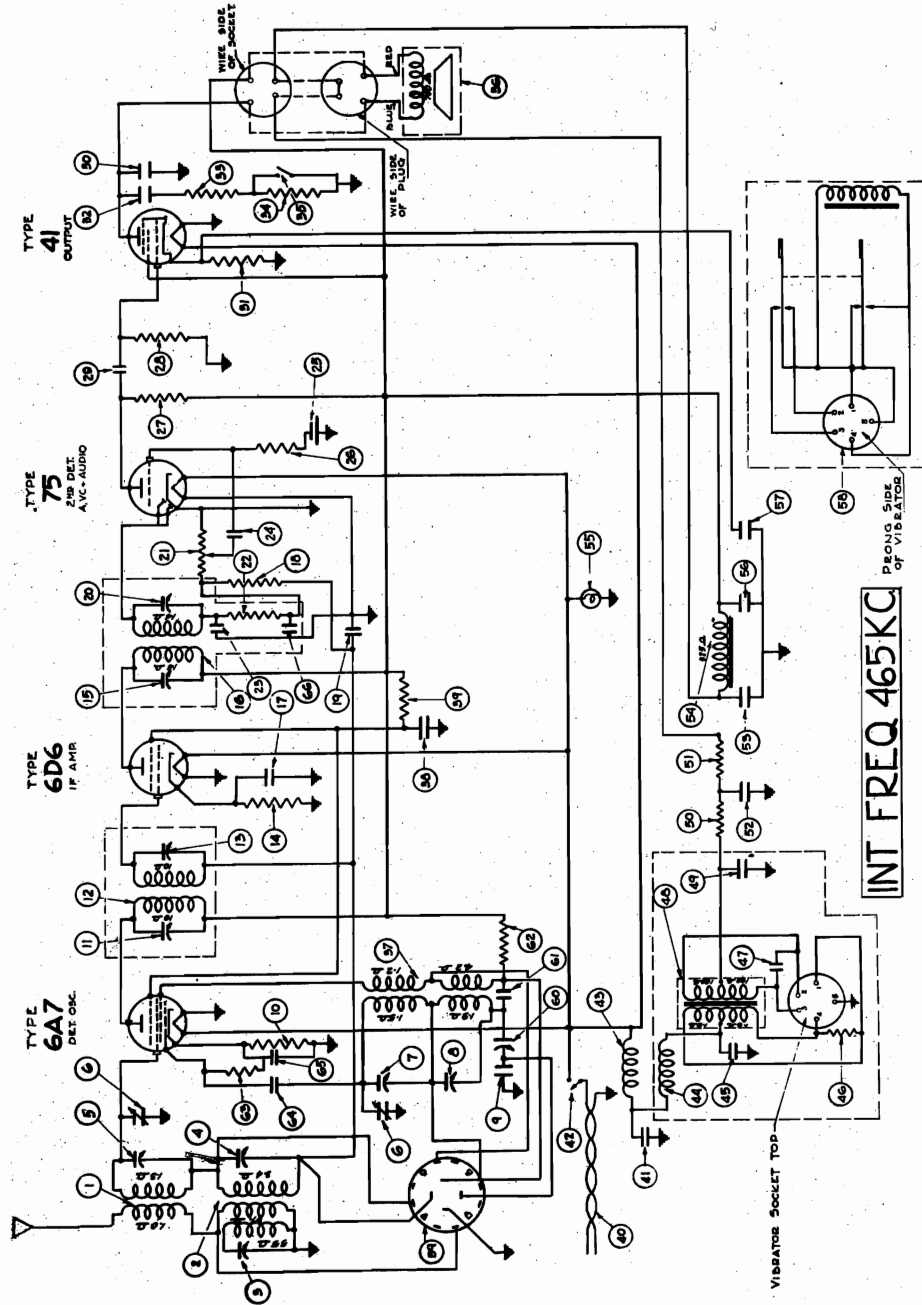

**Test-oscillator.**—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

Precautionary Lead Dress

1. Dress power leads to phono motor switch away from the audio wiring.
2. Dress power cord and motor cable to end of chassis (free from volume control wiring).
3. Dress pilot lamp lead away from 6Q7 grid.
4. Capacitors C13 and C15 (located at volume control) must be dressed at right angles to each other and as far apart as possible.

**Frequency Range.**—Standard Broadcast, 540-1,770 kc

- nal to the antenna of the receiver through a .0002 mfd. condenser.
- Adjust the broadcast oscillator trimmer condenser #6 to maximum output.
  - Adjust the Broadcast presselector trimmer #8 to maximum output.
  - Set the test oscillator and dial indicator to 600 KC. and adjust the oscillator series condenser #11 to maximum output at the same time rocking the variable condenser.
  - Return the test oscillator and dial indicator to 1600 KC. and check the adjust-
- ment of trimmer condensers #6 and #8 for accuracy.
- SHORT WAVE BAND ADJUSTMENTS**
- Set the wave change switch to the short-wave band position.
  - Set the test oscillator and dial indicator to 8000 KC. and adjust the short-wave trimmer condenser #7 to maximum output.
  - Adjust the short-wave presselector trimmer condenser #2 to maximum output.
  - Check the receiver over the short-wave band for sensitivity and calibration.

- BROADCAST BAND ADJUSTMENTS**
- Set the test oscillator and dial indicator to 1600 KC. and apply the test signal to the grid of the type 106 first detector-oscillator tube and adjust the I.F. trimmer condensers #16 and #18 to maximum output.
- Apply the test signal to the antenna lead of the receiver and adjust the wave trap trimmer condenser #4 to minimum output.
- BROADCAST BAND ADJUSTMENTS**
- Set the test oscillator to 465 KC. and apply the test signal to the grid of the type 1A4 tube, through a 0.5 mfd. blocking condenser, and adjust the I.F. trimmer condensers #21 and #22 to maximum output.
- Set the volume control to the maximum position, the tone control to the treble position, the wave change switch on the broadcast band and the dial indicator to approximately 600 KC.
- Set the test oscillator to 465 KC. and apply the test signal to the grid of the type 1A4 tube, through a 0.5 mfd. blocking condenser, and adjust the I.F. trimmer condensers #21 and #22 to maximum output.

MODEL WR256 Schematic, Voltage

Precautionary Lead Dress

1. Power transformer leads and power cord must be dressed toward rear apron away from volume control.
2. Blue lead from "A" terminal of 2nd I-F transformer to volume control must be dressed toward front apron away from other parts.
3. Speaker cable leads must be dressed close to chassis base, away from 6K6-G socket and volume control.

Frequency Range.....540 to 1,720 kc  
 R-F Alignment Frequency.... 1,500 kc (osc., ant.)  
 Intermediate Frequency..... 455 kc

**TUBE COMPLEMENT**

(1) RCA-6A8..... First-Det., Osc.  
 (2) RCA-6K7..... Intermediate Amp.  
 (3) RCA-6Q7-G..... Second-Det., A-F, A.V.C.  
 (4) RCA-6K6-G..... Power Output  
 (5) RCA-5Y4-G..... Rectifier

Dial lamp..... Mazda No. 44, 6.3 volts, 0.25 amps.

**POWER OUTPUT (125-volt, a-c supply)**

Undistorted..... 1.0 watt  
 Maximum..... 2.0 watts

**LOUDSPEAKER**

Type..... 5-inch Electrodynamical  
 Voice-coil Impedance..... 3.4 ohms at 400 cycles

**POWER SUPPLY RATINGS**

Rating A..... 105-125 volts, 50-60 cycles, 50 watts  
 Rating B..... 105-125 volts, 25-60 cycles, 50 watts

Measurements made to chassis unless otherwise indicated.  
 Measurements made with set tuned to quiet point, volume control at minimum, using 1,000-ohm-per-volt meter, having ranges of 10, 50, 250, and 500 volts. (Use nearest range above the specified measured voltage.)  
 Values should hold within approximately ± 20% for 117-volt 60-cycle supply.

Alignment Procedure

**Cathode-ray Alignment** is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

**Output meter alignment.** If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

**Test-oscillator.** For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

**Pre-setting dial.** With gang condenser in full mesh, move dial pointer to coincide with horizontal lines. This is a friction adjustment.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
No. 1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L8 (2nd I-F Transformer)
No. 2	6A8 1st-det. grid cap, in series with .01 mfd.	455 kc		L5 and L6 (1st I-F Transformer)
No. 3	Antenna lead, in series with 200 mmfd.	1,500 kc	1,500 kc	C6* (oscillator) C3 (antenna)

\*Trimmer C18 on gang condenser should be screwed clockwise for maximum capacity before adjusting C6.

Line-Up Frequencies	.....	I.F. 465 K.C.; 1400 K.C.

**LINE-UP CAPACITOR ADJUSTMENTS**

To properly align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied and reduced sufficiently to prevent overload as the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the individual circuits are correctly aligned. The sensitivity of this meter must be sufficient to give satisfactory readings with low input signals.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis and location of the various tubes and alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before actual work is started.

**ALIGNMENT OF I.F. (465 K.C.)**

1. Set the volume control to maximum position and wave change switch to standard broadcast band.
2. Connect the output meter across the voice coil terminals of the speaker.

3. Set the test oscillator to 465 K.C. and adjust its output to produce a measurable reading on the output meter when the test signal is applied to the grid of the type 6A7 first detector-oscillator tube through a 0.5 mfd. blocking condenser.
4. Adjust trimmers #9 and #11 to maximum output.

**ALIGNMENT OF OSCILLATOR AND R. F.**

1. Check the pointer setting to be sure that it is exactly horizontal when the tuning condenser is completely closed.
2. Set the test oscillator and dial indicator to 1400 K.C. and adjust the oscillator trimmer condenser #17 to maximum output.
3. Apply the test signal to the antenna of the receiver through a .0001 mfd. blocking condenser and adjust trimmer condenser #6 to maximum output.
4. Check sensitivity over the band.
5. Turn wave change switch to the shortwave band and check the sensitivity over scale.

MODEL WR209 WESTINGHOUSE ELEC. INTERNATIONAL CO.  
 Alignment, Socket Trimmers, Chassis

Type and Number of Tubes	1 #6F7, 1 #6D6, 1 #75, 1 #42, 1 #80 - Total 5
Power Supply	105 to 125 volts, 50 to 60 cycles A.C.
Power Consumption	46 Watts
Tuning Ranges	540 to 1500 K.C. and 1500 to 3200 K.C.
Maximum Undistorted Output	1.5 Watts
Maximum Output	2.8 Watts
Line-Up Frequencies	I.F. 465 K.C., 1400 K.C.

This model is a five-tube, A.C., two-band superheterodyne receiver whose circuit comprises a combined first detector-oscillator an intermediate frequency amplifier, a combined second detector, A.V.C. and first audio amplifier, a power pentode output stage and a rectifier with its associated filter circuit and power transformer.

This model is designed to work over two bands, the broadcast band extending from 540 to 1500 K.C. and a police band which extends from 1400 to 3200 K.C.

**LINE-UP CAPACITOR ADJUSTMENTS**

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Fig. #1 and #2 and should be carefully studied before the actual work is started.

**ADJUSTMENT OF I.F. (465 K.C.)**

1. Set volume control on full, turn tone control knob to the right hand position. Set wave-change switch on the broadcast position and the dial indicator at approximately 600 K.C.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 K.C. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of the 6D6 I.F. tube thru a .5 mfd. blocking condenser.
4. Adjust #26 (see Fig. #2) to maximum output reducing output of test oscillator as required.
5. Apply test signal to grid of 6F7 first detector-oscillator tube and adjust #18 and #19 (Fig. #1) to maximum output.

6. With test signal still on the grid of 6F7 tube, repeat the above adjustments for greatest sensitivity.

**ADJUSTMENT OF BROADCAST BAND**

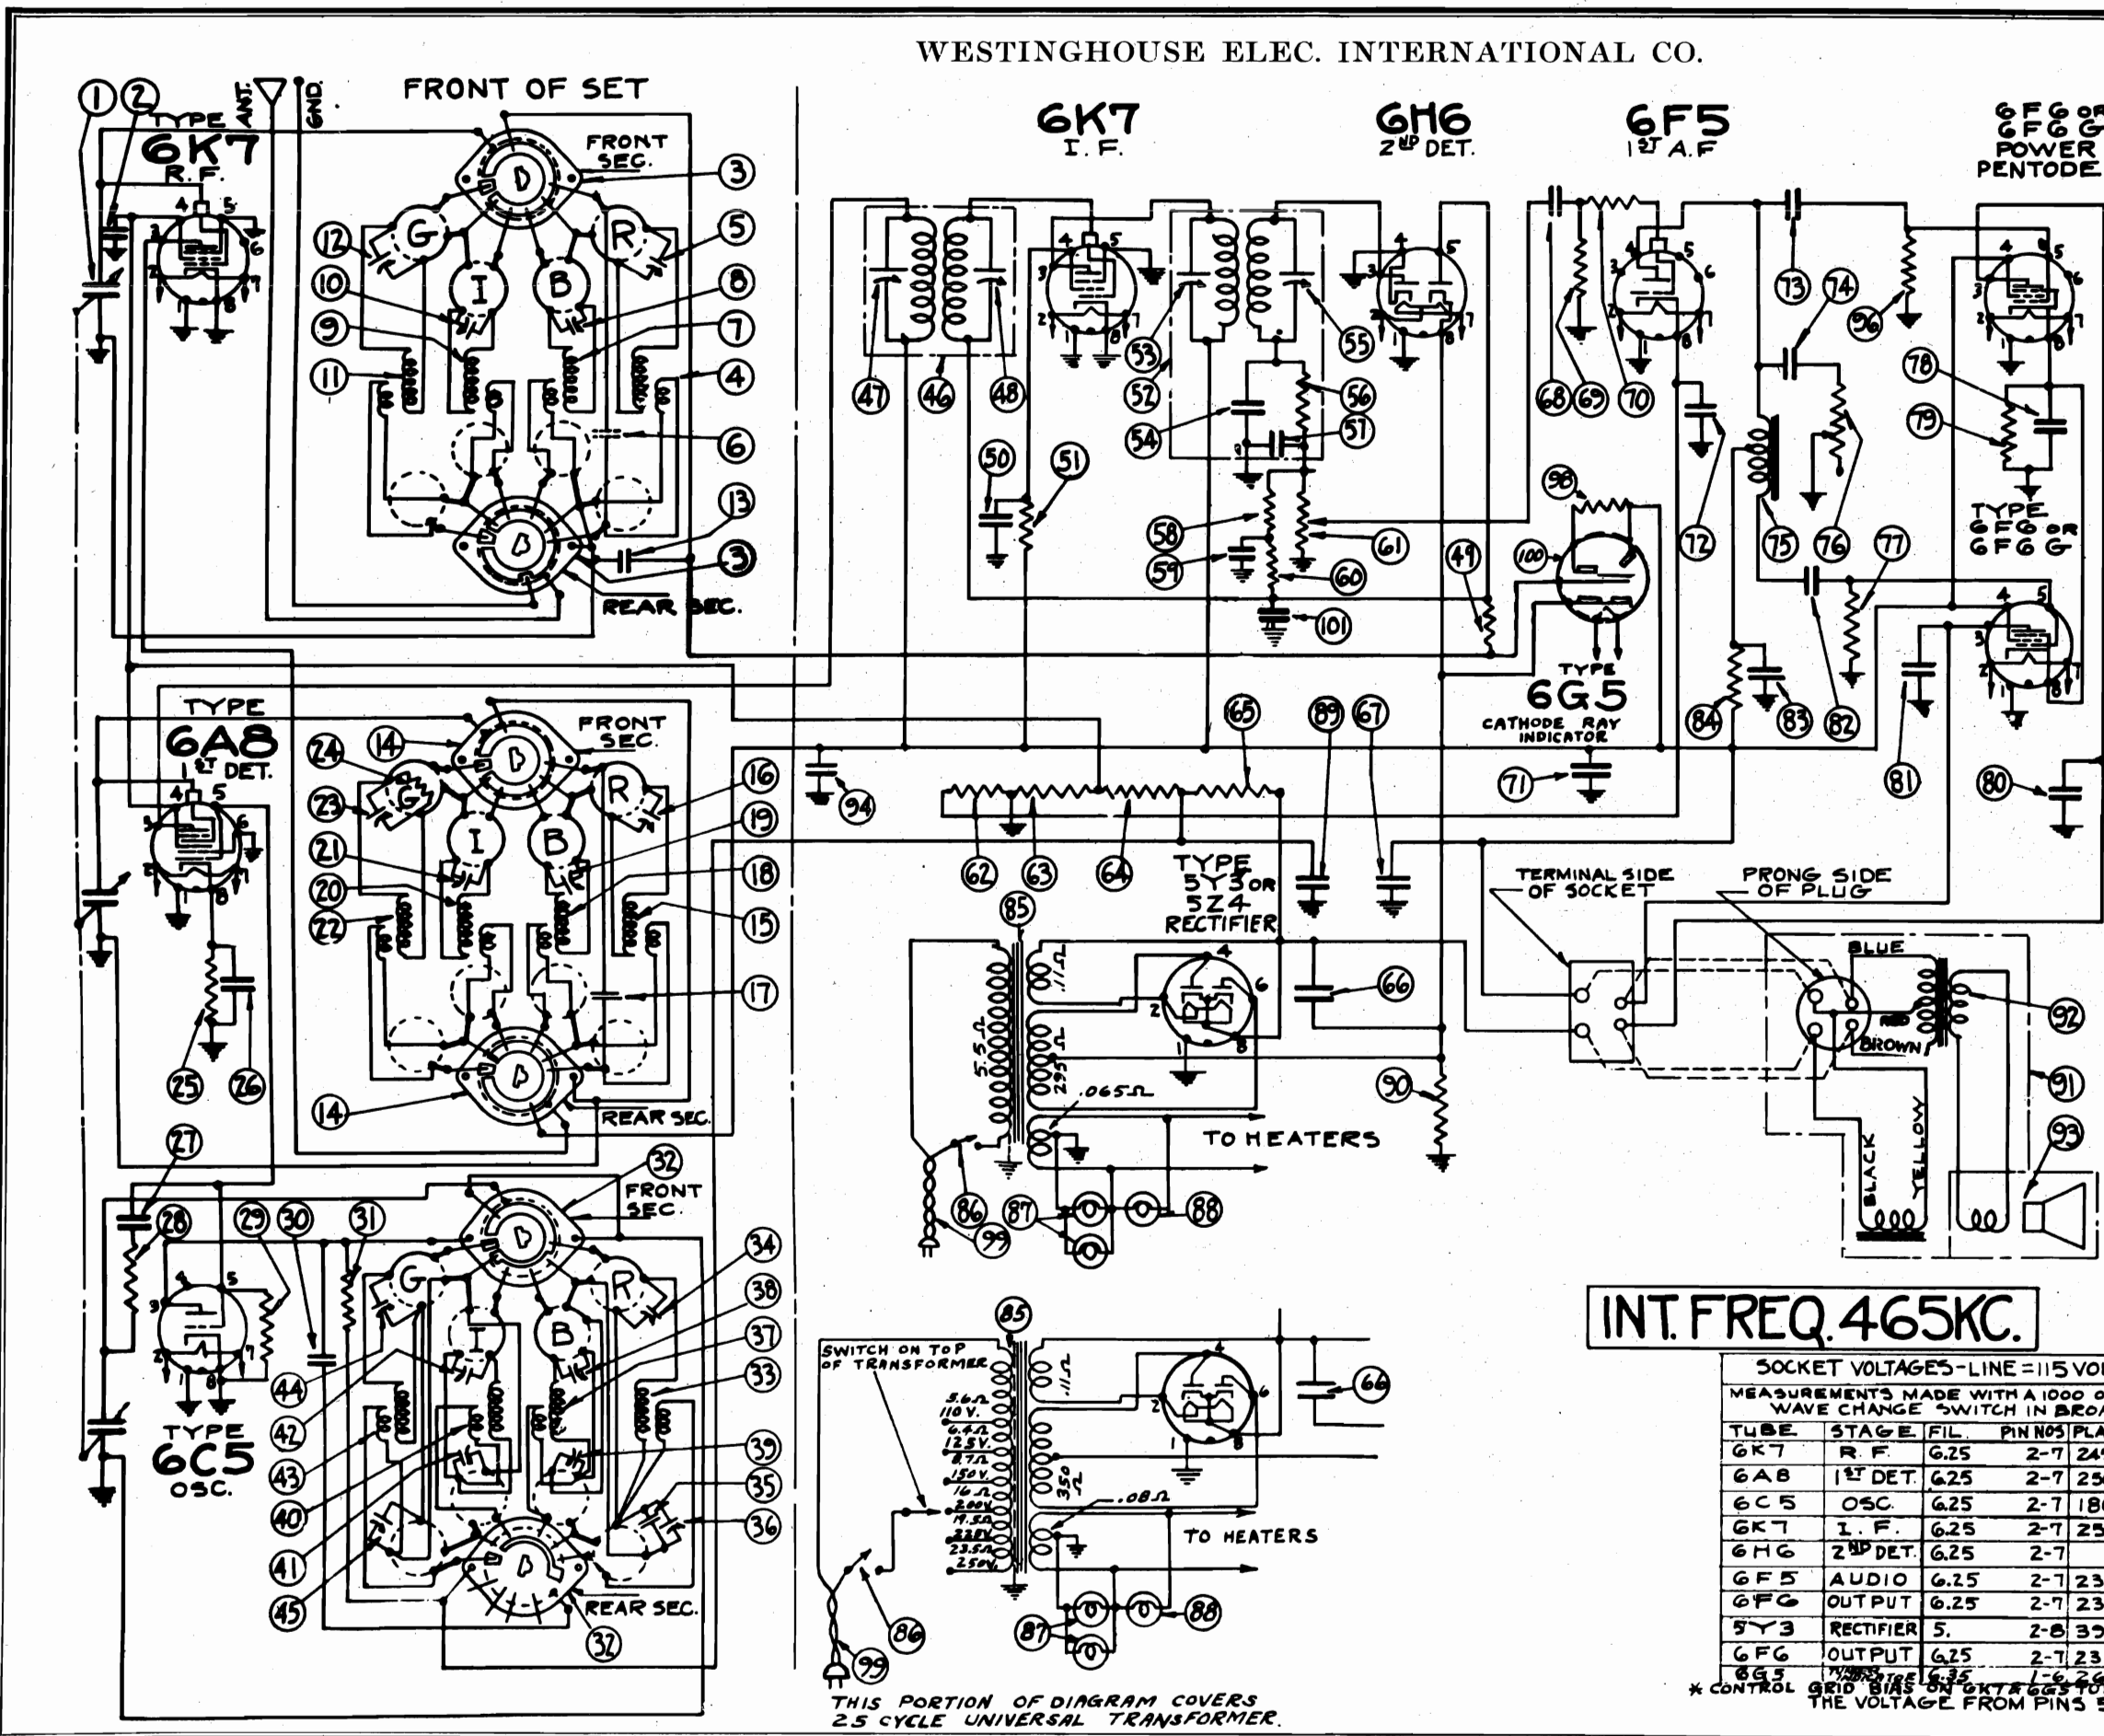

1. Leave test signal on grid of 6F7 tube and set the test oscillator to 1400 K.C.
2. Turn the gang condenser to its maximum position. Adjust dial indicator until either end is directly over the long horizontal lines on the dial scale. Then set dial indicator to 1400 K.C.
3. Adjust trimmer #8 to maximum output.
4. Apply test signal to antenna of set thru a .0002 mfd. condenser and adjust trimmer #7 to maximum output.

**ADJUSTMENT OF POLICE BAND**

When adjustments as outlined under the broadcast band are completed, the police band requires no adjustment unless the coil had been changed. In this event, set test oscillator and station indicator to 1700 K.C. and apply test signal to antenna lead. The police band winding is indicated by "A" in Fig. #2. Adjust the position of this winding by sliding it back and forth on the core until maximum output is indicated on the output meter. This winding should then be secured in place by applying a thin coat of coil cement.

MODEL 169-31 Automatic  
Record Changer

Installation, Operation

## INSTALLATION, OPERATION AND SERVICE

# AUTOMATIC RECORD CHANGER

*used in*  
Models 6-S-306, 9-S-307, 15-S-308

This Record Changer will automatically play a series of eight 10- or seven 12-inch records of the 78 revolutions-per-minute type or, if you so desire, you may change records, of any size up to 12 inches, manually. Records of the last few years with the standard eccentric or spiral stopping groove

will operate the automatic mechanism and change your records for you.

## INSTALLATION

The Automatic Record Changer as supplied consists of two units.

1. The **Motorboard Unit** which includes the automatic record changer mechanism, the turntable, and the pickup.

2. The **Motor Unit** which includes the support plate assembly.

The units are supplied ready for mounting on a cabinet rail. This rail must be drilled in accordance with the information and dimensions shown on page 4. Wooden support blocks as shown, must be provided by the customer. All other necessary parts are included in your purchase. It is essential for proper operation that the rail and support blocks provide for the mounting of the motor support plate exactly  $2\frac{3}{4}$  inches below the top surface of the motorboard. The support blocks should be attached to the rail with heavy wood screws. Details of this mounting, with all necessary dimensions, are given on page 4.

1. Install the Motor Unit with support plate loosely in position as shown on page 4. Do not tighten the mounting screws.
2. Loosen the two set screws in the collar of the flexible coupling on the Motorboard Unit, a detail of which is shown on page 3.
3. Place the Motorboard Unit in position on the cabinet rail with the upper mounting springs in place as shown on page 4. Make sure that the guide pins extending from the motor support plate enter the rubber grommets in the Motorboard Unit without binding.
4. Secure Motorboard in position using the screws and lower mounting springs as shown on page 4. Tighten up the four motorboard mounting screws to compress all eight mounting springs to the dimensions shown. *Make sure that the Motorboard Assembly is level in the cabinet.*
5. Tighten up the mounting screws on the Motor Unit support plate assembly so that they are firmly down against the spacers.
6. Check the installation to be sure that there is no binding between the collar of the flexible coupling and the collar of the motor spindle. See page 3.

7. Tighten the two set screws of the flexible coupling down on the spindle of the Motor Unit.

## Needle Box

The needle box is in a separate package. Place the box in the hole in the motorboard with the needle ejector tab toward the front. To do this tilt the box upwards at front and lower into hole with the lug on back of box in the slot in the motorboard. Slide the lug under the motorboard and the box drops in place.

## Speed Regulation and Lubrication

There are three holes in the top of the turntable which give access to oil holes and a speed regulating screw in the motor mechanism beneath. Revolve the turntable slowly until you can see the holes and screw through the turntable. A few drops of good quality light machine oil should be applied in the oil holes at regular intervals, about once every six months.

**Speed Regulation.**—After the phonograph is in operation the speed should be checked while playing a record.

1. Place a piece of white paper under edge of record so that it is plainly visible.
2. Count the number of revolutions per minute with the aid of a watch.
3. If not 78, stop the turntable, lift off the record and set the turntable to give access to the speed regulator screw through one of the holes.
4. Insert a screwdriver through the hole in the turntable into the groove in the speed regulator screw and turn to right (clockwise) to decrease speed, or to the left (counterclockwise) to increase speed.
5. Replace and replay record, recount and adjust until speed is checked at 78 r. p. m.

## Shipping

Shipping blocks as shown on page 4 should be used in all cases of reshipment.

## OPERATION

Before operating the phonograph, either automatically or manually, be sure that the pickup is down and can be moved by hand. If not, a "cycle" must be completed to bring it down. To do this, throw Turntable Switch "on." The turntable will start to revolve and the cycle of motion on the pickup arm will be resumed. When the pickup arm comes down, turn off the Turntable Switch.

## Cautions

1. Never use force to start or stop the motor or any part of the record-changing mechanism or pickup arm.
2. The use of records which have become warped or damaged through improper care may cause the mechanism to jam and damage the instrument. In addition, records which have become warped will slide on one another when playing, resulting in unsatisfactory reproduction.
3. This instrument is not recommended for playing 10-inch and 12-inch records in mixed sequence. If the user desires this service he must be positive that all records are perfectly flat and free from warp. The Index and Record Reject Lever must be set at "10" and after playing the last selection the pickup will come down in position for a 10-inch record and repeat the playing of the record on a 10-inch diameter unless the Turntable Switch is turned off. Any jamming of the mechanism under these conditions indicates that the records used are not perfectly flat or that their edges are not sufficiently smooth to permit normal operation of the separators in dropping each record in sequence onto the turntable.

4. Do not leave records on the record holder posts, as they are liable to warp, particularly so in warmer climates. Keep your records in a record file (album or cabinet) when not in use. If any records should become warped, place them on a flat surface with a flat heavy article, such as a large book, on top and leave them in this position for a few days.

## Controls and Moving Mechanism

**Index and Record Reject Lever.**—This lever is located near the right front corner of the motorboard with its index plate marked for four positions—"MANUAL," "12," "10," and "REJECT." When you desire to change record selections manually, this lever should be set in the "MANUAL" position. With the lever in the "12" position, the mechanism is set to play a series of 12-inch records automatically. To play either a series of 10-inch records, or 10- and 12-inch records mixed, the lever should be set at the "10" position.

To reject a record being played, or to start the record-changing cycle in case the record just played does not have the standard eccentric or spiral stopping groove, simply push the lever to the "REJECT" position and let go. The pickup will raise up and swing outwards and the next record will drop down. Upon releasing the lever, it will automatically return to the "10" position. If you are playing a series of 12-inch records, the lever should be returned to the "12" position after rejecting a record. Keep the lever in its "MANUAL" position when not actually playing records automatically.

## GENERAL INFORMATION

Before servicing the automatic record changer, inspect the assembly to see that all levers, parts, gears, springs, etc. are in good order and are correctly assembled.

A bind or jam in the mechanism can usually be relieved by rotating the turntable in the reverse direction.

The changer can be conveniently rotated through its change cycle by pushing the index lever to "Reject" and revolving the turntable by hand. Six turntable revolutions are required for one change cycle.

The turntable, spindle, and pinion gear are assembled by means of a 3/32 inch straight pin. This pin may be removed by gently driving with a standard pin punch.

If the record changer or cabinet is not perfectly level, normal operation is likely to be affected.

The 10 and 12 inch records must be absolutely flat for smooth operation when using a mixture of the two sizes.

A shorting switch, located in the pickup head, operates due to pressure when the pickup is placed on the pickup rest.

## ADJUSTMENTS

**A. Main Lever.**—This lever is basically important in that it interlinks the various individual mechanisms which control needle landing, tripping, record separation, etc. One adjustment is provided for the main lever. Rotate the turntable until the changer is out-of-cycle; and adjust rubber bumper bracket (A) so that the roller clears the nose of the cam plate by 1/16 inch.

**B. Friction Clutch.**—The motion of the tone arm toward the center of the record is transmitted to the trip pawl "22" by the trip lever "7" through a friction clutch "5." If the motion of the pickup is abruptly accelerated or becomes irregular due to swinging in the eccentric groove, the trip finger "7" moves the trip pawl "22" into engagement with the pawl on the main gear, and the change cycle is started. Proper adjustment of the friction clutch "5" occurs when movement of the tone arm causes positive movement of the trip pawl "22" without tendency of the clutch to slip. The friction should be just enough to prevent slippage, and is adjustable by means of screw "B." If adjustment is too tight, the needle will repeat grooves; if too loose, tripping will not occur at the end of the record.

**C. Pickup Lift Cable Screw.**—During the record change cycle, lever "16" is actuated by the main lever "15" so as to raise the tone arm clear of the record by means of the pickup lift cable. To adjust pickup for proper elevation, stop the changer "in-cycle" at the point where pickup is raised to the maximum height above turntable plate, and has not moved outward; at this point adjust locknuts "C" to obtain 1 inch spacing between needle point and turntable top surface.

**D. & E. Needle Landing on Record.**—The relation of coupling between the tone arm vertical shaft and lever "20" determines the landing position of the needle on a 10 inch record. Position of eccentric stud "E" governs the landing of the needle on a 12 inch record; this, however, is dependent on the proper 10 inch adjustment.

To adjust for needle landing, place 10 inch record on turntable; push index lever to reject position and return to the 10 inch position; see that pickup locating lever "17" is tilted fully toward turntable; rotate mechanism through cycle until needle is just ready to land on the record; then see that pin "V" on lever "14" is in contact with "Step T" on lever "17." The correct point of landing is 4-11/16 inches from the nearest side of the turntable spindle; loosen the two screws "D" and adjust horizontal position of tone arm to proper dimension, being careful not to disturb levers "14" and "17". Leave approximately 1/32 inch end play between hub of lever "20" and pickup base bearing, and tighten the blunt nose screw "D"; run mechanism through several cycles as a check, then tighten cone pointed screw "D".

After adjusting for needle landing on a 10 inch record, place 12 inch record on turntable; push index lever to reject and return to 12 inch position; rotate mechanism through cycle until needle is just ready to land on the record; the correct point of landing is 5-11/16 inches from nearest side of spindle. If the landing is incorrect, turn stud "E" until the eccentric end adjusts lever "14" to give correct needle landing. The eccentric end of the stud must always be toward the rear of the motor board, otherwise incorrect landing may occur with 10 inch records.

**F. & G. Record Separating Knife.**—The upper plate (knife) "25" on each of the record posts serves to separate the lower record from the stack and to support the remaining records during the change cycle. It is essential that the spacing between the knife and the rotating record shelf "27" be accurately maintained. The spacing for the 10 inch record is nominally .055 inch, and for the 12 inch record is .075 inch.

To adjust, rotate the knife to the point of minimum

vertical separation from the record shelf and turn screw and locknut "F" to give .052—.058 inch separation. Screw "G" must not be depressed during this adjustment. After setting screw "F", adjust screw "G" so that when its tip is depressed flush with top of record shelf, the vertical spacing between the knife, in its lowest rotational position, and the shelf, is .072—.078 inch.

**H. Record Support Shelf.**—The record shelf revolves during the change cycle to allow the lower record to drop onto the turntable. Both posts are rotated simultaneously by a gear and rack coupled to the main lever "15," and it is necessary that adjustments be such that the record is released from both shelves at the same instant. To adjust, place a 12 inch record on the turntable, rotate mechanism into cycle to the point where tone arm is at maximum distance outward from turntable; lift record upward until it is in contact with both separating knives, then loosen screws "H" and shift record shelves so that the curved inner edges of the shelves are uniformly spaced at least 1/16 inch from record edge. Tighten the blunt nose screw "H," run mechanism through cycle several times to check action, then tighten cone pointed screw "H".

*If record shelves or knives are bent, or not perfectly horizontal, improper operation and jamming of mechanism will occur.*

**J. Tone Arm Rest Support (not shown).**—When the changer is out-of-cycle, the front lower edge of the pickup head should be 5/16 inch above surface of motor board. This may be adjusted by bending the tone arm support bracket, which is associated with the tone arm mounting base, in the required direction.

**K. Trip Pawl Stop Pin.**—The position of the trip pawl stop pin "K" in relation to the main lever "15" governs the point at which the roller enters the cam. By bending the pin support either toward or away from trip pawl bearing stud, the roller can be made to enter the cam later or earlier, respectively. This adjustment should be made so that the roller definitely clears the cam outer guide as well as the nose of the cam plate.

**Lubrication.**—Petrolatum or petroleum jelly should be applied to cam, main gear, spindle pinion gear, and gears of record posts.

Light machine oil should be used in the tone arm vertical bearing, record post bearings, and all other bearings of various levers on underside of motor board.

The felt washer between the turntable and spindle bearing should be soaked in light engine oil whenever the turntable is removed, or as required for proper operation.

Do not allow oil or grease to come in contact with, rubber mounting of tone arm base, rubber bumper, or flexible coupling of drive motor.

## MISCELLANEOUS SERVICE HINTS

Incorrect adjustment of a particular mechanism of the changer is generally exhibited in a specific mode of improper operation. The following relations between effects on operation and the usual mis-adjustments will enable ready adjustment in most cases.

1. For any irregularity of operation, the adjustment of the main lever "15" should be checked first as in "A".
2. Needle does not land properly on both 10 and 12 inch records—Make complete adjustments "D" and "E".
3. Needle does not land properly on 12 inch record but correct on 10 inch—Effect adjustment "E".
4. Failure to trip at end of record—Increase clutch "5" friction by means of screw "B". Also, see that levers "7" and "12" are free to move without touching each other.
5. Pickup strikes lower record of stack or drags across top record on turntable—Adjust lift cable per adjustment "C".
6. Needle does not track after landing—Friction clutch "5" adjustment "B" may be too tight; bind in tone arm vertical bearing; levers "7" and "12" fouled; or pickup output cable twisted.
7. Cycle commences before record is complete—Record is defective, or adjustment "B" of friction clutch "5" is too tight.
8. Wow in record reproduction—Record is defective; flexible coupling between motor and changer mechanism not correctly assembled; or instrument is not being operated at normal room temperature (65° F).
9. Record knives strike edge of records—Records warped; record edges are rough; or knife adjustments "F" and "G" are incorrect.
10. Record not released properly—Adjust record shelf assemblies in respect to shaft by means of adjustment "H".
11. Needle lands in 10 inch position on 12 inch record or misses record when playing both types mixed—Increase tension of pickup locating lever spring "30".

Details, Notes

**Turntable Switch.**—The toggle switch located just in front of the Index and Record Reject Lever controls the current to the turntable motor. To start the turntable, throw the switch to the "ON" position. To stop the turntable throw the switch to the "OFF" position.

**Pickup and Top-Loading Needle Socket.**—The pickup is the new crystal type, with a hole in the top for insertion of needles. When not playing records, the pickup arm should be moved out to the right beyond the turntable and placed at rest on the support with the edge of the pickup arm in the groove and the pickup over the needle gauge plate. The pickup must be in this position to change needles.

To insert a needle initially, loosen the needle screw on the front of the pickup, place needle in hole at top so that it drops down against the needle gauge plate and then tighten up the needle screw.

**Needle Ejector.**—The extending tab on the needle gauge plate of the needle box operates the needle ejector. To change a needle, place pickup in rest position, loosen needle screw and press the extending tab on the needle gauge plate to drop the used needle into the box below. Release tab, allowing the needle gauge plate to swing back, and then insert a new needle in the pickup as described above.

**Record Holder Shelves.**—To place a record on the turntable or to remove records, raise the record holder shelves, by lifting with the fingers under the shelf, and swing clear of outer edge of record. Also push back vertical lever adjacent to the rear record holder post. You now have clear access to the turntable. Before loading the magazine for Automatic Operation swing the record holder shelves back into position.

**Automatic Operation**

1. See that pickup is over needle gauge plate with needle properly in place. If not, complete a "cycle" as explained in the first paragraph under "OPERATION."
2. With Index and Record Reject Lever at "MANUAL," place the first of the series of records on the turntable and the remainder of the series (up to seven 10-inch or six 12-

inch records) on the record holder posts (as shown in Figure 1). The records should be arranged in the desired order with the desired selection face up and the last selection on top.

3. Set the Index and Record Reject Lever to the proper position. (See CONTROLS:—INDEX AND RECORD REJECT LEVER.)

4. Throw Turntable Switch to the left—"ON"—turntable should commence to revolve.

5. When turntable has attained speed, lift pickup and lower gently on to the record so that the needle point enters the outside groove.

6. Close the lid of the cabinet to eliminate mechanical reproduction of sound by the needle.

The whole series of records will now play without further attention, and the last record will repeat until the Turntable Switch is turned off. Allow the record-changing mechanism to complete its cycle before the turntable is stopped. Then lift the pickup, swing the arm to the right beyond the edge of the record and lower it onto the pickup rest with pickup over needle gauge plate. The record player is then ready for reloading, or for manual operation.

**Manual Operation**

To play records manually:

1. Proceed as in step 1, under "AUTOMATIC OPERATION."
2. Place record on turntable with desired selection upwards.
3. Set Index and Record Reject Lever to "MANUAL" position.
4. Proceed as in steps 4, 5 and 6 under "AUTOMATIC OPERATION."

When you have finished playing, be sure that the turntable has stopped and the pickup is in the rest position over needle gauge plate. Never leave pickup with needle resting on a record or on the turntable.

Good reproduction can only be obtained with the turntable revolving at 78 revolutions per minute. For speed check and regulation see INSTALLATION,

**IMPORTANT — ANTENNA ALIGNMENT**  
 5-M-294 — CHASSIS 5530

Due to the large variation in electrical capacity of different automobile antennas it is necessary to adjust the receiver to the particular antenna used after installation has been made for maximum performance. Model 5-M-294 is equipped with two adjusting screws to accomplish this alignment. The green tag on the side of the receiver case shows the location of the two adjusting screws.

To align, first turn the receiver on with the center knob shown in Fig. 3. Press the tuning knob IN. This places the tuning mechanism in the manual operating position. Tune to a weak station near 1400 K.C. and adjust the trimmer directly below the antenna connector to maximum volume. Next tune the receiver to a weak station near 600 K.C. and adjust the trimmer nearest the power pack case for maximum volume. Repeat the adjustments for greatest accuracy.

**AUTOMATIC**

To set the automatic buttons, first pull the tuning knob OUT. This shifts the tuning mechanism to the Automatic position. Press Automatic button A and turn the volume up and with a small screw driver carefully adjust screw A at bottom of the Automatic unit shown in Fig. 3 to a local station between 1500 to 1050 K.C. Set to exact position of maximum volume and clearest tone. Next, adjust trimmer A1 for maximum volume

and clearest tone on the same station. It should be noted that there are two trimmer adjustments to each station button. To set the second button press B and tune trimmer B to a local station between 1250 to 850 K.C. Trim with adjustment B1 to best volume and tone on the same station. To set the third button press C and tune trimmer screw C to a station between 1000 to 700 K.C. and corresponding adjustment C1 again for maximum volume of the selected station. Follow the same procedure for the fourth button by pressing button D and using trimmers D and D1 on a local station between 885 to 540 K.C. After all four buttons have been set, cut the call letters of stations selected from the gummed call letter sheet supplied with the receiver. Remove the escutcheon over the automatic buttons by taking out the three screws which hold it in position. Remove the celluloid strip and paste the station call letters in their proper positions by wetting the back of the call letter sticker. The four outlines on the celluloid strip provide the exact points at which the gummed labels are placed. After the call letter stickers are attached replace the celluloid and the escutcheon plate.

**SOCKET VOLTAGES**

6	With Set Connected to Car Antenna — Tune to Weak Station Around 600 K. C. — Trim Antenna Padder "G" for Maximum Peak Output.							

**ANTENNA ALIGNMENT**  
 (Models 5-M-291 and 5-M-294)

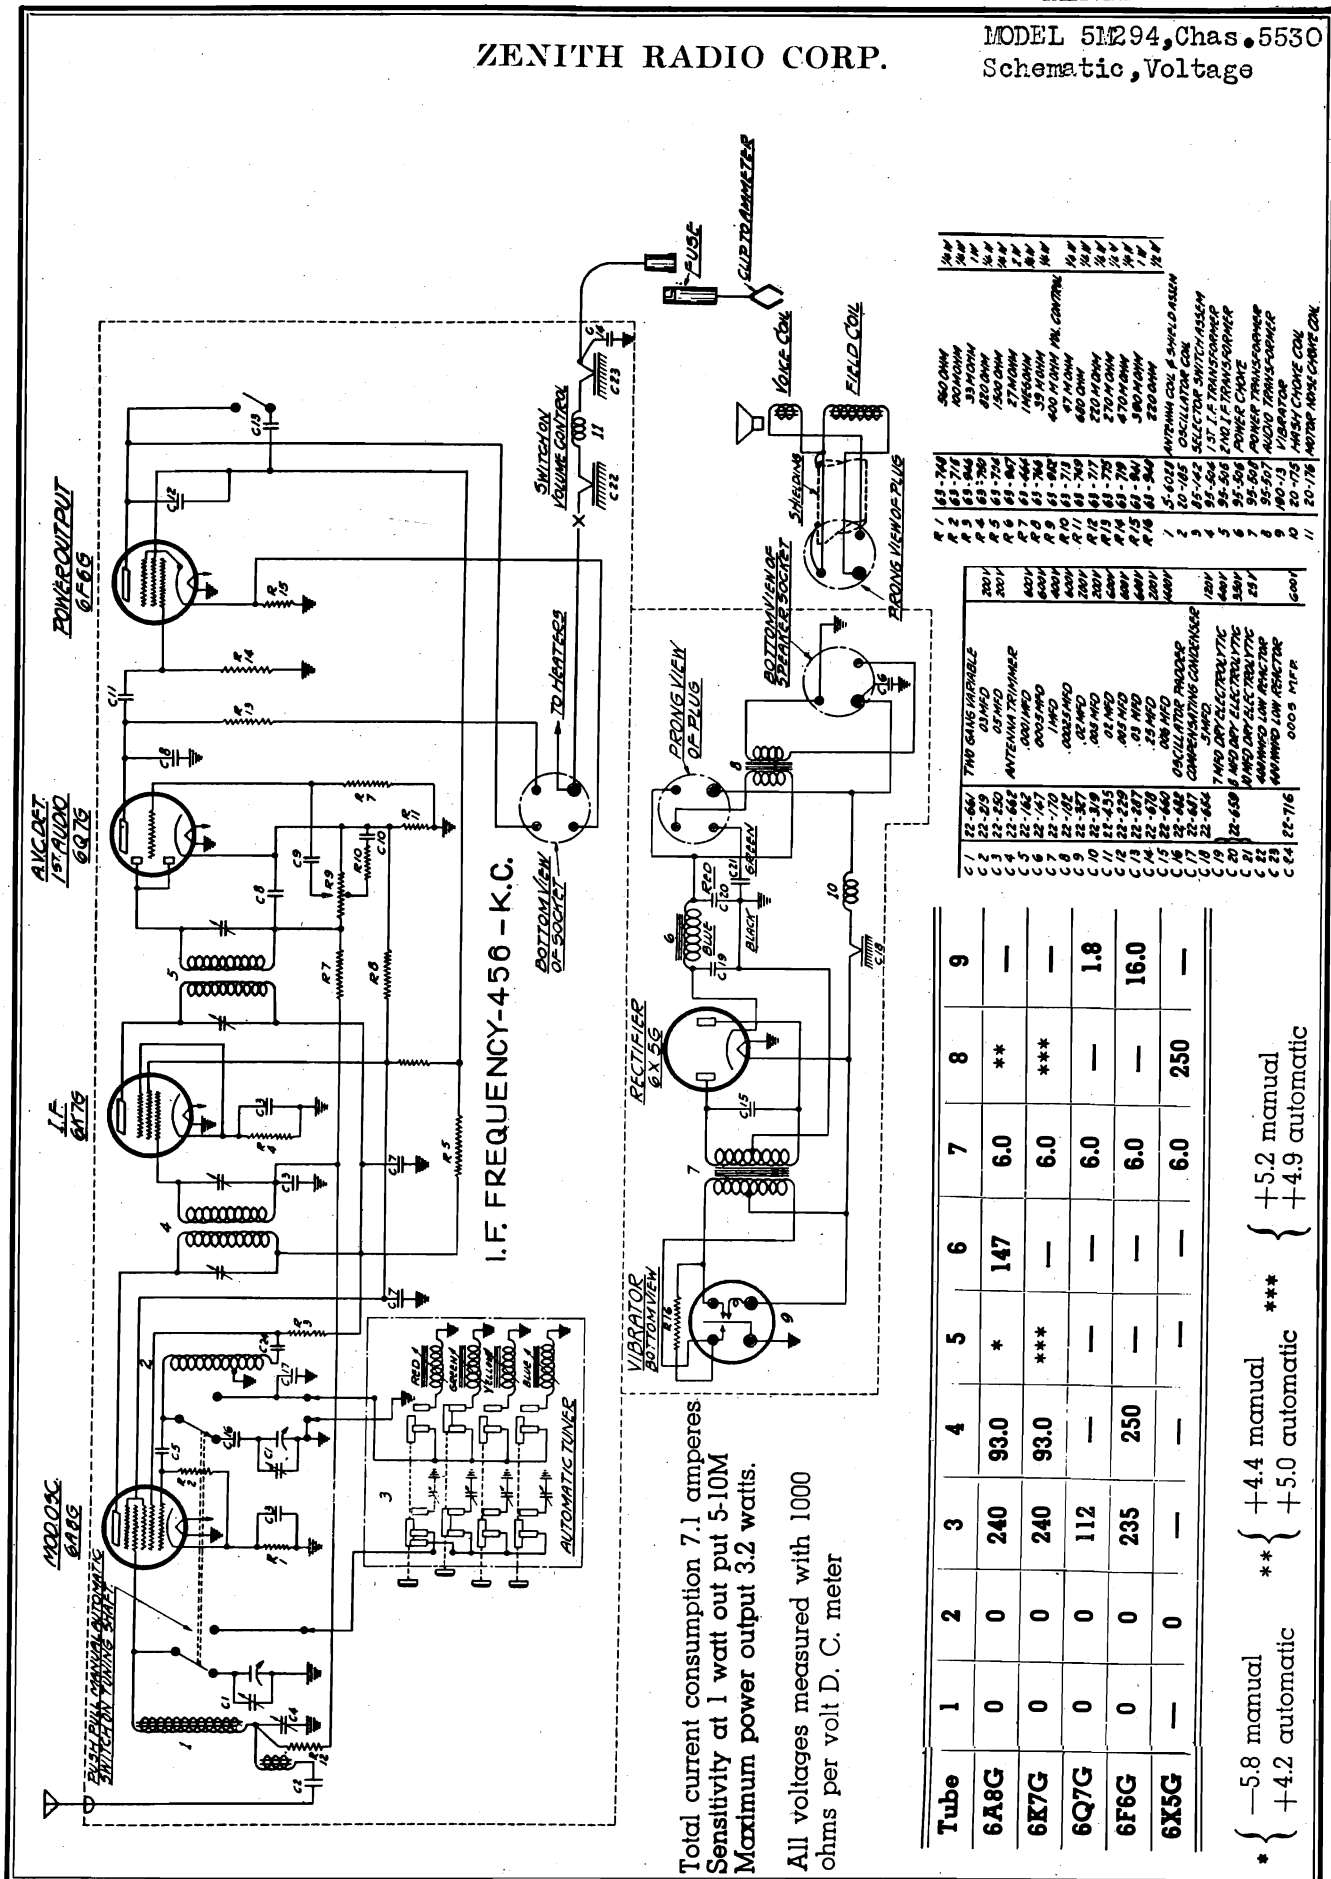

There is such a great variation in the capacity of different antennas that it is impossible to meet every condition without some means of variable antenna alignment. To accomplish this, 2 screw adjustments are provided on the receiver case as shown in Figure 3. After the set has been completely installed, the proper method of antenna alignment is as follows: Tune in a weak signal at or near 1400 K.C. and carefully adjust the lower screw as indicated in Figure 3 to loudest signal strength. Turn the tuning dial to a station at or near 600 K.C. and carefully adjust the upper left screw, also shown in Figure 3. Do not use a loud local signal for either of the adjustments. The adjustments at both 600 and 1400 K.C. should be repeated not only as a check but for more perfect alignment.

CHASSIS 5532A AUTOMATIC

Set the buttons for automatic operation proceed as follows:

1. Select a station in the tuning range of the No. 1 button.
2. Place the band switch on BROADCAST and tune this station manually in the conventional manner.
3. Set the band switch to the AUTOMATIC position and press No. 1 button.
4. Remove the cap above the button by inserting a pin or your finger nail under the edge and pulling out.
5. Turn the exposed screw in either direction until the previously selected station is heard. (Recheck by switching back to BROADCAST.) Adjust the screw very carefully for best tone, greatest freedom from noise, and maximum volume.
6. Replace cap and cut the call letters of the station from the call sheet furnished with the receiver. Wet the rear surface of the tab, and place it in the space provided on the cap.
7. Follow the above operations in setting the remaining four buttons.
8. The call letter sheets should be preserved for use in the event it is desired to change any of the buttons to some other station.

5 Tube A.C. receiver—Chassis No. 5535BT

GENERAL

This receiver is a modern five tube superheterodyne with a dual tuning range covering frequencies between 18.2 to 5.4 megacycles and 540 to 1750 kilocycles. The tuning is explained under "Operation."

UNDER NO CIRCUMSTANCES SHOULD THIS RECEIVER BE CONNECTED TO DIRECT CURRENT (D. C.).

This receiver is designed to operate on 50 to 100 cycle alternating current (A.C.) and may be adjusted for use on either 110 or 235 Volt power lines by means of the switch on top of the power transformer. The proper position of the switch for either voltage is marked on the transformer case.

CHASSIS 5535BT

ZENITH RADIO CORP.

CHASSIS 5640, 5804A Secret Volume Governor

Where it is desired to limit the maximum volume of the receiver to a pre-determined level such as for hospital use, use in public places, etc., this may be done as follows:

1. Tune the receiver carefully to a local station, and adjust the volume to the loudest desired setting.
2. Remove the knob by pulling directly away from the panel, and insert the short headless screw into the hole provided in the rear of the knob closest to the right side of the elongated cut-out around the volume control shaft.
3. It may be necessary to move the screw to the next hole in either direction before it is definitely determined what volume level is desired.

Alignment Procedure

ZENITH RADIO CORP.

**Alignment Procedure**

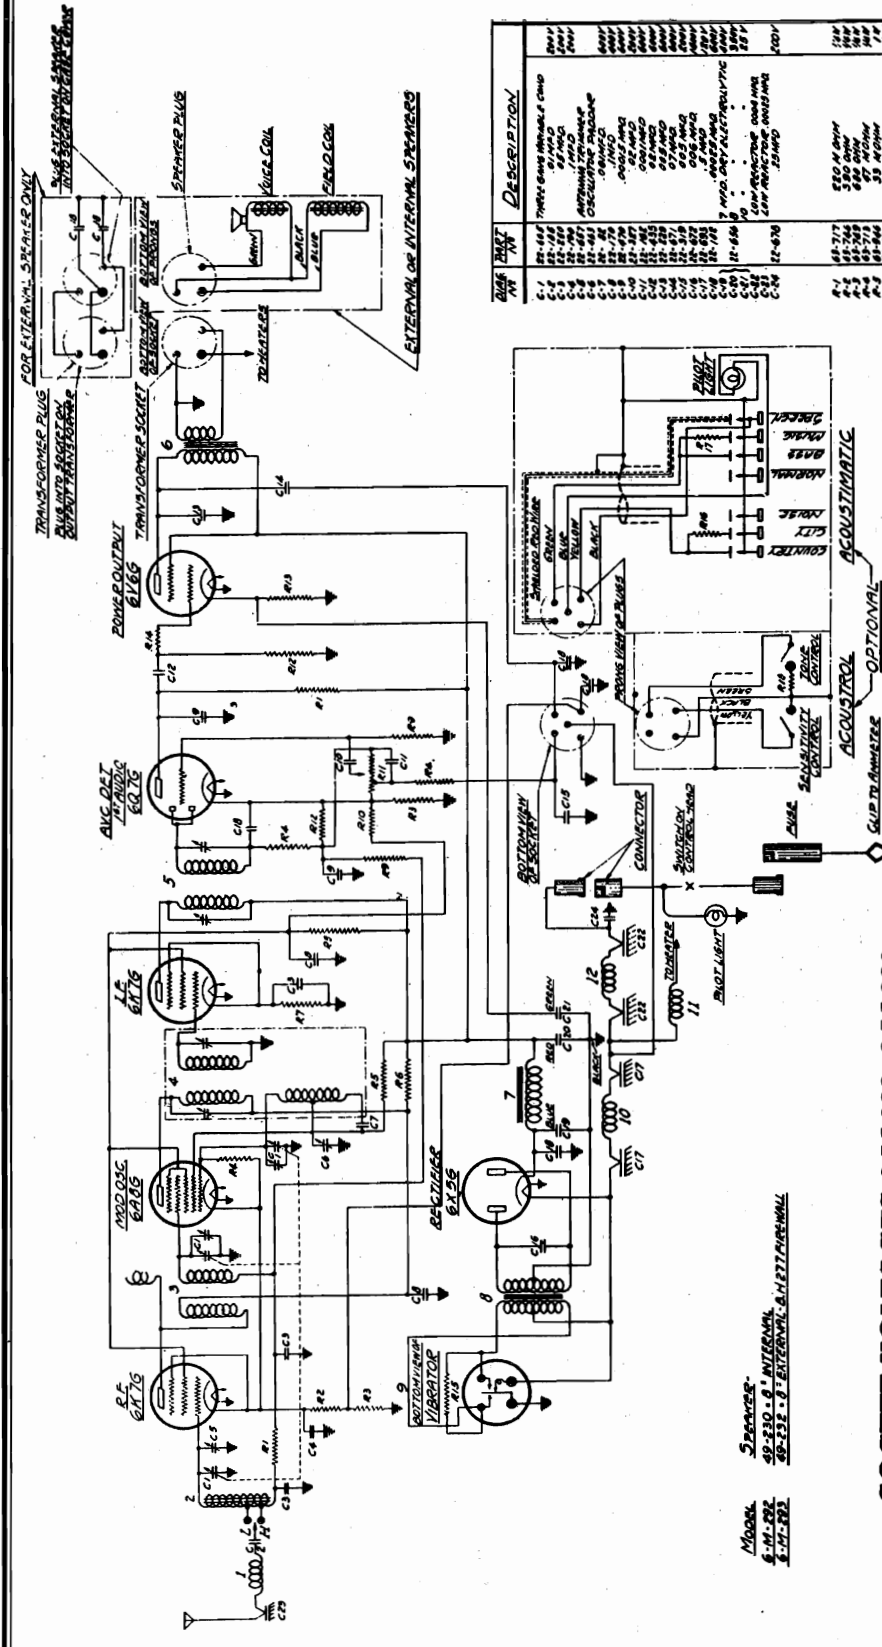

- (1) Connect the output leads of the signal generator to the grid of the first detector and receiver ground. Also connect an output meter across the speaker transformer leads.
- (2) Set the signal generator at 456 K. C. and carefully adjust the four I. F. trimmers to the point giving the highest reading of the output meter. These adjustments should be repeated several times to secure the greatest accuracy.
- (3) All adjustments should be made using as weak an output from the signal generator as possible in order to prevent the A.V.C. action from affecting the output readings.
- (4) Change the signal generator leads to the antenna and ground terminals of the receiver.
- (5) Set signal generator at 1500 K. C., switch receiver to broadcast band and adjust oscillator trimmer on gang for correct dial reading at 200 meters. Also adjust antenna trimmer on gang to resonance.
- (6) Set signal generator to 600 K. C. and rock pointer past 500 meters on dial while adjusting the broadcast padder (adjacent to gang) to combination giving the greatest output reading.
- (7) Repeat operation No. 4.
- (8) Set signal generator at 375 K. C. Switch receiver to long wave band and adjust long wave oscillator trimmer (located on oscillator coil underneath chassis) for correct dial reading at 800 meters. Also adjust trimmer on top of coil adjacent to gang for greatest output reading.
- (9) Set the signal generator at 167 K. C. Rock the pointer past 1800 meters on dial and adjust the long wave padder to point giving the highest output.
- (10) Repeat operation No. 7.

**ALIGNMENT PROCEDURE**

- (1) Connect the output leads of the signal generator to the grid of the first detector and receiver chassis. Also connect an output meter across the speaker transformer leads.
- (2) Set the signal generator at 456 K.C. and carefully adjust the four I.F. trimmers to the point giving the highest reading of the output meter. These adjustments should be repeated several times to secure the greatest accuracy.
- (3) All adjustments should be made using as weak an output from the signal generator as possible in order to prevent the A.V.C. action from affecting the output readings.
- (4) Change the signal generator leads to the antenna and chassis of the receiver.
- (5) Adjust the wave trap (located on rear of chassis) for minimum output reading.
- (6) Set signal generator at 6 M.C. Switch receiver to band B and adjust osc. trimmer on gang for correct dial reading at 50 meters.
- (7) Set signal generator at 1400 K.C. Switch receiver to band A and adjust broadcast trimmer (see diagram) for correct dial reading at 215 meters. Also adjust det. trimmer on gang for greatest output reading.
- (8) Set signal generator to 600 K.C. and rock pointer past 500 meters on dial while adjusting the broadcast padder (adjacent to gang) to combination giving the greatest output reading.
- (9) Repeat operation No. 6.
- (10) Set the signal generator at 17 M.C. Switch the receiver to band C and adjust short wave trimmer while rocking pointer past 17.5 meters on dial to combination giving the greatest output.
- (11) Set the signal generator at 375 K.C. Switch receiver to Band D and adjust the long wave trimmer for correct dial reading at 800 meters. Also adjust the long wave ant. trimmer to resonance.
- (12) Set the signal generator at 167 K.C. Rock the pointer past 1800 meters on dial and adjust the long wave padder to point giving the highest output.
- (13) Repeat operation No. 10.

**ANTENNA ALIGNMENT**

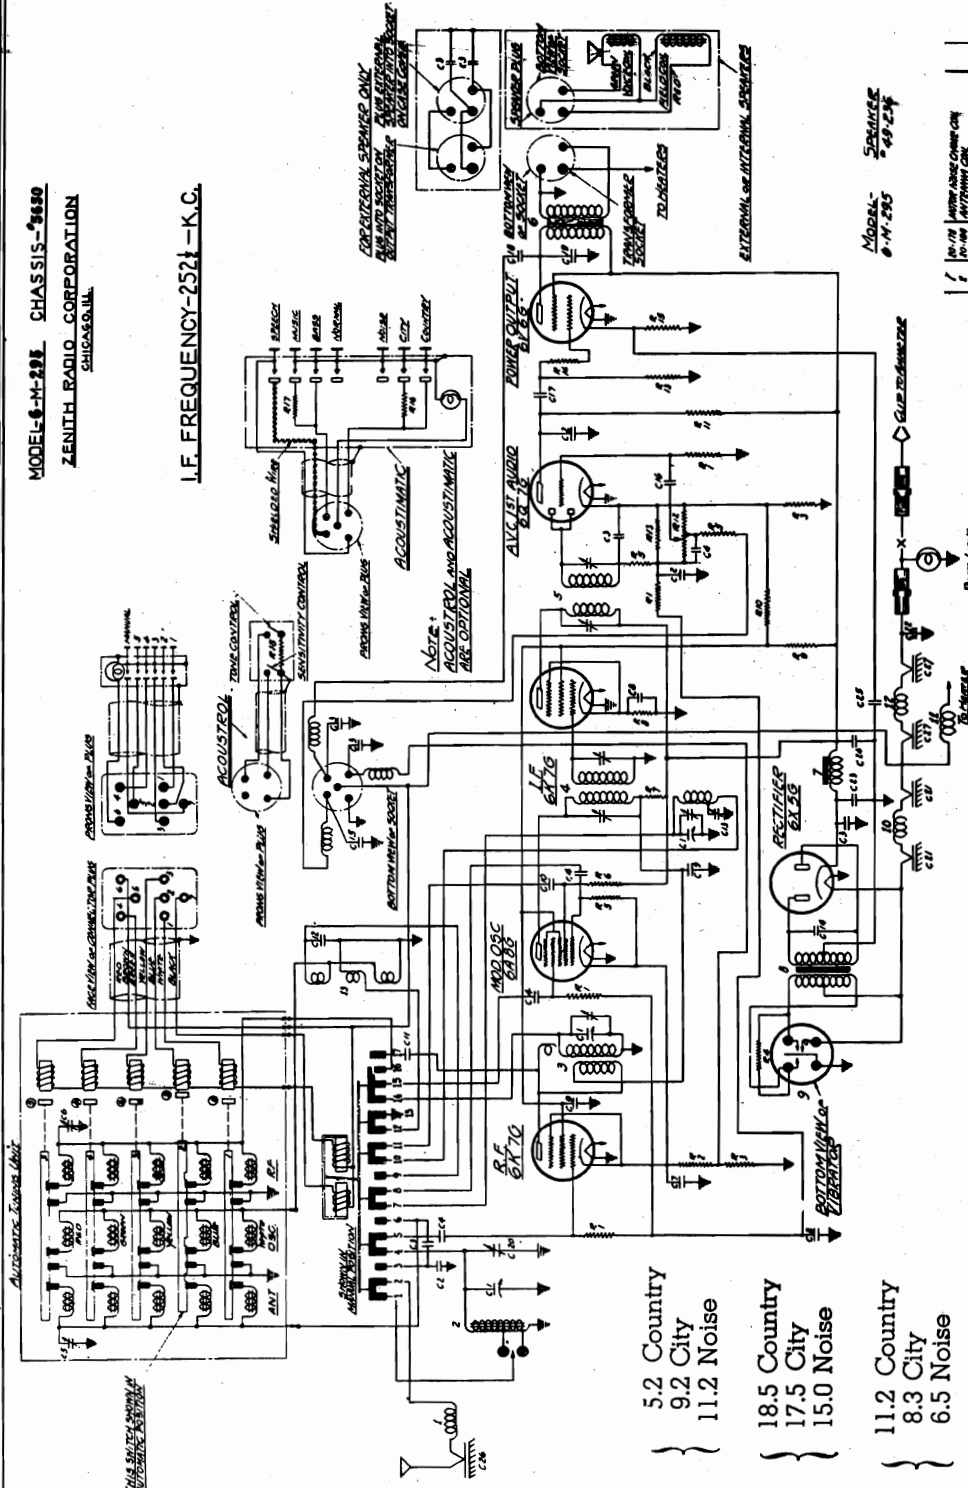

Fig. 8 shows the location of the antenna tap jacks on the side of the receiver case. Remove the capping plug from over this jack assembly, and insert the antenna pin lead in the "H" or "L" position, depending on the capacity of the antenna being used. The "H" position must be used for antennas with a capacity in the range of from 100 to 500 mmfd. The "L" connection must be used for low capacity antennas of from 0 to 125 mmfd. Compare this listing with that given under the various antennas, and the proper position will easily be recognized. After selecting the position desired, place the capping plug back over the hole to prevent motor noise from entering into the antenna circuit of the receiver. Connect the antenna proper by means of the Delco-Remy connector shown in Fig. 8.

 Chassis 5650  
 Socket, Trimmers  
 Antenna Data, Tuner

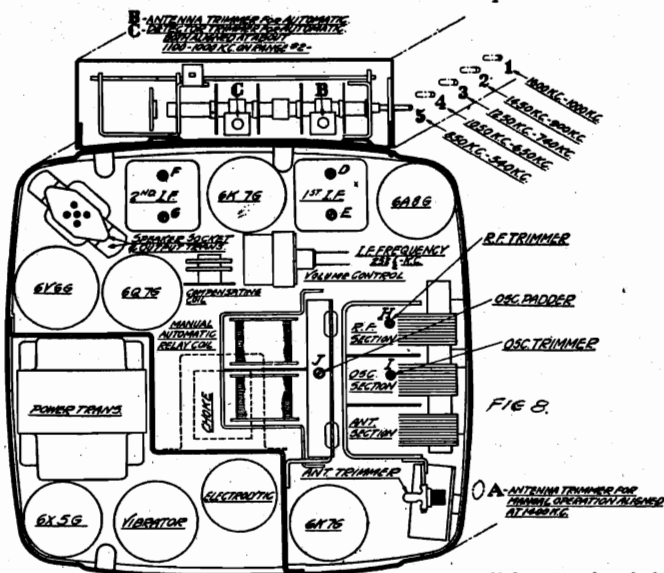

ZENITH RADIO CORP.

ANTENNA ALIGNMENT

**Manual Tuning:** Press the MANUAL button on the automatic key board.

This disconnects the automatic system and allows operation of the receiver from the standard tuning mechanism. After adjusting the dial calibration accurately, turn the volume control up full and tune to a weak station near 1400 K.C. Adjust the antenna trimmer A (Fig. 8) to the point of greatest volume. This completes antenna alignment for manual operation. The trimmer does not have to be adjusted at any other point on the dial.

**Automatic Tuning:** Press automatic button 2 (Fig. 8) This will disconnect the manual tuning mechanism and place the automatic buttons into service. After button 2 has been pressed, turn adjusting screw 2 in either direction until a weak station between 1100 to 1000 K.C. is heard. Now adjust trimmers B and C on the automatic assembly for maximum signal strength of the weak station tuned in by the number 2 adjusting screw. The automatic is in complete resonance with the antenna over the entire automatic button range and need not be resonated at any other button setting. Adjusting screw 2 may now be tuned to a local station as outlined under "AUTOMATIC" with no further attention to adjustments B or C.

AUTOMATIC

Study Fig. 8 carefully. Although simple in adjustment, best results will only be obtained if made accurately and by the following procedure.

1. Press button 1. (This button will be on the left if automatic unit is mounted on edge of instrument panel.)
2. Adjust automatic trimmer screw (until a desired local station between 1600 and 1000 K.C. is heard. Turn the screw slowly back and forth over the station as if tuning the dial of a receiver, for clearest reception and best tone quality and allow the screw setting to remain at that point.
3. Press button 2 and tune for a station between 1450 and 900 K.C. on automatic adjusting screw 2.
4. Follow above procedure for buttons 3, 4 and 5 using the ranges shown on Fig. 8.

5. Remove the chrome bezel over the parts adjacent to the automatic buttons and insert the station call letters cut from the sheet supplied. After placing the proper station calls in correct order over the port holes, fasten the escutcheon back in place.

6. Repeat careful adjustment of each automatic trimmer pressing the corresponding button in order from 1 to 5 to obtain best tone, loudest signal and greatest freedom from noise.

Alignment, Trimmers  
Tuner Data

ZENITH RADIO CORP.

**NOTE:** This receiver is equipped with a fixed-variable sensitivity control located on the chassis base below the tuning control shaft of the variable condenser. (See Fig. 5.) The control can be adjusted with a screw driver either from above or below the chassis, and is set at the factory to a position which gives a sensitivity of 10 microvolts at 1 watt output. In practice it is found advisable to hold the receiver to this level as any higher sensitivity might result in increased motor noise or excessive background noise. Unless laboratory equipment capable of accurately measuring the input and output of the receiver is available, it is not advisable to alter this setting.

**MANUAL DIAL ADJUSTMENT:** The manual control dial must be aligned with the receiver for correct calibration. To do this, turn the manual tuning knob in one direction as far as it will go. Now do the same in the opposite direction. Then tune in a station of known frequency, and note if the dial reading corresponds. If the frequency reading is not correct, hold the tuning knob firmly and move the dial drum with your fingers through the bezel to the correct frequency reading of the station being received.

**AUTOMATIC DIAL SYNCHRONIZATION:** Before setting the station adjusting screws for automatic tuning, it may be necessary to synchronize the automatic dial to the receiver which is done as follows: Turn on the receiver, and try to tune in a station with the manual tuning control. If no station can be picked up, push the automatic station selector button until a position is found where stations can be tuned in manually. Remove the automatic dial assembly by pulling out from the rear and turn the station indicator drum downward until the word "Dial" appears in the opening. The adjusting screws in the receiver can now be resonated for the stations shown around the automatic dial as the automatic button is operated. It is very important that these adjusting screws be set on a weak signal from the station so that the circuit may be sharply tuned. A very short piece of wire used as an antenna will hold down the signal strength. Always be sure the antenna characteristics are similar to actual car conditions. A 38 mmfd. condenser from antenna to ground will provide the necessary input capacity.

**AUTOMATIC TUNING ADJUSTMENTS:** 1. Turn the receiver on and allow it to operate until thoroughly heated. Loosen the screws holding the cover plate over the automatic adjustments, and slide it upward exposing the adjusting screws and recording strip. This plate is on the front of the receiver. (See Fig. 4.)

2. Push the automatic station selector button until the word "Dial" is at the automatic dial window. Tune in manually the station whose call letters are in the No. 1 position on the dial (the lowest frequency station—see Fig. 3) and note the program so that it can be identified. Push the automatic station selector button once, and this station's call letters will appear at the automatic window.

3. With a small screw driver, turn the station setting screw A (see Fig. 4) in the upper row to the right or left until that station is tuned in accurately. Now adjust the corresponding screw A1 in the lower row until maximum volume is obtained. Make these adjustments very carefully as it is quite easy to pass the resonant point due to the unusual selectivity of the receiver.

4. Press the automatic station selector button until "Dial" again is at the automatic window and tune in manually the station whose call letters are in the No. 2 position (the next higher frequency) on the automatic dial. Press the automatic station selector button twice to bring the No. 2 station's call letters in view, and adjust B and B1 screws to this station. Repeat this procedure until each of the five pairs of adjusting screws have been carefully set to their respective stations. It is necessary that the

**IMPORTANT:** Unless certain dummy antenna capacities are employed with either the signal generator or in making adjustments on stations, the receiver will not respond properly. The values provided in the Zenith dummy antenna unit shown in Fig. 6 are identical with the conditions in the Ford car, and if adjusted accordingly the instrument will operate properly when reinstalled in the automobile. The Zenith dummy antenna S6740 is especially priced at 25c net to service stations, and should be purchased for use in servicing Zenith built Ford receivers.

setting of the adjusting screws be repeated in the order given to be sure that they are properly set for maximum performance.

If the station setup on the automatic tuning dial should appear in the wrong position, the dial can easily be re-synchronized to the receiver as ex-

plained under "Dial Synchronization." If it is necessary to examine the automatic dial mechanism or change call letters it may easily be removed from the speaker housing by pressing the spring catch directly beneath the assembly and pulling out from the rear.

If difficulty is experienced in setting the adjusting screws for the desired station, first turn the antenna trimmer screw down tight, and then adjust the station setting screw (oscillator) to the station, and follow with a readjustment of the antenna trimmer screw for resonance.

**ALIGNMENT:** I. F. Connect signal generator set at 455 K. C. through .1 mfd. condenser direct to 6A7 grid cap. Adjust I. F. trimmers A, B, C, D, (Fig. 5) to resonance. This should be done with the volume control of the receiver on full, and the generator signal reduced to a weak level.

**Wave Trap:** Remove signal generator lead from 6A7 grid, and attach to 78 R. F. tube grid. Using the same signal frequency of 455 K. C. carefully adjust the wave trap trimmer E for minimum response with a strong generator signal.

**R. F.** Press the automatic button to where the "Dial" position shows, or until the set can be tuned manually. Now rotate the manual tuning control until the condenser plates are completely out of mesh. Remove the generator lead from the 78 R. F. tube and connect it direct through a Zenith dummy antenna unit (Zenith part No. S6740) to the antenna socket on the receiver. Set the signal generator to 1580 K. C., and adjust the oscillator trimmer F on the gang condenser to resonance. Reset the signal generator to 1400 K. C. turn the dial until the signal is heard and adjust the gang condenser trimmer G to maximum response. Reset the signal generator to 600 K. C., and again turn the manual dial until the signal is heard. Rock the condenser gang slightly while adjusting padder H to maximum response at this point.

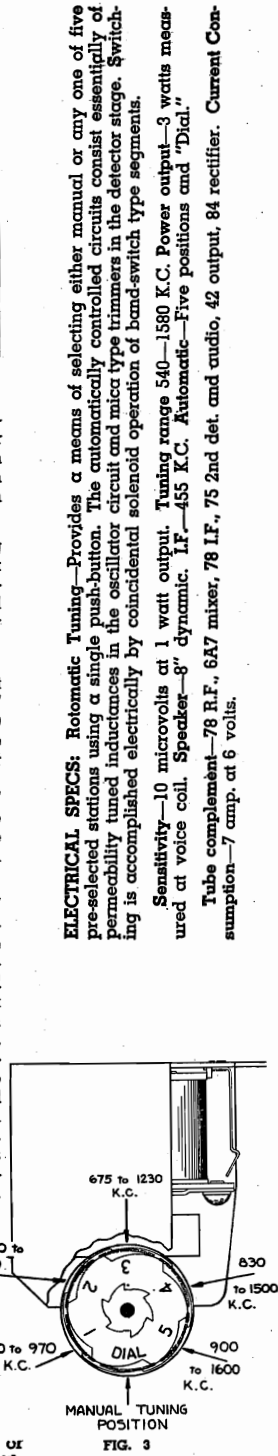

FIG 6 DUMMY ANTENNA REQUIREMENTS. Figure 6 shows the dummy antenna requirements necessary where the special Zenith dummy connector S6740 is not available.

**ELECTRICAL SPECS:** Rotomatic Tuning—Provides a means of selecting either manual or any one of five pre-selected stations using a single push-button. The automatically controlled circuits consist essentially of permeability tuned inductances in the oscillator circuit and mica type trimmers in the detector stage. Switching is accomplished electrically by coincidental solenoid operation of band-switch type segments.

**Sensitivity**—10 microvolts at 1 watt output. Tuning range 540—1580 K.C. Power output—3 watts measured at voice coil. Speaker—8" dynamic. I.F.—455 K.C. Automatic—Five positions and "Dial."

**Tube complement**—78 R.F., 6A7 mixer, 78 I.F., 75 2nd det. and audio, 42 output, 84 rectifier. Current Consumption—7 amp. at 6 volts.

CHASSIS 5517A

IMPORTANT!

Connect ordinary single wire antenna to A. Jumper wire placed between Z and G (shipped from factory in this manner.)  
 When using a ZENITH DOUBLET ANTENNA, remove jumper wire between Z and G and attach doublet lead-in to A and Z.

CHASSIS 5517A ALIGNMENT PROCEDURE

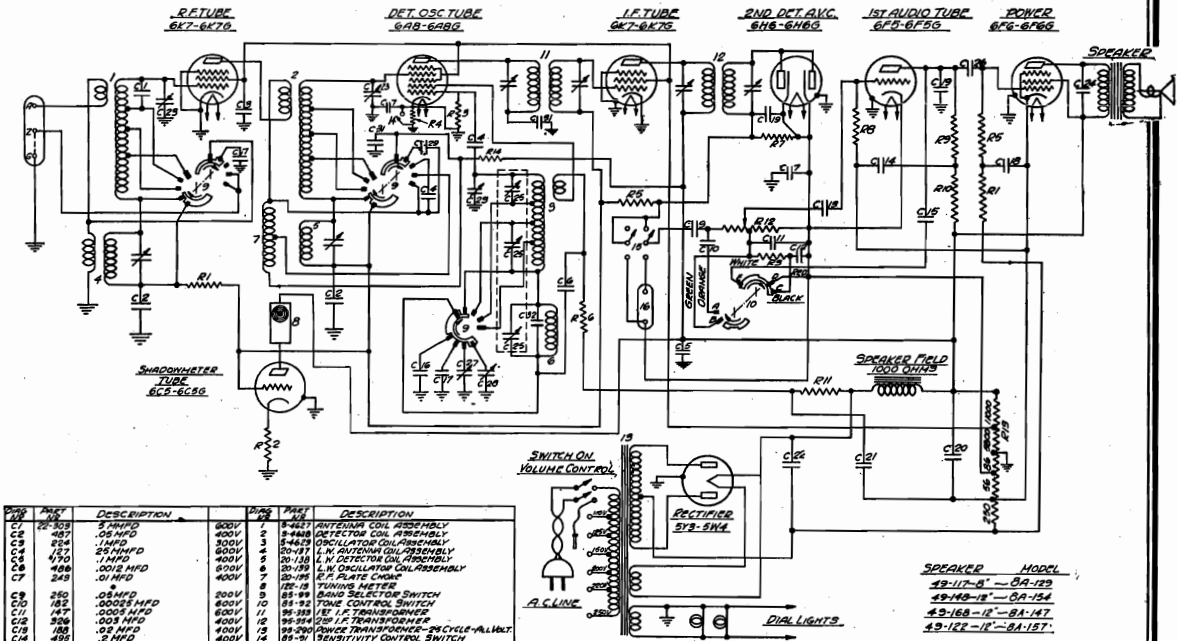

- (1) Connect the output leads of the signal generator to the grid of the first detector and receiver ground. Also connect an output meter across the speaker transformer leads.
- (2) Set the signal generator at 456 K.C. and carefully adjust the four I.F. trimmers to the point giving the highest reading of the output meter. These adjustments should be repeated several times to secure the greatest accuracy.
- (3) All adjustments should be made using as weak an output from the signal generator as possible in order to prevent the A.V.C. action from affecting the output readings.
- (4) Change the signal generator leads to the antenna and ground terminals of the receiver.
- (5) Adjust the wave trap (located on rear of chassis) for minimum output reading.
- (6) Set signal generator at 6 M.C. Switch receiver to band B and adjust osc. trimmer on gang for correct dial reading at 50 meters.
- (7) Set signal generator at 1400 K.C. Switch receiver to band A and adjust broadcast trimmer (see diagram) for correct dial reading at 215 meters. Also adjust det. trimmer on gang for greatest output reading.
- (8) Set signal generator to 600 K.C. and rock pointer past 500 meters on dial while adjusting the broadcast padder (adjacent to gang) to combination giving the greatest output reading.
- (9) Repeat operation No. 6.
- (10) Set the signal generator at 17 M.C. Switch the receiver to band C and adjust short wave trimmer while rocking pointer past 17.5 meters on dial to combination giving the greatest output.
- (11) Set the signal generator at 375 K.C. Switch receiver to Band D and adjust the long wave trimmer for correct dial reading at 800 meters. Also adjust the long wave ant. trimmer to resonance.
- (12) Set the signal generator at 167 K.C. Rock the pointer past 1800 meters on dial and adjust the long wave padder to point giving the highest output.
- (13) Repeat operation No. 10.

Location of tubes and trimmers

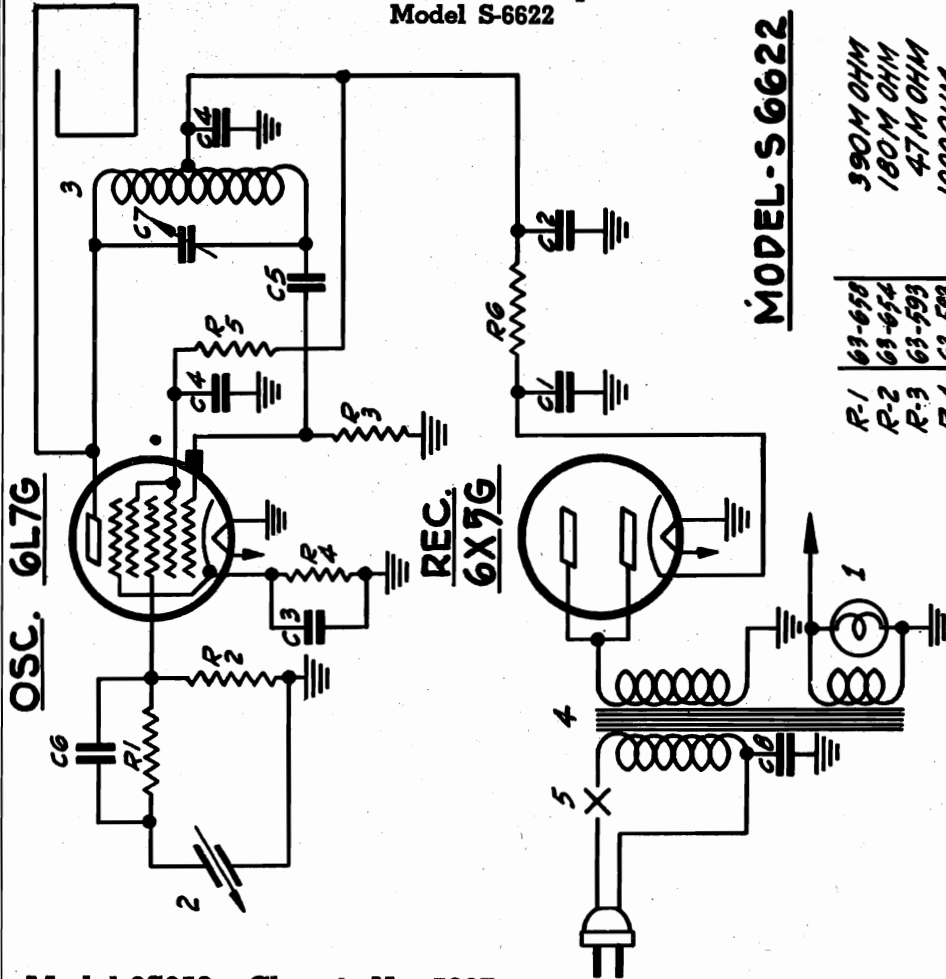

All voltages measured from chassis to point indicated using a 1000 ohm per volt meter. Antenna disconnected. Volume control at minimum. Band switch on manual B.C. position. Line voltage 114 v. (A) Grid bias for 6A8 and 6K7 tubes measured from chassis to K of 6J5 tube is neg. 1.3 volts.

ZENITH RADIO CORP.

MODEL 200  
Schematic

MODEL 200

MODELS 1102,1106, and 834. CHASSIS 1002

All components used in these models are the same as those used in Zenith Chassis 1001 - 1001A excepting the following changes.

Parts added

26-75 Complete Dial and Drive Assem.

26-73 Dial scale only

22-305 (2) 35 mfd. Condensers

22-245 Padder

S-3317 Long wave ant coil Assem.

S-3318 Long wave osc. coil ..

S-3321 Long Wave Detector Coil Assem.

The long wave band has two trimmers on each stage. The oscillator stage has a trimmer and padder assembly of the nut and screw type. The nut is the trimmer and the screw is the padder.

The detector and R.F. stages each have two trimmers whose actions are dependent. The arrangement consists of a coupling condenser and a coil trimmer.

The coil trimmer can be distinguished in that one side is grounded. Maximum gain with this system is obtained by having the coupling condenser with as much capacity as possible and still be able to obtain a peak on the coil trimmer.

BALANCING PROCEDURE FOR LONG WAVE

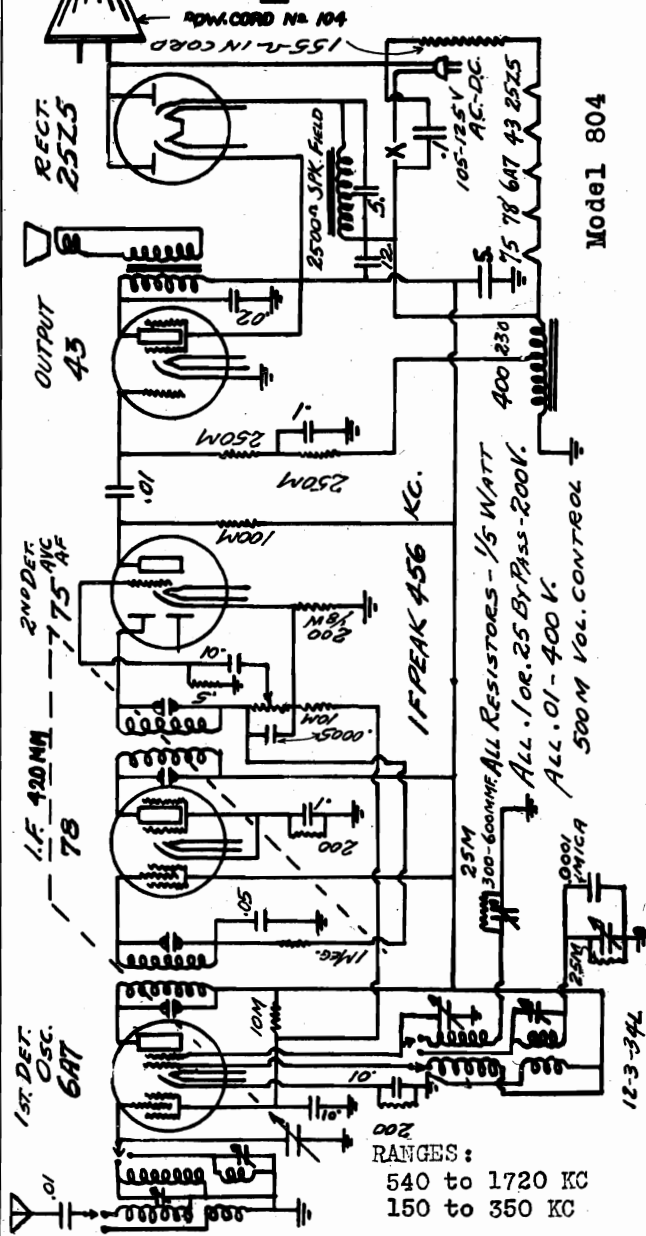

Connect service oscillator to antenna post and set at 375 KC. Set dial at 375 KC. Adjust nut on oscillator trimmer assembly to bring in signal. Open R.F. and detector coil trimmers as far as possible and still leave enough capacity for peaking (about 2 or 3 turns). Open coupling condensers until what appears to be resonance is obtained. Then repeak coil trimmers to resonance. Remember the resonance obtained by means of the coupling condensers is not true resonance and the coil trimmers must be re-adjusted for true resonance.

Move I.F. selector switch to 160 KC. and set dial at this point. Adjust padder screw in oscillator coil assembly for maximum gain, rocking condenser to reach this point, wherever it happens to fall. Repeak 375 KC. as it will be thrown off by the movements of the padder.

MODEL 804  
Schematic, Alignment

ZENITH RADIO CORP.

Socket, Trimmers

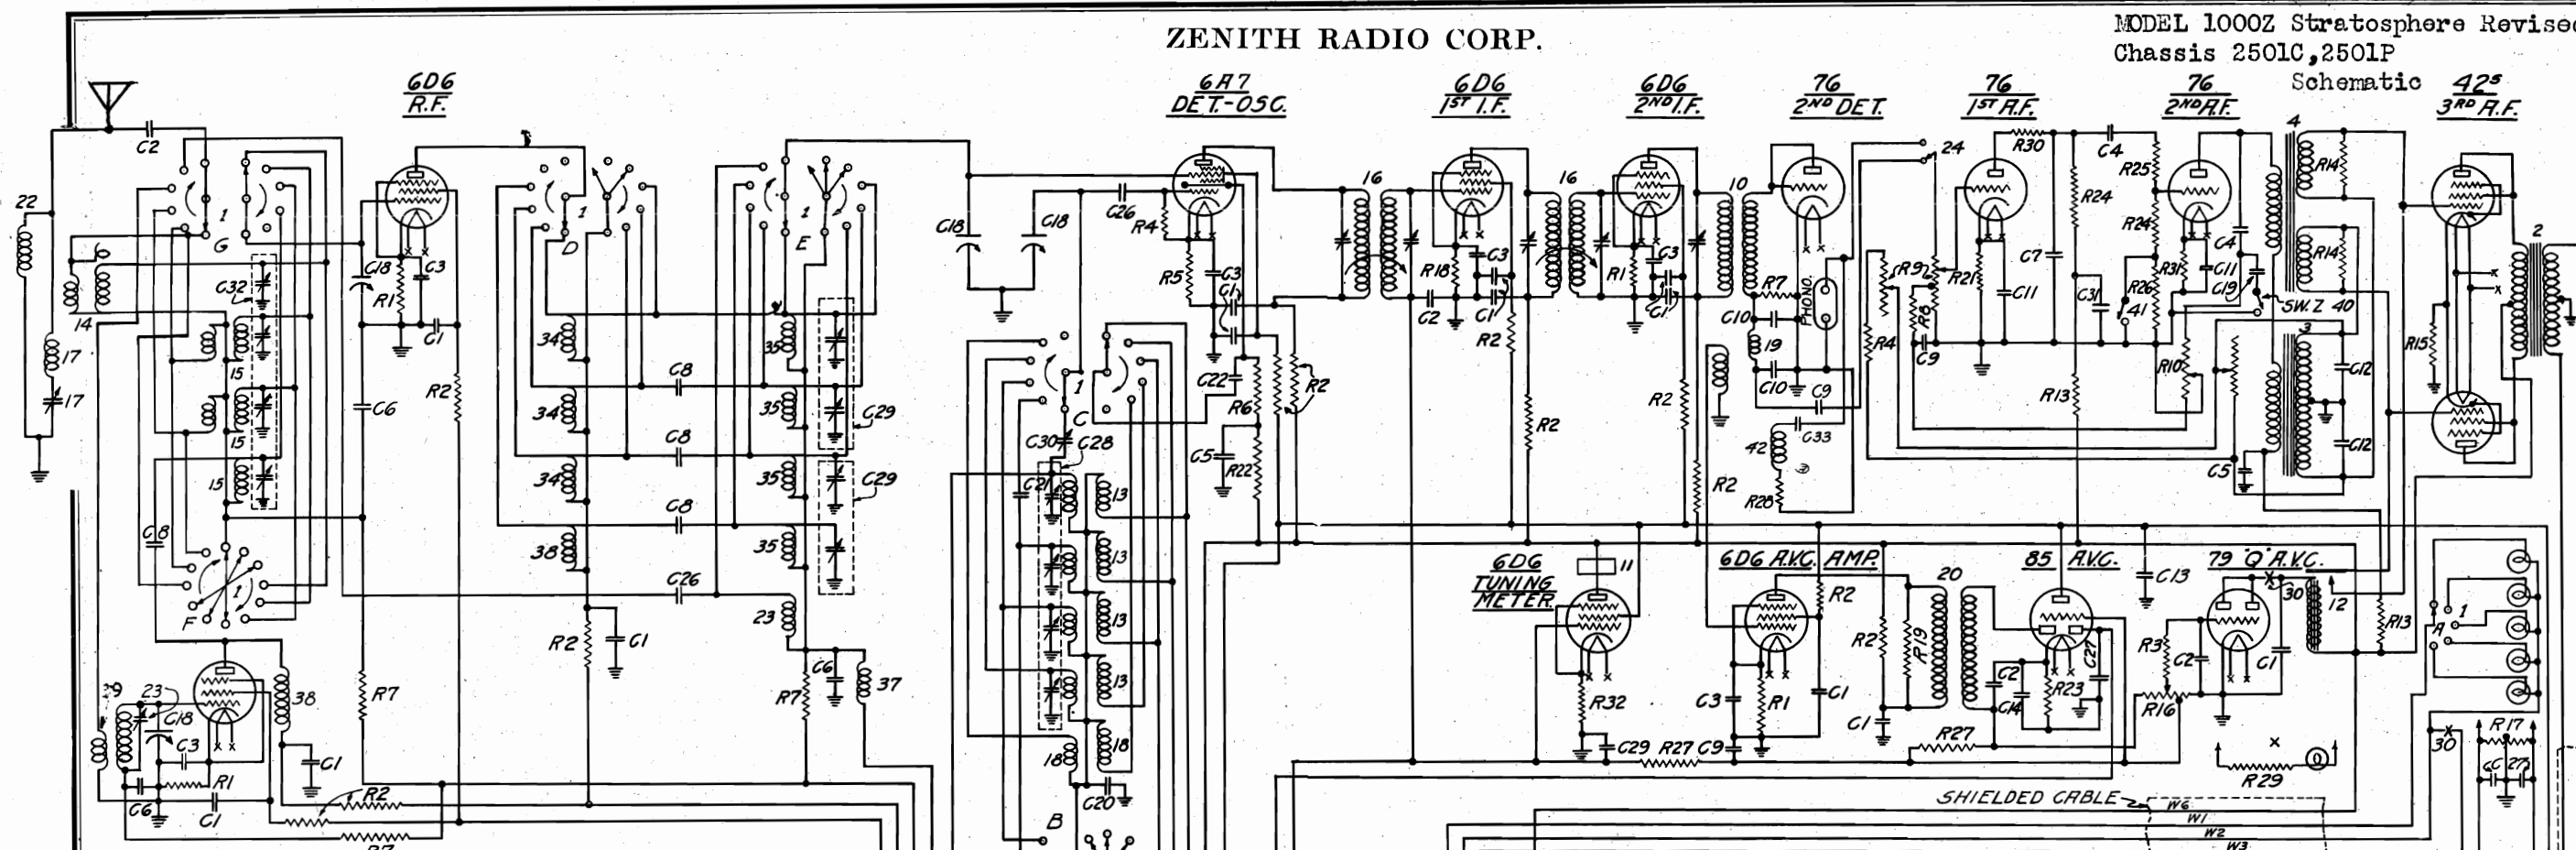

RANGES:  
540 to 1720 KC  
150 to 350 KC

- To align receiver, proceed as follows:
1. Peak I R transformer, applying a 456 KC note on the 6A7 control grid.
  2. Turn variable condenser all the way open and apply a 1712 KC note to the antenna. Set oscillator trimmer on oscillator section of variable condenser first, then line up R F section.
  3. Adjust low frequency padder at 600 KC, rocking condenser back and forth across 600 KC signal and adjust for maximum gain.
  4. Go back and check 1400 KC alignment.
  5. Long Wave- Apply 150 KC note to antenna. Set long wave oscillator and R F trimmers, through holes at front of chassis, for maximum gain.
  6. Apply a 300 KC note to the antenna and adjust long wave padder, through hole on front of chassis, for maximum gain - rocking condenser back and forth while adjusting.
  7. Go back and check 150 KC again for alignment.
- NOTE: Supply cord of set gets warm while operating set, this is normal. Make sure that all tubes are pushed firmly in their proper sockets. Unreel antenna supplied with set, to full length and place along the floor or drop out of window, if an outdoor antenna is used, make sure connection to set antenna (brown wire) is good.  
DO NOT ATTACH A GROUND WIRE TO THIS SET.  
If necessary to service chassis, under no circumstances remove the chassis without first removing plug from receptacle.

Line Voltage 112.  
f - filament; k - cathode; g1 - control grid; g2 - screen grid; g3 - suppressor grid; p - plate.  
Balance Procedure: Caution - Test set thoroughly for defective tubes, antenna and ground, check line voltage and chassis voltages before any attempt is made to rebalance. All balancing should be done with a calibrated oscillator capable of a steady signal and minimum attenuation of signal input strength. The screw driver used should be of non-metallic type and output meter usually connected across plates of 45 tubes at point where the two green speaker wires come out of power pack.  
Warning: Do not rebalance this chassis unless absolutely necessary as all chassis are balanced on an accurate signal generator before shipment. Set volume control in full on position, tone control on treble, high fidelity control in selective position. Band switch set on broadcast position, gang 590 K.C., approximately. Connect 485 K.C. service oscillator to grid of 6A7 and chassis ground, adjust I.F. transformers, to maximum output with minimum input signal. Rotate selectivity control to broad position, I.F. output should remain constant 6 k.c. plus and minus 485 K. C. Next, connect the same 485 K.C. signal directly across aerial and ground binding post. Balance wave trap to minimum signal. Gang set at 550.  
Notes: Refer to drawing of trimmer assembly to identify trimmers. Set service oscillator at 600 K.C. Adjust broadcast padder "N" meanwhile rocking pointer past 600 K.C. on dial to combination giving greatest output. Set chassis dial to exactly 1400 K.C., and service oscillator to 1400 K.C. Balance "M" oscillator trimmer to scale. Reset oscillator to 600 K.C., rotate gang to 600 and re-check 600 padder for maximum output. Next, return oscillator trimmer at 1400 K.C. Adjust detector trimmer "H" and R.F. trimmer "W" to maximum output.  
Police or Orange band. Rotate chassis band switch to police band, gang should be rotated to 3 megacycles, oscillator to 3 megacycles also. Adjust oscillator

trimmer "W" to scale, peak "W" detector and "W" R.F. trimmers to maximum peak. Yellow band. Set dial and oscillator to 9 megacycles, peak oscillator trimmer "W" for scale, "W" detector and "W" R.F. trimmers for maximum peak. Red band. Set dial and oscillator at 21 megacycles, peak "W" oscillator for scale, "W" detector and "W" R.F., and trimmer "W" located at back of band switch for maximum peak. There are no adjustments on the Blue band. On all short wave adjustments be careful not to balance the oscillator circuit to the image frequency of the signal. This is equal to signal frequency minus twice the I.F. frequency.

**PROCEDURE FOR SETTING UP AUTOMATIC PUSH BUTTONS**

1. A glance at Fig. 1 will show that there are eight (8) push buttons, six (6) of which are for automatic use; the adjusting screws are located directly below these.
  2. Fig. 1 also shows the tuning range or frequencies covered by each button. The remaining two (2) push buttons, located at the extreme left hand end of the push button plate are for tone control.
  3. Choose a station having a frequency within the range of button No. 1 (540 K.C. to 930 K.C.)
  4. With the middle knob in the "broadcast" position, tune this station conventionally by using the selector knob.
  5. Repeat the above procedure for the remaining five (5) stations.
- NOTE:** It is advisable to retain the call letter sheet in case of station change letter on.

 IF PEAK 456 KC

MODELS 40Y8, 40Y8C

MODEL 41X6  
Schematic  
Alignment

ZEPHYR RADIO CO.

IF PEAK 456 KC

ALIGNMENT PROCEDURE

**I. F. Alignment.** Connect a signal generator set at 456kc to the 6A7 input and connect an output meter to the speaker output. Using a weak signal tune the two I. F. condensers on the first I. F. coil and the two I. F. condensers on the output I. F. coil for maximum response.

**R. F. Alignment.** Connect the signal generator set at 1400kc to the antenna lead using a dummy antenna of 200mmf. Tune the set by means of the dial to 1400kc position. Adjust oscillator trimmer for this frequency. Pad at 600kc. Recheck 1400kc and trim antenna stage for maximum response. Repeating the alignment may result in improved sensitivity.

**CAUTION**

**DO NOT CHANGE TUBES  
WHEN SET IS TURNED ON.**

Setchell-Carlson - - - - PORTABLE "55"

**Arvin 618, 618A, etc.**

In order to eliminate the hum in the chassis used in these and other six-tube models, follow this procedure:

Remove the chassis from the cabinet. Locate the ground lug on the 6Q7G tube socket (see chassis layout on page 8-16 of *Rider's Volume VIII*). This lug is fastened to the chassis by a rivet which attaches the 6Q7G socket to the chassis. Bend this lug over and solder it to the chassis and then recheck for hum. If this is soldered correctly, the hum level should be brought to a minimum.

**Pilot X114, X115**

Changes have been made in the chassis used in these models, which have a similar schematic to the one shown on page 6-15 in *Rider's Volume VI*. The condensers C32 and C33 in the plate circuit of the second detector have been removed from the circuit, so that now the switch S3 is used to short out only the one condenser, C34, which now has a value of 250 mmf.

The value of the 10,000-ohm resistor No. 26 has been changed to 6,000 ohms. This is in the primary circuit of the pushpull input transformer.

A line condenser (1000-volt, paper) has been added across the primary of the power transformer. This is a dual condenser, grounded between the 0.01-0.01 mf sections.

**Automatic 960A**

The accompanying partial schematic shows a change which was incorporated in the 960 series, the schematic of which is shown on page 9-2 in *Rider's Volume IX*. Note also that the receivers in which this change has been made have an i-f peak of 480 kc, instead of 456 kc and that they are identified by the letter "A" after the model number.

New antenna circuit of the Automatic 960 A Series.

**Arvin 818, 828, etc.**

In order to reduce the hum level of the models in which the 8-tube chassis is used, follow this procedure:

Remove the chassis from the cabinet. Unsolder the 250,000-ohm plate resistor of the 6F5G tube from the B+ terminal, which is the lug on the 16-mf—300 volt electrolytic condenser. See chassis layout on page 8-20 of *Rider's Volume VIII*. Connect this resistor to the first tap down from B+ on the voltage divider resistor R87. This voltage tap supplies the potential for the 6A8G anode grid. Recheck for hum, which now should be reduced to a satisfactory level.

**Oldsmobile 982043**

In some of the early receivers (under serial A-20,000) of this model, several differences exist which should be noted on page 9-1 in *Rider's Volume IX*.

Resistor No. 46 is 100,000-ohms instead of 20,000.

Resistor No. 54 is 125,000 instead of 100,000-ohms and No. 55 is 75,000 instead of 100,000-ohms.

Resistor No. 44 and condenser No. 26 have been transposed, i.e. the resistor is connected to the grounded end of resistor No. 53 instead of the condenser.

The value of condenser No. 82 is indicated as 0.000063-mf and its connections are as follows: one terminal is connected to the junction of condenser No. 26 and the tap from resistor No. 58 and the other terminal is connected to the junction of condenser No. 18 and the left end of resistor No. 58.

**Emerson Chassis AF**

Receivers using this chassis and bearing serial numbers above 1,244,716 differ from the schematic shown on page 8-45 in *Rider's Volume VIII*. The condenser C-17 is omitted and the negative side of the filament circuit is grounded to the chassis.

**Fairbanks-Morse 9A**

Refer to the schematic shown on page 8-9 of *Rider's Volume VIII*. During production, the 47,000-ohm resistor (8) and the filter condenser (7) were removed and the r-f secondary was grounded directly, thus removing AVC from the 6L7G mixer tube. The bottom of the antenna coil secondary was then connected directly to the 1-meg-ohm resistor (9). A 1000-ohm variable resistor was added in the cathode circuit of the 6J7G AFC control tube (at 37) to make possible compensation for variation in calibration due to variation in tube characteristics. This control was found unnecessary and was removed in later runs.

**Fairbanks-Morse 8A**

Refer to schematic shown on page 8-7 of *Rider's Volume VIII*. During production, the 47,000-ohm resistor (16) and the 0.05-mf condenser (7) were removed and the r-f secondary was grounded directly, thus removing AVC from the 6L7G mixer tube. The bottom of the antenna coil secondary was then connected directly to the 470,000-ohm resistor (17).

**G.E. G-57**

This model is identical to model G-55, except for the cabinet and the loud speaker, which has a part number RS-095. The 12-inch cone of this unit has a part number RC-943.

The servicing data for model G-55, found on pages 9-3, 9-4, and 9-5 of *Rider's Volume IX*, apply to the G-57. This additional model number should be added to the listing in your Index.

**Stromberg-Carlson Push-Button Tuners**

The push buttons on all the new receivers, such as those whose servicing data are found in *Rider's Volume IX*, which employ padding condensers for tuning purposes are set up from the front of the chassis. It is unnecessary to get into the back of the receiver to set up the desired stations, except to adjust the electric tuning switch on the rear of the chassis.

To set up the stations, it is only necessary to remove the escutcheon over the push buttons and the adjusting screws become readily accessible. These escutcheons are held in place by several Phillips type screws, which can be removed with any small pointed instrument, such as a small nailfile or an old knife blade. However, the use of a special tool is recommended, as this will not mar the surface of the screw head.

**DeWald 1106**

This model is identical with the Models 1104 and 1105, shown on pages 9-1 and 9-10 of *Rider's Volume IX*, except that the new model has an additional short-wave band for the 14-40 mc range, giving it a total of five bands.

**RCA 8M3, 8M4**

On 8M3 and 8M4 receivers, it is often advantageous to connect the 22-mmf condenser (C1, on page 9-37 of *Rider's Volume IX*) from the output end of coil L1 to ground, instead of from the antenna end. Later runs of sets include this change. Note also that good electrical contact is required between vibrator-transformer and chassis to minimize internal noise.

**Majestic 11356**

This model is found on pages 9-8, 9-11 and 9-12 of *Rider's Volume IX*. A new electric tuning system has been incorporated in later runs of this receiver and is illustrated in Fig. 1. The procedure for indexing this tuning system for desired stations is as follows:

- (1) Set receiver to Standard Broadcast band.
  - (2) Place "Manual-Electric" lever in "Manual" position, which is extreme counter-clockwise. Be sure the tone control is in the "Normal" position as shown by the indicator.
  - (3) Pull out Indexing Rod located at center bottom half of the escutcheon. This rod has numbers on it which correspond to the push buttons (counting from left to right.)
  - (4) Set Indexing Rod so that the number on the rod corresponding to the push button you wish to index is in line with the escutcheon plate.
  - (5) Turn tuning knob until the pointer has covered the entire dial. This is essential to engage the tuning disc.
  - (6) Tune in the desired station accurately, using the tuning eye.
  - (7) Push Indexing Rod all the way in, and that particular station will always be tuned in automatically when that particular button is depressed while the "Manual-Electric" lever is in the "Electric" position.
- To index more than one station, go through steps (3) to (6) for each station desired and when finished, push the Indexing Rod back as far as it will go.

**Caution:** When using electric tuning, do not depress more than one button at a time. Depressing two buttons will cause the motor to run continuously or until the automatic thermal switch operates to prevent the motor from burning out. If this happens, it may take fifteen minutes for the motor to become cool enough for the electric tuning to become operative again.

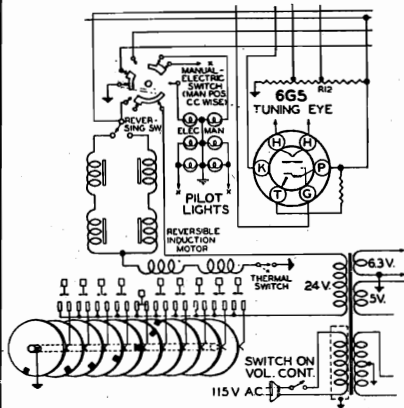

Fig. 1. How the new electric tuning unit is connected in the Majestic Model 11356. Philco 38-10 (121, 124)

Run No. 5. Resistor No. 11, 70,000-ohms changed to 40,000-ohms, Part No. 33-340339 in order to improve the oscillator circuit performance. See page 8-67 in *Rider's Volume VIII*

**Spiegel Chassis X1**

This chassis is used in the following models: 1900, 1920, 1931, 1970, 4502, 9922, and 9925. It is quite similar to the chassis used in the Spiegel Model 100 found on page 9-1 of *Rider's Volume IX*, the difference being as follows:

The 250,000-ohm resistor in the plate circuit of the 75 second detector is connected directly to +B. This means that the 100,000-ohm resistor and the 0.1-mf by-pass condenser are not used in this chassis. An 0.05-mf condenser is used across the 110-volt a-c leads to the power transformer primary instead of one with a value of 0.02 mf.

No wave trap is used in the X1 chassis, such as is shown in the broadcast-band antenna coil. Also no condenser is shunted across the short-wave oscillator coil. The value of the fixed condenser connected between the Police-band oscillator coil and ground is 0.005 mf instead of 0.012 mf.

**RCA 10K11, 10T11**

The chassis and speakers of these two models are identical to models 10K and 10T, which will be found in *Rider's Volume VII* on page 7-132. The service data starting on that page applies to these new model numbers with the exception of some minor replacement parts for the new cabinets in which these chassis are housed.

**Majestic 11056, 11057, 11058**

Models 11056 and 11058 are found on pages 9-8 to 9-10 of *Rider's Volume IX*. The data given there also apply to Model 11057. Alignment instructions for these three models are given in the table below.

Signal Generator Connection	Signal Generator Frequency	Band Switch Position	Dial Position	Trimmer Designation	Output Signal
6A8G Mixer Control Grid	455 kc (1)	BC	(2)	Trim 455 kc	Max.
Antenna (3)	18 mc	SW	18 mc	Osc— 18 mc R-F— 18 mc Ant— 18 mc	(4) Max. Max.
	11 mc	SW	To Gen.		(5)
	6 mc	SW	To Gen.		(5)
Antenna (3)	19 mc	SW	18 mc		(6)
	6 mc	POL	6 mc	Osc— 6 mc R-F— 6 mc Ant— 6 mc	(4) Max. Max.
Antenna (7)	7 mc	POL	6 mc		(6)
Antenna (7)	1500 kc	BC	1500 kc	Osc—1500 kc R-F—1500 kc Ant—1500 kc	(4) Max. Max.
Antenna (7)	600 kc	BC	600 kc	Pad— 600 kc	Max. (8)
Antenna (7)	1500 kc	BC	1500 kc	Osc—1500 kc R-F—1500 kc Ant—1500 kc	(4) Max. Max.
Antenna (7)	600 kc	BC	600 kc	Pad— 600 kc	Max. (8)

Note (1)—Apply through 0.1-mf condenser; use smallest possible signal from generator to prevent AVC action from affecting output readings.  
 Note (2)—Gang condenser about 50% engaged; if a squeal is heard, rotate gang until squeal is removed.  
 Note (3)—Apply through 400-ohm dummy antenna.  
 Note (4)—Unscrew trimmer to minimum, then slowly turn screw to increase capacity until the signal is heard.  
 Note (5)—Check sensitivity.  
 Note (6)—Image check: If alignment is correct, about 10 times as much signal-generator input will be required to give image same output reading as did the desired signal.  
 Note (7)—Apply through 200-mmf mica condenser as dummy antenna.  
 Note (8)—While rocking gang condenser.

**DeWald 1004**

This model is identical with the Models 1002 and 1003, shown on page 9-6 of *Rider's Volume IX*, except that the new model has an additional short-wave band for the 14-40 mc range, giving it a total of five bands.

**Fairbanks-Morse 5A**

During production runs, a 10-mf, 25-volt condenser was added across the cathode resistor of the type-41 output tube to increase sensitivity. In the schematic shown on page 9-5 of *Rider's Volume IX*, the cathode resistor mentioned bears the number, 21.

**Fairbanks-Morse 6C**

Referring to the schematic shown on page 8-5 of *Rider's Volume VIII*, the 10,000-ohm resistor (15), in the screen circuit of the 6D8G and 15 tubes, was changed during production to 22,000 ohms. Both resistors are of 2-watts rating.

**Silvertone 4600, 4601**

A receiver is occasionally encountered in which the volume goes to a low value as the volume control is turned down, but then increases again as the control is turned still lower. This can usually be corrected as follows: Remove the chassis from its case and remove the connections to the two outside terminals of the volume control. Then connect a 22.5-volt "B" battery between the center terminal and the case of the control. Rotate the control a couple of times throughout its range. This should repair the control and the connections should be soldered back on to the outside terminals.

**Philco 38-12**

Run No. 3. It is important that the following leads be dressed in order to eliminate hum:

Dress the green wire connecting the diodes of the 75 tube to the 2nd i-f transformer as far as possible from the filament prongs of the 75.

The brown wire connecting the 51,000-ohm resistor to the high side of the volume control should be dressed under the coil of the 2nd i-f transformer.

The grid lead of the 75 tube should be dressed toward the back of the receiver and between the tube and shield.

New i-f transformer for Philco models 38-12 and 38-14.

The second i-f transformer, No. 12 in the schematic on page 8-69 of *Rider's Volume VIII*, has been changed from Part No. 32-2674 to No. 32-2944. Note that condenser 12B and 12C are part of the padder in these transformers. The wiring of this new transformer is shown in the accompanying illustration.

**Philco 38-14**

In the list of parts on page 8-72 in *Rider's Volume VIII*, the parts numbers of the following are incorrect:

Schematic No.	Incorrect No.	Correct No.
12—Compensator	31-6209	31-6100
20—Volume Control	33-5236	33-5230

A condenser, 5 mmf, was connected across the secondary of the short-wave transformer, No. 2. This condenser is connected to lugs Nos. 3 and 4 of the transformer shown on the schematic. See page 8-71 of *Rider's Volume VIII*.

Run No. 2. The second i-f transformer, No. 17, was changed from Part No. 32-2674 to No. 32-2944. The wiring lugs on the new transformer are slightly changed. The drawing of this transformer is shown in the preceding change notice covering Philco 38-12. Note that in the case of Model 38-12, the middle left-hand lead in the sketch goes to chassis ground, but in the Model 38-14, this same lead goes to -B.

**Philco 38-4**

Run No. 5. The two condensers, Part No. 30-1097, which were connected in parallel with the new air padder, No. 16 in Run No. 3 receivers (see *SUCCESSFUL SERVICING*, July 1938, page 2) have been removed, starting with Run No. 5. For schematic see page 8-61 in *Rider's Volume VIII*. In place of these condensers, a thermal compensator, Part No. 31-6227 is connected in parallel with the air padder. The air padder, No. 16, Part No. 31-6206, has also been relocated and is now mounted between the 6U7G r-f tube and the 6F6G output tube. (See page 8-63 for chassis layout). The thermal compensator, Part No. 31-6227, is also mounted in the same position with the thermostatic plate facing the power transformer.

The oscillator transformer, No. 15, was changed from Part No. 32-2631 to 32-2894. Connection No. 1 of the new transformer has been increased in length for soldering to the air padder in the new location.

**Philco 38-14 (121, 124)**

Run No. 4, Code 121. In order to eliminate hum modulation, the electrolytic condenser, No. 32, was changed from 16-mf to 40-mf, Part No. 30-2237. The electrolytic condenser in Code 124 receivers was also changed from 16- to 40-mf, Part No. 30-2256. The oscillator blocking condenser No. 8, 250-mmf was changed to 50-mmf, Part No. 30-1029.

See page 8-71 in *Rider's Volume VIII* for schematic of both codes.

**Philco 38-33 (121)**

Run No. 3. Resistor No. 20, 8000-ohms, was changed to 20,000-ohms, Part No. 33-320339. It was removed from the 90-volt wire (see schematic on page 9-3 of *Rider's Volume IX*) and reconnected to the 135-volt wire of the battery cable. The battery cable assembly was also changed to Part No. 41-3402.

**Belmont 665,765**

It will be noticed that another model number, 765, has been added to 665, which appears in the Index to *Rider's Volume IX*. This new series starts with serial 9A532400 for which the model numbers are 665 Series A, Issue B and 765 Series A. The servicing data on both these models are the same as the information published in *Rider's Volume IX* with the following changes:

A 6U5 tuning indicator tube has been added in the model 765. The grid of the 6U5 is connected to the junction of No. 5 terminal of the 6Q7G and R8; the target to +B; and the cathode to the junction of R10 and R12. See schematic on page 9-21 in *Rider's Volume IX*.

The short pieces of wire on the antenna coil, which are designated as CA and CB in the schematic, have been removed.

A resistor, R17, 2000 ohms, has been shunted across the P and H terminals of the oscillator coil.

A 0.008-mf, 800-volt condenser, C21, has been added between the plate of the output tube, 6AC5G, and ground.

The short-wave oscillator padder, C12, was not shown on the bottom view of the chassis. This is located on the layout just above and between the trimmers C8 and C11. Note that this padder C12 is adjusted at the factory and needs no other adjustment.

**Zenith Chassis 5516, 5634, 5707**

The alignment instructions for the three chassis mentioned above are identical and will be found below. The model numbers of the receivers in which these chassis are used will be found on the pages of *Rider's Volume VII*. The schematics and trimmer locations for the respective chassis will be found on these pages: Chassis 5516, schematic page 7-7, trimmers page 7-2; Chassis 5634, schematic page 7-17, trimmers page 7-9; Chassis 5707, schematic page 7-18, trimmers page 7-11.

Signal Generator Connection	Signal Generator Frequency	Dial Position	Wave-Band Switch Position	Trimmer Number	Output Signal
Det.-Osc. Control Grid	456 kc <sup>1</sup>	—	—	4 I-F Trimmers	Max.
Antenna	456 kc	—	—	Wave-Trap Trim. (Rear of chassis)	Min.
Antenna	6 mc	6 mc	Band B	Osc. Trim. <sup>2</sup>	—
Antenna	1400 kc	1400 kc	Band A	Broadcast Trim. <sup>2</sup>	Max.
Antenna	18 mc	18 mc	Band C	Short-Wave Trim.	Max. <sup>3</sup>
Antenna	600 kc	600 kc	Band A	Broadcast Pad.	Max. <sup>3</sup>
Antenna	1400 kc	1400 kc	Band A	Broadcast Trim. <sup>2</sup>	—
				Antenna Trim.	Max.

Note 1—Use smallest possible signal from generator to prevent AVC action from affecting output readings.  
 Note 2—Adjust for correct dial reading.  
 Note 3—While rocking.

**RCA U-112, Late U-111 and U-112**

The U-112 is a 5-tube superheterodyne-Victrola combination similar to U-111 except that the cabinet has been enlarged to permit the playing of 12-inch records. The service data for the U-111 found on pages 9-169 and 9-170 of *Rider's Volume IX* apply to these later models, with the following exceptions:

In the U-112, the rectifier has been changed to a 5W4.

A 12,000-ohm resistor, R18, has been added in series with the 0.005-mf condenser across the pickup in U-112.

Model U-112 is made in three power supply ratings, all 105-125 volts with 80 watts consumption:

Rating	Frequency
A-6	60 cycles
A-5	50 "
B-2	25 "

The 25-cycle power transformer for U-112 has a d-c resistance of 13.7 ohms in its primary and 1190 ohms in the secondary. The speaker in this model, 84265-4, has the following d-c resistances: Field coil—1300 ohms; Primary of output transformer—420 ohms; Voice coil—2 ohms.

Later production of both the U-111 and U-112 models have the following changes:

The antenna coil has been changed from stock number 30894 (1-ohm primary) to 32338 (35-ohm primary). This last coil may be used to replace the former.

A 270-mmf condenser, C23, is connected from the triode plate of the 6Q7G to the chassis.

The following additional alignment data apply to both models: On r-f alignment, turn the gang condenser all the way out of mesh and with the test oscillator tuned to 1720 kc, align the oscillator trimmer C18. Set the test oscillator to 1500 kc, tune the receiver to the 1500-kc signal and align the antenna trimmer C3 for maximum output.

Note that the connections for the motor coil assembly, shown on page 9-170, has been revised. The connections shown in the left-hand view of the stator are used for both 25-cycle and 60-cycle operation on 110 volts and are unchanged. For 110-volt, 50-cycle operation, the red and yellow designations in the right-hand sketch should be reversed; in other words, the yellow of the left-hand coil is connected to the red of the right coil, making the leads at the bottom, red from the left coil and yellow from the right. Note also that the d-c resistance of each coil for 25-cycles in 250 ohms, those for 50- and 60-cycles remaining 82 ohms. These notes apply to both U-111 and U-112.

**RCA 5T**

Two different speakers are used on Model 5T, and are identified by the numbers stamped on them as follows: (1) RL-63C1 and (2) 72203-5. Replacement parts for No. RL-63C1 are listed in the service data for Model 5T, shown on page 7-14 of *Rider's Volume VII*, and the replacement parts for No. 72203-5 are listed below:

Stock No.	Description
9579	Coil—Field coil
9533	Cone—Reproducer cone mounted and centered in housing
5118	Connector—3-contact male connector for reproducer
9578	Reproducer complete
4818	Transformer—Output transformer

**RCA 5X**

Late-production Model 5X receivers include the following minor changes from the original Model 5X which is found on pages 7-18 to 7-20 of *Rider's Volume VII*: (1) a fixed-tuned wave-trap is used in place of the adjustable wave-trap and (2) a few changes in component parts which are listed below. For late-production Model 5X, under "Alignment Procedure," omit the wave-trap adjustment. Early- and late-production receivers can be distinguished readily by inspection of the wave-trap. Component part changes for late-production models are as follows:

Stock No.	Description
11414	Capacitor—0.1 mf (C19)
13837	Capacitor pack—Comprising one 10-mf and two 16-mf sections (C23, C24, C26)
12695	Resistor—15,000 ohms, insulated, ¼ watt (R2)
12679	Resistor—2.2 megohms, insulated, ¼ watt (R3, R7)
13836	Switch—Range switch (S2, S3, S4, S5)
13838	Trap—Wave trap (L1, C1)
13149	Coil—Reproducer field coil (L13, L15)

Stock Nos. 12537, 4835, 12398, 12410, 12411, 12399, 3404, 12402, 12395, 12497, 12499, 12731, 12498, 9684, 12500, 13150, 13071, 12936 and 12937 are not used in Model 5X with fixed-wave-trap.

**RCA 8T2**

Four different speakers are used with Model 8T2 receiver, and are identified by the numbers stamped on them as follows: (1) RL-63-4, (2) 76365-1, (3) 76365-3 and (4) RL-63E2. Replacement parts for Nos. RL-63-4 and 76365-1 are listed on page 8-40 of *Rider's Volume VIII*, and No. 76365-3 is listed on the schematic on page 8-41. The replacement parts for No. RL-63E2 are listed below:

Stock No.	Description
12641	Board—Reproducer terminal board
12640	Bracket—Output transformer mounting bracket
11254	Coil—Field coil
11233	Coil—Hum neutralizing coil

12642	Cone—Reproducer cone and dust cap
5118	Connector—3-contact male connector for reproducer
9773	Reproducer complete
11253	Transformer—Output transformer

**RCA 8U**

Two different phonograph turntable motors are used on Model 8U, and are distinguished by the numbers stamped on the motor name plate as follows: (1) 72444-1 and (2) 56992-1. No. 72444-1 is an induction motor with a governor-type speed regulator; No. 56992-1 is a synchronous motor. Replacement parts for No. 72444-1 are listed on page 8-51 of *Rider's Volume VIII*; replacement parts for No. 56992-1 are listed below:

Stock No.	Description
8989	Motor complete, 105-125 volts, 60 cycles
8993	Rotor and shaft for Stock No. 8989
3398	Spring—Motor mounting spring assembly
3817	Stud—Motor mounting stud

**RCA 87K1, 87K2, 87T2**

The service data and replacement parts for the Model 87K1 are shown on pages 9-83 to 9-86 of *Rider's Volume IX*. Three replacement parts have been added as follows:

Stock No.	Description
30846	Core—Inductance adjustment for instantaneous tuning coils
12007	Spring—Retaining spring for core Stock No. 30846
30695	Card—Station call-letter card for push buttons

All service data and replacement parts for Model 87K1 apply directly to Model 87K2, including the three additional replacement parts listed above for Model 87K1.

All service data and replacement parts for Model 87K2 apply directly to Model 87T2, except that the Reproducer Replacement Parts listed below should be used instead of those listed for Model 87K1.

Stock No.	Description
14614	Cone—Reproducer cone and dust cap (L17) (for speaker marked 84091-1 or 84001-3)
14934	Cone—Reproducer cone and dust cap (L17) (for speaker marked 84091-2 or 84001-6)
5118	Plug—3-contact male plug for reproducer
14613	Reproducer complete (marked 84001-3 or 84001-6 but interchangeable with speaker marked 84091-1 or 84091-2 respectively)
14615	Transformer—Output transformer (T2) (for speaker marked 84091-1 or 84001-3)
14935	Transformer—Output transformer (T2) (for speaker marked 84091-2 or 84001-6)

Stock Nos. 13866, 14354, 11469, 12667, 14395; 14358, 14355 and 14357 for Model 87K1 Reproducer Assemblies are not used in Model 87T2.

**Silvertone 7127, 7133**

The schematic for the chassis used in these models will be found on *Sears page 7-63 in Rider's Volume VII*. The alignment has just been obtained and will be found below.

Apply a 456-kc signal at the control grid of the 2A7 and adjust the i-f trimmers.

Apply a 1712-kc signal at the antenna. Turn condenser all the way open. First adjust oscillator trimmer on the oscillator coil, then the r-f trimmer on the condenser.

Adjust the low-frequency padder at 600 kc while rocking the condenser.

Check at 1400 kc for alignment.

Short-wave Adjustment: adjust the small trimmer found under the chassis on short-wave antenna coil for maximum output. If short wave does not track with dial, adjust trimmer on oscillator section of variable condenser until correct. Make all adjustments for short wave with the variable condenser turned to center of 25-meter location on scale.

**Silvertone 4600**

A .1-mf condenser should be added to eliminate bad chassis pickup as shown in Fig. 1, the partial schematic. This type of pickup is heard as noise when the car engine is running and the antenna is disconnected from the receiver.

Fig. 1. Partial schematic of Silvertone model 4600 in which is shown where the .1-mf condenser is connected to eliminate chassis pickup.

This instruction applies to sets having identification number 101.458 on the label inside the receiver case cover; the condenser has been added at the factory when the number reads 101.458B or a subsequent letter. See location in Fig. 2. Note that the schematic is shown on *Sears page 9-35 of Rider's Volume IX*.

Fig. 2. Bottom of chassis showing location of the added condenser.

**Silvertone 4601**

A .1-mf condenser should be added to eliminate bad chassis pickup, as shown in the partial schematic of Fig. 1. This type of pickup is heard as

Fig. 1. Where the 0.1-mf condenser is added in Silvertone 4601 to eliminate chassis pickup.

noise when the car engine is running and the antenna is disconnected from the receiver. This instruction applies to sets having identification number 101.463 on the label inside the receiver case cover; the condenser has been added at the factory when the number reads 101.463B or a subsequent letter.

Fig. 2. Location of added condenser.

The location of this condenser is shown in Fig. 2, the bottom view of the chassis. Note that the Silvertone 4601, shown on *Sears page 8-75 of Rider's Volume VIII*, does not show this condenser; it may be assumed, therefore, that this is Chassis 101.463.

**Silvertone 4414, 4415, etc.**

The original production of this chassis (No. 101,393) used part number 1012814032, r-f coil and detector coil (iron core). Later production, which can be identified by the letter "C" or a subsequent letter rubber-stamped on the chassis, used part number 1012818509 detector coil and number 1012818510, r-f coil (air core). When the new air-core type coils are used, the 350-ohm resistor, R2, in series with the volume control, is changed to 150 ohms.

Later production used part number 1012418344 as volume control, instead of the one used originally. The new control incorporates the 150-ohm resistor, R2, mentioned above, as a tap on the resistance element, eliminating R2 as an external resistor. The new control can be used to replace the old

one in those sets using a 350-ohm R2 by substituting a 200-ohm resistor, as the 150 ohms are incorporated in the control itself. It can be used to replace the original control in those sets that use a 150-ohm external resistor for R2 by removing R2 and connecting to the tap on the volume control.

Please notice that three more model numbers have been added to this chassis and these should be added to the listing in the Index, which should now read: 4414,4415,4500,4505,4506, 4509,4510,4511, Chassis 101.393. The schematic for this chassis will be found on *page 8-15 in Rider's Volume VIII*.

**Silvertone 4502, 4504, etc.**

The same changes relating to Chassis 101.393 also apply to these models, with the exception that the later production is identified by the letter "A" or a subsequent letter rubber-stamped on the chassis.

New model numbers have also been added to this chassis and they should be incorporated in your Index, which should read: 4502, 4502A, 4504, 4508, 4512, 4513, 4514, Chassis 101.427. The schematic of this chassis will be found on *page 8-58 in Rider's Volume VIII*.

**Silvertone 4487, 4587, 4587A**

If one of these models has been out of service for several months, the 25-mf electrolytic condenser may lose its formation, causing the 5Y3G rectifier tube plates to become redhot or the tube to burn out. While this condition seldom occurs, the electrolytic can be reformed and the condition remedied as follows:

Using a 5Y3 plug and a 5X4 socket, make an adapter by connecting together the prongs indicated below. Then put a 5X4G rectifier tube in the adapter socket and push the adapter plug into the rectifier socket of the receiver. (It is advisable to remove the output tubes from their sockets during the reforming period.) The receiver should be turned on for about five minutes, the 5X4G tube being used to reform the electrolytic. After this period, the 5Y3G tube can be replaced in its socket and the receiver will perform normally.

This same remedy can be applied to other chassis, although it is very unlikely that this condition will be often encountered.

**Stewart-Warner-Firestone R-1332**

The filter system and rectifier tube are protected against breakdown during the warming-up period by the Globar resistor (No. 15 in the schematic on page 6-16 in *Rider's Volume VI*), which functions as follows: The resistance of this unit drops rapidly as the voltage across it rises, so that it acts as a load on the power transformer during the warm-up period and keeps the voltage under the danger point until the tubes are heated and take their normal current. Because of its unique voltage characteristics, this resistor can not be checked with an ordinary ohmmeter as it will show a resistance of several megohms.

**I-F Alignment:**

This is conventional, the i-f peak being 456-kc. The trimmers are located on the top of the i-f transformers and may be reached by removing the top cover. The signal generator is connected between the control grid of the 6A7 and ground.

**Dial Calibration:**

Tune in a station of known frequency between 800 and 1000-kc. Insert a screwdriver in the slotted end of the dial shaft projecting through the back of the control head. Hold the tuning control knob so that the station remains tuned in properly and adjust the dial pointer with the screwdriver so that the exact station frequency is indicated.

If the set is badly out of calibration, such that it calibrates correctly at one part of the dial but not at another, it is necessary to adjust the oscillator shunt trimmer. In order to reach this trimmer the chassis must be removed from the case as follows:

Remove the flexible shafts and dismount the receiver.

Remove the four terminals of the speaker cable from the speaker.

Remove the black antenna lead from the coil and unsolder the coil shield grounding braid.

Remove the blue dial-light lead from the socket terminal.

Remove the yellow tone-control lead from the tone control switch.

Remove the six slotted chassis fastening screws and slide the chassis from the case.

Reconnect the red and yellow leads of the speaker cable to the speaker.

Insert the tuning shaft in the gang condenser fitting and reconnect the battery lead.

Set the chassis on a flat metal plate and adjust as follows:

Connect a 0.00025-mf condenser in series with the output of the signal gen-

erator and the antenna lead plug on the antenna coil and the ground lead of the signal generator to the chassis of the set. Set signal generator to 600-kc and tune the receiver to maximum volume and set the dial to read exactly 6.0 (600-kc). Set the signal generator to 1400-kc and turn the tuning knob until the dial pointer reaches 14.0 (1400-kc). Adjust the oscillator shunt trimmer (on the gang condenser second from the control end) until the meter indicates maximum output. Then adjust the other gang trimmer as directed below.

**R-F Alignment:**

With the signal generator tuned to 1400 kc, tune the receiver carefully for maximum output. Adjust the output of the signal generator to minimum value which will give sufficient output meter deflection. Adjust the trimmer nearest to the shaft end of the gang condenser for maximum output.

**Stewart-Warner AC-DC Receivers**

There is a tendency for filter condensers and rectifier tubes in AC-DC receivers to fail prematurely. The Stewart-Warner Engineering Department has developed a simple remedy which will be incorporated in all future production of Stewart-Warner AC-DC receivers, and which can be applied easily by the serviceman to existing receivers.

With certain power-line impedances, extremely high surge voltages are developed across the filter condenser. These voltages may be as high as 300 volts, and occur only if the set is turned off on a particular part of the a-c cycle of the power-line current. Such a surge often punctures the filter condenser, and this causes the rectifier tube to fail. Since this difficulty is caused by a power-line condition, if it happens once in a certain customer's home, it is very likely to happen again.

The remedy for this trouble is to connect an inexpensive 50-ohm 1-watt resistor in series with the connection from the rectifier-tube cathodes to the electrolytic filter condensers. The proper connection of the resistor is shown in the accompanying diagram. The Stewart-Warner part number for this resistor is 116013.

The 50-ohm resistor added in the rectifier circuit for line surge protection.

**Firestone-Stewart-Warner R-1322**

The alignment instructions for this receiver are practically the same as those which will be found on page 8-16 in *Rider's Volume VIII*. As this set is used with a steering column control head, the portion of the instructions pertaining to the dash control head can be disregarded. Also the trimmers on the gang condenser are reached by removing the back cover instead of the bottom cover.

A note is contained in the circuit description which should be observed. The correct position of the vibrator in its socket depends upon which car battery terminal is grounded. If the negative terminal is grounded, the vibrator should be inserted so that the arrow points away from the adjacent transformer cover. If the positive side of the battery is grounded, this arrow should point towards the transformer cover. The schematic for this receiver will be found on *Stewart-Warner page 6-15 in Rider's Volume VI*.

**Stewart Warner R-160 Chassis**

The circuit description and alignment notes found on page 8-16 in *Rider's Volume VIII*, are practically the same as those which apply to models 1601 to 1609 inclusive, the major difference occurring in the section devoted to dial calibration. In the instructions for calibrating a dial for receivers having a dash control head, only the 1400-kc adjustment is used, the 600-kc setting being neglected. The schematic for the R-160 chassis will be found on page 7-8 in *Rider's Volume VII*.

**RCA 262,263**

The a-f driver transformer, T3 has a revised coil design, the d-c resistance of the primary now being 1350 ohms and that of the secondary being 2000 ohms. An extra connection has also been provided on this unit for equalizing the primary and core potentials so that electrolysis between these parts will be reduced. This additional lead is colored red-green and it should be connected to plug "B" of the primary circuit. See schematic diagrams of the early models on pages 5-102 and 5-103 of *Rider's Volume V* and the late models on pages 6-51 and 6-53 of *Rider's Volume VI*.

**Bosch 376BT, 376F, 376S**

Please make a note in the table of socket voltages on page 6-2 in *Rider's Volume VI* that the filament voltages should be 2.0 instead of 6.2 volts.
