Perpetual Trouble Shooter's Manual Volume I

About 1000 pages. Price \$7.50

Perpetual Trouble Shooter's Manual Volume II

About 800 pages. Price \$7.50

Perpetual Trouble Shooter's Manual Volume III

About 1185 pages. Price \$7.50

Perpetual Trouble Shooter's Manual Volume IV

About 1060 pages. Price \$7.50

The Perpetual Trouble Shooter's Manuals listed above are the "standard" of the radio service industry.

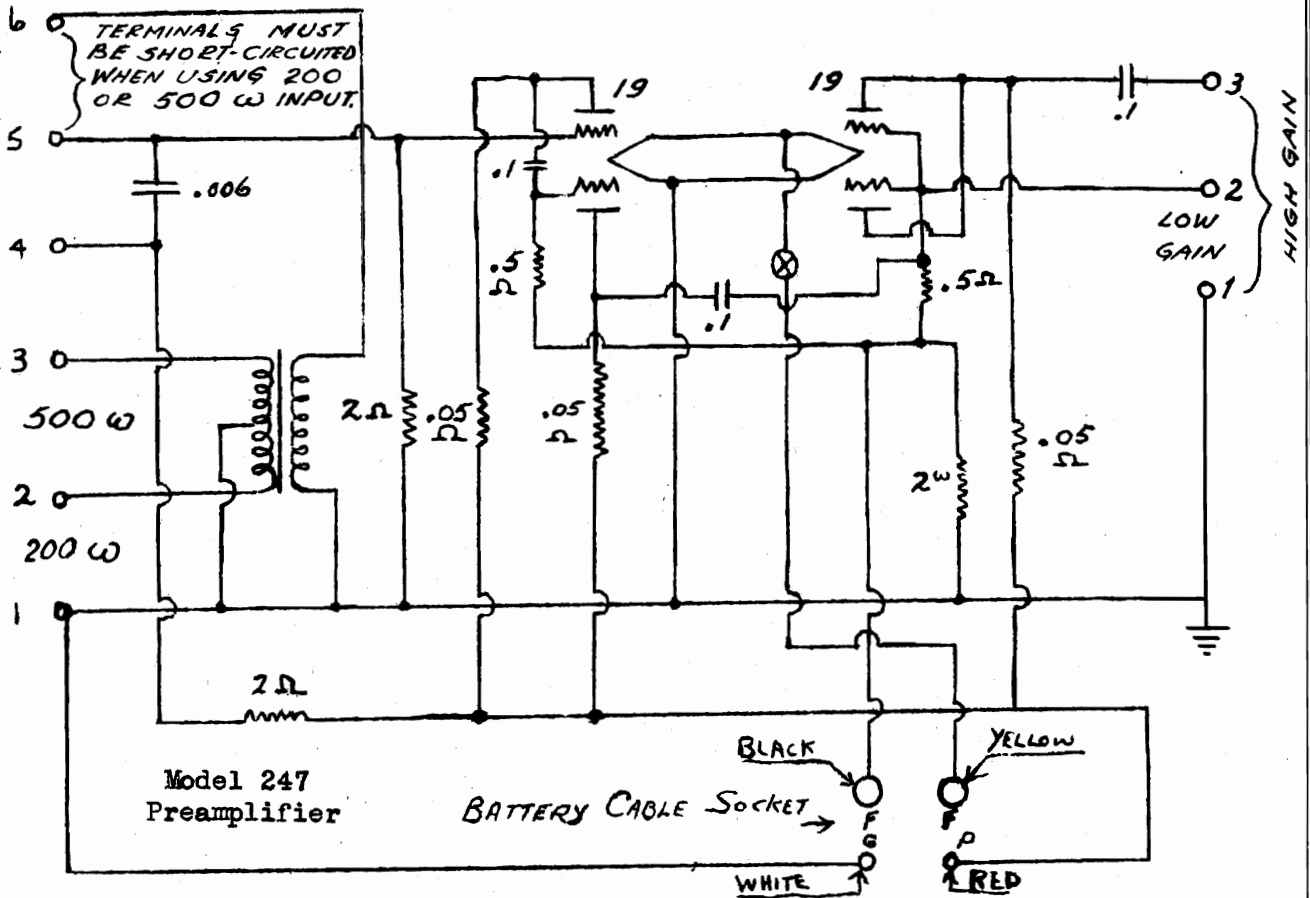

Their absolute supremacy as sources of accurate—complete and detailed radio service data is established by their use by the world-famous tube manufacturing organizations, such as E. T. Cunningham, Inc., National Union Radio Corp., RCA Radiotron, Inc., Arcturus Radio Tube Co., Raytheon Production Corp., Hygrade Sylvania Corp.—the most famous service instrument manufacturers, like Weston, Hickok, Readrite and Supreme and their use and recommendation by the world's leading radio receiver manufacturers.

ALLIED RADIO CORP.

MODEL F-9515
Schematic, Alignm't
MODEL F-9521
Schematic, Alignm't

CAUTION: Do not attempt to operate on current other than that noted on instrument.

INSTALLATION: The Built-in Antenna in the back of set is usually satisfactory. If more sensitivity is required attach same to a good out-door aerial. A .5 mfd condenser connected across the 32 volt line near generator to eliminate generator noise and a spark-plug-resistor connected in lead to spark plug to eliminate ignition noise may sometimes be required for satisfactory reception while batteries are charging.

USE NO GROUND CONNECTION ON SET. SHORT WAVE: Left hand knob, when clear to left, is on Short Wave. A one-quarter inch movement to the right and it is on regular broadcast. Beyond this point it functions as a tone control. **PHONOGRAPH:** Use single pole toggle switch mounted as near as possible to socket marked "75". Connect one side to green resistor with yellow dot found shunted by .00025 mica condenser and connected to black wire coming from coil can adjacent to 75 tube, connect other side of switch in series with phonograph pickup to ground.

SERVICE NOTES: Intermediate stage is carefully phased to 456 K. C. at the factory. Should repatching be necessary feed 456 K. C. signal into grid cap of 6A7 tube and adjust double trimmers in top of coil cans to loudest signal. Phase tuning condenser by setting dial to 1400, carefully remove chassis from cabinet, feed 1400 K. C. Signal into "ANT", lead and adjust trimmers on tuning condenser to loudest signal.

Model F-9515

CAUTION: Do Not Attempt to Operate on Current Other Than That Noted on Instrument.

INSTALLATION: Twist "ANT" and "BLT-IN-ANT" leads together for operation without aerial. Best results, however, may be had with a good outdoor aerial, especially on short wave.

SHORT WAVE: Left hand knob, when clear to the left, is on Short Wave. A one-quarter inch movement to the right and it is on regular broadcast. Beyond this point it functions as a tone control.

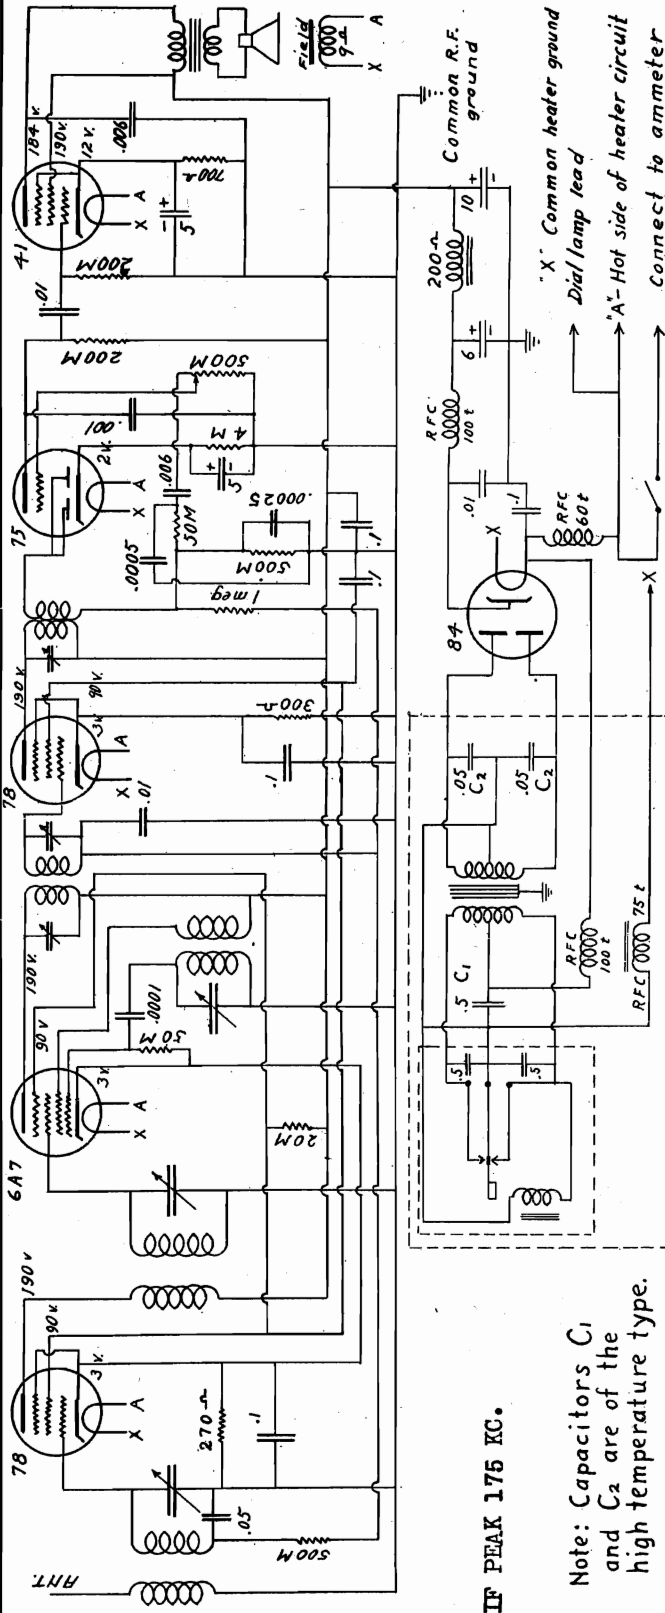

PHONOGRAPH: Use a single pole switch mounted as near as possible to detector socket, connect in series with lead from ground end of grid coil of detector tube. Solder phonograph pickup leads to switch terminals.

SERVICE NOTES: To balance, set dial to 1400 KC, remove from cabinet, feed 1400 KC signal from test oscillator into antenna lead and adjust trimmers on tuning condenser to loudest signal.

Model F-9521

MODEL F-9541
Schematic, Alignment

ALLIED RADIO CORP.

IF PEAK 175 KC.

Note: Capacitors C₁ and C₂ are of the high temperature type.

After the set has been unpacked, remove the four screws from bottom of cabinet, remove the front cover by carefully inserting screw driver at either side and exerting slight twisting pressure, slide chassis forward out of cabinet and inspect tubes to make sure if they are completely down in their sockets, after which replace chassis, front of cabinet and four screws as they were originally.

Determine most satisfactory mounting position on bulkhead which should be at the left hand side or directly in front of steering column. Spot the mounting bolt location and drill 1/8" diameter hole. Insert bolt through hole and assemble washer and nut on engine side. Hang receiver over bolt head and tighten nut.

Attach flexible shafts to control unit by first inserting shaft as far in as possible and then tighten set screws of shaft housing, being careful it is not so tight as to cause shaft to bind in housing.

Mount control unit on steering column in approximately correct position, set pointer to 530 on dial, turn upper control of receiver to extreme clockwise position, carefully place right hand shaft in position on upper receiver control and left hand shaft on lower control and tighten set screws securely.

Adjust control unit position so that shafts leave set with least amount of bend possible and fasten securely in this position. Trial of controls will show best location for smooth operation.

Attach heavy rubber covered lead to ammeter terminal. Connect pilot light wire from control head to short black wire on set, making connection close to set, and tape up joint. Ground

shield by loosening screw under nearest corner of set and connecting wire therefrom to end of shield and tighten up screw.

Disconnect ignition leads from spark plugs, attach one suppressor to top of each plug and reattach the ignition lead to free end of suppressor. Disconnect center wire from distributor head, and substitute distributor suppressor, then plug center wire into free end of suppressor.

Attach generator bypass condenser to generator frame by means of screw holding cut-out. Connect wire from condenser to generator side of cut-out switch.

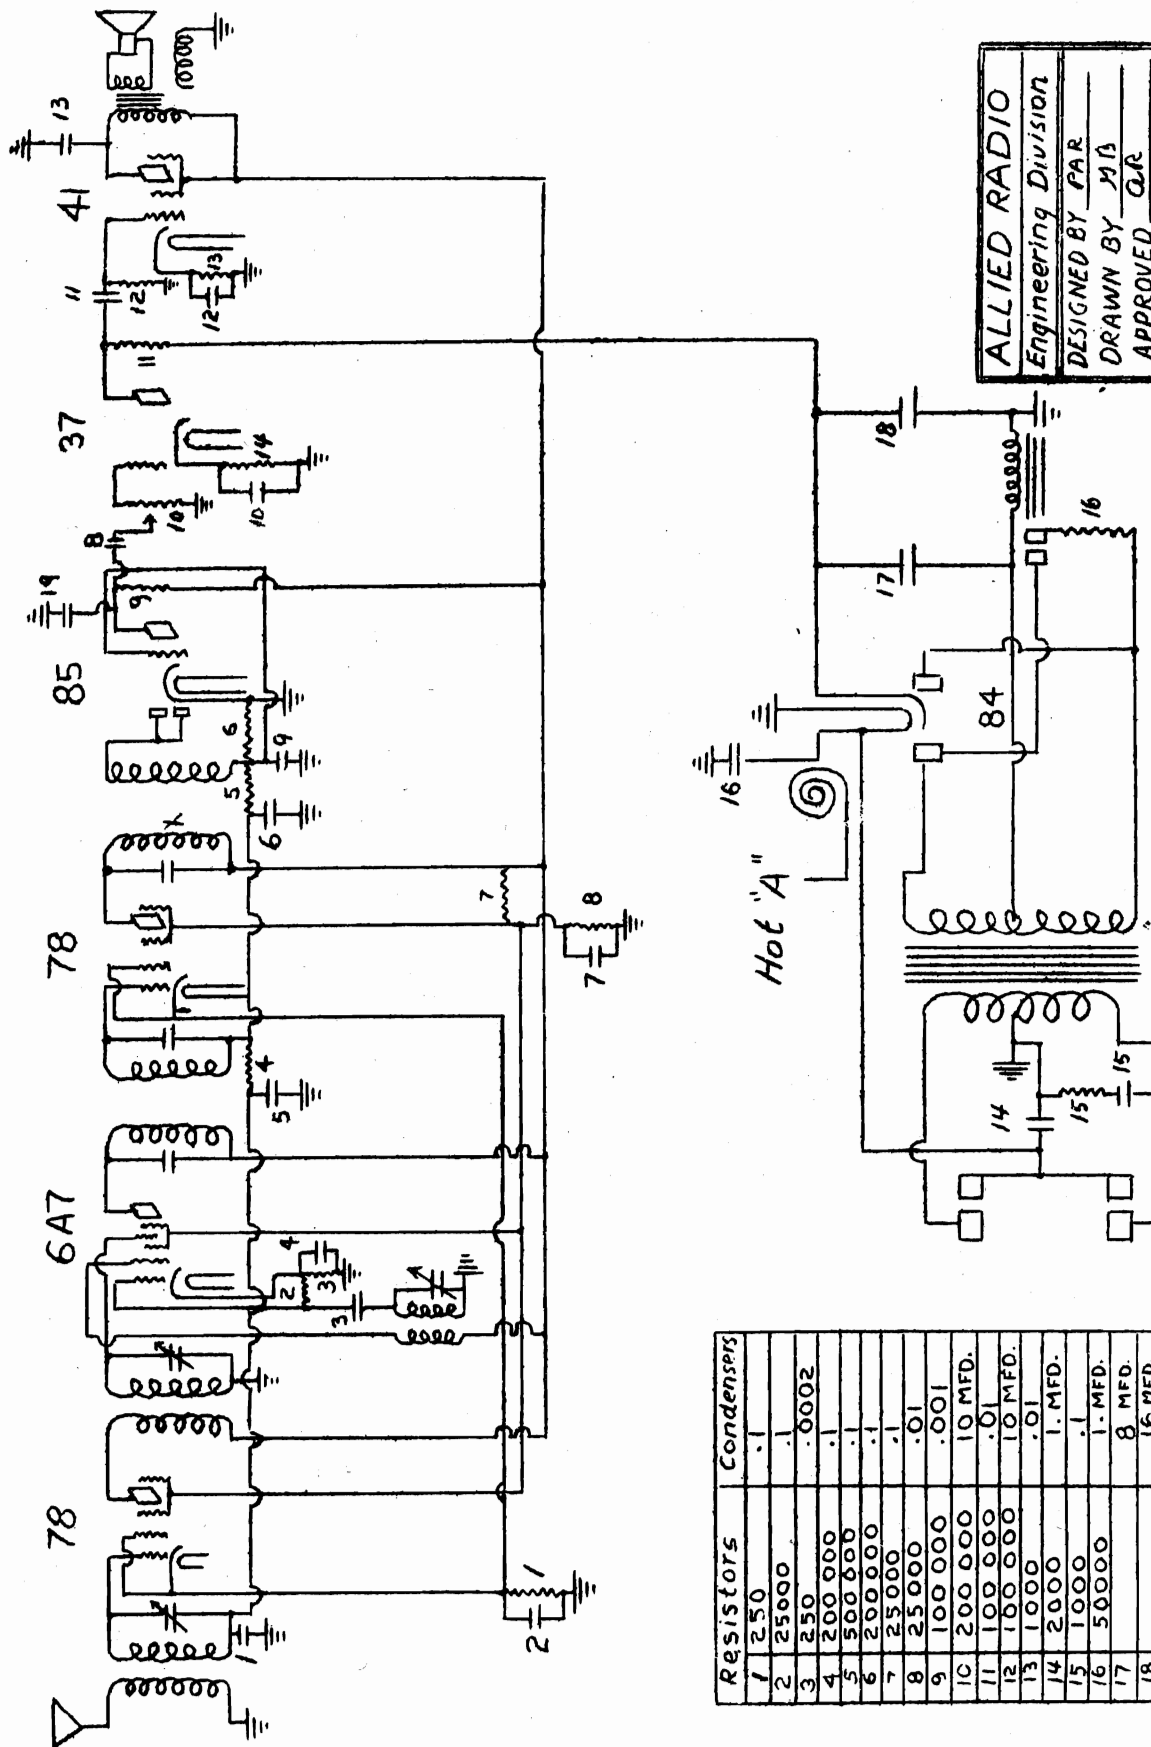

Turn left hand knob on control head to right. If connection directions have been correctly followed, dial should become illuminated immediately and the tubes reach correct operating temperature in approximately 30 seconds.

Balancing Intermediate Frequency Coils. These are peaked to 175 K. C. and are trimmed through the top of the tall cans by means of a small screwdriver and a 5-16" socket wrench. Chassis must first be removed from cabinet and signal from test oscillator fed into grid cap of the 6A7 tube.

Balancing R. F. Coils. The tuning control must first be attached to tuning condenser shaft with pointer set to 530 when tuning condenser is turned to maximum. Tune in a weak signal at its proper dial marking near 1400 and adjust first and second trimmers on variable from front of chassis for loudest signal. If signal does not come at proper dial setting carefully adjust rear trimmer on variable to shift signal to its proper location and then readjust first and second trimmers. After reinstalling set in car slightly readjust first trimmer through hole in top of cabinet.

RESISTORS

- | Code No. | Part No. | Name of Part |
|----------|----------|----------------------------|
| R1 | 30340 | Red-blue, .1 U, 1/3-W. |
| R2 | 30390 | Red-bl'k, 20,000 Ω, 1/3-W. |
| R3 | 30340 | Red-blue, .1 U, 1/3-W. |
| R4 | 30380 | Red-green, 3,300 Ω, 1/3-W. |

Speaker Adjustment: When adjustment is required, put the set and speaker in operation and tune in a signal. Loosen screw A and tighten B, or vice versa, in order to center the armature in the magnet gap. If the armature is not correctly centered, it may strike against one pole of the magnet and cause chattering. If the speaker overloads or chatters only on a very strong signal, turn screw C anti-clockwise. This tightens the armature movement. (In general it is not advisable to disturb the adjustment of screw C.)

- R5 36430 Blue-ye., 5,000 Ω, 1/3-W.
 - R6 30370 Green, 2 U, 1/3-W.
 - R7 31970 Red-ye., .25 U, 1/3-W.
 - R8 30340 Red-blue, .1 U, 1/3-W.
 - R9 30360 Gray-blue, 1 U, 1/3-W.
 - R10 30320 Maroon, 10,000 Ω, 1/3-W.
 - R11 36240* Wire wound, 1.03 Ω
- * A No. 37120 resistor (1.03 Ω) is supplied with set for use with 3-V. dry "A" battery.

ATWATER-KENT MFG. CO.

MODEL 185-A Schematic

MODEL 185-A

May, 1934.

I. F. = 264 KILOCYCLES

Model 185-A covers 540 to 1650 kilocycles and 5.5 to 15.5 megacycles. The short-wave range includes the four principal international short-wave broadcast bands.

Above voltages were made with a line supply of 110 volts. The trap circuit CK2 and A7 shown in dotted lines is used only in some Model 185-A sets. This trap is tuned to the I. F. frequency.

MODELS 206 AND 376 (1st TYPE)

Switch in High-Frequency position.

The 1st type of Modicis 206 and 376 have cylindrical I. F. transformer shields. The 2nd type has square I. F. shields and the circuit is different from that shown above.

Doublet Antenna Data

ATWATER-KENT MFG. CO.

INSTRUCTIONS FOR
CONNECTING DOUBLET ANTENNA
TO RECEIVER

The Model "DT" doublet transformer has a convenient mounting bracket to permit mounting on the rear of cabinet. The transformer has four terminals which are clearly marked. The connections are shown in Fig. 3.

Model "DT" transformer has a two-position switch. For short-wave broadcast reception, turn knob on this switch so the dot is at "SW" (short wave).

For standard broadcast reception turn the knob so dot is at "BC" (broadcast).

IMPORTANT

In some cases, depending on local conditions, a better ratio of signal-to-noise may be obtained **WITHOUT** a ground connection to the receiver. Try it both ways, and if there is less electrical interference without the ground, leave the ground connection off. (Of course, this does not apply to the ground on the lightning arrestor, which must be connected as shown in the illustration.)

If the receiver is provided with doublet antenna connections (as on Atwater Kent Models 112, 318, 447, and 559), connect the transmission line as specified in the instructions for the set. (See Fig. 2.) **Do not forget to remove the jumper wire** which is used on these models between the ground terminal and one of the antenna terminals. This jumper is required when using a plain antenna, but is not used with a doublet.

On the Atwater Kent models just mentioned, the frequency-range switch on the set automatically changes the doublet to a plain antenna on the standard broadcast and police bands.

DOUBLET TRANSFORMER

For receivers which are not provided with doublet antenna connections, it is necessary to use Atwater Kent Model "DT" Doublet Transformer, part No. 28083. This transformer is not included in the Atwater Kent Type "D" doublet antenna kit, but can be purchased separately.

Fig. 2. How to connect the doublet transmission leads to receiver that is provided with doublet-antenna terminals, such as Atwater Kent Models 112, 318, 447, and 559. The leads to the set may be twisted for a distance of 2 or 3 feet without loss of signal strength.

Fig. 3. For short-wave sets that are not provided for doublet-antenna connections, it is necessary to use Atwater Kent Model "DT" doublet transformer and connect it as shown in this drawing. The transformer has a bracket for attachment to the rear of cabinet, and a two-position switch to change from short-waves to standard broadcast.

ATWATER-KENT MFG. CO. MODEL 387 Above 7873966 MODEL 427Q Above 1948501 Schematic

DWG. NO. MODEL 387 427Q TYPE 2ND

MODEL 387 ABOVE No. 7873966 MODEL 427-Q ABOVE No. 1948501

I.F. = 264 K. C.

Total "B" voltage at time measurements were made equaled 120 volts. Tube voltages are taken from —F of each tube. Resistor R9 is used with 2-volt air cell, but is not used with 2-volt storage cell. An extra resistor of the same value as R9 is used with a 3-volt dry-cell "A" battery, and is connected in series with R9.

May, 1934.

ATWATER-KENT MFG. CO.

MODEL 511 Tun-O-Matic
Schematic Data

ACTION OF ATWATER KENT Tune-O-Matic

A simple diagram of the Tune-O-Matic is shown on this page. It is NOT necessary to understand the circuit details in order to set up the Tune-O-Matic, but a few notes on the mechanical action are given below for your convenience.

The tuning motor is a shaded-pole induction type. The motor shaft rotates in only one direction, and the required forward and reverse drive for the variable condenser is secured by an ingenious and simple arrangement for tipping the motor, which is pivoted for this purpose. Tipping is accomplished by a solenoid and lever.

The motor drive shaft extends between two rubber-tired wheels, one large, and one small. When the solenoid is not energized, the motor drive shaft rests against the small wheel and the resulting motion drives the variable condenser in the direction from 540 to 1600 K. C. When the solenoid is energized, the motor is tipped so that its drive shaft rests against the large wheel, and the variable condenser is then driven in the direction from 1600 to 540 K. C.

The current that energizes the solenoid is controlled by a switch (mounted above the top rear of the variable condenser). This switch opens at 1600 K. C. and closes at 540 K. C. The switch is operated by a cam on the shaft of the variable condenser.

Eight adjustable discs are mounted on the shaft of the variable condenser, which is extended out in back of the condenser. Each disc has a small insulated sector on the rim. Normally, the discs do not move with respect to the shaft, but by holding the front gear of the variable condenser, and using a special wrench which is furnished with Model 511, each disc may be rotated on its shaft so that the insulated sector is in the desired position. Between adjacent disc there is a spacer which is keyed to the shaft. This prevents the movement of any disc other than the one moved with the wrench.

Eight contact fingers are mounted at one side of the discs, each finger contacting with the rim of its corresponding disc.

The electrical action is briefly as follows:

Assume that we have one lead of station "G" plugged in the 4:30 jack and the switch is set to automatic.

When the contact blade on the rear of the jack panel comes to the 4:30 jack, the electric circuit through the motor and solenoid is completed and the solenoid tips the motor shaft against the large rubber-tired wheel. The motor turns the variable condenser from the automatic-off position, near 1600 K. C., across the dial to the frequency of station "G".

When the motor reaches this point, the insulated sector of disc "G" has come under its contact finger and the circuit, from the finger through the disc to ground, is broken. This cuts the high-impedance relay into the motor circuit and reduces the current through the motor and solenoid to such a low value that the motor stops turning and the solenoid lever comes up, throwing the motor drive shaft against the small rubber-tired wheel which acts as a mechanical brake, bringing the motor to a dead stop on station "G". Simultaneously, the relay has completed the 110-volt circuit to the set power transformer and the set, now tuned to station "G", begins to operate.

Now plug one of the "off" leads into the 4:45 jack. When the contact finger moves off the 4:30 jack, the circuit through the relay is broken, the set is turned off, and the contact finger, now on the 4:45 jack, completes the circuit through the motor and solenoid, driving the condenser to 540 K. C., where a cam on the shaft trips the

switch, thus cutting out the solenoid, and the motor tips back against the small rubber-tired wheel, driving the condenser back in the opposite direction to 1600 K. C.

Beyond the 1600 K. C. end of the dial, the cam on the variable condenser shaft again trips the switch, which opens, and the solenoid, being energized, tips the motor shaft against the large wheel, starting the condenser moving back. But at 1600 K. C. the insulated sector of the "off" disc comes under its contact finger, breaking the circuit and stopping the motor. **In the off position, NO CURRENT IS DRAWN BY THE SET;** the only current is the small amount required by the electric clock.

Inspection of the diagram will show that the jack panel is shorted out by the switch when the condenser is moving from 540 to 1600 K. C. For greatest accuracy all tuning is done while the condenser is moving from 1600 to 540 K. C.

MODEL 511 Tune-O-Matic
Data

ATWATER-KENT MFG. CO.

SETTING UP THE Tune-O-Matic

The Tune-O-Matic mechanism should be adjusted by the dealer in his store, and not in the customer's house. If the customer indicates his choice of seven different stations, the dealer should adjust the Tune-O-Matic for these seven stations. If the choice is left to the dealer, he should select the seven strongest and most reliable stations. In any case, do not select a weak station, a station with pronounced fading habits, nor a station that has interference; such stations can be received better with manual tuning.

1. Make a list of the seven desired stations, listing them numerically by frequency, and mark the call letters of the seven stations on the station index plates at the front of the clock unit, beginning at the top of the left-hand row and working down the left hand row, then to the top of the right-hand row and working down the right-hand row. The bottom index plate on the right-hand row is marked "OFF". Each celluloid plate has two spring-return tip-jack leads. There are two leads for each of the seven stations and two "off" leads.

2. Remove the small cover at center rear of chassis. This cover is held by two screws and encloses eight adjustment discs and eight corresponding contact fingers. (The disc nearest the front of the set is the "off" disc and it is adjusted at the factory to a point beyond the 1600 K.C. end of the dial.

3. Turn the tone control extreme right (high pitch), and turn the on-off switch to the "manual" position (right). Tune in the first station on the list; we will refer to this as station "A".

4. Without disturbing the tuning, firmly grasp the dial gear at front of variable condenser in one hand and move the rear disc, by means of special wrench furnished with set, until the rear contact finger is on the small insulated sector of the rear disc.

The wrench is designed to fit loosely on the rim of the disc in order that it may be moved easily to any desired point on the rim. In using the wrench to move the disc, it is necessary to press against the wrench in such a way that the wrench grips the rim of the disc, and then press slowly but firmly in moving the disc.

If you have not held the dial gear securely while turning the disc, the set may have detuned slightly. (Detuning is most readily noticed when the tone control is set at high pitch). In this case retune the station carefully and re-adjust the rear disc.

5. Plug one of the top left-hand pair of tip leads into the jack at which the HOUR hand points or has just passed.

Note that the clock is marked in 15-minute intervals, not in minutes. Turn on the on-off switch to "automatic" (left) and tune off the station. This will cause the set to shut off and start the Tune-O-Matic motor. Allow the automatic mechanism to bring the pointer back to the station, at which point the motor will stop and the set will be turned on. After the tubes have heated and the station comes in, note whether the station is correctly tuned in. If the station is not tuned in correctly, a slight readjustment of the disc in the correct direction is necessary. Again throw the station off tune and repeat the procedure if necessary.

6. Proceed with the 2nd station as outlined in paragraphs numbered 4 and 5, above, but adjust the 2nd disc from the rear and use one of the 2nd pair from the top left row of tip leads to plug into the jack at which the hour hand points.

7. Adjust for the remaining stations in the same way, noting that the adjustment discs and the corresponding pairs of tip leads shown on page 1 of customer's instructions are as follows:

Rear disc.....(Station "A").

2nd from rear disc (Station "B").

3rd from rear disc (Station "C").

4th from rear disc (Station "D").

5th from rear disc (Station "E").

6th from rear disc (Station "F").

7th from rear disc (Station "G").

Front disc (OFF). This is set at factory.

ADDITIONAL AUTOMATIC "OFF" POSITIONS

If more than two automatic "off" positions are required, it is possible to obtain two additional "off" positions by using one of the seven station discs for this purpose.

Use the 2nd disc from the front and adjust it so its insulated sector is in the same position as the front or regular "off" disc. Mark "OFF" on the index plate directly above the regular "off" plate.

This arrangement provides selection of six different stations with four automatic "OFF" positions.

ADDITIONAL STATION LEADS

If seven good stations are not continuously available, it is necessary to double up on the good stations. Use two adjacent discs for each good station, marking the index plates to correspond.

INSTALLING ATWATER KENT REMOTE CONTROL ON MODEL 511 Tune-O-Matic

The Atwater Kent remote control consists of a small control box with a ten-point switch and illuminated switch dial. Seven of these ten points are used to select the seven different stations for which the Tune-O-Matic has been previously adjusted. There are two "off" points (one at each end of the switch movement), and one point marked "time" which restores the set to automatic time operation.

THE SWITCH ON THE CONTROL UNIT MUST BE PLACED IN THE "TIME" POSITION WHEN IT IS DESIRED TO HAVE THE SET TUNE AUTOMATICALLY.

The remote control has 25 feet of cable so the control unit may be placed across the room or in an adjoining room from the set.

The other end of the remote control cable has a multi-prong socket and plug. Attach the socket to the left-rear side of the cabinet by means of the two screws furnished with the unit.

Remove the plug of the Tune-O-Matic clock unit from the socket at top-left of chassis and insert it in the socket which you have just fastened to rear of cabinet. Then insert the plug at end of remote control unit into the socket on top of chassis.

This control unit does not have a volume control, but Model 511 has a super-automatic volume control circuit which ensures constant volume level from one station to another.

TRIMMER CONDENSERS

Code No.	Part No.	Name of Part
A3, 4	32880	Double I. F. trimmer
A5	24495	Single I. F. trimmer
A6	31870	Single trimmer

CHOKES

Code No.	Part No.	Name of Part
CK1	17015	R. F. "B" filter choke
CK2	33450	A. F. filter choke
CK3	23530	R. F. "A" filter choke

TRANSFORMERS

Code No.	Part No.	Name of Part
T1	33710	No. 1 R. F. T.
T2	33720	Oscillator T.
T3	25651	No. 1 I. F. T.
T4	33790	No. 2 I. F. T.
T5	25371	Power T.
T6	25606	Output T.

RESISTORS

Code No.	Part No.	Name of Part
R1	30360	Blue-gray, 1 U, 1/3-W.
R2	30380	Red-green, 3300 Ω, 1/3-W.
R3	30380	Red-green, 3300 Ω, 1/3-W.
R4	15820	Flexible, 70 Ω
R5	26160	White, 40,000 Ω, 1/2-W.
R6	30340	Red-blue, .1 U, 1/3-W.
R7	30370	Green, 2 U, 1/3-W.
R8	31970	Red-yellow, 1/4 U, 1/3-W.
R9	30360	Blue-gray, 1 U, 1/3-W.
R10	20120	Flexible, 800 Ω
R11	30350	Bl'k-purple, .5 U, 1/3-W.
R12	30370	Green, 2 U, 1/3-W.

SOCKETS

Part No.	Name of Part
24493	5 prong
25196	3 prong
24494	6 prong
23147	Fuse

POWER UNIT SUPPLY

Part No.	Name of Part
25595	Vibrator assembly
25563	Connector card, female
25564	Connector card and bracket, male
25344	Insulator (fish paper)

MISCELLANEOUS PARTS

Part No.	Name of Part
21406	Fuse, 10 amp.

Refer below for names of trimmers on these models.

R. F. TRIMMERS ON MODELS 112 AND 559

	10-18 MC Range	4-10 MC Range	1.5-4 MC Range	540-1600 KC Range
R. F.	A4	A3	A2	A1
1st-Detector	A12	A11	A8	A9
Oscillator	A14	A13	A7	A6
Tracking	None	None	A10	A5

The I. F. trimmers are A15 to A22, inclusive.

ADJUSTING TRIMMER CONDENSERS

EQUIPMENT.

1. **OSCILLATOR.** The oscillator should extend from the lowest I. F. frequency (125 KC in Atwater Kent sets) to at least 18 MC. The oscillator should have a good attenuator and should be well shielded. If the oscillator is not well shielded, it may be difficult to peak the pre-selector trimmers on some models, owing to pick-up by the 1st-detector grid circuit. In general, it is advisable to connect an .00025MFD fixed condenser in series with the oscillator pick-up lead at the antenna terminal of the set.

2. **OUTPUT METER.** Use a sensitive output meter and keep the radio volume control turned on full volume. This is necessary to minimize the effect of the automatic-volume-control action of the set which would otherwise prevent sharp peaking of the trimmers.

3. **BALANCING UNIT.** Build two of the Type "A" balancing units and one of the I. F. coupling units shown on right. These are required for correct adjustment of Atwater Kent super-heterodynes. The Type "B" balancing unit, also described, is used on earlier models of Atwater Kent sets.

4. Use a non-metallic screw driver for adjustment of the trimmers.

ADJUSTING TRIMMER CONDENSERS (Contd.)

GENERAL NOTES.

1. Do not make any trimmer adjustments and do not disturb the dial gear or the dial indicator adjustments unless absolutely necessary.
2. With all-wave sets, it is very desirable to use a test oscillator that extends to 18 MC (18,000 KC). If you attempt to use harmonics of a broadcast oscillator, you are likely to use the wrong harmonic and set the trimmers incorrectly.
3. When using a test oscillator, you will experience "double-spot" or image reception, particularly on the highest frequency range of the set. The double-spot point is twice the I. F. frequency below the correct point. For instance, if a set has an I. F. frequency of $472\frac{1}{2}$ kilocycles, and you are tuning in an 18 MC signal, the double-spot or image will be twice $472\frac{1}{2}$ or 945 KC (.94 MC) below 18. In such a case you will hear the signal at 18 MC and also at 17.06 MC. In properly aligned sets of six tubes or more, the image should be weaker than the desired signal.
4. Because of the facts mentioned in paragraphs 2 and 3 above, it is very desirable, wherever possible, first to check the short-wave dial calibration and determine how far, and in what direction, the readings are "off." This should be done on actual reception of short-wave stations of known frequency. This pre-checking will assist you in selecting the correct harmonic (in case you are using a broadcast oscillator), and it will also minimize possibility of confusing the correct signal and the image signal.
5. On oscillator trimmers there may be two different settings at which the signal is received. Always use the *first* of these two positions as you screw the trimmer in from a loose or minimum-capacity position. **THIS IS IMPORTANT.**
6. On sets with a combined oscillator and 1st-detector tube, tune the set to a quiet point near 1,000 KC while adjusting the I. F. trimmers.

OSCILLATOR GOVERNS DIAL ACCURACY.

It is essential to understand definitely that in a super-heterodyne the dial calibration depends on the oscillator circuit of the set, providing that the I. F. trimmers are correctly aligned. The pre-selector (R. F. and 1st-detector) trimmers do not affect the dial calibration but simply affect sensitivity.

If the dial calibration of one or more of the frequency ranges of the set is "off", check the oscillator trimmer, the oscillator tracking condenser and tracking trimmer, and the oscillator transformer for the particular range or ranges in question.

The oscillator trimmer is used to adjust the **high-frequency** end of the particular range.

The oscillator tracking condenser adjusts the **low-frequency** end of the particular range.

In Atwater Kent sets the fixed tracking condenser on the broadcast range (and in some models also on the police range) is shunted with an adjustable tracking trimmer condenser. The adjustable tracking trimmer condenser is not used on the high-frequency ranges.

The adjustment of the trimmers for the high-frequency and low-frequency end of a particular range is slightly interlocking. For example, assume that the broadcast range of a set is off calibration. First turn the tuning knob so the dial pointer is at 1500 KC and, using a 1500 KC signal, peak the broadcast oscillator trimmer. Then turn the set to 560 KC and, using a 560 KC signal, peak the oscillator broadcast tracking trimmer for maximum output. This adjustment will have slightly affected the previous adjustment at 1500 KC so it will be necessary to repeat the adjustment at 1500 KC and also possibly at 560 KC.

If adjustment of the oscillator trimmer and the oscillator tracking trimmer does not correct the dial readings, it may be necessary to replace the fixed oscillator tracking condenser or the oscillator transformer for that particular range.

Naturally, the I. F. trimmers should be checked, and adjusted if necessary, before any attempt is made to align the R. F. or oscillator trimmers.

GENERAL PROCEDURE.

First check the I. F. trimmers. If reception is satisfactory and the dial calibration is correct on the broadcast range, it is safe, to assume that the I. F. trimmers are correctly adjusted.

If the dial calibration is "off" (or the set is weak) on only one range, adjust the trimmers for that range only. If this does not correct the trouble, inspect the resistors, condensers, transformers, and switch contacts associated with that particular range.

In checking a set, do not disturb the position of the wiring any more than necessary.

MODELS 112 AND 559

I. F. TRIMMERS.

Connect an I. F. test oscillator to the 1st-detector tube by means of the I. F. coupling unit shown in Fig. 1. Adjust the I. F. oscillator to $472\frac{1}{2}$ KC. Connect a sensitive output meter to the set. Use the weakest possible oscillator signal that will give a reading on the output meter with the radio volume control on full. Put tone control in 2nd-position from right.

Put balancing unit A (shown in Fig. 2) across trimmer A21 and peak A22.

Put unit A across A22 and peak A21.

Put unit A across A19 and peak A20.

Put unit A across A20 and peak A19.

Put one unit A across A17 and another unit A across A15; peak A18 and A16.

Put one unit A across A18 and another unit A across A16; peak A17 and A15.

In case of instability while adjusting A21 and A22, place an extra balancing unit A across A18.

Remove the I. F. coupling unit and the balancing units and seal the trimmer screws.

R. F. TRIMMERS.

Connect an R. F. oscillator to the antenna and ground terminals of the set. Use the weakest possible signal to give a reading on the output meter. Loosen the trimmer screws for the frequency range or ranges that are to be re-adjusted.

10 to 18 MC range. Tune oscillator exactly to 18 MC and turn tuning knob of set so indicator is at 18 MC mark. Adjust trimmers A14, A4 and A12 for peak output.

4 to 10 MC range. Tune oscillator exactly to 10 MC and turn set to 10 MC mark on the 4 to 10 MC range. Peak trimmers A13, A3 and A11.

1.5 to 4 MC range. Tune oscillator to 4 MC and turn set to the 4 MC mark on the 1.5 to 4 MC scale. Peak trimmers A7, A2 and A8. Tune oscillator to 1.5 MC and, with set at 1.5, peak A10. Repeat adjustments on A7 and A10 if necessary.

Broadcast range. Tune oscillator and set to 1500 KC. Peak trimmers A6, A1 and A9. Tune oscillator to 560 KC and turn set to the 560 KC mark. Peak A5. Repeat adjustments on A6 at 1500 and A5 at 560 if necessary.

MODELS 145 AND 325

I. F. TRIMMERS.

Connect an I. F. test oscillator to the 1st-detector tube by means of the I. F. coupling unit shown in Fig. 1. Adjust the I. F. oscillator to 264 KC. Connect a sensitive output meter to the set. Use the weakest possible oscillator signal that will give a reading on the output meter with the radio volume control on full. Turn the set to a quiet point near 1000 KC.

Peak trimmer A7, A6 and A5. Remove the I. F. coupling unit and seal the trimmer screws.

MODEL 318,447
Alignment, Trimmers

ATWATER-KENT MFG. CO.

MODEL 206,376 (1st)
Alignment, Trimmers

DIAL POINTER ADJUSTMENT.

With the variable condenser all the way in, the dial pointer should be set at 535 KC.

R. F. TRIMMERS.

Connect an R. F. test oscillator to the antenna and ground terminals of set. Use the weakest possible oscillator signal. Loosen the trimmer screws.

Short-wave range. Oscillator at 15 MC, and set turned to 15 MC mark, peak trimmer A3

Police range. There are no trimmer adjustments for this range.

Broadcast range. Oscillator at 1500 KC and dial pointer at 1500 KC mark, peak trimmers A8, A2 and A1. Tune oscillator and set to 560 KC. Peak A4. Repeat adjustments on A8 at 1500 KC and A4 at 560 KC if necessary.

MODELS 206 AND 376 (1st type)

I. F. TRIMMERS.

Connect an I. F. test oscillator to the 1st-detector tube by means of the I. F. coupling unit shown in Fig. 1. Adjust the oscillator to 472½ KC. Use the weakest possible signal that will give a reading on the output meter with the radio volume control on full.

Turn the set to a quiet point near 1000 KC.

Peak trimmers A8, A7 and A6 for maximum output. Remove the I. F. coupling unit and seal the I. F. trimmers.

DIAL POINTER ADJUSTMENT.

With the variable condenser rotor completely meshed, the dial pointer should be set at 535 KC.

R. F. TRIMMERS.

Connect a suitable R. F. oscillator to the antenna and ground terminals of set.

Broadcast range. Oscillator at 1500 KC and dial pointer at

R. F. TRIMMERS ON MODELS 206 AND 376

	Short-Wave Range	Police Range	Broadcast Range
R. F.	A1	None	A2
1st-Detector	A4	None	A3
Oscillator	A10	None	A9
Tracking	None	None	A5

The I. F. trimmers are A6, A7 and A8.

1500 KC mark, adjust trimmers A9, A2 and A3. Tune oscillator and set to 560. Peak A5. Repeat adjustments on A9 at 1500 KC and A5 at 560 KC if necessary.

Police range. There are no trimmer adjustments for this range.

Short-wave range. With oscillator at 15 MC and set turned to 15 MC, peak trimmers A10, A1 and A4.

MODELS 318 AND 447

I. F. TRIMMERS.

Connect an I. F. test oscillator to the 1st-detector tube by means of the I. F. coupling unit shown in Fig. 1. Adjust oscillator to 472½ KC. Connect a sensitive output meter to the set. Use the weakest possible oscillator signal that will give a reading on the output meter with the radio volume control on full.

Put balancing unit A (shown in Fig. 2) across trimmer A19 and peak A20.

Put unit A across A20 and peak A 19.

Put unit A across A17 and peak A18.

Put unit A across A18 and peak A17.

Put unit A across A15 and peak A16.

Put unit A across A16 and peak A15.

Remove the I. F. coupling unit and balancing unit and seal the I. F. trimmers.

R. F. TRIMMERS.

Connect an R. F. test oscillator to the antenna and ground terminals of set. Use the weakest possible oscillator signal that will give a reading on the output meter. Loosen the trimmer screws for the frequency range or ranges that are to be re-adjusted.

12 to 22.5 MC range. Oscillator at 18 MC, dial pointer at 18 MC, peak trimmers A13, A4 and A8.

4.6 to 12.2 MC range. Oscillator at 12 MC, dial pointer at 12 MC, peak trimmers A14, A2 and A6 for maximum output.

R. F. TRIMMERS ON MODELS 318 AND 447

	12-22.5 MC Range	4.6-12.2 MC Range	1.6-4.6 MC Range	540-1600 KC Range
R. F.	A4	A2	A3	A1
1st-Detector	A8	A6	A7	A5
Oscillator	A13	A14	A12	A11
Tracking	None	None	A10	A9

The I. F. trimmers are A15 to A20, inclusive.

* Model 275 may be used on 110 Volts, 25-60 cycles, or 110 Volts, D. C. It has a police switch to tune in the 2400-kilocycle police band.

† Has police switch to tune in the 2400-kilocycle police band.

** The "B" consumption of Models 387 and 427Q is from 20 to 27 milliamperes depending on signal strength and volume level. (25 milliamperes is average.) Late Models 387 and 427Q have a police switch for both police bands.

†† The "B" consumption of Models 165Q and 525Q is from 16 to 25 milliamperes depending on signal strength and volume level. (22 milliamperes is average.)

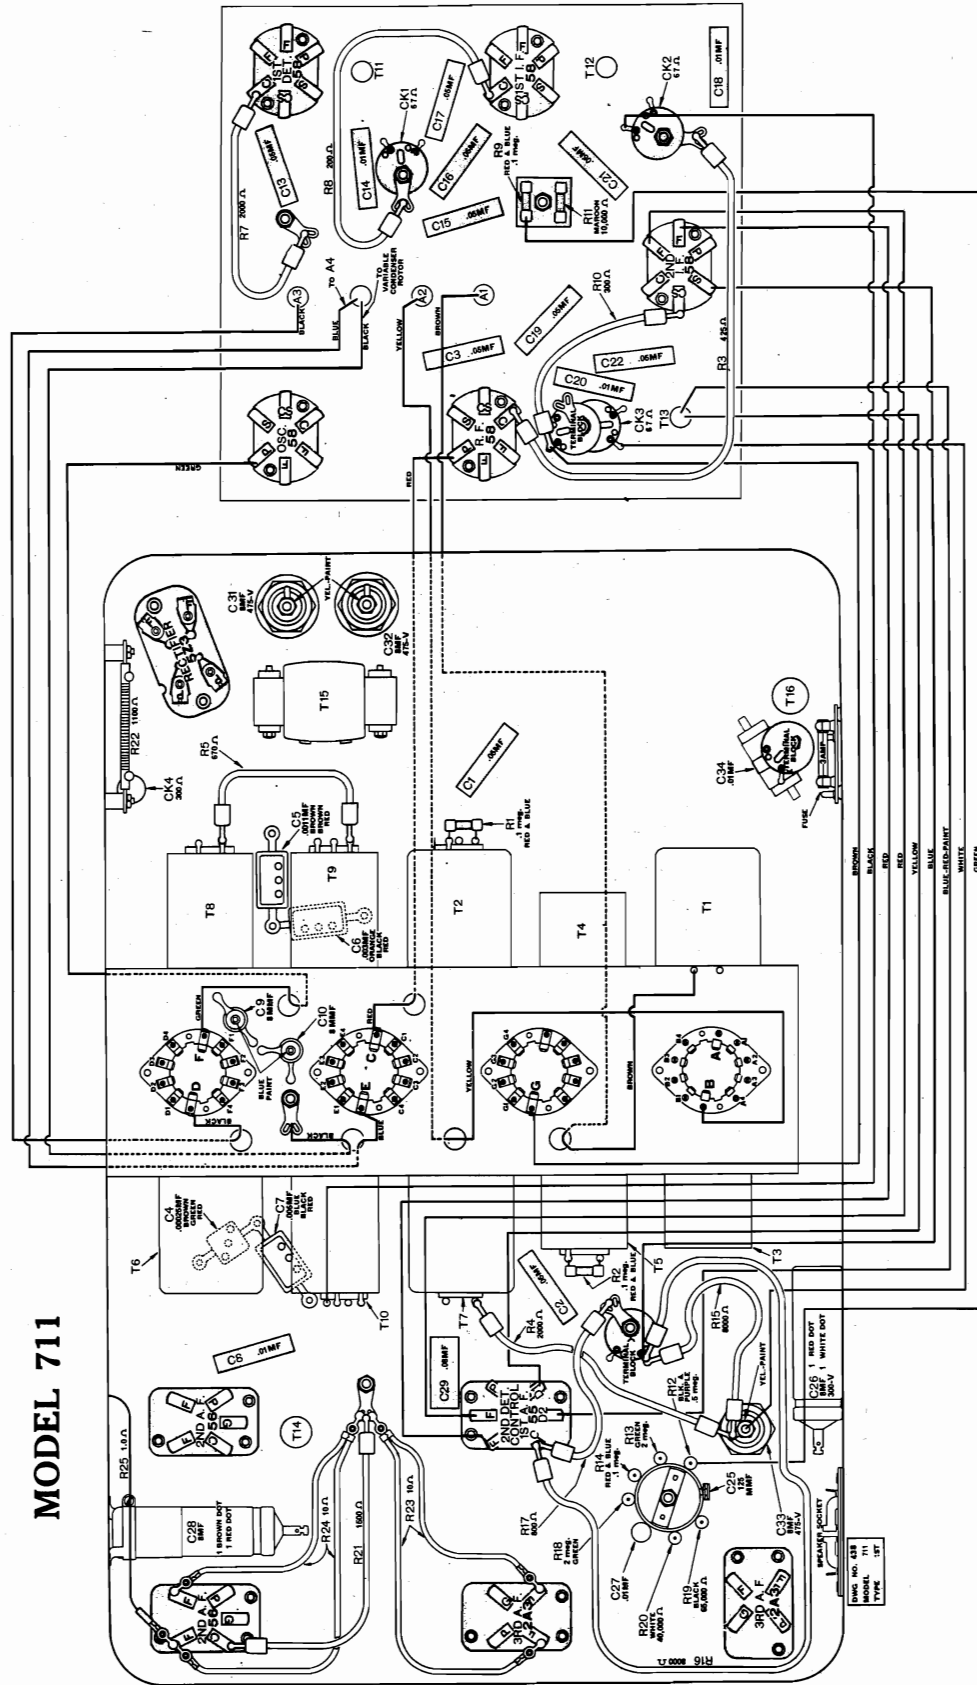

*** The J cabinet is rounded-front. The T cabinet has doors.

† Late 816 926 and 936 utilize 6D6 tubes instead of 39 tubes for R. F. and I. F.

†† Model 185A also covers the short-wave range of 5.5 to 15.5 megacycles, which includes the four principal international short-wave broadcast bands.

ATWATER-KENT MFG. CO.

MODEL 711
Chassis Wiring

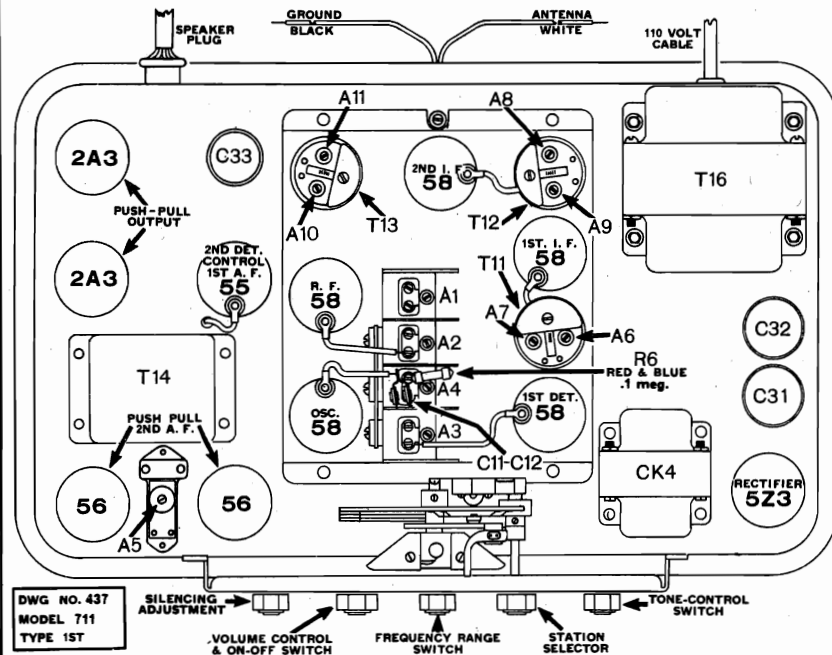

MODEL 711

This bottom chart shows all connections between the upper tube base and the main base. In late 711, the R. F. bias resistor R3 is grounded at the front ground lug (near C13) instead of as shown, in order to reduce tendency to oscillation.

ATWATER-KENT MFG. CO.

MODEL 808-A
Chassis Wiring

MODEL 808-A

There are three types of quality Alter in the plate of the 2A5.
 The first type used an .007-MF condenser.
 The second type used an .005-MF condenser.
 The third type uses resistor R23 in series with .05-MF.

MODEL		
TYPE		

MODEL 816,926,936 (1st)
Socket, Trimmers, Parts, ATWATER-KENT MFG. CO.
Power Unit Schematic

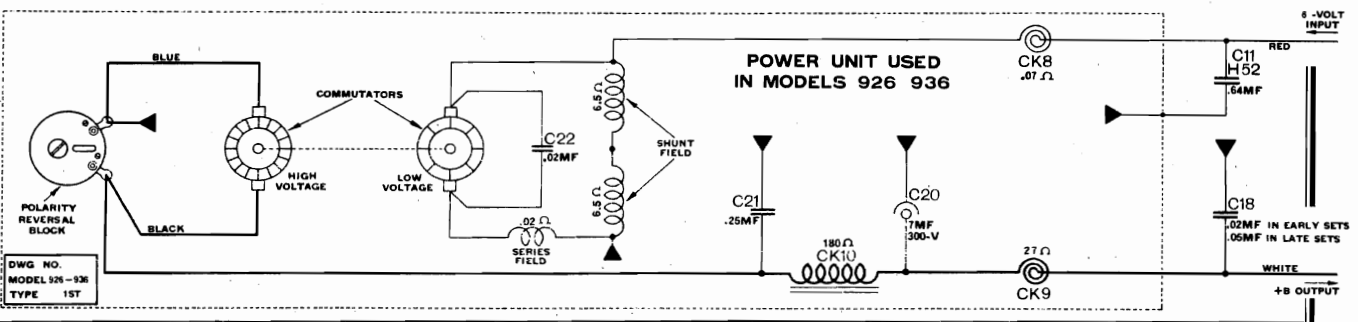

In late type sets, the "A" battery cable is brought out the top side, near the speaker plug.

1st TYPES OF
MODELS 816, 926 AND 936

Model 936 has a separate speaker which plugs into a three-prong socket on the inside of lid of set container.

ATWATER-KENT MFG. CO.

MODEL 816,926,936 (1st)
Parts List

MODEL 816

(Below Serial No. 1121818)

Part No.	Name of Part
26586*	Set container complete, less lid
26496	Set container lid (bl'k)
26549	Tuning cable bushing
26036	Inner plate for above
26102	Polarity reversal cover
26096	Sound insulators (felt)
26452	Lid mounting bracket
26128	Thumbscrew
19455	Mounting washer
26462	Variable cond. assembly
25478	Grommet for var. cond.
26072	Shield for No. 1 I. F. T.
26538	Insulator for above shield
26589	Shield for No. 1 R. F. T.
26591	Shield for No. 2 R. F. T.
25818	Clamp for No. 36440 cond.
26505	Volume control, .5 U
26033	Volume control bracket
26039	Volume control coupling
24540	Tone control switch
26127	Knob for above
13664	Sensitivity switch
21143	Plug suppressor
21144	Distributor suppressor
23260	Generator cond., 1 MF, 200-V.

* When ordering cabinet, specify brown or black

TRANSFORMERS

C18**36880 .02 MF, 450-V., NI
C19 30270 Tone control cond. (B-16)
* C16 is .02 MF, 450-V., NI 29030 in some of these sets.
** C18 is .05 MF, 200-V., NI 26820 in later sets.

TRIMMERS

Code No.	Part No.	Name of Part
A4, 5	37960	Double I. F. trimmer
A6	36570	Single I. F. trimmer

CHOKES

Code No.	Part No.	Name of Part
CK1	26594	2nd detector plate choke
CK2	36630	R. F. "A" filter choke
CK3	36610	R. F. "A" filter choke
CK4	36610	R. F. "A" filter choke
CK5	36620	R. F. "B" filter choke
CK6	36620	R. F. "B" filter choke
CK7	25416	A. F. "B" filter choke

POWER UNIT ASSEMBLY

Part No.	Name of Part
26863	Vibrator
26854	Rubber (2)
26855	Rubber (1)
26061	Inside vibrator container
26062	Lid for above
2652'	Grommet
2608'	Tubular condenser clamp
26663	Middle container body
26091	Middle container lid
26136	Vibrator lid insulator
26664	Outer container body
26665	Outer container lid

SPEAKER

Part No.	Name of Part
26851	Speaker less cable
26826	Cone head assembly
26827	Field coil, 6.5 Ω
26559	Speaker cable and plug

MISCELLANEOUS PARTS

Part No.	Name of Part
21878	Disc shield, No. 2 I. F. T.
26578	Disc (insul.) for No. 2 I. F. T.
21406	Fuse, 10 amp.

REMOTE CONTROL HEAD

Part No.	Name of Part
26646	Remote control head complete with mounting parts (less cables)
26893	Pointer gear (fibre)
26894	Spring washer
26108	Mounting strap and bushing
26884	Head assembly
26892	Pointer and shaft
26886	Screw No. 4—36 x 1/4
26888	Cork gasket
26889	Dial assembly
26891	Diffusing strip
26107	Mounting bracket
26528	Screw 1/4—20 x 1/2
26104	Assem. vol. cont. cable, 35 in.
26105	Assembled tuning cable, 31 in.
26109	Key
26887	Glass
27118	Lamp (6-8-V., 1/4A), green
26895	Gear shaft assembly
26896	Tuning knob
27312	Tuning knob spring
26897	Key knob
26898	Screw No. 10—32 x 1/4 F. H. cup pt.

26899	Shielded wire (dial lite lead)
26901	Wire clamp
26531	Screw 1/4—20 x 1/8
24082	Wire tip
27059	Steering column mounting bracket assembly
26107	Mounting bracket (column type)
26531	Column clamp screw
26108	Column clamp

21141	Lockwasher
26528	Mounting screw
26943	Panel mounting bracket assem.
26944	Mounting bracket (panel type)
26945	Wing screws
26946	Flat head screws
26947	Felt pad

EXTRA LENGTH ASSEMBLED CABLES

27114	Assem. vol. cont. cable, 3 1/2 ft.
27115	Assembled tuning cable, 3 1/2 ft.
27016	Assem. vol. cont. cable, 11 ft.
27017	Assembled tuning cable, 11 ft.

MODEL 926

(Below Serial No. 8276401)

Model 926 speaker and chassis is identical to Model 816, but the 926 uses a genemotor power unit

POWER UNIT
MODELS 926 and
936

Part No.	Name of Part
26093	Power unit container
26942	Lid for above
36610	R F "A" filter choke (CK8)
36620	R F "B" filter choke (CK9)
22359	A F "B" filter choke (CK10)
26864	7 MF, 300-V., dry electrolytic (C20)
35930	.25 MF, 200-V., NI (C21)
36420	.02 MF, 200-V., IND. (C22)

GENEMOTOR No. 26734

Part No.	Name of Part
26964	Motor end bracket assembly
26965	Generator end bracket assembly
26966	Generator brushes assembly
26967	Motor brushes assembly
26968	Field coils and field core assembly
26969	Field coils set
26971	Armature
26972	Ball bearing
26973	Motor mounting bracket
26974	Rubber bumpers
26975	Steel studs 4 5/8" x 8/32 thd.
26976	Hex. iron nuts—cadmium plated
26977	Ground lug
26978	2 5/8" long—No. 18 extra flexible bare ground lead
27043	Field core assembly
27044	Shunt field (2 leads)
27045	Shunt and series field (4 leads)

MODEL 936

(Below Serial No. 4542201)

Model 936 chassis is identical to Model 816, but the 936 uses a genemotor power unit (listed above), and a separate speaker (listed below).

Part No.	Name of Part
26806	Lid
25196	Socket (3 prong)
26831	Cable and plug assembly (5 wire)
21963	Tone control knob

936 SPEAKER No. 38900

Part No.	Name of Part
26822	Diaphragm
30710	Field coil
26823	Cable and plug assembly (3 wire)

Ω=ohms. U=megohms. IND.=inductive. NI=non-inductive. W.=watt.

1935 Set Model Specifications

ATWATER-KENT MFG. CO.

DATA FOR CURRENT MODELS

The last figure in the model number indicates the number of tubes; for instance, Model 145 has 5 tubes; Model 511 has 11 tubes, etc. The letter "Q" indicates battery operation; the letter "D" indicates D. C. operation; the letter "Z" indicates 32-volt operation. All models listed below have tone control, and all models with exception of 465Q and 655Q have automatic volume control. All models have dynamic speakers, with exception of battery sets, which have special magnetic speakers.

Parts List, see Index

AUDIOLA RADIO CO.

Six Tube Auto Radio

MODEL 346, B-6
Schematic, Socket
Alignment

This receiver is a six tube superheterodyne using the most modern circuit design and tubes. Tubes used are: one 6D6 R.F. Amplifier; one 6A7 combination 1st detector and oscillator; one 6D6 I.F. Amplifier; a 75 diode detector with delayed A.V.C. and one stage audio; one 41 power output tube; and one 84 rectifier tube.

In the installation of this receiver there are a few important fundamental principles to adhere to:

- (1) Avoid having any battery wires in close relation to the high voltage spark coil or plug wires.
- (2) The antenna must be routed over the most quiet location. Interference will often go through the antenna shielding if touching brake, accelerator, or steering column rods. The lead in must be shielded up to the antenna and the shield bonded to the set chassis. In many installations the antenna shield must also be bonded to the chassis of the car where the shield turns up to the top.
- (3) If the chassis has to be removed from housing, be certain to tighten the three screws on the bottom when replacing the chassis.
- (4) After installation is completed, adjust antenna trimmer on some distant station around 1400 to 1500 K.C. turn in either direction for loudest signal. The antenna trimmer is directly under the serial number on the top of the set. The front cover screws must always be tight.
- (5) The gang condenser control (tuning) must run very freely and have not less than 1/32 of an inch end play.

Shield antenna lead-in and bond the shield to frame at center post. If antenna comes down front post, shield as high as possible and also ground the shield to dash.

In case of antenna pick-up, use heavy "A" choke and double condenser as in diagram #1.

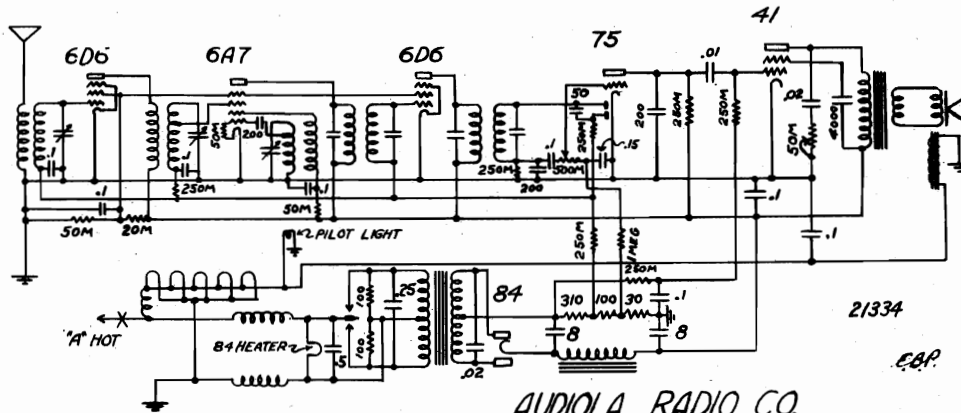

In case of chassis pick-up, separate primary and high tension ignition wires, shield and ground the shield at both ends.

In Chevrolet, it is sometimes necessary to shield the floorboards on the right hand side and ground with floorboard screws.

In Ford V8 shield primary and "A" lead to generator separately and ground shields to spark plug housing brackets as in diagram #2.

In case of floating power, bond center bolt on Audiola set to motor block.

Seven Tube Auto Radio

This receiver is a seven tube superheterodyne using the most modern circuit design and tubes. Tubes used are: one 6D6 R.F. Amplifier; one 6A7 combination 1st detector and oscillator; one 6D6 I.F. Amplifier; an 85 diode detector with delayed A.V.C. and one stage audio; two 41 power output tubes and one 84 rectifier tube.

In the installation of this receiver there are a few important fundamental principles to adhere to:

- (1) Avoid having any battery wires in close relation to the high voltage spark coil or plug wires.
- (2) The antenna must be routed over the most quiet location. Interference will often go through the antenna shielding if touching brake, accelerator, or steering column rods. The lead in must be shielded up to the antenna and the shield bonded to the set chassis. In many installations the antenna shield must also be bonded to the chassis of the car where the shield turns up to the top.
- (3) If the chassis has to be removed from housing, be certain to tighten the three screws on the bottom when replacing the chassis.
- (4) After installation is completed, adjust antenna trimmer on some distant station around 1400 to 1500 K.C. turn in either direction for loudest signal. The antenna trimmer is directly under the serial number on the top of the set. The front cover screws must always be tight.
- (5) The gang condenser control (tuning) must run very freely and have not less than 1/32 of an inch end play.

347

Audiola is first to develop an auto radio that eliminates motor noise without the use of spark plug suppressors.

This is an important engineering advancement in the auto radio art. We are pleased to have made this contribution to the radio industry.

It is important that you understand this new pioneering development.

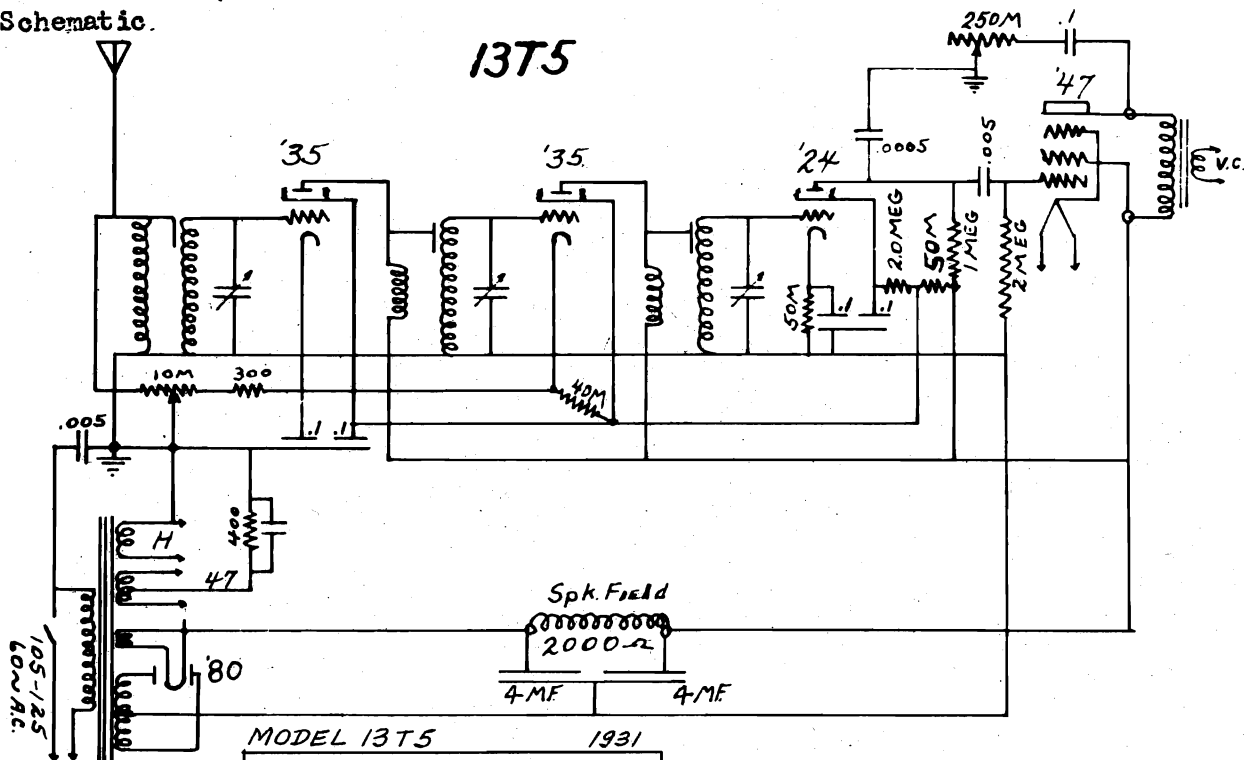

We have successfully installed the Audiola auto radio without spark plug suppressors, and eliminated all motor noise and other noise, from every car that we have tried. This has covered almost every make and model of automobile.

For Elimination of Interference data, see Model 346.

OPERATING INSTRUCTIONS FOR TEN TUBE SHORT WAVE SUPERHETERODYNE

A drawing is included showing correct placement and type of tubes. This receiver covers a frequency range of 540 to 20,000 kilocycles (555 to 15 meters) by the use of four overlapping wave bands, each selected by means of the band switch as indicated. When the band switch is in extreme left position, set covers band No. 1, which is the broadcast band, and subsequent positions cover the other three bands.

Band No. 1 readings may be converted to kilocycles by adding two ciphers (multiplying by 100). Bands Nos. 2, 3, and 4 are calibrated in megacycles and may be converted into kilocycles by adding three ciphers (multiplying by 1000).

Too much emphasis cannot be placed on the desirability of tuning the set extremely slowly when tuning on bands Nos. 2, 3, and 4. Due to extreme sharpness and selectivity in these positions, stations would be otherwise passed by unless the tuning operation is done slowly. The foregoing is especially true when "tuning in" weak and far-distant stations.

Under the right conditions of time, location, and weather, one may reasonably expect to tune in distant or foreign stations. We do not make unsubstantiated claims that it is possible to tune in foreign stations at will.

There is very little "static" in the short wave bands, but due to the extreme sensitivity, all sorts of electrical disturbances may be heard if conditions are not correct. Even the ignition system of a passing car may impair reception. Practice proper handling and tuning of the short wave bands and you will be rewarded with many interesting and entertaining broadcasts.

Always bear in mind the difference in time in different parts of the world when tuning for foreign stations. For example, when it is seven o'clock in the evening in Chicago, it is two o'clock in the morning in most of Europe.

The majority of reliable United States and Canadian short wave broadcasting stations may be found around 6 and 7 (6000 and 7000 kilocycles) on band No. 3, and around 9 and 10 (9000 and 10,000 kilocycles) on band No. 4.

A good aerial and good ground are necessary if the best results are to be secured.

BELMONT RADIO CORP.

To peak I.F. transformers connect oscillator (set at 175 KC) to grid of 57 first detector and (Black) ground wire. Adjust four trimmers from bottom of chassis (one nut and one screw on each transformer trimmer) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).

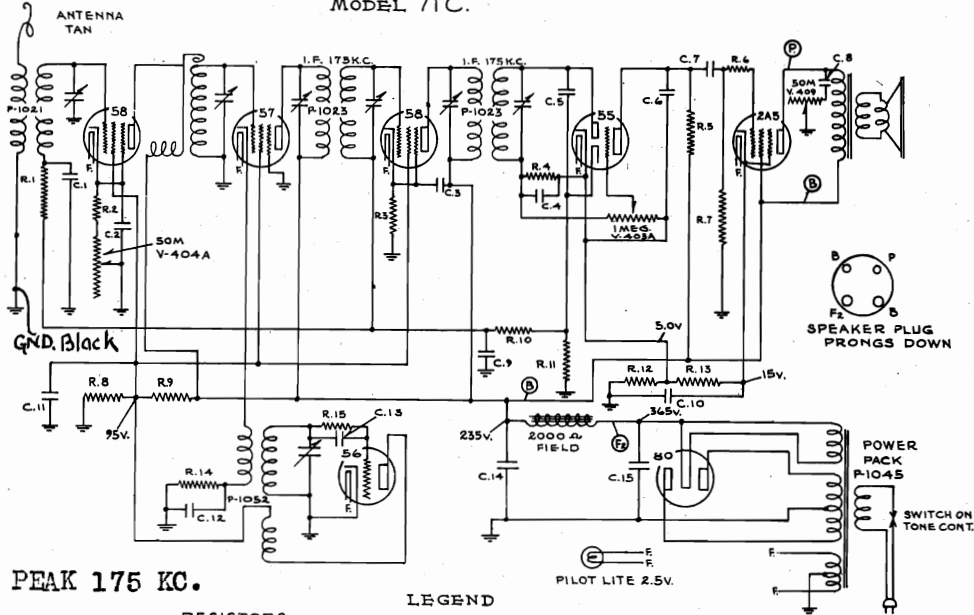

Connect an oscillator in series with a 200 MMFD condenser to the Tan (Antenna) wire and Black (ground) wire, with the oscillator set at 1720 KC and the variable condenser at its minimum position (extreme right of its rotation) adjust trimmer of oscillator (front) section of variable condenser to resonance. Set oscillator to 1400 KC and rotate variable condenser until signal is tuned in, then adjust ANT. and R.F. trimmers (center and rear sections of condenser) to resonance. Check output at 1200, 1000, 800, and 600 Kilocycles, bend plates of center and rear sections of variable condenser only if necessary.

BELMONT RADIO CORP.

SERVICE MANUAL FOUR TUBE T.R.F. RECEIVERS

105-115 Volts Alternating (any cycles) or Direct Current - 40 Watts

530 - 1720 Kilocycles

Both of the above models are four tube T.R.F., two gang receivers, the principle difference being that model 420 is equipped with a permanent magnet speaker and the model 430 with an electro dynamic speaker.

The tube complement of model 420 is as follows:

- 1 - Type 6D6 - remote cut-off pentode as an R.F. amplifier.
- 1 - Type 76 - triode as a detector.
- 1 - Type 38 - pentode as an output tube.
- 1 - Type 12Z3 - high vacuum rectifier.

The tube complement of model 430 is as follows:

- 1 - Type 6D6 - remote cut-off pentode as an R.F. amplifier.
- 1 - Type 76 - triode as a detector.
- 1 - Type 12A5 - pentode output tube.
- 1 - Type 12Z3 - high vacuum rectifier.

SERVICE NOTES

Should it ever become necessary to check alignment or re-align these receivers, the correct procedure is as follows:

Before any adjustments are made, the chassis must be removed from the cabinet. To do this it is necessary to pull off the volume and selector knobs, remove the back of the cabinet and the four screws which fasten the chassis to the base of the cabinet.

FREQUENCY ALIGNMENT:

1. Disconnect antenna wire from lug on antenna coil to which it is attached and connect in its place, in series with a 50 mfd. condenser, a test oscillator. With this oscillator set at 1400 kilocycles and the R.F. (front trimmer) opened as far as possible, trim the antenna (rear) trimmer to resonance with oscillator (maximum deflection on an output meter connected across the two leads of the PM speaker on the model 420 and across the primary of the speaker input transformer on the model 430).
2. Check tracking at 1200-1000-800-600-530 kilocycles, bending plates only if absolutely necessary.
3. Re-set oscillator to 1712 kilocycles, tuning oscillator by rotating variable condenser for a check to ascertain if receiver tunes to 1712.

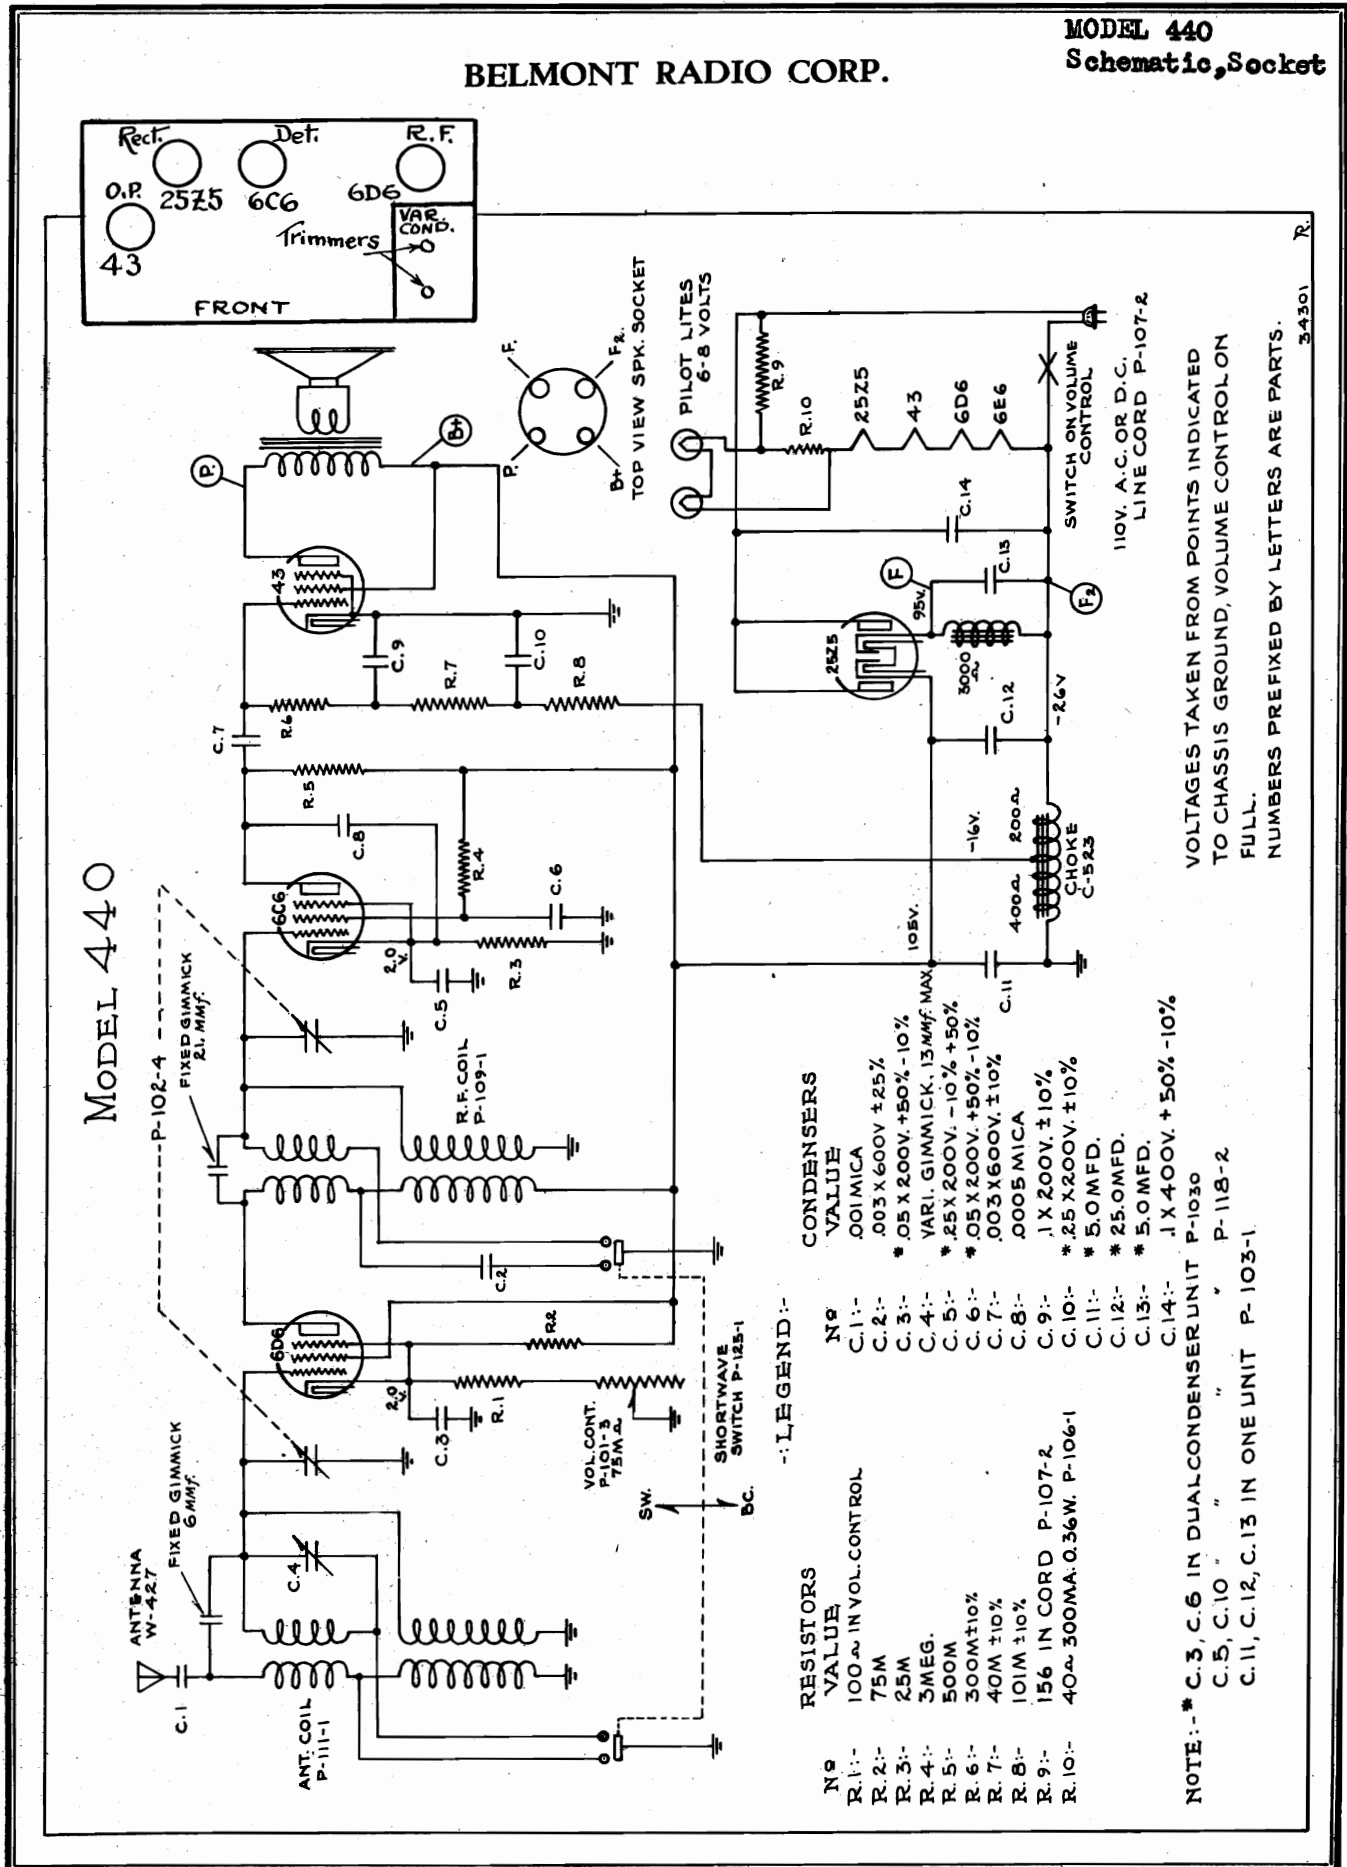

NOTES:

If trouble is experienced in getting receiver tuned down to 1712, look for the following:

That the green grid and black ground wires connected to the antenna coil are well separated from each other and that both the green leads to the grid cap and the antenna are clear of the tube shield (this reduces to a minimum the external capacity of the antenna coil).

BELMONT RADIO CORP.

MODEL 440
Schematic, Socket

MODEL 440
Alignment

BELMONT RADIO CORP.

105-115 Volts Alternating (any cycles) or Direct Current - 40 Watts.

530-1500 Kilocycles - 1500-4000 Kilocycles

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

BROADCAST BAND ALIGNMENT:

Remove chassis from cabinet by pulling off volume, selector and wave changing switch knobs, removing back and four screws which hold chassis in cabinet, replace knobs and disconnect antenna wire from coil.

1. Set wave changing switch in broadcast position by rotating in clockwise (right) direction.
2. With gang condenser in its minimum capacity position, plates entirely out of mesh, extreme left of its rotation, and with volume control full on, make the following adjustments:
 - (a) Connect an oscillator set at 1500 kilocycles in series with a 50 mmfd. condenser to the antenna terminal of the coil (from which antenna lead has been removed) and to ground (chassis), adjust both antenna and R.F. trimmers of the variable condenser to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
 - (b) Reset oscillator to 1400 kilocycles, adjust variable condenser to pick up oscillator and re-align antenna trimmer (rear section of variable condenser) to resonance.
 - (c) Check output at 1200-1000-800-600 kilocycles. Bend plates only at 1200 and 1000 kilocycles to increase output, and then only if necessary. No bending is necessary at 600 or 800 kilocycles.

SHORT WAVE BAND ALIGNMENT:

1. Set wave changing switch in counter-clockwise (left) position.
2. With oscillator adjusted to 3700 kilocycles, adjust the condenser mounted on top of the antenna coil and consisting of a center piece of heavy enameled copper wire about which is wrapped a spiral of a smaller enameled copper wire, with your fingers sliding the spiral to and fro until maximum output is attained, as indicated by maximum deflection on the output meter.
3. Next reset oscillator to 1550 kilocycles and adjust slip coil at the bottom of antenna coil assembly until maximum output is obtained (this coil is wound on a paper tube which has been slipped over the dowel on which the other coils are wound). Seal this slip coil with wax after making adjustment.
4. Now reset oscillator to 3700 kilocycles and readjust the condenser previously adjusted, as explained in 1. On completing this readjustment, seal the adjustment by dropping some wax in the hole of the terminal strip at the top of the antenna coil assembly where the spiral enameled wire passes through the strip. Do not put wax on the spiral wire, as this will change the capacity of this small condenser.

NOTES

When making these adjustments with the small condenser at the top of the coil and with the slip coil at the bottom of the antenna assembly, keep the receiver tuned to the generator at all times by gently rocking the variable condenser to and fro.

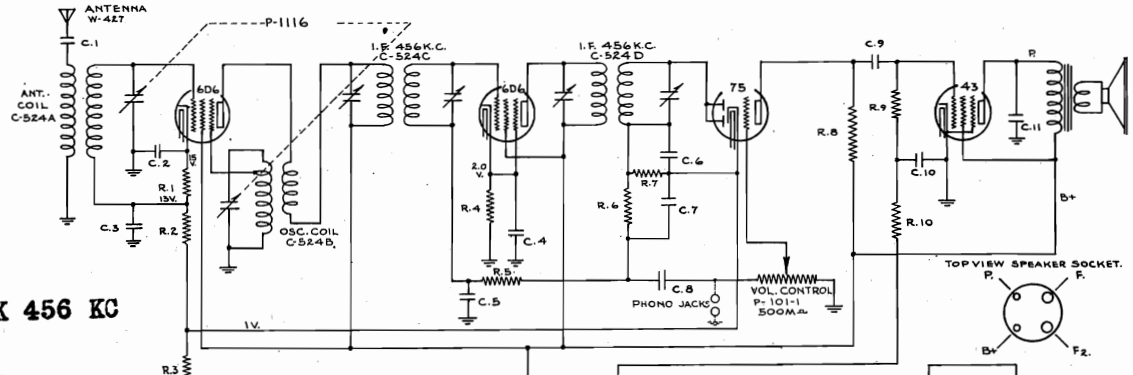

In order to replace pilot lights, it is necessary to remove the chassis. These lamps are connected in series, if one of them burns out the other one will not light. They are 6-8 volt, .15 ampere lamps.

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

1. Volume control on full during all alignment.
2. Variable condenser in minimum capacity position, plates open, at start of all aligning.

I.F. ALIGNMENT

1. To peak I.F. transformers, connect oscillator set at 456 kilocycles to the grid of the 6D6 tube directly in back of the variable condenser and adjust the trimming condensers of the I.F. transformers to resonance (Maximum deflection on an output meter connected across the primary of the speaker input transformer).

Each I.F. trimmer has two adjustments, one nut and one screw, both of which are adjustable from the top.

BROADCAST BAND ALIGNMENT

1. Disconnect antenna wire and connect oscillator in series with a 75 mmfd. condenser to the antenna coil. With the variable condenser set at its minimum capacity position, at the extreme right of its rotation, and with an oscillator output adjusted to 1720 kilocycles, adjust trimmer of oscillator section of variable condenser (rear section) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer). Next adjust the trimmer condenser of the front section of the variable condenser to resonance.
2. Check alignment at 1400-1200-1000-800-600-530 kilocycles, bending the slotted plates of the front section of the variable condenser only if absolutely necessary.

MODEL 575
Schematic,
Alignment

BELMONT RADIO CORP.

Service Notes

Voltagess taken from different points of circuit to chassis are measured with volume control full on, using a voltmeter having a resistance of 1000 ohms per volt. These voltages are indicated on the schematic circuit diagram.

Part No. 145-2

Common Black to Brown	— .003	x 600 Volts
Common Black to Green	— .1	x 200 Volts
Common Black to Red	— .1	x 200 Volts
Common Black to Orange	— .25	x 200 Volts
Blue to Blue	— .05	x 400 Volts

Part No. 145-3

Common Black to Brown	— .1	x 200 Volts
Common Black to Green	— .05	x 200 Volts
Common Black to Orange	— .05	x 200 Volts
Common Black to Yellow	— .05	x 200 Volts

Aligning I. F. Transformer

1. With volume control full on, at extreme right of its rotation, and with variable condenser at its maximum capacity position (extreme right of its rotation) make the following adjustments:

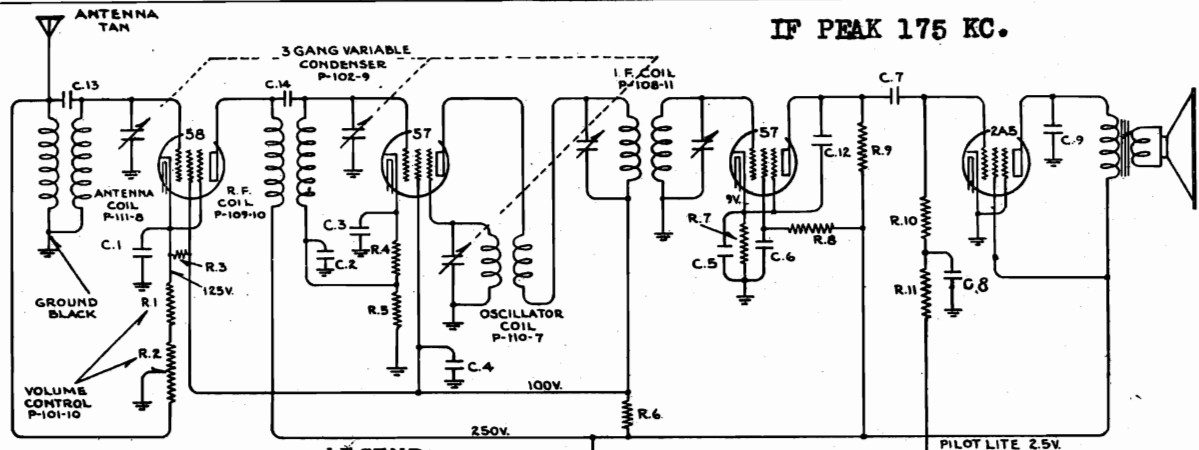

- (a) Connect an external oscillator adjusted to 175 kilocycles, in series with a .1 mfd. condenser, to the control grid cap of the type 57 tube located between the R. F. coil (part numbers 109-10) and the I. F. transformer (part number 108-11) and chassis.
- (b) Adjust trimming condensers of I. F. transformer (part number 108-11) to resonance. See top view of chassis. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or between the plate and screen terminals of the type 2A5 tube, by means of an adapter. Maximum deflection of the meter indicates resonance. Care must be taken to use only enough signal to give a readily readable output, as excessive input will result in overload and a false resonance point.

NOTE: The two trimmer condensers which tune the primary and secondary of the I. F. transformer are adjusted by set screws accessible from the back of the chassis.

Aligning R. F. and Oscillator Circuits

1. Connect the external oscillator set at 1720 kilocycles and in series with a 200 Mfd. condenser, between the antenna (tan) and ground (black) leads.

- (a) With volume control full on and variable condenser plates in minimum capacity position, plates entirely out of mesh (extreme left of its rotation), adjust trimmer of rear oscillator section of variable condenser to resonance.
- (b) Shift external oscillator frequency from 1720 to 1400 kilocycles, pick up signal by rotating variable condenser and peak R. F. (center) and antenna (front) section trimmers of variable condenser to resonance.
- (c) Check tracking at 1500, 1200, 1000, 800, 600 and 530 kilocycles by changing external oscillator frequency and rotating variable condenser to pick up signal. Adjust slotted end plates of R. F. (center) and antenna (front) sections to increase output, if necessary. DO NOT BEND OSCILLATOR PLATES.

BELMONT RADIO CORP.

SERVICE NOTES

Voltages taken from different points of the circuit are measured with a voltmeter having a resistance of 1000 ohms per volt and are made between the points indicated and the chassis pan. These voltages are indicated on the circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNMENT:

No aligning adjustments should be made until the set has been thoroughly checked for all other possible causes of trouble, such as poor installations, low line voltages, defective tubes, condensers and resistors.

ALIGNING I.F. TRANSFORMERS:

1. With volume control full on, at extreme right of its rotation, and with wave changing switch in the long wave position, extreme left of its rotation, and with variable condenser at its minimum capacity position, extreme left of its rotation, plates entirely out of mesh, adjust the I.F. transformers, parts number 108-15 and 108-16, in the following manner:
 - (a) Connect an external oscillator which has been adjusted to 370 kilocycles, in series with a .1 mfd. condenser to the control grid cap of the type 57 first detector tube (see diagram and chassis).
 - (b) Adjust trimming condensers of both I.F. transformers (parts number 108-15 and 108-16) to resonance. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between plate and screen terminals of type 2A5E output tube. Maximum deflection of the meter indicates resonance. Care should be taken to use only enough signal to give a readily readable output.

Note: The two adjustments on each transformer are accessible through holes in the transformer cans from the back of the chassis.

LONG WAVE BAND ALIGNMENT:

1. Shift frequency of external oscillator to 1000 meters and connect in series with a 200 mmfd. condenser to the tan antenna wire and the black ground wire, set wave changing switch to extreme left of its rotation and variable condenser at its minimum capacity position, extreme left of its rotation, plates entirely out of mesh.
 - (a) Adjust long wave shunt trimmers of antenna coil, part number 111-14 and oscillator coil, part number 110-11 to resonance (these adjustments are located nearest to the chassis and each of these coils are adjustable from side of the chassis).
 - (b) Shift frequency of external oscillator to 2000 meters, rotate variable condenser to pick up signal.
 - (c) Adjust series trimmer to resonance. This adjustment is accessible from top of the chassis between the variable condenser and the power transformer and is marked "A" on top view of chassis.

BROADCAST BAND ALIGNMENT:

1. Set wave changing switch in the broadcast, center, position and re-set external oscillator to 196 meters (1530 kilocycles), set variable condenser at its minimum capacity position, extreme left of its rotation
 - (a) Adjust oscillator shunt trimmer, upper adjustment part number 110-11, to resonance.
 - (b) Re-set external oscillator to 214 meters (1400 kilocycles), rotate variable condenser to pick up signal, adjust shunt trimmer of antenna coil, upper adjustment part number 111-14, to resonance.
 - (c) Re-set external oscillator to 542 meters (550 kilocycles), rotate variable condenser to pick up signal and adjust oscillator series trimmer (between condenser and transformer, marked "B" on diagram) to resonance.

SHORT WAVE BAND ALIGNMENT:

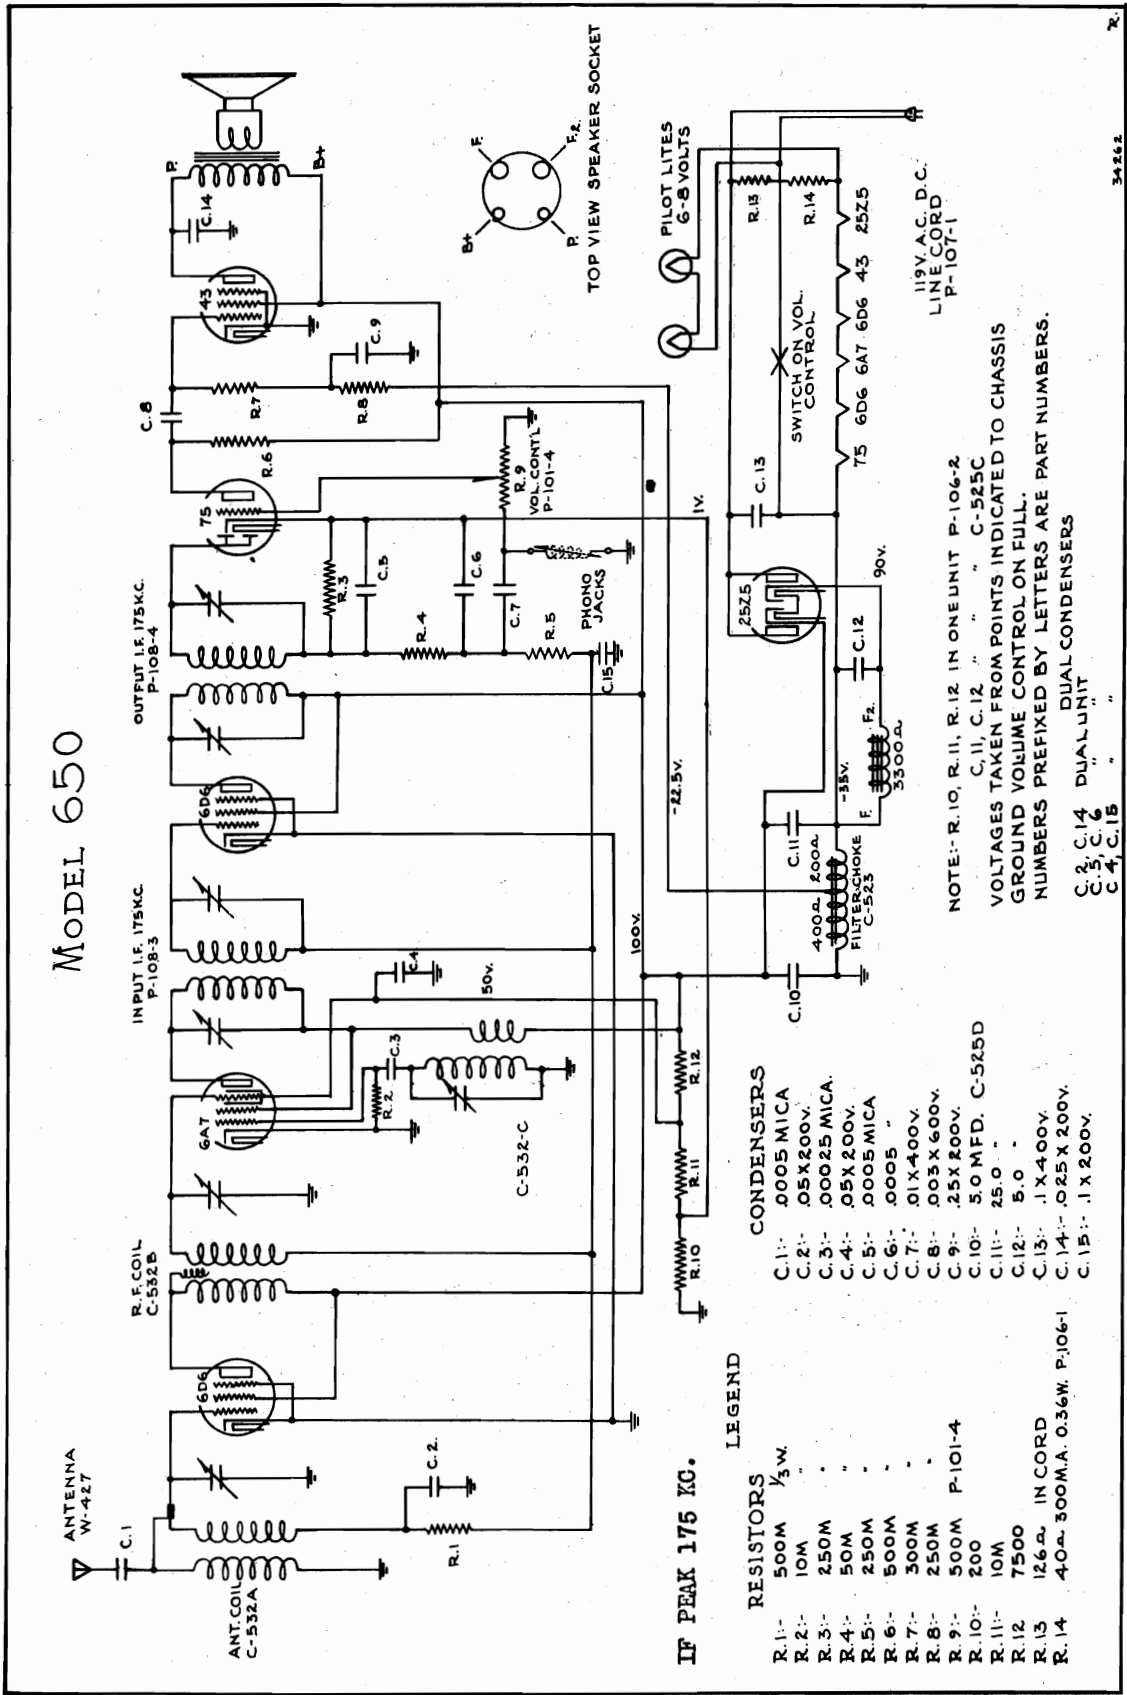

1. Set wave changing switch in the short wave position, extreme right of its rotation, and change external oscillator frequency to 20 meters (15 megacycles), connect oscillator in series with a 300 ohm resistor to tan antenna wire and black ground wire.
 - (a) Adjust variable condenser with selector knob so that pointer is opposite the 20 meter calibration on the dial. Adjust center trimmers of oscillator coil, part number 110-11 and antenna coil part number 111-14, to resonance. These adjustments are accessible from side of the chassis.

NOTES:

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. This drive may be dis-assembled by removing the two screws which fasten it to the dial bracket. The part number of the compression spring is 112-31, All of the other dial parts are hardened and should cause no trouble.

MODEL 650
Socket, Alignment
BELMONT RADIO CORP.

Before attempting any adjustment, the chassis must be removed from the cabinet. This is accomplished by pulling off the volume and selector knobs, removing the back and the four screws which fasten the chassis to the cabinet.

I.F. ALIGNMENT:

1. With volume control on full, at the extreme right of its rotation, and with variable condenser at its maximum capacity position (extreme left of its rotation) make the following adjustments:
 - (a) Connect an oscillator set at 175 kilocycles in series with a .1 mfd. condenser to the control grid (cap at top of type 6A7 oscillator first detector tube).
 - (b) Adjust trimming condensers of both input and output I.F. transformers, parts number 108-3 and 108-4, (see top view of chassis) to resonance. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer. Maximum deflection on the meter indicates resonance.

Note: Each I.F. transformer trimmer has two adjustments, one nut and one screw, both of which are adjustable from the top.

FREQUENCY ALIGNMENT:

1. Disconnect antenna wire from lug on antenna coil to which it is attached and connect to this lug, in series with a 50 mmfd. condenser, an oscillator which has been set at 1720 kilocycles.
2. Adjust trimmer condenser of the oscillator section of variable condenser (the shaft end section) to resonance with oscillator (maximum deflection on an output meter).
3. Change input oscillator to 1400 kilocycles and pick up signal by rotating variable condenser, then adjust trimmers of antenna and R.F. detector sections of variable condenser (center and rear respectively) to resonance with oscillator.
4. Check tracking at 1200-1000-800-600-530 kilocycles by setting oscillator at these frequencies and picking it up by rotating variable condenser. Bend slotted plates of condenser only if necessary.

NOTES:

The pilot lights are connected in series. Should one burn out, the other will not light. To replace them it is necessary to remove chassis from cabinet. The lamps used are 6-8 volts, .15 amperes.

Voltages from chassis to different points are indicated on the schematic circuit diagram and should be measured with a volt meter having a resistance of 1000 ohms per volt.

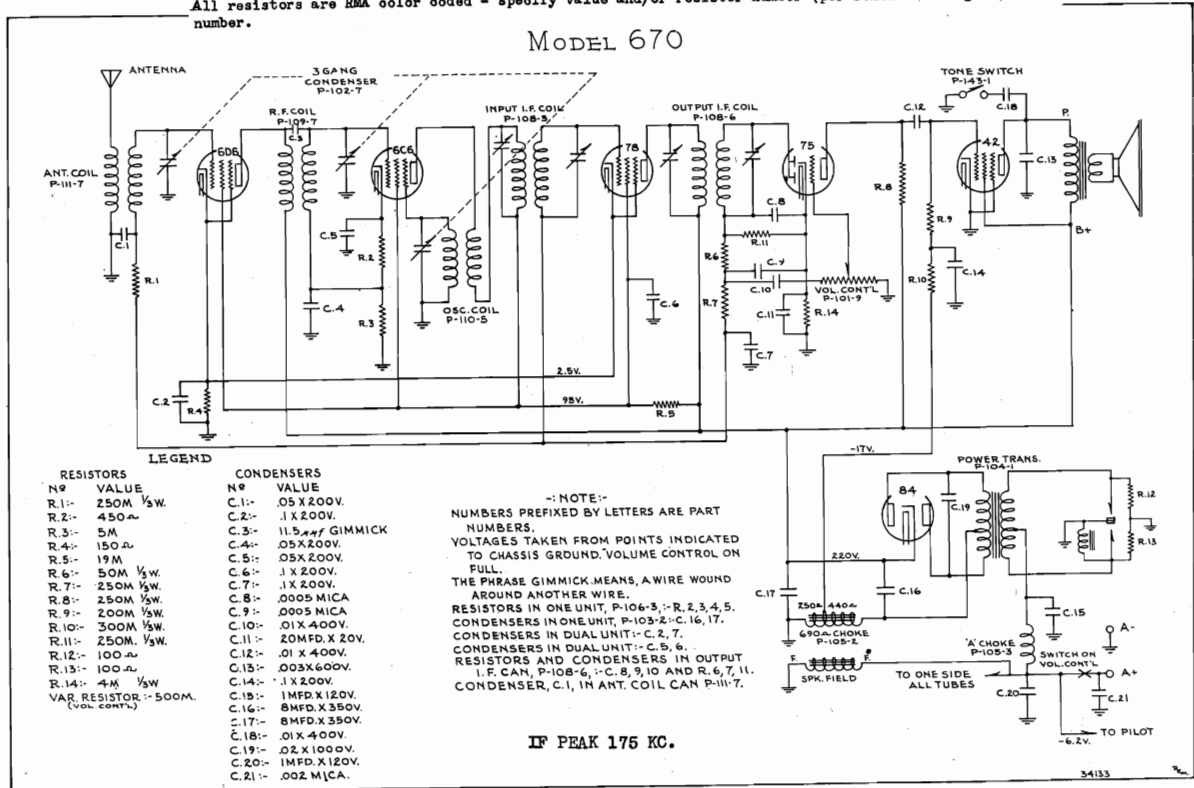

If receiver fails to function at the low frequencies, the trouble is apt to be a defective 6A7 tube. The remedy of course, is to replace the 6A7. They sometimes fail to oscillate on the lower frequencies.

BELMONT RADIO CORP.

MODEL 670 Schematic Socket, Trimmers

Vibrators can be reconditioned at a cost of \$3.00 each, if the old unit is returned.

All resistors are RMA color coded - specify value and/or resistor number (per schematic diagram) and model number.

MODEL 670
Alignment
Service Notes

BELMONT RADIO CORP.

ELIMINATION OF MOTOR NOISES (Cont'd)

In some few cases, such as Buicks, it is necessary to use screw type suppressors. Cut lead about two inches from distributor and screw one end of suppressor into the wire attached to distributor, screw wire from coil into other end of suppressor.

Generator capacitor, number 14E-1, is connected to generator side of outout. The ground side of capacitor can be fastened to the generator housing under the same screw that holds the relay housing to generator. In some cases, an additional capacitor, number 14E-1, (obtainable from your dealer) must be installed between the battery side of ignition coil and the car frame.

If after connecting suppressors and condensers as outlined above there is still motor noise, make the following tests:

Shield high tension leads.

Bond flexible shaft leads, such as free wheeling, which run close to distributor, radiating ignition interference which is picked up by the antenna inside of car.

Cars using wooden floor boards, place a grounded copper screen under toe board.

Excessive gap between distributor rotor and high tension contacts, replace with a special radio rotor arm or build up end with solder and dress end with file so that its original shape is retained. The rotor should not brush or wipe the contacts, but should just clear them.

In some cases, such as V-8 Ford, it is necessary to pull battery and primary leads out of special tube which houses high tension leads, shield and ground these leads. Also on V-8 Fords it is necessary to install a capacitor at primary terminal of coil housing.

Additional suppressors can be obtained from your dealer.

The ignition system of car must be kept in good condition.

Fouled plugs or plugs with improperly adjusted gaps will affect the operation of receiver as well as of the automobile. Burned or poorly adjusted breaker points will also impair the performance. It is advisable to advance the generator charging rate in order to compensate for the additional drain of the receiver on car storage battery.

It is sometimes necessary to connect a condenser (14B-3) between the hot side of the dome light switch and ground.

BALANCING SET TO ANTENNA:

When this set has been installed and is ready for operation, it may be found necessary (depending on antenna) to balance set to this antenna. This is accomplished as follows:

With the receiver tuned to a very weak station, about 150 to 140 (1300 to 1400 kilocycles) on the dial, adjust the antenna trimmer with a screw driver until maximum volume is attained. To reach the antenna trimmer remove the plug button from the top of the case.

 SERVICE NOTES

Should it ever be necessary or desirable to re-align this receiver, the proper method is as follows:

Adjustments can be made with the receiver mounted in the cabinet, being necessary only to remove the top cover.

I.F. ALIGNMENT:

1. With variable condenser at its maximum capacity position and with volume control full on, connect in series with a .1 mfd. condenser, an oscillator set at 175 kilocycles to the grid cap of the 6C6 tube.
2. Adjust trimming condensers of both input and output I.F. transformers, parts number 108-5 and 108-6 (see top view of chassis) to resonance with oscillator, as indicated on an output meter connected across the primary terminals of the speaker input transformer. Maximum deflection on the meter indicates resonance.

Notes: Each I.F. transformer trimmer has two adjustments, one nut and one screw, both of which are adjustable through the top of the can.

FREQUENCY ALIGNMENT:

1. Attach oscillator connected in series with a 200 mmfd. condenser to the antenna lead and with the variable condenser at its minimum capacity position (extreme right of its rotation) and with an oscillator set at 1550 kilocycles, adjust condenser trimmer of oscillator section (shaft end) to resonance.
2. Re-set oscillator to 1400 kilocycles, rotate variable condenser to pick up signal, adjust antenna and R.F. trimmers to resonance.
3. Check alignment at 1200-1000-800-600-530 kilocycles by setting oscillator to these frequencies and picking up signal by rotating condenser.
4. Bend slotted plates of antenna and R.F. sections only if necessary. UNDER NO CIRCUMSTANCES BEND PLATES OF OSCILLATOR SECTION.

NOTES:

Voltages from chassis to different points are indicated on schematic circuit diagram, and should be measured with a volt meter having a resistance of 1000 ohms per volt.

Failure to operate, noisy or weak reception, may be due to defective tubes or poor contact between cap on top of tube and grid clip.

Tubes may be checked by replacing with another tube which is known to be good.

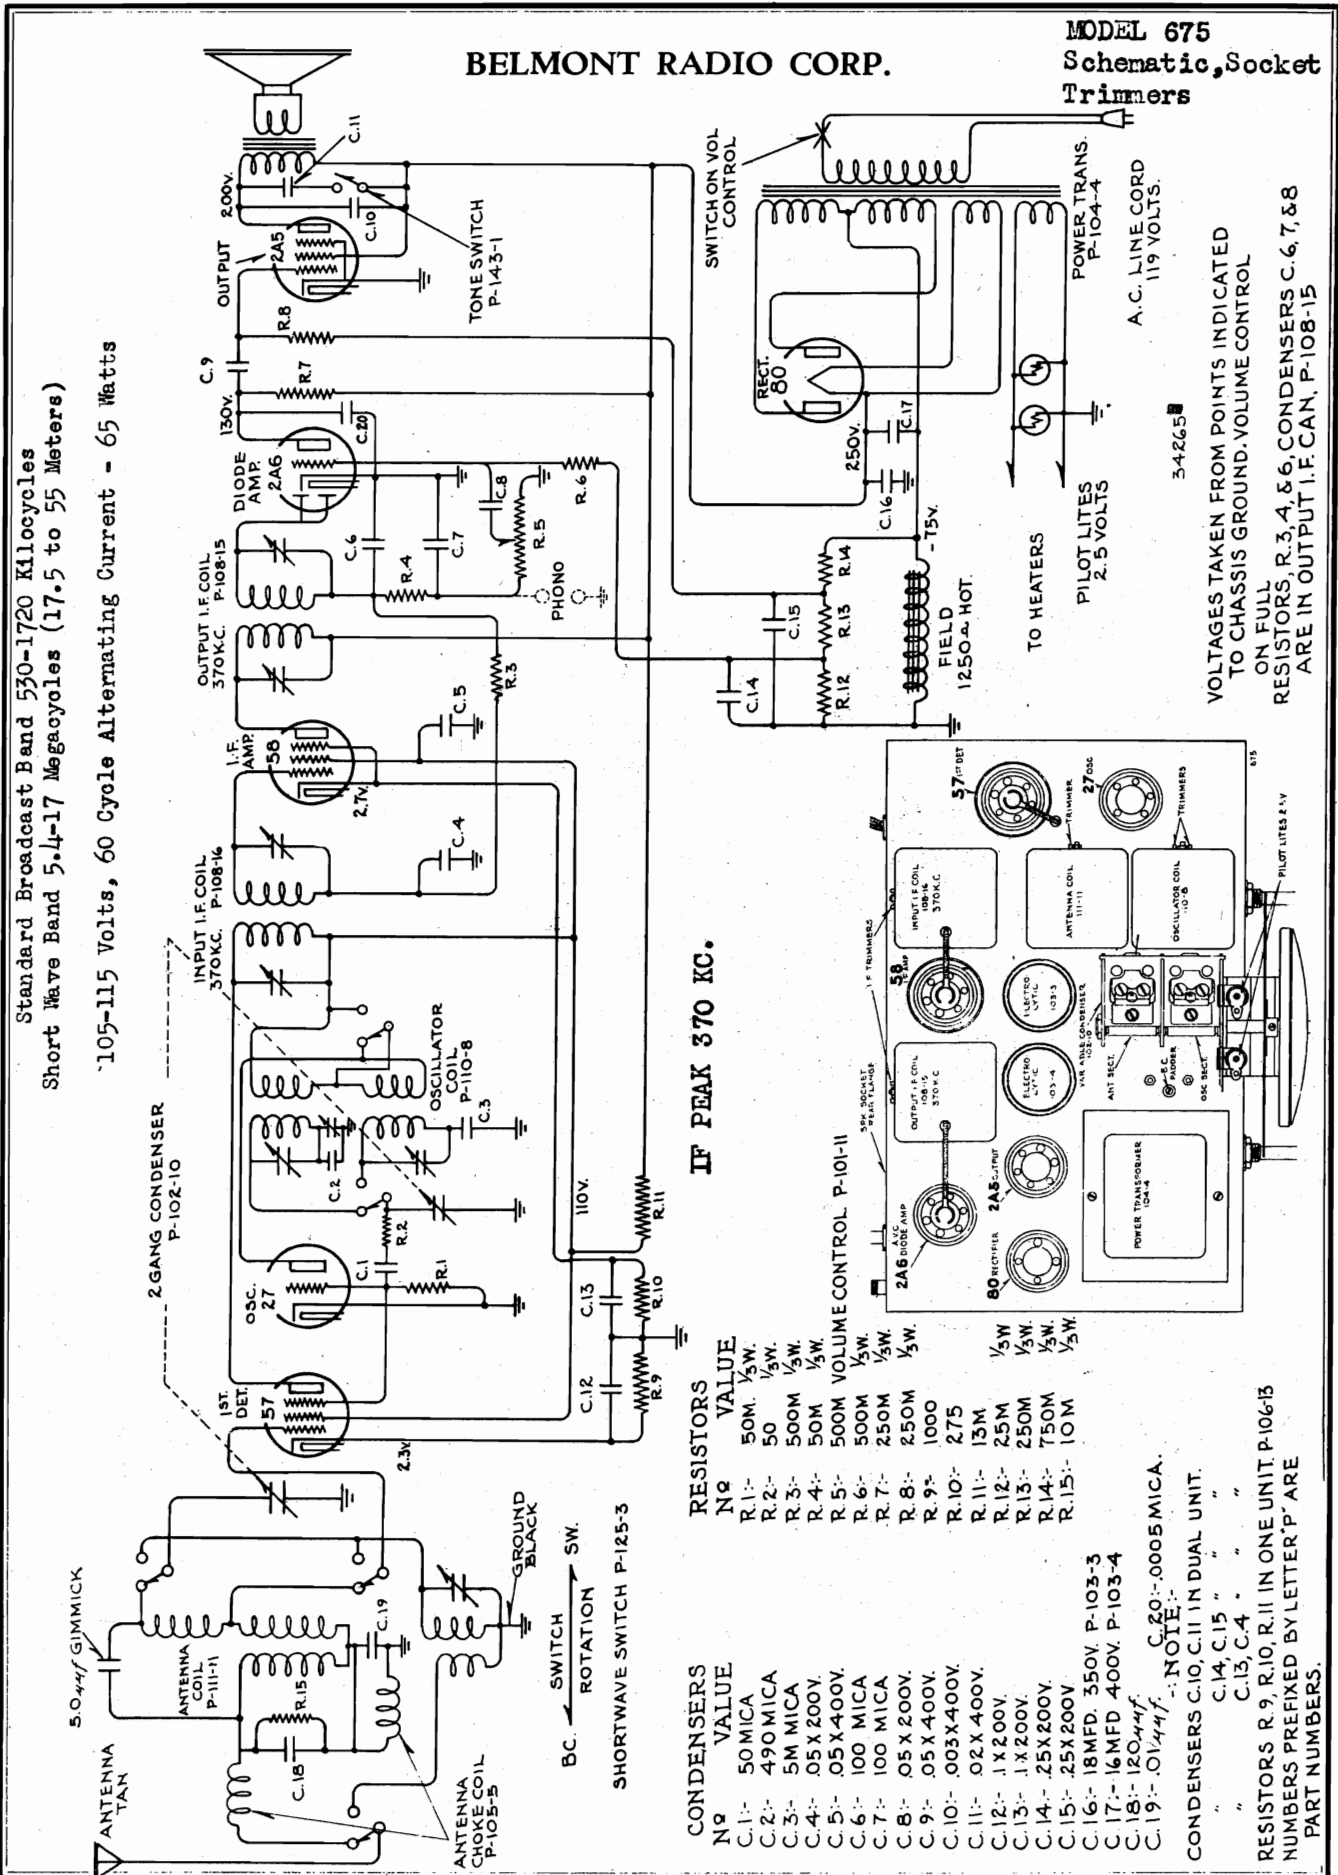

If fuse blows out frequently, and insulating sleeve has been properly placed over fuse, the trouble probably is in the vibrator and vibrator should be replaced.

NEVER ATTEMPT TO ADJUST VIBRATOR POINTS.

SERVICE NOTES

Voltages taken from different points of the circuit are measured with a voltmeter having a resistance of 1000 ohms per volt and are made between the points indicated and the chassis pan. These voltages are indicated on the circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNMENT:

No aligning adjustments should be made until the set has been thoroughly checked for all other possible causes of trouble, such as poor installations, low line voltages, defective tubes, condensers and resistors.

ALIGNING I.F. TRANSFORMERS:

1. With volume control full on, at the extreme right of its rotation, and with wave selector switch in the broadcast position, extreme left of its rotation, and with variable condenser at its minimum capacity position, extreme left of its rotation, plates entirely out of mesh, adjust the I.F. transformers (parts number 108-15 and 108-16) in the following manner:
 - (a) Connect an external oscillator which has been adjusted to 370 kilocycles, in series with a .1 mfd. condenser to the control grid cap of the type 57 first detector tube (see diagram and chassis).
 - (b) Adjust trimming condensers of both I.F. transformers (Parts number 108-15 and 108-16) to resonance. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between plate and screen terminals of type 2A5 output tube. Maximum deflection of the meter indicates resonance. Care should be taken to use only enough signal to give a readily readable output.

Note: The two adjustments on each transformer are accessible through holes in the transformer cans from the back of the chassis.

BROADCAST BAND ALIGNMENT:

1. Shift frequency of external oscillator to 535 kilocycles and connect in series with a 200 mmfd. condenser to the tan antenna wire and the black ground wire.
 - (a) Set the variable condenser in its maximum capacity position, extreme right of its rotation.
 - (b) Adjust the broadcast oscillator series trimmer to resonance with oscillator. This trimmer is located between the gang condenser and the power transformer (see top view).
2. Shift frequency of external oscillator to 1712 kilocycles and set variable condenser in its minimum capacity position, extreme left of its rotation, plates entirely out of mesh.
 - (a) Adjust the broadcast oscillator shunt trimmer to resonance. This adjustment is the top adjustment in the oscillator coil can, part number 110-8.

SHORT WAVE BAND ALIGNMENT:

1. Set the wave changing switch in the short wave position, extreme right of its rotation, and change external oscillator frequency to 15 megacycles.
 - (a) Adjust variable condenser with selector knob so that pointer is opposite the 15 megacycle calibration on the dial.
 - (b) Adjust the short wave oscillator shunt trimmer to resonance with the signal (use extreme care and make certain that you do not adjust to resonance with the image instead of the signal). This trimmer is the bottom trimmer (closest to the chassis) on the oscillator coil, part number 110-8, and is accessible from the side of the chassis.
 - (c) Adjust the short wave antenna trimmer to resonance (single trimmer in antenna can, part number 111-11, accessible from the side of the chassis, between type 27 and 57 tubes).

NOTES:

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. This drive may be dis-assembled by removing the two screws which fasten it to the dial bracket. The part number of the compression spring is 112-31. All of the other dial parts are hardened and should cause no trouble.

34114 APPROVAL

MODEL 775

Alignment

BELMONT RADIO CORP.

SERVICE NOTES

Should it ever become necessary or desirable to re-align this receiver, procedure is as follows:

Before making any adjustments, the chassis should be removed from the cabinet. This is accomplished by removing the four bolts which anchor it to the base of the cabinet and removing the knobs from the front of the cabinet, chassis can then be slipped out.

To properly align this receiver, especially the short wave band, it is essential that the oscillator used have good stability and include an attenuator in addition to covering the frequencies required. An output meter must be used to indicate resonance. It may be connected across the primary of the speaker input transformer.

I.F. ALIGNMENT:

1. With volume control full on, at extreme right of its rotation, and with variable condenser at its maximum capacity position (plates entirely in mesh) and with band selector switch in broadcast position, left (counter-clockwise), make the following adjustments:
 - (a) Connect an oscillator set at 370 kilocycles in series with a .1 mfd. condenser to the control grid of the first detector (cap at top of 2A7 tube), and connect the ground side of the test oscillator to the ground lead of the set (black wire).
 - (b) Adjust trimming condensers of all three I.F. transformers, part number 108-12 input I.F., 108-12 second I.F. and 108-14 output I.F. to resonance.
2. Adjustments are provided on each transformer and are accessible from the back of the chassis (see top view of chassis).

BROADCAST BAND FREQUENCY ALIGNMENT:

1. With volume control full on and the gang condenser set to its minimum capacity:
 - (a) Re-set test oscillator to 1712 kilocycles.
 - (b) Adjust broadcast oscillator shunt trimmer to resonance. This trimmer is the one nearest the top of the oscillator coil and can assembly, part number 110-6.
 - (c) Re-set test oscillator to 1400 kilocycles and shift the test oscillator lead from grid cap of the oscillator tube to the grid cap of the R.F. tube (type 58).
 - (d) Tune the gang condenser to resonance with the test signal (1400 k.c.)
 - (e) Adjust the R.F. tuned circuit to resonance by bending adjustable condenser plate of the R.F. (rear) section of the gang condenser.
 - (f) Shift test oscillator lead to the antenna lead (tan wire) and substitute a 200 mmfd. condenser for the .1 mfd. condenser which is in series with the test lead.
 - (g) Adjust the antenna tuned circuit to resonance by bending the adjustable condenser plate of the antenna (front) section of the gang condenser.
 - (h) Turn the gang condenser to maximum capacity.
 - (i) Adjust the broadcast series trimmer (located to the left of the gang condenser and accessible through the top of the chassis) to resonance with the test oscillator, with the test oscillator set at 535 kilocycles.
 - (j) Check alignment at 1400, 1000 and 800 kilocycles, bending plates of the R.F. (rear) and antenna (front) sections of the variable condenser if necessary. DO NOT BEND PLATES OF OSCILLATOR (CENTER) SECTION UNDER ANY CIRCUMSTANCES.

SHORT WAVE BAND FREQUENCY ALIGNMENT:

1. Turn the band selector switch to the short wave position, right (clockwise) position.
 - (a) Adjust input oscillator to 15 megacycles and attach to grid of first detector (cap at top of 2A7 tube).
 - (b) Adjust short wave oscillator shunt trimmer to the oscillator signal. Be careful that you don't adjust it to the image. This adjustment is the one closest to the chassis on the side of the oscillator coil and can assembly, part number 110-6.
 - (c) Move the signal generator clip to the grid of the first R.F. tube (type 58).
 - (d) Adjust short wave R.F. trimmer to resonance. Adjusting screw is located on side of R.F. coil and can assembly, part number 109-8.
 - (e) Connect oscillator in series with a 200 mmfd. condenser to the tan antenna lead and black ground lead and adjust short wave antenna trimmer to resonance (adjustment on side of antenna coil and can assembly, part number 111-9).
 - (f) Check sensitivity at 6 megacycles.

NOTES:

Should the planetary vernier dial drive mechanism fail to function properly, it will probably be found to be due to a cracked or broken compression spring. This drive may be dis-assembled by removing the two screws which fasten it to the dial bracket. The part number of the compression spring is 112-31. All of the other dial parts are hardened and should cause no trouble.

BELMONT RADIO CORP.

MODEL 750
Alignment, Socket

SERVICE MANUAL SEVEN TUBE SUPERHETERODYNE WITH A.V.C. AND SHORT WAVE

105-115 Volts Alternating Current, 50-60 Cycles, 80 Watts. 530-1720 Kilocycles - 1700-4500 Kilocycles.

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

1. Volume and tone controls on full during all alignment.
2. Squelch switch in "no squelch" position (counter-clockwise (left) rotation) during all alignment.
3. Adjust variable squelch control on rear flange of chassis to maximum counter-clockwise (left) position.
4. Set variable condenser in minimum capacity position (plates open) at the start of all aligning.

I.F. ALIGNMENT

The intermediate frequency of model 750 is 175 kilocycles, and is aligned as follows:

1. Connect oscillator (set at 175 kilocycles) to I.F. grid (second 58 tube) and adjust both trimmers of second I.F. transformer (underneath chassis) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
2. Connect oscillator output to converter grid (2A7 tube) and adjust both trimmers of first I.F. transformer to resonance. Under no conditions touch the trimmers of the second I.F. transformer after adjusting them (see No. 1).

The four trimmers of the two I.F. transformers are all adjusted from the bottom of the chassis (one nut and one screw adjustment on each I.F. transformer trimmer).

BROADCAST BAND ALIGNMENT

Wave changing switch in clockwise (right) position.

1. Connect an oscillator in series with a 200 mmfd. condenser to the Tan (antenna) lead and Black (ground) lead. With the oscillator set at 1720 kilocycles and the variable condenser at its minimum position (extreme right of its rotation), adjust trimmer of oscillator (rear) section to resonance.
2. Change oscillator to 1400 kilocycles, rotate variable to this frequency and adjust R.F. and antenna trimmers (center and front trimmers respectively) to resonance. Do not touch the oscillator trimmer.
3. Check tracking at the following points only: 1200-1000-800-600-534 kilocycles. NOTE: This receiver will be slightly out of track at 534 kilocycles - do not bend plates in an attempt to track it at this frequency. Rotor plates of condensers should not be bent, except if absolutely necessary, and then only on the center and front sections.

SHORT WAVE BAND ALIGNMENT

Wave changing switch in counter-clockwise (left) position.

1. The frequency range of this short wave band is approximately 1700 to 4500 kilocycles.
2. Peak short wave antenna coil to resonance with oscillator set at 1720 kilocycles by slipping primary.
3. Check for sensitivity at the following frequencies only: 1720 and 3700 kilocycles - under no conditions touch trimmers or plates of variable condenser while checking short wave band.

NOTES:

For failure to operate over both bands, check 2A7 tube and connections to and contacts of wave changing switch.

Condenser shaft to which pointer is attached is rotated by means of a celluloid dial attached to the condenser shaft and a bronze friction drive assembly, to which is attached the selector knob. Should this drive ever slip or become rough, it can be adjusted for smooth operation by sliding the bronze washer drive assembly either closer to the variable shaft or farther away from it in the slot in which it is mounted, to insure smooth operation.

MODEL 1050
Alignment, Socket
BELMONT RADIO CORP.

SERVICE MANUAL TEN TUBE SUPERHETERODYNE WITH A.V.C., SQUELCH AND SHORT WAVE

105-115 Volts Alternating Current, 50-60 Cycles, 105 Watts. 530-1720 Kilocycles - 1700-4500 Kilocycles:

SERVICE NOTES

Should it be at any time necessary to rebalance this set, the correct procedure is as follows:

1. Volume and tone controls on full during all alignment.
2. Squelch switch in "no squelch" position (counter-clockwise (left) rotation) during all alignment.
3. Adjust variable squelch control on rear flange of chassis to maximum counter-clockwise (left) position.
4. Set variable condenser in minimum capacity position (plates open) at the start of all aligning.

I.F. ALIGNMENT

The intermediate frequency of model 1050 is 175 kilocycles, and is aligned as follows:

1. Connect oscillator (set at 175 kilocycles) to I.F. grid (second 5B tube) and adjust both trimmers of second I.F. transformer (underneath chassis) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer).
2. Connect oscillator output to converter grid (2A7 tube) and adjust both trimmers of first I.F. transformer to resonance. Under no conditions touch the trimmers of the second I.F. transformer after adjusting them (see No. 1).

The four trimmers of the two I.F. transformers are all adjusted from the bottom of the chassis (one nut and one screw adjustment on each I.F. transformer trimmer).

BROADCAST BAND ALIGNMENT

Wave changing switch in clockwise (right) position.

1. Connect an oscillator in series with a 200 mmfd. condenser to the Tan (antenna) lead and Black (ground) lead. With the oscillator set at 1720 kilocycles and the variable condenser at its minimum position (extreme right of its rotation), adjust trimmer of oscillator (rear) section to resonance.
2. Change oscillator to 1400 kilocycles, rotate variable to this frequency and adjust R.F. and antenna trimmers (center and front trimmers respectively) to resonance. Do not touch the oscillator trimmer.
3. Check tracking at the following points only: 1200-1000-800-600-534 kilocycles. NOTE: This receiver will be slightly out of track at 534 kilocycles - do not bend plates in an attempt to track it at this frequency. Rotor plates of condensers should not be bent, except if absolutely necessary, and then only on the center and front sections.

SHORT WAVE BAND ALIGNMENT

Wave changing switch in counter-clockwise (left) position.

1. The frequency range of this short wave band is approximately 1700 to 4500 kilocycles.
2. Peak short wave antenna coil to resonance with oscillator set at 1720 kilocycles by slipping primary.
3. Check for sensitivity at the following frequencies only: 1720 and 3700 kilocycles - under no conditions touch trimmers or plates of variable condenser while checking short wave band.

Tun-a-lite.

VISUAL TUNING CHECK

The visual tuning indicator (tun-a-lite tube) is mounted horizontally on the front of the variable condenser assembly and its operation in this respect can be checked as follows:

1. Normally there will be a small continuous glow in the base of the tube when no signal is being received.
2. With a strong oscillator input at 1000 kilocycles, the tun-a-lite should glow to approximately the end of the bulb, varying slightly with different tun-a-lites. If the glow "travel" is short, or none at all, remove the tun-a-lite tube and check its socket connections and contacts. If the tube still fails to indicate satisfactorily, replace the tube.

SQUELCH CHECK

The tun-a-lite tube is also used for noise suppression between stations. Its operation can be checked as follows:

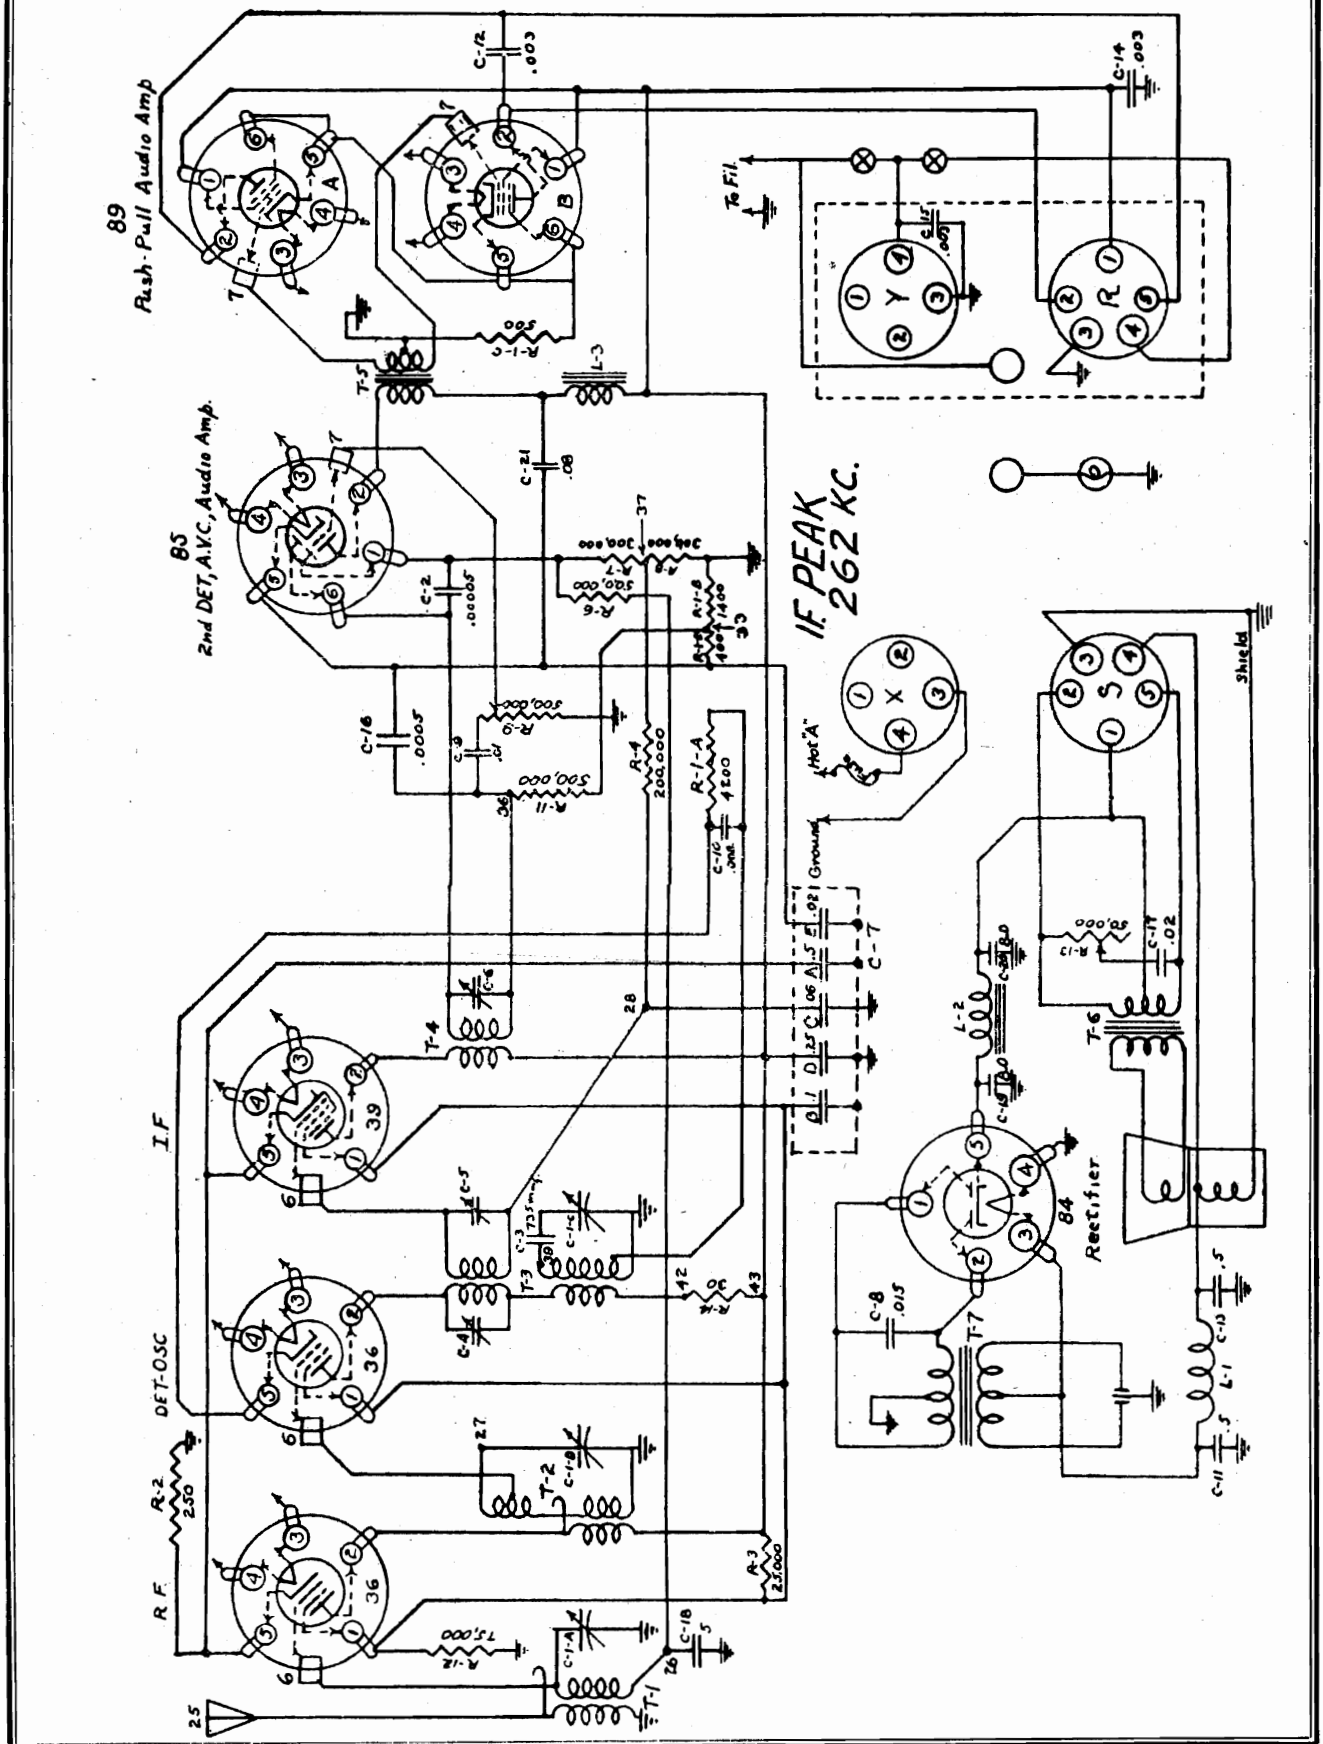

1. Squelch switch adjusted to squelch (clockwise (right) position).
2. Disconnect oscillator, connect antenna, tune set to a position where no signal is received. Noise level at this position should be quite high.
3. Rotate set screw of squelch control on rear flange of chassis, and at some point the noise should cease and the set sound "dead", indicating that the tun-a-lite is squelching and eliminating between station noise.

NOTES: For failure to operate over both bands, check 2A7 tube and connections to and contacts of wave changing switch.

Condenser shaft to which pointer is attached is rotated by means of a celluloid dial attached to the condenser shaft and a bronze friction drive assembly, to which is attached the selector knob. Should this drive ever slip or become rough, it can be adjusted for smooth operation by sliding the bronze washer drive assembly either closer to the variable shaft or farther away from it in the slot in which it is mounted, to insure smooth operation.

PEAKING ADJUSTABLE CONDENSERS

The complete Condenser Aligning Kit is now available under part No. 1207804. This kit contains all the small parts which are necessary for the proper aligning of the condensers on the U.M.S., B-O-P, and Chevrolet Radio Receivers.

All of the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I. F. transformer is changed or the adjustments are tampered with in the field.

DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and an accurate test oscillator and a screw driver (with fibre handle) are available. Using a standard metal screw driver for this purpose will not give accurate adjustment

Proceed as follows:

- A. Disconnect the antenna lead-in from the chassis.
- B. Ground the antenna terminal on the chassis to the frame of the chassis.
- C. Set "test oscillator" to 262 kilocycles. Some oscillators are not equipped with a frequency of 262 K.C. but do have a frequency of 130 K.C. In this case, the second harmonic of 130 K.C., namely 260 K.C., may be used.

D. Connect the output leads of the test oscillator to the grid of the 1st Detector tube and to ground (frame of the chassis). Leave grid cap in place.

E. Connect an output meter across the plates of the type 89 tubes. If the output meter is not protected, place a .1 mfd. condenser in series with the meter.

F. Turn the tuning condenser rotor to minimum capacity (rotor plates out of stator places).

G. Adjust I. F. Trimmers in the following order, in each case leaving the trimmer set for maximum output as shown by the output meter.. (See note

- * C-4, Plate circuit of 1st Det.
- C-5, Grid circuit of I. F. Amp.
- C-6, Diode Input circuit.

* See Fig 2. and 3 for location of condensers.

H. Remove connection grounding the antenna (reverse of instructions under B)

- I. Insert the Calibration Block, Part No. 1206418, between the center (2nd R. F.) condenser and the rear of the chassis as follows: Lay the block on the bench with the largest flat side down and the cut-out edge toward the operator. Pick up the block between the first and second fingers of the hand so that the side having the beveled and cut-out edges faces the knuckles of the hand, and the fingers are as close to the beveled corners as is possible. Insert the hand in the case over the center tuning condenser (condenser plates fully closed) and place the Block between the condenser bracket and the chassis back, with the largest face of the Block flat against the back of the chassis. The Block will fit quite tightly and the left side must rest against the shield between the 1st and 2nd R.F. condensers in order to clear the condenser wiper spring.

J. Attach the test oscillator to antenna terminal and ground (frame) of the chassis. (Ant. on test oscillator to Ant. on chassis and ground on test oscillator to frame of chassis.)

K. Set test oscillator at 1400 K.C.

L. Open tuning condenser until it stops against the Calibration Block

M. Place Tube Shield in position around 236 Det.-Osc. tube. Adjust the trimmer condensers on the tuning condenser to maximum output, as measured by the output meter, in the following order:

- C-1-C--Oscillator trimmer
- C-1-B--2nd R. F. trimmer
- C-1-A--1st R. F. trimmer

*NOTE: To insure sharp peaking of all trimmers, set the oscillator output below the point of start of A.V.C. action. Set the output of the oscillator so that it is less than half the maximum output available.

MODEL 980393

Test Data

BUICK MOTOR

LOCATING TROUBLES ISOLATED BY VOLTAGE TESTS

The voltmeter tests of the chassis merely serve to isolate the defect in some particular stage of the circuit. The actual fault must be located, in that stage, by means of a point-to-point check of the resistance values of the defective stage.

NOTE: All tubes should be removed from the chassis before making these tests, unless they are known to be good tubes.

MODEL 600, 601, 605, 610
Trimmers, Alignment

BULOVA WATCH COMPANY

READJUSTING TRIMMERS

Number 1 is the antenna trimmer.

Number 2 is the gang condenser trimmer tuning the grid of the Super-autodyne.

Number 3 is the gang condenser trimmer tuning the plate (or oscillator of the super-autodyne).

Number 4 is the oscillator padding trimmer.

Number 5 is the Super-autodyne plate trimmer.

Number 6 is the I. F. grid trimmer.

Number 7 is the second detector grid trimmer.

To readjust the trimmer, it will be necessary that a good design of 175 k. c. oscillator be employed, and that a dependable broadcast test oscillator be on hand so that stages handling intermediate frequency, and those handling radio frequency can be thoroughly checked. It is advisable to use a bakelite screwdriver when making any of these adjustments.

First, connect the 175 k. c. oscillator output leads from the control grid cap of the super-autodyne tube to ground. Do not remove any of the tubes from the sockets, and it is not necessary to disconnect the grid cap clip from the tube. Reset trimmers numbers 5, 6 and 7 for maximum output. While this test oscillator is working into the intermediate fre-

quency stages, no adjustment of the tuning condenser on the receiver will have any effect, inasmuch as the intermediate frequency stage is fixed tuned.

If your test oscillator is properly designed, it will supply exactly 175 k. c., and when trimmers number 5, 6 and 7 are set for maximum output, they will be correctly adjusted and should be sealed.

Next, disconnect the 175 k. c. test oscillator and connect to the antenna binding post of the receiver, the output lead from your broadcast test oscillator, or tune in a broadcast signal around 1400 k. c., then reset trimmers numbers 2 and 1 respectively for maximum output. This adjustment will track the super-autodyne grid circuit of the R. F. stage.

To check the calibration of the receiver, whether it be high or low, trimmer number 3 should be reset until a station of known high frequency is brought in on the correct dial marking with peak volume. If your broadcast test oscillator is accurately calibrated, it might be used in place of the broadcasting station signal. In this adjustment, a broadcast station or test oscillator signal at about 1400 k. c. should be chosen. The setting of the trimmer at 1400 k. c. is more critical than it would be at 600 k. c.; calibration, therefore more accurate.

The next adjustment is important and not easily explained in writing, so pay close attention to the following instruction. We will now balance the oscillator to the r. f. and first detector stages.

Tune the external broadcast test oscillator and the receiver both to 600 k.c., then slowly increase or decrease the capacity of No. 4 (oscillator padding trimmer), at the same time and continuously tuning back and forth across the signal with the receiver tuning condenser gang. The output meter needle will now be swinging up and down in step with the variation in tuning. Watch the peak of this swinging closely and readjust No. 4 trimmer until the swinging needle reaches its highest peak.

Retune the receiver and broadcast test oscillator to 1400 k.c. and re-check trimmer No. 3 to make sure that the adjustment of No. 4 has not thrown the receiver out of calibration. If it has, then readjust No. 3 until the calibration is correct, (as previously explained), and check on trimmers No. 2 and No. 1, to make sure that the adjustment of No. 4 has not reduced the sensitivity.

MODEL 06W
Notes on Mounting

CADILLAC

Cadillac and La Salle
MOTOR CAR RADIO
SERIES 06W ~ 1933-34

CADILLAC MOTOR CAR COMPANY DETROIT, MICHIGAN

Description

The new 06W Series Auto Radio Receivers are made up in three units: the chassis unit, speaker-"B" eliminator unit and control unit. The control unit is mounted to the instrument panel, while the speaker-"B" eliminator unit and chassis are mounted on the dash. Current to operate the chassis and "B" eliminator is obtained from the automobile storage battery. Two flexible shafts mechanically connect the control unit to the chassis. One of these is for the volume control and switch, while the other is for the tuning mechanism. A roof antenna is used. In this manual are covered detailed instructions for the installation of each part and information for completing and maintaining the installation. The following tools are required: portable electric drill, screw drivers, pliers, a heavy soldering iron, hack saw, files, small wrenches, and cutters.

Before making the installation it is suggested that this manual be completely read.

Mounting the Chassis

Before mounting the chassis read the articles on "Mounting the Control Unit" and "Attaching the Flexible Drive Shafts." Hold the control unit in position or mount it in place temporarily, so that the position of the flexible shafts can be determined. The chassis is mounted in back of the dash at the left side, as shown in Fig. 1. It should be mounted in such a way that the tuning condenser flexible drive shaft to the control unit will be in substantially a straight line as shown in Figs. 1 and 2. The chassis is mounted with the anchor bushings in which the flexible shafts go, facing the control unit, and with the cover at the bottom. It is secured to the dash by means of the dash mounting plate, see Fig. 4. In some of the earlier models it will be necessary to move the out-out box to a higher location in order to mount the chassis.

First drill the three mounting holes required for the dash mounting plate. The location and size of these holes is shown in Fig. 3. A template for drilling these holes is supplied with the set. Three 4" square head mounting bolts are supplied. Take two of these, which will be used for the rear part of the mounting plate and screw on nut "A" (see Fig. 4). The nut should be just far enough away from the head of the bolt to permit the bracket of the mounting plate to slip down as shown in the illustration.

Fig. 1 - General Installation - Top View

All the tubes should be in the sockets, the antenna trimmer adjusted (as explained later) and the flexible shafts connected before the chassis is permanently installed. Complete information on the latter procedure is contained in the article on attaching the flexible drive shafts.

The four mounting screws pass through the four slots in the mounting plate (Fig. 3). After they are in place and tight, the dash mounting plate with chassis attached is slipped over the three mounting bolts. The two upper brackets on the plate slip down in back of nut "A" as shown in Fig. 4 and the

Fig. 2 - General Installation - Side View

slot at the bottom of the plate slips over the shank of the lower mounting bolt in back of nut "E." The plate will then hang with the bottom farther away from the dash than the top. A washer, lockwasher, and nut "D" are then put on the lower mounting bolt. Nut "D" is screwed on until the mounting plate is tight up against the washer in back of nut "E." In this position, the bracket at the top of the mounting plate should butt up against nut "A" and be tight. Also the mounting plate will be approximately parallel with the dash.

Mounting the Control Unit

The control unit is mounted to the instrument panel as shown in Figs. 1 and 2. In the 1932 and 1933 models there are two holes on the flange at the bottom of the instrument panel on the left side, which line up with the two holes on the mounting lugs of the control unit. In the earlier models, it will be necessary to drill these holes. Two 1/4" holes with centers 4 7/8" apart are required. The best location

for these holes is at a point where the tuning condenser flexible drive shaft to the chassis will be in substantially a straight line (see Figs. 1 and 2). Before mounting the control unit permanently attach the flexible shafts, as explained in the next article, and attach the pilot lamp plate to the bottom of the unit, as explained in the article on "Completing the Wiring Connections."

Mounting the Speaker-"B" Eliminator

The speaker-"B" eliminator is mounted on the back of the dash by means of two brackets as shown in Fig. 5. The best location is at the right side of the dash under the glove compartment as shown in Figs. 1 and 2. It should be mounted with the bracket at the side as shown in (A) Fig. 3, and with the inner bracket mounting holes as indicated in (B) Fig. 5. The box is mounted with the tone control knob at the upper left, as shown in Fig. 1. The

grilled portion of the box at the front should face the listener. In some of the older models which have a hot water heater mounted at the right side of the dash, it will be necessary to mount the speaker-"B" eliminator unit at the center of the dash. In those models which have the coil mounted on the dash, it will be necessary to move the coil to the engine compartment, as explained in the article "Suppression of

MODEL 06V

Notes on Mounting

CADILLAC

which holds the bushing in place. Then insert the shaft in the coupling and tighten the set screws as explained below. This will center the bushing and the nut may then be tightened.

Next, take the tube cover plate off. This is the large plate held on the chassis box by 5 screws. Extend the volume control flexible shaft and casing several inches through the hole in the anchor bushing of the tube cover plate so that the plate will be on the casing and out of the way. Turn the volume control coupling counter-clockwise until the switch is snapped to the off position. Lock the receiver on the control unit and turn the volume control knob counter-clockwise until it is in the locked position. Then loosen both set screws in the volume control coupling and insert the flexible shaft in the coupling (see Fig. 6). Tighten the outer set screw first on one of the four flat faces of the flexible shaft and then tighten the inner set screw. Then again loosely bearing the chassis on the mounting bolts. Next, check the operation of the switch, volume control and lock. The switch should be off when the volume control knob is in the locked position. It may be necessary to loosen the inner set screw and do a slight amount of adjusting until the proper setting is obtained.

Next, slide the tube cover plate into position and fasten it in place by means of the five screws. Then tighten down the clamping nut on the volume control shaft casing but do not tighten this nut excessively.

To attach the tuning condenser flexible shaft, first check the centering of the anchor bushing by eye as was explained above. Then extend the tuning condenser flexible shaft into the hole at the center of the tuning condenser drive pinion. With the rotor plates completely in mesh, turn the dial gear in the control unit until it is at the low frequency end stop. The set screw may then be tightened and the clamping nut secured on the casing as was explained above. In some instances, it may be necessary to loosen the set screw of the large gear on the tuning condenser rotor shaft, and adjust the setting of this gear in order to get an accurate calibration.

Antenna

If any installations are made in cars which do not have a roof antenna, one will have to be put in. The roof antenna is by far the most satisfactory type and should be used in all cases except in sport models, in which case a plate antenna under the car may be used.

Completing the Wiring Connections

The shielded antenna lead from the receiver is not long enough to reach to the column at which the antenna lead-in comes down. If motor noise is experienced, cover the exposed portion of the lead-in wire with loom and braided shield from the point where it leaves the column to the point of connection to the antenna lead of the receiver. Connect the two wires together and connect the two shields together, care being taken that no strand of the shield touches the antenna wire.

Fig. 6—Details of Flexible Drive Shaft Connections

taken out to cut), it is necessary only to secure them at the chassis end. Before attaching the shafts, see if the set is in working order. Put the 8-prong socket in place on the chassis and operate the set with the cover off.

In Fig. 6 is shown a cross-sectional view of the flexible drive shaft connections at the chassis end. First check the centering of the volume control anchor bushing by eye. The center of the bushing should be in a line with the center of the volume control coupling. In case the center of the bushing is not in line or the shaft turns hard, loosen the nut

As the Cadillac and LaSalle cars come equipped from the factory with built-in antennas, the antenna portion of the installation is very simple. The lead-in wire from the antenna will be found behind the right cowl, pad at the top edge.

Antenna Cable

Bring the antenna cable of the receiver in the most direct manner possible to the lead-in from the antenna and connect it to the latter. Keep it as high as possible and as far away from any car wiring as possible. Care should be taken not to have the antenna wire come in contact with the shield wires. Ground the pigtail of the antenna cable shield at the antenna end. The pigtail of this shield at the chassis end is grounded.

Fig. 4—Details of Chassis Mounting on Dash after which the lockwashers and nuts are then put on.

Fig. 5—Method of Mounting Speaker

supplied with the receiver are too long. For that reason, these shafts (inside portion) are squared for a length of 3/4" at one end. The shaft may then be cut at any point along the squared portion to what ever length is required. It should be cut with a three-cornered file or the edge of a grinding wheel. Do not use a hack saw. The casing, which is 1 1/2" shorter, must be cut to correspond. This should be trimmed first at the point to be cut and may then be cut with hack saw.

After the length and position of the shafts is decided on, remove the chassis and mounting plate from the mounting bolts. As the shafts are already secured at the control unit (if they have not been

Fig. 5—Dash Mounting Plate Ignition and Generator Noise, before this can be done.

In Fig. 5 (B) is shown how the brackets may be mounted vertically if space does not permit their being mounted horizontally, as is the case in some cars.

After the position of the speaker is decided on, drill the four 1/4" holes required for the bracket mounting bolts in the template. The mounting holes is supplied with the receiver. The holes are arranged in a rectangle. The centers of the holes, the small dimension are 2 1/2" apart and the long dimension 10" apart. Four 1/4" x 3" mounting bolts, nuts and lock washers and two reinforcement plates are provided. The mounting bolts are put through the bracket and the dash with the shafts extending into the engine compartment. The reinforcement plates are then put on, one being used for each bracket,

Attaching the Flexible Drive Shafts

After the chassis is temporarily mounted and the position of the control unit is known, the flexible shafts may be attached. Remove the chassis from the mounting bolts to make the connection.

Two flexible shafts are supplied with the Cadillac and LaSalle cars, one 9" and one 12" long. The 9" shaft is the tuning condenser flexible shaft, and is put on in substantially a straight line, as shown in Figs. 1 and 2. The 12" shaft is the volume control shaft. This shaft bends upward from the control unit, as shown in Fig. 2.

The distance between the instrument panel and the dash varies in Cadillac and LaSalle cars. In some cars the flexible shaft lengths of 9" and 12"

CADILLAC

MODEL 6W
Schematic, Socket
Alignment

Battery Cable and Six Lead Cable

As shown in Figs. 1 and 2, the battery cable is brought down the dash, through a hole in the dash and thence over to the battery. It passes through the raised portion of the battery compartment cover.

The lug on the lead marked "positive" is connected to the positive side of the battery and the lug on the negatively marked lead is connected to the negative side of the battery. Ground the pigtail of the shield by screwing the No. 6 Parker Kalon screw through the end of the pigtail and through the hole in the lug which is grounded.

The six-lead cable between the chassis and the speaker—"B" eliminator is usually brought over along the dash as shown in Fig. 1.

Pilot Lamp

Before the control unit is permanently mounted, complete the pilot lamp connections. The pilot lamp cable is attached to the eight-prong socket. At the end of this cable is the pilot lamp socket and clip, the latter being attached to an angle bracket. This bracket is to be screwed to the pilot lamp plate which will be found in the bag of parts. A 1/4" 6-32 binding head screw, nut and lockwasher are provided for this purpose. The bracket is put on the pilot lamp plate in such a way that the leads will come out at the back of the control unit. The pilot lamp plate is then screwed to the bottom of the control unit by means of the lug on each side of the plate.

Trying Out the Set and Adjusting

Fig. 7—Location of Tubes

After the wiring has all been completed and before the chassis is permanently installed, try out the set and adjust the antenna trimmer condenser.

To adjust the antenna trimmer, tune in a weak signal between 1200 and 1400 KC with the volume control about three-quarters on. On one end of the chassis box is a small metal plate. Remove the two screws which hold this plate in place. Directly under the hole in the chassis box is the antenna trimmer condenser screw. Turn this adjusting screw up or down until maximum output is obtained.

The location of the tubes is shown in Fig. 7.

leads from a voltmeter. By providing a link in the plate line, screen line, or other lines, as desired, the current flowing in these circuits can be easily read by opening the link and connecting a milliammeter in place of the link. An extension lead should be made for the control grid line.

Continuity Tests

The auto chassis is very compactly built and when "ringing it through" for servicing, considerable time might be spent in tracing through the wiring. For that reason, we are including in this supplement the complete wiring diagram.

After the chassis has been removed from the box and before making the continuity tests, make a careful inspection of all exposed wiring and soldered connections for opens, grounds, shorts and faulty through the various circuits, using as a guide the wiring diagram, Fig. 3.

Make the continuity tests in an orderly manner, starting with the E. F. and working through the I. F. into the audio system. An exception to this is when there is an indication as to where the trouble is, in which case, time may be saved by starting the tests at the part or circuit in question.

In "ringing through" the various circuits in the chassis, take into consideration the amount of resistance in the circuit and also whether there is an external closed circuit around the one under test. Most service men at the present time use direct reading ohmmeters as continuity meters and in this way check for continuity while at the same time determining the resistance of the circuit. To see whether there is an external closed circuit, reference should be made to the schematic circuit diagram, in the installation manual.

When making continuity tests which are across the electrolytic condensers, the positive test prod must be on the positive lead. This is due to the fact that the anodes of the electrolytic condensers must be kept at a positive potential. If the anode is made negative, the condenser will pass current considerably more readily than if it is positive and the reading will be different than the standard reading which should be obtained.

Alignment of Tuning Condensers

The condensers are aligned at the factory with signal generators and output meters and the receiver will not, as a general rule, lose its alignment unless mishandled or tampered with. When the tuning condensers are out of alignment, the receiver may tune broadly, it may be low in volume all over the band, or a lack of volume on certain parts of the broadcast band may be noticed.

Broad tuning is most frequently caused by misalignment of the intermediate frequency tuning condensers. It may also be caused by mistuning between the oscillator and E. F. condensers.

radically incorrect reading at any point will give a clue as to where the trouble may lie. In the installation manual and in this supplement there is a voltage chart showing all of the voltages and plate currents.

As stated above, the best place to check the voltages would be on a service shop bench, but as this involves removal of the other units and cables, it will be quickest in most cases to make the readings in the car.

In most cases, it will be necessary to remove the chassis either from its mounting on the steering column or from the mounting plate on the dash in order to satisfactorily check the voltages at the sockets. The procedure is as follows:

Turn off the lock switch.
Take off the cable head by removing the five screws.

Take the chassis off of the mounting and lay it on the floor board, on a board, or on a wood box, wherever is the most convenient. This can be done if sufficient slack was left in the wiring cables at the time of installation.

In some instances, it will be necessary to disconnect the flexible drive shaft and casing at one end in order to get the chassis out far enough. In other cases, it might be advisable to take off the control unit entirely to get the chassis off far enough.

It is advisable to take the chassis out of the box, although this is not absolutely necessary. If the chassis is taken out, an inspection of the wiring and parts can be made. If the chassis is not taken out, a long plug and external socket arrangement, such as is provided with a set analyzer, or the plug as described below, will be necessary.

In either case, re-insert the multi-point plug in the socket. Be sure to push the plug all the way in, to insure contact on all prongs.

Then turn on the lock switch.

CAUTION—If the chassis is taken out of the box, be sure to keep it on a dry wood or other insulated location in the front compartment of the auto. Great care should be taken to prevent an A+ or B+ point on the chassis from coming in contact with a ground, such as the car frame, levers, cable shields, etc.

A thousand-ohm-per-volt meter of 0-250 volt range is required for the plate and screen voltages. Lower ranges will be necessary for the grid and heater voltages. It is not necessary to have a high resistance meter for the heater or "A" battery reading.

Two of the sockets are partially covered under the chassis by the bypass condenser block. If the voltages are read under the chassis, at the bottom of the socket, by means of test leads and prods, it is necessary to make top socket contacts for these two tubes or else use the plug method as described.

A handy method of reading the voltages on an auto set is to make a plug about 5/8" long with an old five-prong tube base at the bottom and a five-prong socket at the top. The five line set are then brought out at the top to binding posts or other terminals which can be reached with the tips of the test prods on the

Turn on the lock switch.

Read the "A" voltage between terminals 6 and 7.
Read the "B" voltage between terminals 3 and 6, using a high resistance voltmeter.

CAUTION—In all of the above procedure great care should be taken not to ground the A+ or B+ to the car frame, chassis, cable, or any other ground.

Fig. 1. Using Resistors for Load

The above readings are made under load conditions and indicate that proper power is being supplied to the receiver as far as the multi-post socket.

A very handy method of applying these resistors to the multi-point socket is to mount them in an insulated unit or plug with three prongs extending out and arranged in the shape of contacts three, six and seven in the above diagram. This unit could then be plugged in the correct terminals very easily.

TESTING AND REPAIRING CHASSIS

If all accessories are found, upon test, to be in working order, it will be necessary for the service technician to check the chassis over.

The most convenient place to test and repair a chassis is on a service shop bench. In the case of the auto set, however, it is advisable to do part of the testing in the car, due to the fact that the power units, speaker, control unit and cables are installed in the car and cannot be conveniently taken out for use in testing the receiver. Of course, if a duplicate set of parts are available, then all of the testing can be done on the bench.

Reading Voltages at Sockets

One of the first checks to be made is that of reading the voltages at the sockets. A good percentage of all the circuits in the chassis are involved, and a

Power Units
The "A" battery and "B" eliminator or "B" batteries may not be delivering the correct voltages to the set due to a defect in the units themselves, or to a defect in the wiring, connecting plug, or any of the associated apparatus.

CAUTION—In the installation manual it was stated that the voltages should not be read by removing the cable head and reading them at the multi-post socket. The reason for this is that when the lock switch is turned off with the cable head removed the inductive surge caused by the speaker field may burn out the pilot lamp.

Also, as the voltages are not read under load conditions, a true picture is not obtained of the actual operating voltages.

However, the service technician equipped with the proper apparatus can read the voltages at the cable head in accordance with the instructions as given below. By the method as explained, load conditions are simulated, thus permitting actual working voltages to be read.

If "A" or "B" voltages are not read at the multi-post socket, it will be necessary to check the voltages at the unit in question. If the voltages at the "A" battery and "B" eliminator or "B" battery are O. K., then there is an open in the wiring or connections at some point. Disconnect the wire from the "A" or "B" unit and "ring through" the leads to the cable head with the continuity meter.

In the case of no "B" voltage, take off the cover of the "B" eliminator and see if there is voltage at the "A" supply terminal strip. Should there be no voltage at the latter point, it may be due to the fact that the relay is not contacting, thus causing no power to be supplied to the "B" eliminator.

To Read Power Supply Voltages at Cable Head

Turn off the lock switch and remove the cable head from the chassis.

The following parts are required:
3—Phone tips or prongs taken from an old tube base.

1—Resistor for the "A" circuit as indicated in Fig. 1.

1—Resistor for the "B" circuit as indicated in Fig. 1.

Place these resistors in a wooden box or insulated mounting of some kind, with rubber covered leads extending out of the box. Note that the ground leads of the two resistors are common.

Solder the phone tips to the ends of the three leads.

Then insert the tips in the multi-post socket as shown in Fig. 1.

turn the tuning condenser rotor until the output meter shows maximum deflection. Then, using the non-metallic screwdriver, adjust the 600 K.C. trimmer condenser screw, rocking the rotor back and forth at the same time, until maximum output is obtained.

Next, set the signal generator for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output. The tuning condenser should then be properly aligned.

Fig. 2. Location of Intermediate and 600 K. C. Trimmer Condensers

meter. In either method of connection, opening the voice coil of the speaker will give a better deflection on the output meter.

First set the signal generator for a signal of exactly 262 K.C. The rotor of the tuning condenser should be completely out to avoid interference from the oscillator. Remove the grid cap from the grid connection of the '36 first detector tube. Connect the antenna lead from the signal generator to the grid of the '36 first detector. Connect the ground lead of the signal generator to the chassis sub-panel or ground at any convenient point.

Attenuate the signal from the signal generator so as to prevent the levelling-off action of the A. V. C. Using the non-metallic screwdriver, adjust the first I. F. primary and secondary trimmer condensers and the second I. F. trimmer condenser adjusting screws until maximum output is indicated on the output meter.

After all three have been adjusted the first time, go over them again and check the setting for maximum output.

If when alignment has been completed, the output is satisfactory at 600 K.C. and 1400 K.C., but is low in the center of the broadcast band, the intermediate condensers have probably been lined up at some frequency other than 262 K.C. signal generator checked and if it is more than 3 K.C. off, either way, it should be re-calibrated.

Aligning R. F. and Oscillator Condensers—Before aligning and tracking the oscillator and R. F. condensers, connect the flexible drive shaft to the control unit and to the chassis. As explained in the service manual, the dial scale should be at the low frequency end stop when the rotor is completely in mesh. Then turn the fraction selector knob until the dial scale is at 1400 K.C. The tuning condenser will then be correctly set for the 1400 K.C. signal.

Set the signal generator for a signal of exactly 1400 K.C. The signal input from the signal gener-

Lack of volume at certain points of the dial is generally caused by mistacking between the R. F. and oscillator condensers. This occurs generally at the high frequency end and may be corrected by adjustment of the oscillator 1400 K. C. trimmer condenser. In a few instances, lack of volume at certain parts of the dial may be caused by R. F. condenser misalignment. If this occurs at the high frequency end, the condition may be corrected by the adjustment of the R. F. trimmer condensers. If the set is weak at both ends of the dial, mistacking between the R. F. and oscillator condensers is generally the cause and may be corrected by adjustment of both 600 K. C. and 1400 K. C. trimmers, as explained below.

Low volume all over the band is generally due to I. F. condenser misalignment.

CAUTION—We do not recommend that realignment be attempted unless other possible causes of faulty operation have first been investigated and unless the service technician has the proper equipment. Realignment by anyone other than a qualified radio service technician is not advisable, as one not experienced in the work is almost certain to get into difficulty and throw the set completely out of alignment.

A local and accurately calibrated signal generator as well as an output indicating meter are absolutely essential for correct alignment. This signal generator must provide a signal at the broadcast frequencies of 550 to 1500 K.C. and in addition a signal of 262 K.C. for the intermediate frequency. The broadcast band signals of the signal generator must be accurately known, as the dial scale of the receiver is calibrated in kilocycles. The intermediate frequency of the signal generator likewise must be accurate in order to align the I. F. stages at 262 K.C.

A non-metallic screwdriver is necessary. As in the case of reading the voltages at the sockets, the best place to realign the chassis would be on the service shop bench. However, to avoid removal of the other units and cables, realignment may be done in the car, in the front compartment, on a box, wood board, or other insulated location. The chassis must be removed from the box.

The complete procedure for realignment and re-tracking is as follows:

Aligning Intermediate Condensers—First align the intermediate condensers. The adjusting screws of the first I. F. primary and secondary trimmer condensers are on the porcelain base of this assembly at the side of the '39 I. F. socket. The adjusting screw of the second I. F. primary trimmer is reached through the hole near the base of the can of this assembly.

One of the best ways of reading the output is by means of a rectifier type meter. This meter, if of low range is connected across the secondary of the output transformer in the speaker. If it is of high range, it may be connected across the primary of the transformer in series with a large condenser to prevent the flow of D.C. plate current through the

MODEL 2722 (072-A)
Voltage, Parts List
Special Notes

No. 072A Series Receivers (41 Output)

The form 375J Installation Manual and foregoing service supplement cover the 072 Series (38 output) receivers. The copy in general is applicable to the 072A Series (41 output) as the sets differ only in the audio amplifier.

In Fig. 4 is shown the schematic circuit diagram of the 072A set. The schematic circuit diagram of the 072 set is shown in Fig. 1 of the Form 375J Installation Manual. By looking at the two circuits the similarity as well as the points of difference can be noted.

On this page is given an explanation of the parts which are different in the 41 output set, a supplement to the chassis parts list covering the new parts used, and a complete voltage chart for the receiver.

Differences in 072A Chassis

In comparing the No. 072 Series (38 output) receivers with the No. 072-A Series (41 output) the following parts changes in the chassis have been made:

- R-2 changed from 7,000 ohms to 6,000 ohms.
- R-12 changed from 50,000 ohms to 25,000 ohms.
- R-13 changed from 900 ohms to 800 ohms.

R-14, as shown in the old schematic circuit diagram (Fig 1 in the installation manual) is not used in the new receiver.

C-9 is changed from a .02 mfd. condenser to a .25 mfd. condenser.

The No. 38 sockets are changed to No. 41 sockets.
A new audio transformer is used.

No. "B" fuse is used with the No. 072-A series receiver.

COLONIAL RADIO CORP.

General Alignment
Image Frequency DataGENERAL NOTES ON ALIGNMENT

In the service notes on ALIGNMENT PROCEDURE, directions are to couple the test oscillator to the receiver. Since test oscillators of different makes vary considerably in their design and construction, it is not possible to give specific instructions for coupling any particular test oscillator to the receiver. However, the following general method can be applied with practically any test oscillator.

Most test oscillators have two output leads. One of them is the "hot" lead and the other the ground lead. The ground lead should be connected directly to the receiver chassis, except in the case of AC-DC receivers. The connection then should be made through a .1 mfd condenser since the chassis of such receivers is above ground potential. If the test oscillator has only one lead, this information about the ground lead may be disregarded.

As mentioned in all of the service notes, for IF alignment the test oscillator should be connected through a .1 mfd. condenser directly to the control grid cap of the IF or Translator tubes. It is important to leave the grid clip attached to the cap and to leave the tube shields in place. The oscillator tube of the receiver also should be in its socket.

For RF alignment, whether broadcast or short wave, the "hot" lead of the test oscillator should be coupled to the antenna lead of the receiver. The exact means of coupling will depend upon several factors. Among them are the power of the test oscillator, the sensitivity of the receiver, and the extent to which the receiver is out of align-

ment. If the test oscillator is quite powerful and the receiver one of high sensitivity, merely placing the test oscillator lead parallel to, and several inches away from the receiver's antenna lead may provide sufficient coupling. In some cases it may be necessary to bring the leads very close to each other or it may even be necessary to twist the antenna lead and the oscillator lead together for several inches. (Of course, the two leads must be separated by their insulation and not make metallic contact.) As the receiver is brought into alignment, thereby increasing its sensitivity, it will be possible to decrease the amount of coupling between the test oscillator lead and the antenna lead. (Move the leads further apart.) Always use the lowest amount of coupling that still will provide a signal strong enough for working purposes. If the test oscillator has a variable control for its power output, it is better to turn this control to its high position and decrease the signal input to the receiver by decreasing the amount of coupling between the test oscillator and the receiver's antenna lead. This procedure will insure the greatest possible accuracy in alignment.

When adjusting the oscillator trimmer condenser, set the variable condenser to the frequency or condenser position indicated in the Service Notes. Do not change this position while adjusting the trimmer. However, when adjusting the antenna or translator trimmers, the proper method is to continually "rock" the variable condenser a degree or two both sides of the alignment frequency and, at the same time, adjust the trimmer.

PREVENTING ADJUSTMENT AT THE IMAGE FREQUENCY

When adjusting trimmers for short wave alignment, it sometimes will be found that a peak can be obtained at two different positions of the trimmer. Only one of these peaks is the correct one to use. The other is the image response. The proper procedure follows.

Oscillator Trimmer:

Screw the oscillator trimmer all the way in (maximum capacity). Then reduce the capacity until a peak is reached. Now continue to reduce the capacity until a second peak is reached. Almost always, this second peak is con-

siderably lower than the first one. The first peak is the image frequency adjustment, and must be avoided.

Antenna and Translator Trimmers:

Screw the trimmers all the way in and then reduce capacity until a peak is reached. If the capacity is reduced still further, a second peak will be obtained. However, the correct setting is the first one, the one using the greater amount of capacity. Note that this is exactly opposite to the procedure for the oscillator trimmer.

MODEL 150,164,182
Supplementary Data

COLONIAL RADIO CORP.

SUPPLEMENTARY SERVICE NOTES

MODELS 150 - 164 - 182

MODEL 150

Certain improvements have been incorporated in the Model 150 auto receivers since the Instruction Booklets and Service Manuals for this model were printed. For the most part these improvements facilitate removal of the chassis from its case when necessary.

1. The permanently connected shielded antenna lead has been replaced with one using a bayonet and socket type of connection.

2. In order to eliminate the necessity for going through the operation of polarity changing in the field, some of the sets are shipped with the polarity connection correct for positive grounded batteries and others for negative

grounded batteries. The shipping cartons are stencilled to indicate the polarity connection of the set.

3. The vibrator unit has been improved and it is suggested that a couple of them be carried in stock to replace any that may break down in service. Defective units should be returned to the Colonial Radio Corp., 254 Rano St., Buffalo, N.Y., for replacement.

4. Any letters appearing after Model 150, on the chassis or carton, have no significance. All changes and improvements were incorporated in all of the chassis before being shipped.

MODELS 164 AND 182

As mentioned on Page 138 of the Service Manual, drive cable grounding springs (Part #R-10165), were supplied in later production of Model 164 and 182. When these springs are used, it makes no difference whether an insulated or an uninsulated tip drive cable is used for the tuning condenser, and two brass tip cables are supplied when the grounding springs are included in the original package. Accordingly, if the grounding springs are used, all reference to the insulated tip drive cable in the Instru-

tion Leaflets and in previous Service Manuals may be disregarded.

Two types of speakers have been used on the Model 164. They can be told apart by the fact that one type has a patent notice sticker pasted under the output transformer. Should parts of this speaker need replacement, return the entire speaker. The list of replacement parts for the other type speaker follows:

Part No.	Description	Price
S-9967-A	Speaker - Complete	\$8.28
S-9988-A	Speaker cone and voice coil	1.38
S-10152	Speaker field coil	1.65
S-9994	Speaker clamping ring	.05
S-9968	Speaker eyelets	10 for .03
S-10144-A	Speaker transformer	1.28

Two types of set screws for binding the flexible drive cables and casings have been used in the Model 164 and 182 remote controls. One is a 6/32 X 1/8" screw, Part #R-5386, price - .01. The

other is 8/32 X 3/16", Part #R-6498, price - .02. It is suggested that a small stock of both of these screws be carried.

INTERFERENCE ELIMINATION

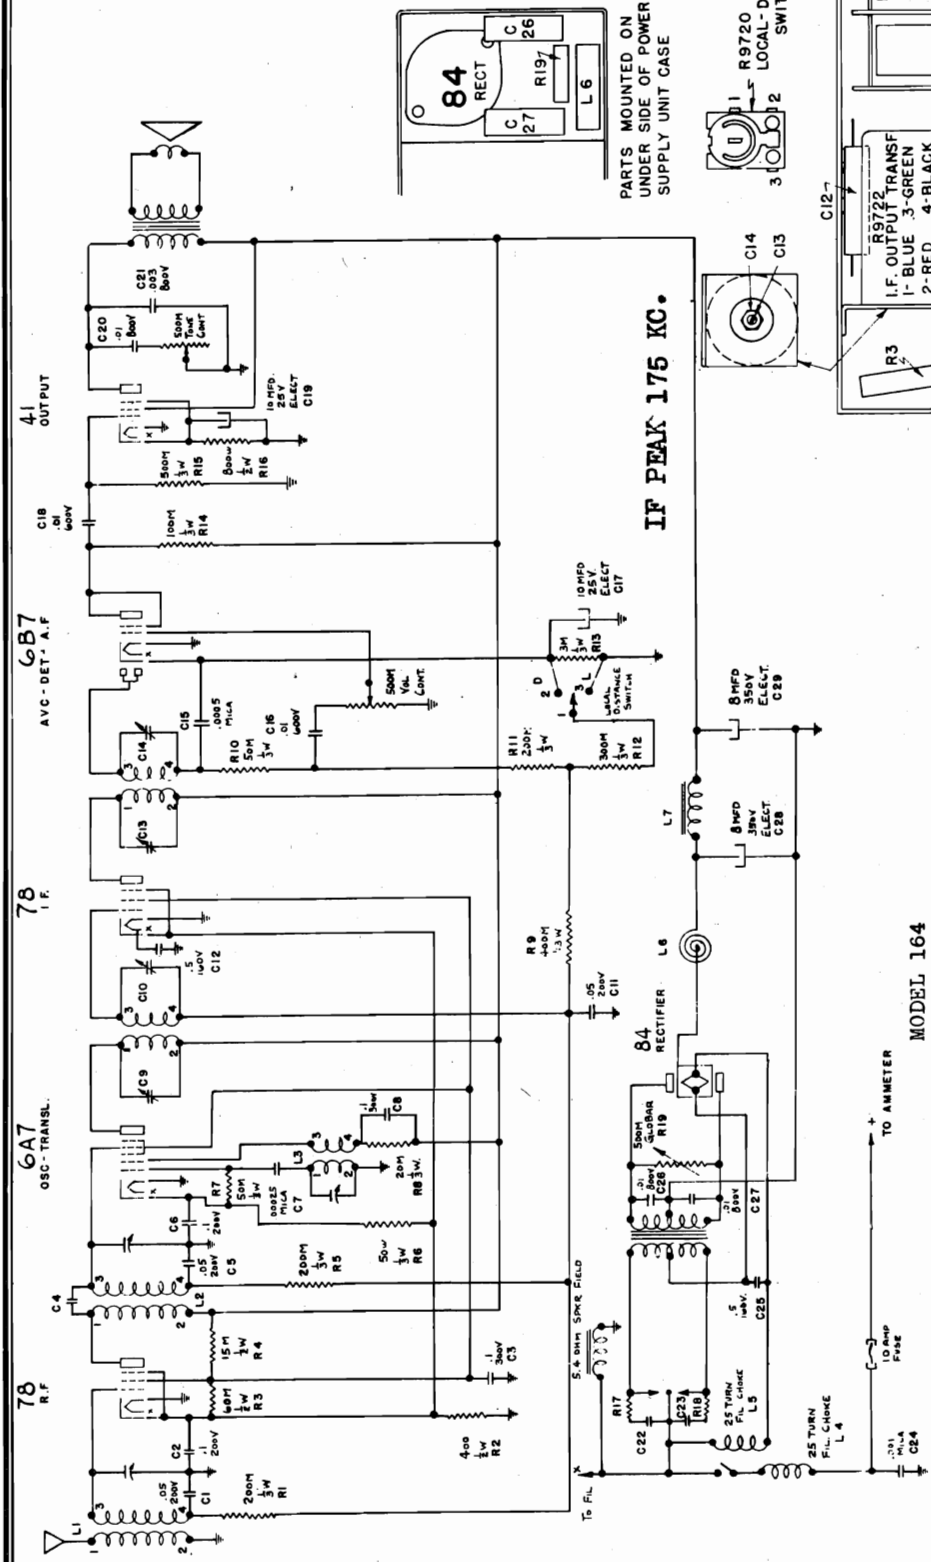

Occasionally a car is encountered in which the "dirt" at the ammeter is exceptionally great. To remedy a condition of this sort, solder a .001 mfd mica condenser, (Part #R-6759), from

the fuse container shell to a point about an inch away, on the ammeter end of the "A" lead. Wrap tape around the condenser and lead to protect them.

84 - Rect.	20 m.a. per plate Total battery drains 6.2 amperes.			

MODEL 164

Remote Control Data
Alignment Data

COLONIAL RADIO CORP.

THE REMOTE CONTROL UNIT

As mentioned in the Instruction Booklet, the flexible drive shaft with the black, insulated tongue at its end, MUST be used for the condenser drive. The insulation is to prevent ignition noise pick up by the cable from being fed into the tuning condenser. Failure to observe these instructions will result in motor noise.

The pilot light switch, in the remote control unit, works coincidentally with the set switch in the chassis. Flickering of the pilot light may be due to poor contact between the phosphor-bronze spring and the rotating drum. Bending of the spring and sandpapering of the drum will correct the condition.

To gain access to the switch, proceed as follows:

1. Disconnect the flexible cables from the remote control unit and remove the unit from the steering column.
2. Remove the outer shell from the unit by bending up the tabs.
3. Pull the pointer off of its shaft and then remove the dial.
4. Remove the three flat head screws holding the cover and remove the cover, exposing the mechanism.

The illustration shows how to replace the pointer drive cable. Note

that the end of the cable coming from the clamped end of the spring passes OVER the other end of the cable. Also note that when the large pulley is set into place, the spring is diametrically opposite the drive pulley.

When replacing the pointer, turn the Station Selector shaft clockwise to its limit and set the pointer one division to the right of the bottom center line. Then when the shaft is turned all the way counter clockwise, the pointer will stop one division to the left of the center line.

Failure of the set switch and the remote control switch and lock to coincide in their operation will be caused by movement of the cables or of the control unit, after the synchronizing adjustment has been made. To secure simultaneous action of the two switches again, it will be necessary to disconnect the cable, turn the set switch to its "Off" position with a screw driver, turn the Volume Control knob in the control unit to its "Off" position with the key out, and then securely tighten the cable coupling and set screws. If the control unit is not moved then, the operation of the two switches will remain in synchronism.

The pilot light is accessible for replacement when the single screw at the back of the case is removed.

POWER SUPPLY UNIT

The plate supply unit is of the vibrating reed type with rectifier tube. No attempt should be made to repair the vibrator proper. Return it to your distributor for repair or replacement. The unit can be pulled out of its case when the five terminal screws are loosened.

It is very important that the proper polarity connection be made. For cars with the negative battery terminal grounded, the blue lead should be connected to the terminal nearest the outside of the case. For cars with grounded positive terminal, the positions of the blue and black leads are interchanged so that the black lead is connected to the outside terminal. Failure to observe these instructions will cause damage to the vibrator in a very few

minutes of operation.

R17, R18, C22 and C23 are part of the assembly of the vibrator proper. C25, C26, C27, L6 and R19 are all mounted within the power supply case. R19 is a resistor whose value varies with the voltage applied to it. When the receiver is first turned on, the output voltage tends to become very high until the tubes heat sufficiently to draw their normal load. Under this condition, the value of R19 drops to a comparatively low value, loading the transformer sufficiently to prevent damage. As the tubes become heated, tending further to lower the voltage, the resistance of R19 increases greatly so that it no longer constitutes a load on the power supply.

THE IF TUNING ADJUSTMENTS

When peaking the IF stages, use a low enough output from the test oscillator to render the AVC action inoperative.

The screw adjusts the primary tuning condenser; the nut adjusts the secondary, as shown in the illustrations.

THE RF TUNING ADJUSTMENTS

There are three holes at the back of the chassis through which the condenser trimmers are accessible. The unit nearest the control end of the chassis is the RF unit. The next one is the translator and the last one the oscillator.

Any trouble with oscillation will be due to proximity between grid and plate leads of the RF and IF stages. Moving the leads apart will correct the trouble.

COLONIAL RADIO CORP.

MODEL 164
Vibrator Data
Noise Data

The following chart will be helpful for making tests of the power supply

unit. A continuity meter or ohmmeter may be used.

VIBRATOR UNIT ONLY

<u>TEST</u>	<u>PROPER EFFECT</u>	<u>TROUBLE IF IMPROPER EFFECT IS HAD</u>
Between brass contact adjusting screws. (With piece of paper inserted between contact points.)	Reading	Open transformer primary.
Grey lead to either red lead	Approx. 400 ohms	Open or shorted transformer secondary.
Blue and black leads, (with paper out.)	Reading	Contact points not making contact.
<u>POWER SUPPLY (With Vibrator Disconnected)</u>		
Fahnstock clip to switch	Reading	Open fuse or open L4
Fahnstock clip to ground (With tubes out of sockets.)	Approx. 5. ohms	Open field coil
84 cathode to ground	Approx. 75 M ohms	If low res. reading, shorted C28 or C29. If no reading, open L6, L7, R2 or R4

REMEDIES FOR UNUSUAL NOISE CONDITIONS

If a condition is met in which the installation of standard suppressor equipment still leaves objectionable noise, proceed as follows:

1. Ground the antenna shield to the case by jamming a Parker-Kalon screw between the shield and the case.

2. Bond the bulkhead to the nearest point on the motor.

3. Disconnect the high tension lead running from the coil to the center of the distributor. Disconnect it both at the coil end and at the distributor end. Turn the ignition switch on and turn the motor over with the hand crank. If clicks are heard as the distributor breaker makes and breaks contact, interference comes from this source.

Additional capacity should NOT be put across the breaker points as it will interfere with the proper operation of the coil. (A condenser, connected across the points, is built into all distributors.) Rewire the entire low tension ignition system, using shielded low tension ignition cable which must be well grounded. Do not run the wiring along side of other wiring, but keep it separate, and if possible, along the car chassis channels.

4. If the trouble still persists, it may be necessary to use shielded high tension cable from the distributor to the coil. The shielding must be well grounded.

5. Very often the interference is fed into the antenna through the dome light wiring. This can be determined by disconnecting the dome light lead from the ammeter. If an improvement results, by-pass the dome light at the point where it enters the corner post.

6. Metal windshield tubing, gas and oil lines sometimes have to be bonded to the bulkhead with heavy copper braid.

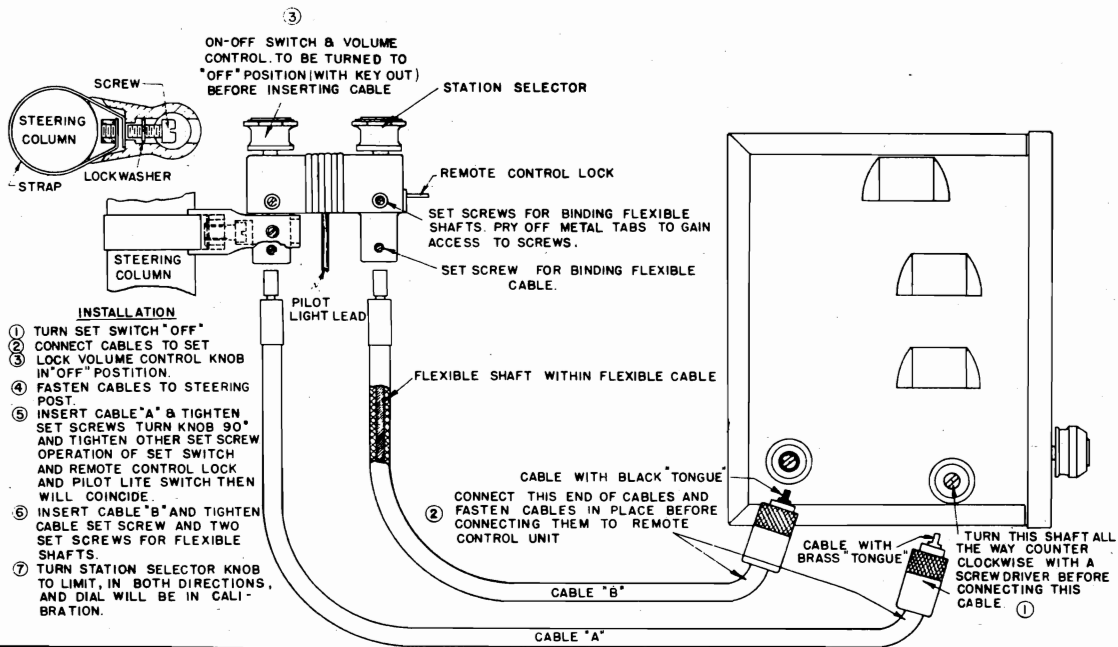

7. In some cars the high tension coil or leads come very close to the motor side of the floor board. As a result, interference is picked up by the occupant's body and transferred to the car antenna. Trouble of this sort is manifested by noisy reception ONLY when a person is sitting in the car. It can be remedied by tacking a grounded metal plate or screen to the motor side of the floor board, or by placing a grounded screen between the floor matting and the floor board.

It should be understood that it practically never is necessary to apply ALL these remedies. How many of them are needed will depend on the particular car and installation.

MODEL 164

Socket, Assembly, Speaker

COLONIAL RADIO CORP.

IMPORTANT
IF THE REMOTE CONTROL UNIT IS MOVED AFTER THE CABLE ADJUSTMENTS HAVE BEEN MADE, IT WILL BE NECESSARY TO READJUST IN ORDER TO MAINTAIN PROPER CALIBRATION AND OPERATION OF THE PILOT LIGHT, SWITCH AND LOCK.

THE REMOTE CONTROL MECHANISM

THE CONNECTIONS ILLUSTRATED ARE CORRECT ONLY IF THE GROUNDED BATTERY TERMINAL IS NEGATIVE. THE BLUE AND BLACK WIRES MUST BE REVERSED WHEN THE GROUNDED TERMINAL IS THE POSITIVE ONE.

ADJUSTING THE SPEAKER

Should the speaker cone ever need centering, it will be necessary to remove the speaker from the chassis. Two screws, their heads accessible from the under side of the chassis, hold the speaker to the chassis.

Loosen the two nuts and screws that hold the cone spider, insert thin paper spacers between the pole piece and voice coil support, and re-tighten the spider nuts and screws. Then remove the paper spacers.

Schematic, Parts

SERVICE NOTES

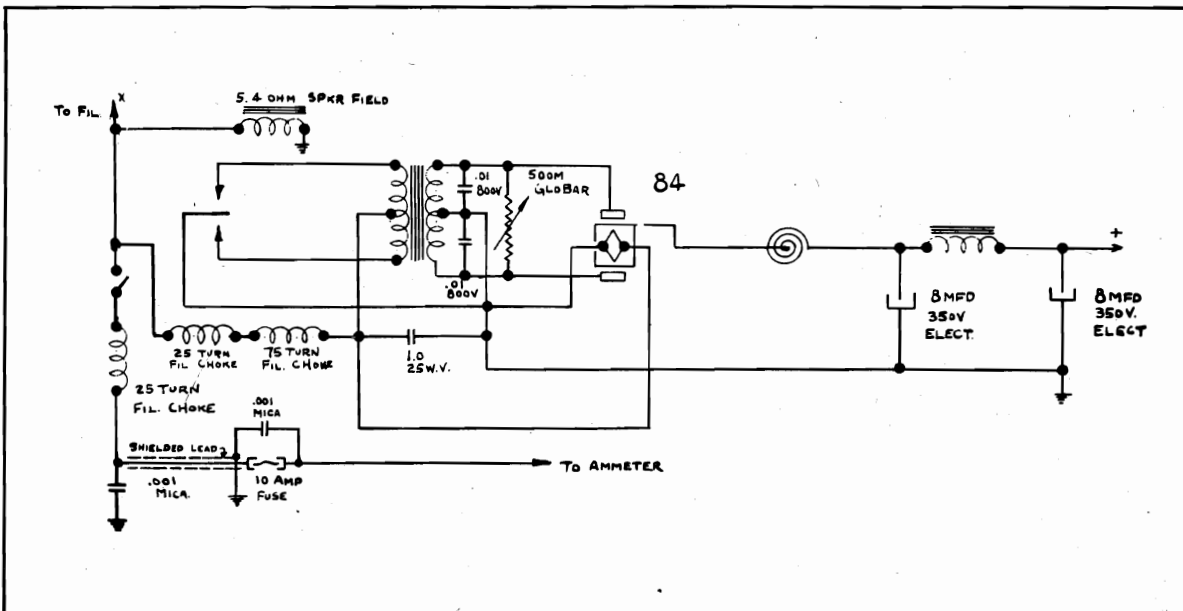

MODEL 164B

This manual applies to receivers having a serial number above 50600.

A different power supply unit is employed in these receivers, using a plug-in type of vibrator, making replacement of it very simple. Its construction is such that no attention need be paid to polarity. Accordingly, pro-

vision for changing polarity is omitted from this model.

The schematic of the chassis is the same as that shown in Fig. 76, Page 136, for the Model 164. The revised schematic for the power supply unit is shown in Fig. 82.

Service Data

COLONIAL RADIO CORP.

NOTES ON IGNITION INTERFERENCE ELIMINATION FOR MODELS 164 AND 182

The following changes should entirely eliminate ignition interference

in instances where difficulty of this sort has been experienced.

SHORTENING THE SHIELD GROUNDING PIGTAIL

The Model 164 has a pigtail soldered to the "A" lead shield, with its other end clamped under one of the acorn nuts. The Model 182 has, in addition, a similar pigtail on the speaker cable shield. These pigtails should be removed and a shorter ground provided as follows:

Drill a hole in the case immediately alongside the point where the shields come through the case. Fasten a large soldering lug (R-8311) to the inside of the case by means of a nut and screw passed through the drilled holes and solder the shields to the lugs.

GROUNDING THE SHIELD CABLES AND ANTENNA

To completely eliminate any pickup by the drive cables, grounding springs (Part R10165) are put between the collar on both flexible cable couplings and the case. It will be necessary to scrape away the paint on the case, under the springs, so that they can make good contact with the case.

In cars having an intense interference field near the antenna shield, further improvement can be had by soldering an Antenna Shield Grounding Clip to the antenna shield. (Part No. R-10166). The clip makes contact with the case at the point where the shield enters the case. Sandpaper the case to insure good contact.

INSTRUCTIONS FOR SHORTENING THE DRIVE CABLES

1. Remove the split sleeve from the chassis end of the cable casing.
2. Heat the chassis end of the cable until the solder melts, permitting removal of the brass sleeve. Then take the cable out of its casing.
3. Determine the point where the cable is to be cut and clean it thoroughly with fine sandpaper. Tin this point thoroughly.
4. Cut the casing 5/8" shorter than the length desired for the cable. Re-

place the split sleeve.

5. Put the cable back in the shortened casing. Slide the brass sleeve along the cable to the tinned portion and solder it there. Do not let it bind against the end of the casing. Then cut the cable at the end of the sleeve with a fine toothed hacksaw.

If the cables are cut in the foregoing manner, there can be no difficulty from unravelling of the strands since the soldered sleeve holds them.

COLONIAL RADIO CORP.

MODEL 182
Circuit Data

MODEL 182

The COLONIAL Model 182 is a six tube superheterodyne automobile radio receiver. The circuit is shown in block form in Fig. 78 and schematically in Fig. 80.

A 78 RF tube feeds the incoming signal to the 6A7 translator-oscillator. The 175 kc output of this tube is ampli-

fied by the pentode portion of the 6F7 tube and then fed to the 6B7. This tube provides AVC, diode detection and, together with the triode portion of the 6F7, furnishes audio amplification for input of the 41 push-pull output stage. The speaker is a separate 8" dynamic. A dynamotor furnishes the plate supply, drawing its power from the car's battery.

THE AVC AND SENSITIVITY CONTROL CIRCUITS

The 175 kc output of the 6F7 IF stage is impressed between the cathode and diode plates of the 6B7, in series with R12, R13, R14. The diode current flowing causes a voltage drop across these resistors. Only the drop across R12 is used for AVC. Since the grid returns of the 6A7, 78 and 6F7 are connected to R12, the negative bias across it is impressed upon the grids of these tubes. Increases in signal strength are offset by decreases in tube amplification resulting from this increased negative grid bias. The effect is to tend to maintain the output of the 6F7 IF at a constant value.

Residual bias for the tubes is furnished by R2. In addition, the residual bias and therefore the tube amplification is affected by the setting of the Local-Distance switch. When the switch lever is on contact #2, the drop across R15, due to the plate current of the 6B7,

bucks the residual from R2, decreasing the total negative bias and increasing tube amplification. In the "Local" position, contact #1, only the residual from R2 is applied to the tube grids.

Be sure the sensitivity control is either FULL clockwise or FULL counter clockwise. If allowed to remain half way between the two positions, R15 will be shorted, removing the 6B7 bias.

The volume control shunts R12 and R13 for audio frequencies. Accordingly, any desired amount of the audio component across R12 and R13 can be picked off by the moveable arm of the volume control and fed to the control grid of the pentode portion of the 6B7.

When peaking the IF transformers, use a low enough output from the test oscillator to render the AVC action inoperative.

THE RF TUNING ADJUSTMENTS

There are three holes at the back of the chassis through which the condenser trimmers are accessible. The unit nearest the control end of the chassis

is the RF unit. The next one is the translator and the last one the oscillator.

THE 6F7 PHASE CHANGER CIRCUIT

In any push-pull circuit, the instantaneous voltage on the grid of one of the tubes must be opposite in polarity to the voltage on the other tube's grid. Ordinarily, this polarity difference or phase change is accomplished by the push-pull input transformer. In the Model 182, it is accomplished as follows:

At some particular instant the polarity of the signal voltage on the 6B7 plate will be negative. This negative voltage is coupled through C18 to the control grid of one of the 41's. This signal voltage on the 6B7 plate also

causes a drop (audio frequency) across C17, R16, R10, and C27, with the polarities becoming increasingly negative toward C27. Accordingly, the control grid of the triode portion of the 6F7 is driven in a positive direction by the drop across R10 and C27. This causes the plate current to increase, which is to say that the plate becomes more positive. This positive potential is coupled through C19 to the grid of the other 41 tube. The result, then, is that the grid of one 41 is going in a positive direction while the other is going negative.

THE POWER SUPPLY UNIT

The plate supply unit is of the rotating dynamotor type. To remove it, take out the three Parker-Kalon screws at the bottom edge of the dynamotor housing and then take out the two screws holding the metal can type of condenser to the housing. The housing and dynamotor then can be loosened from the chassis. Unsoldering the leads under the dynamotor and removing the four screws that hold the dynamotor to the

housing case permits complete removal of the dynamotor. After considerable use, the dynamotor commutator may need cleaning. Use the finest sandpaper. NEVER USE EMERY CLOTH.

If the receiver is set up on the bench, outside of its case, be sure to connect a wire from the speaker cable to the chassis, to complete the speaker field circuit.

Trimmer, Assembly

TUBE VOLTAGE AND CURRENT CHART

TUBE	PLATE VOLTAGE	SCREEN VOLTAGE	PLATE M. A.	SCREEN M.A.
78 - RF	200	95	8	2.25
6B7 - AVC-Det-AF	60	60	1.25	.3
421- Output	205	208	14	2.5
6A7 - Osc-Transl.	Ep=200v; Eg#2=125v; Eg#3=95v; Ip=3.5ma; Ig#2=3ma; Ig#3=3.5ma;			
6F7 - IF & AF	Ep=200v; Eg#2=75v; Eg#3=95v; Ip=5ma. Ig#2=3ma; Ig#3=1ma.			

Care should be used when taking readings with a set analyzer as the capacity of the cables may cause circuits to oscillate, giving rise to erratic readings. Usually, touching the finger to grid or plate is sufficient to stop oscillation. If an analyzer is not used, the voltage readings can be taken with a 1000 ohms per volt voltmeter, from the cathode to the respective elements of each tube. Ordinarily, a 20% deviation from the chart value may be allowed.

THE REMOTE CONTROL MECHANISM - MODEL 182

MODEL 182

Remote Control Data
Parts List

COLONIAL RADIO CORP.

THE REMOTE CONTROL UNIT

As mentioned in the Instruction Booklet, the flexible drive shaft with the black, insulated tongue at its end, MUST be used for the condenser drive. The insulation is to prevent ignition noise pick up by the cable from being fed into the tuning condenser. Failure to observe these instructions will result in motor noise.

The pilot light switch, in the remote control unit, works coincidentally with the set switch in the chassis. Flickering of the pilot light may be due to poor contact between the phosphor-bronze spring and the rotating drum. Bending of the spring and sandpapering of the drum will correct the condition.

To gain access to the switch, proceed as follows:

1. Disconnect the flexible cables from the remote control unit and remove the unit from the steering column.
2. Remove the outer shell from the unit by bending up the tabs.
3. Pull the pointer off of its shaft and then remove the dial.
4. Remove the three flat head screws holding the cover and remove the cover, exposing the mechanism.

The illustration shows how to replace the pointer drive cable. Note

that the end of the cable coming from the clamped end of the spring passes OVER the other end of the cable. Also note that when the large pulley is set into place, the spring is diametrically opposite the drive pulley.

When replacing the pointer, turn the Station Selector shaft clockwise to its limit and set the pointer one division to the right of the bottom center line. Then when the shaft is turned all the way counter clockwise, the pointer will stop one division to the left of the center line.

Failure of the set switch and the remote control switch and lock to coincide in their operation will be caused by movement of the cables or of the control unit, after the synchronizing adjustment has been made. To secure simultaneous action of the two switches again, it will be necessary to disconnect the cable, turn the set switch to its "Off" position with a screw driver, turn the Volume Control knob in the control unit to its "Off" position with the key out, and then securely tighten the cable coupling and set screws. If the control unit is not moved then, the operation of the two switches will remain in synchronism.

The pilot light is accessible for replacement when the single screw at the back of the case is removed.

COLONIAL RADIO CORP.

MODEL 602
Circuit Data

SERVICE NOTES

MODEL 602

The COLONIAL Model 602 is a 12 tube, four wave band superheterodyne embodying such features as AVC, sensitivity control, tone control, neon visual tuning indicator, and twin speakers. The circuit is shown in block form in Fig. 85 and schematically in Fig. 86.

A 56 tube is used in the oscillator circuit. A 6A7 serves as an electron coupled translator. Its 175 kc output is amplified by the two 78 IF stages and then fed to the 37 detector, which is used as a diode. Two 37 AF tubes comprise a push-pull input stage to drive the push-pull 2A3H output stage. A 6B7 tube is used in the AVC stage, a 6B7 in the neon visual tuning circuit, and an 83V is the rectifier. The speakers are both moving coil dynamics. One is a 12" and the other an 8".

The incoming signal is fed to the translator control grid through coils L1 and L2 for the broadcast range, L3 for the next range, L4 for the next and L5 for the highest frequency range. L6

is the broadcast oscillator coil. L7 is the oscillator for the next range. L8 is the next, and L9 the one for the highest frequency range. C1 is the broadcast antenna coil trimmer. C3 is the broadcast translator coil trimmer. C2 is the translator trimmer for the first high frequency range. C4 the one for the next range, and C5 is the translator trimmer for the highest frequency range. C6 is the broadcast range oscillator trimmer. C7 is the trimmer for the first high frequency range, C8 the one for the next range, and C9 is the trimmer for the highest frequency oscillator coil. C10 is the padder for the low frequency end of the broadcast range, C11 the one for the next range, C12 for the next and C13 is the padder for the highest frequency oscillator coil.

The location of the coils and condensers is shown in the Service Illustrations. The numbering and lettering corresponds to that used in the Schematic.

6B7 TUNING LIGHT CIRCUIT

The 6B7 tuning light circuit is shown schematically in Fig. 83. A portion of the IF signal voltage, that existing across condenser A, is stepped up and impressed on the diode part of the 6B7 by means of the sharply tuned transformer, T, which is wound with Litz wire. The rectified signal current flows through the 1 megohm resistor from point (1) to point (2) so that point (2) is negative with respect to point (1). The control grid of the 6B7 is connected to point (2) and the cathode to point (1). As the signal is tuned in, the voltage across the 1 megohm resistor increases, increasing the negative control grid bias on the 6B7, thereby cutting down

its plate current. The reduced plate current means a decreased voltage drop across the 130 M ohm resistor, making available a greater voltage across the neon tuning flasher. When the signal is properly tuned in, the plate current of the 6B7 is sufficiently decreased to permit the neon lamp to light. Until a signal is tuned in, the plate current of the 6B7 causes sufficient drop across the 130 M ohm resistor to prevent the neon bulb from lighting. The sharply tuned transformer insures that voltage is not applied to the diode part of the 6B7 until the station is accurately tuned in.

FIG. 83. THE NEON TUNING LIGHT CIRCUIT

MODEL 602

Circuit Data

COLONIAL RADIO CORP.

6B7 AVC CIRCUIT

The AVC circuit is shown schematically in Fig. 84.

If there were no plate current through the 6B7, its cathode would be negative with respect to diode plate (A) by the amount of the voltage drop across the 2500 ohm speaker field. However, because of the 6B7 plate current and consequent voltage drop across the 50 M ohm resistor, the cathode potential of the 6B7 is raised so that it is approximately 15 volts positive to diode plate (A).

A portion of the IF signal is fed through C1 to diode plate (B). The resulting current, flowing through R1 creates a voltage drop across it with point (1) positive with respect to point (2). This voltage is impressed through R2 onto the control grid of the 6B7. This increased negative control grid bias decreases the plate current and the voltage drop across R3. As a consequence, the cathode bias with respect to ground decreases. This is equivalent to saying that diode plate A becomes positive with respect to the cathode. Current therefore flows from diode plate (A) to the cathode, creating a voltage drop across R4 with point (3) positive with respect to point (4). Since the grid returns of the translator and IF stages are connected to point (4), the voltage drop across R4 is impressed on the control grids of these tubes. This negative bias, which varies in step with the strength of the signal, controls the amplification of these tubes. An in-

crease in signal strength is offset by a decrease in tube amplification so that the output of the IF stage tends to remain at a constant value. Because the cathode is 15 volts positive with respect to diode plate (A) the AVC action is delayed until the received signal is strong enough to cause diode plate (A) to go positive with respect to the cathode. In this way the full sensitivity of the receiver is maintained for stations too weak to give full output from the receiver.

Residual bias for the first IF tube is supplied by the 15 M ohm variable cathode resistor, which serves as a sensitivity control. Set owners should be instructed not to increase the sensitivity any further than necessary for satisfactory reception. Unnecessarily high sensitivity will result in unwanted between-station-noise.

When peaking the IF stages, use a low enough output from the test oscillator to render the AVC action inoperative.

To peak the tuning flasher transformer, tune in a station whose strength is just about sufficient to operate the neon light. Then try retuning it very accurately by ear. If the flasher transformer is off calibration, the light will go out when the station is accurately tuned. With the station accurately tuned in, adjust the transformer tuning condensers until the neon bulb lights.

HUM CONTROL

COLONIAL RADIO CORP.

MODEL 602
Voltage, Alignment

HUM ADJUSTMENT

There is a hum adjustment to be turned with an insulated handle screwdriver, at the rear of the chassis, under the type 2A3H tubes. With the volume control all the way off, turn the hum adjustment to the point of minimum

hum. If this point appears to be beyond the end of the control, interchange the positions of the 2A3H tubes. If a balance still cannot be had, the 2A3H tubes must be replaced by ones more nearly matched in their characteristics.

ALIGNMENT

BROADCAST

Disconnect the antenna and connect a .00025 mfd. condenser between the set's antenna and ground leads, to take the place of the normal antenna capacity. Adjust the test oscillator to a frequency near the high frequency end of the broadcast range and couple the oscillator to the receiver antenna lead. With the wave switch in the broadcast position, set the dial accurately to the test oscillator's frequency. Then peak C1, C3, and C6.

Retune the test oscillator and the receiver to a frequency near the low frequency end of the broadcast range. Peak C10.

100 METER RANGE

Turn the wave switch to the first high frequency range. Adjust the test oscillator to a frequency near the high frequency end of this range. Turn the

dial to this frequency and peak C7 and C2. Then change the test oscillator's frequency to the low frequency end of the range and peak C11.

40 METER RANGE

Turn the wave switch to the next high frequency range. Adjust the test oscillator to a frequency near the high frequency end of this range. Turn the dial to this frequency and peak C8 and C4. Then change the test oscillator's frequency to the low frequency end of the range and peak C12.

20 METER RANGE

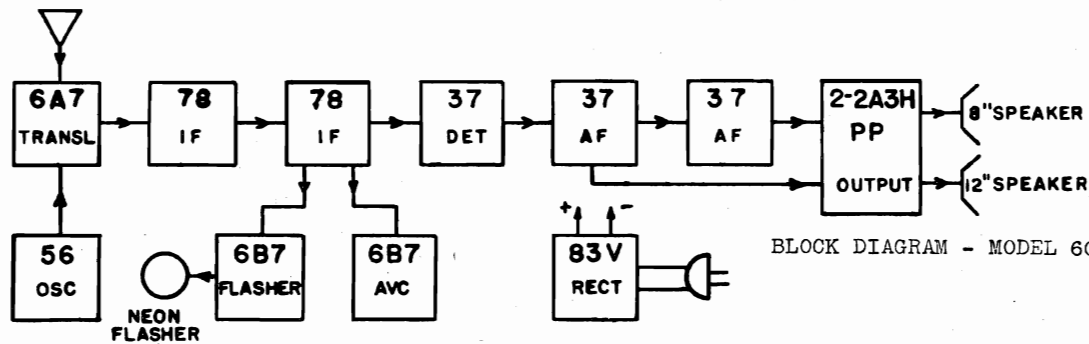

Turn the wave switch to the highest frequency range. Adjust the test oscillator to a frequency near the high frequency end of this range. Turn the dial to this frequency and peak C9 and C5. The padder for this range, C13, is fixed.

TUBE	PLATE VOLTAGE	SCREEN VOLTAGE	PLATE M. A.	SCREEN M. A.

6B7 - AVC	60	60	4	1
6B7 - Flasher	7 - No. sig. 90 - With sig.			
83V - Rect	DC volts = 350. Plate current = .87ma. per plate.			
6A7 - Transl	Ep = 180; Eg#2 = 80; Eg#3 & #5 = 95. Ip = 4ma; Ig#2 = 2ma; Ig #3 & #5 = 4ma.			

Readings taken with 1000 ohms per volt voltmeter, sensitivity control on full, no signal received. Care must be used if measurements are made with an analyzer since the capacity of the cables may cause circuits to oscillate, giving rise to erratic readings. Usually, touching the finger to grid or plate is sufficient to stop oscillation. If an analyzer is not used, voltage readings can be made from cathode to the respective elements of each tube. Ordinarily, a 20% deviation from the chart value may be allowed.

MODEL 603
 Socket Layout
 Trimmers
 Alignment

COLONIAL RADIO CORP.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the receiver chassis.
3. Connect the other lead of the test oscillator in series with a .1 mfd. condenser to the grid of the 78 IF tube. Leave the grid clip attached to the cap and the tube shield in place.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid of the 78 Translator tube and adjust the IF input transformer.

6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment (Broadcast):

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.
2. Set the test oscillator to 1660

kilocycles.

3. Screw the oscillator padder condenser to approximately three quarters of its maximum capacity.

4. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output.

5. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the translator trimmer, mounted on the variable condenser section nearer the dial, for maximum output.

6. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.

7. Repeat the 1660 kc and 1400 kc adjustments.

Always use as low an output from the test oscillator as possible.

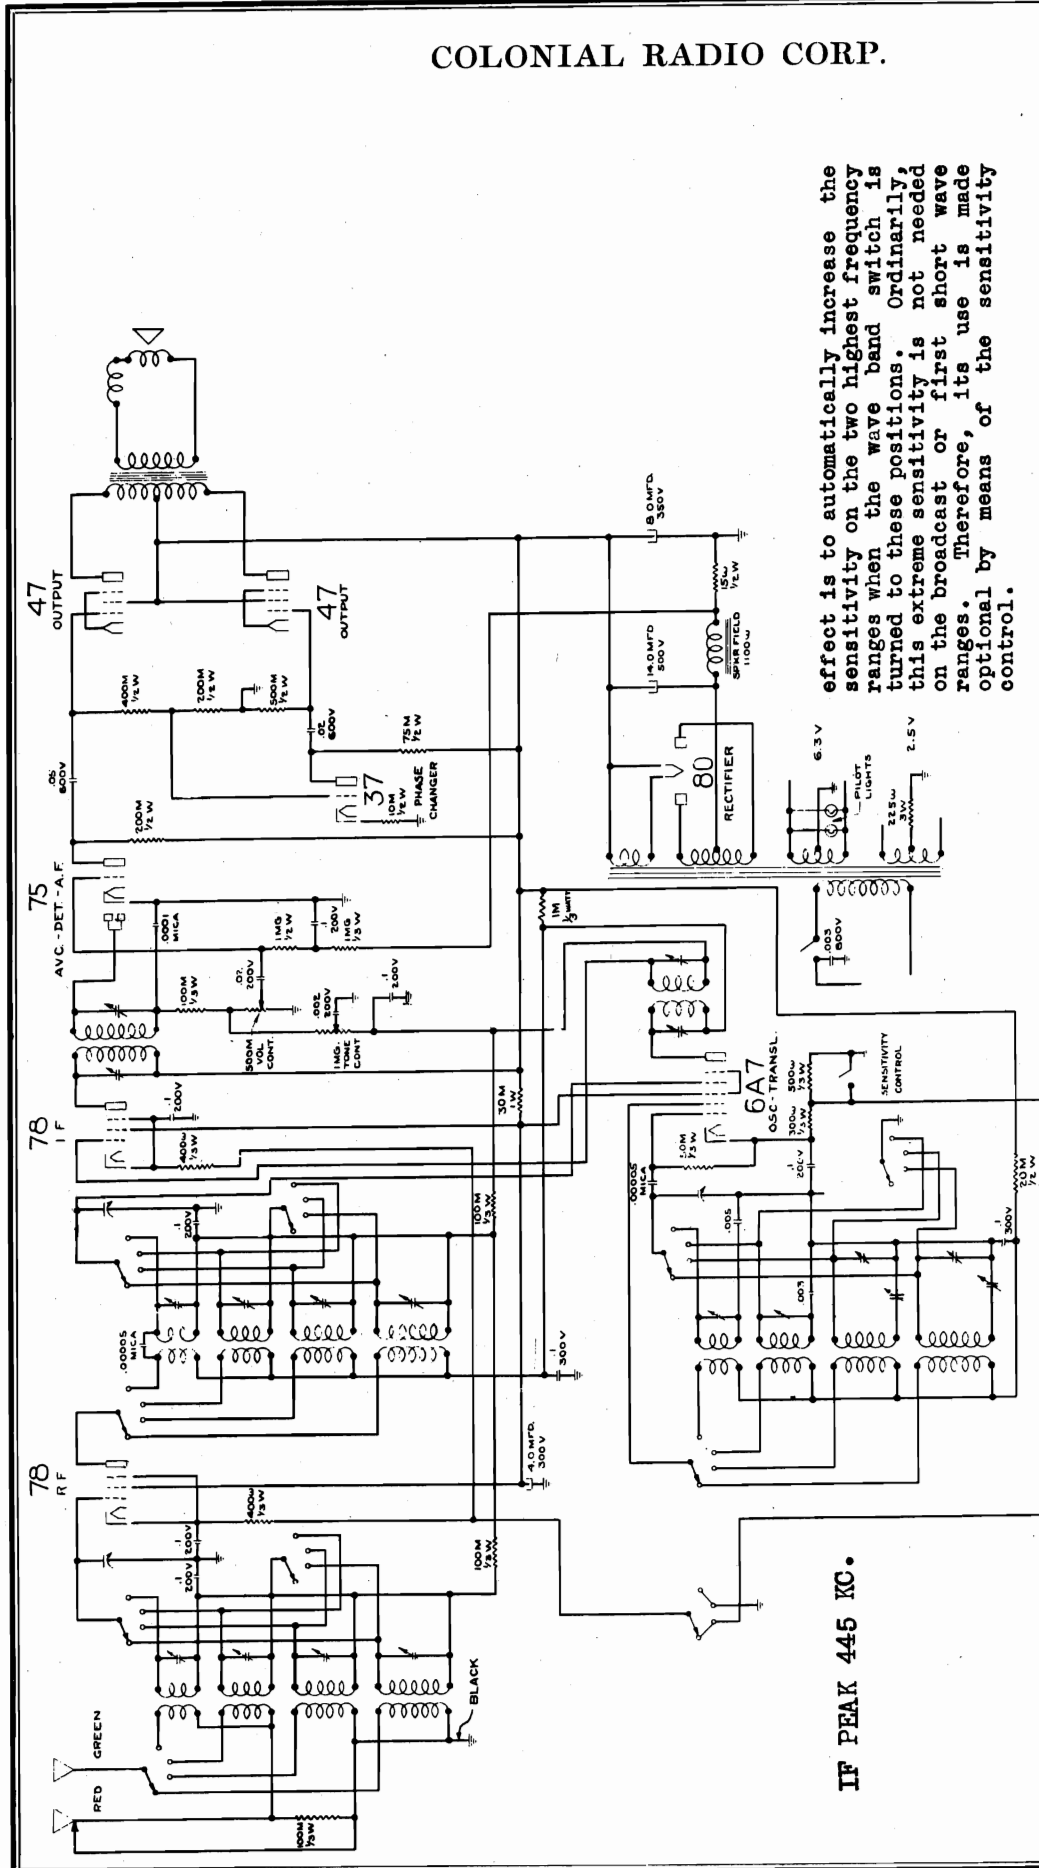

Short Wave Alignment:

1. Leave the test oscillator coupled to the green antenna lead as for broadcast alignment.

2. Set the test oscillator to 15 megacycles and tune in its signal. Then adjust the trimmer, mounted on the short wave translator coil, for maximum output.

COLONIAL RADIO CORP.

MODEL 604
Schematic
Circuit Data

IF PEAK 445 KC.

effect is to automatically increase the sensitivity on the two highest frequency ranges when the wave band switch is turned to these positions. Ordinarily, this extreme sensitivity is not needed on the broadcast or first short wave ranges. Therefore, its use is made optional by means of the sensitivity control.

The voltage drop created across the 500 M ohms of the Volume Control, due to the diode current of the 75 tube, is used for AVC voltage.

The triode portion of the 75 AVC-Detector-AF tube, in conjunction with the 37 Phase Changer tube, acts as a push-pull input stage to the 47 push-pull output stage. The use of the 37 Phase Changer tube eliminates the need for a push-pull input transformer.

Therefore, when this resistor is shorted, the control grid bias on the 6A7 and 78 tubes is reduced, thereby increasing the sensitivity of the receiver. When the wave band switch is in positions "C" or "D", the cathode returns of the 78 tubes are connected to ground instead of to the 500 ohm resistor so that the sensitivity control then only affects the bias of the 6A7 tube. The

The knob operating the "On - Off" switch also acts as a sensitivity control when it is turned all the way to the right. In this position the 500 ohm resistor in the cathode circuit of the 6A7, is shorted out. When the wave band switch is in either the broadcast or first short wave range positions, the cathodes of the 78 RF and IF tubes are returned to this 500 ohm resistor.

MODEL 604

Voltage, Alignment

COLONIAL RADIO CORP.

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, through a .1 mfd condenser, to the control grid of the 78 IF tube. The grid clip should be left attached to the cap and the tube shield must be in place.
4. Set the test oscillator to 445 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid cap of the 6A7 tube and tune the IF input transformer.
6. In order to secure greater accuracy repeat the adjustments, starting with the IF output transformer.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment; Band "A" (Broadcast):

1. Couple the output of the test oscillator to the antenna lead of the set, with the antenna connected.
2. Set the test oscillator to 1520 kilocycles.
3. Turn the variable condenser plates all the way out. Then adjust the #1 oscillator trimmer for maximum output. The locations of all of the trimmers are shown in the Service Illustrations.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the #1 antenna trimmer and the #1 translator trimmer for maximum output.
5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same

time, adjust the #1 oscillator padder for maximum output.

6. Repeat the 1520 kc and 1400 kc adjustments for greater accuracy.

Band "B":

1. Leave the test oscillator coupled to the antenna lead as for broadcast band alignment.
2. Set the test oscillator to 4250 kilocycles.
3. Turn the variable condenser plates all the way out. Then adjust the #2 oscillator trimmer for maximum output.
4. Set the test oscillator to 4000 kc and tune in its signal. Then adjust the #2 antenna trimmer and the #2 translator trimmer for maximum output.

5. If turns have been shifted, repeat the 10 megacycle and the 9 megacycle adjustments, since they will have been affected by shifting of the turns.

Band "D":

1. Set the test oscillator to 19 megacycles.
2. Turn the variable condenser plates all the way out. Then adjust the #4 oscillator trimmer for maximum output.
3. Set the test oscillator to 18 megacycles and tune in its signal. Then adjust the #4 antenna trimmer and the #4 translator trimmer for maximum output.
4. Set the test oscillator to 9 megacycles and tune in its signal. If necessary, shift turns on the antenna and translator coils to secure maximum sensitivity. Be sure to cement the turns in place.
5. If turns have been shifted, repeat the 19 megacycle and 18 megacycle adjustments since they will have been affected by shifting of the turns.

	Max d.c. voltage=285v. Plate current=17 m.a. per plate			

A 6A7 serves as oscillator and translator. The resultant 175 kc signal in its plate circuit is amplified by the 78 IF stage and then coupled to the 75 tube. This tube functions as diode detector, AVC, and 1st audio. Its audio output is fed to the 41 output pentode and then to the dynamic loudspeaker. An 80 rectifier completes the tube complement.

Use care when taking readings with a set analyzer as the capacity of the cables may cause circuits to oscillate, giving rise to erratic readings. Usually touching grid or plate with finger will stop oscillations. If an analyzer is not used, readings should be made with a 1000 ohms per volt voltmeter from cathode to the respective elements of each tube. Ordinarily, a 20% deviation from the chart values may be allowed.

COLONIAL RADIO CORP.

A vernier tuning condenser, with its knob on the front panel, is connected across the transistor section of the ganged tuning condenser. Through its manipulation, it is possible to bring the circuits into perfect alignment at any frequency setting, thereby greatly increasing the sensitivity and short wave performance of the receiver. When the dot on the vernier knob is at its upper center position, the condenser is set at half capacity. Customers should be instructed to turn the knob either side of this normal position, when tuning, as described in the Instruction Leaflet accompanying the receiver.

R-9858	Resistor - 50 ohms, 1/2 watt carbon
R-8562	Resistor - 400 ohms, flexible

Some of these receivers have a 14 mfd. first filter condenser, others an 8 mfd. one. Either may be used for replacement purpose.

The trimmer condenser on the pre-selector section of the ganged condenser should be adjusted at about 1500 kc. The oscillator trimmer, C3, should be adjusted so that the set is tuned to 2000 kc when the ganged condenser is at its minimum capacity setting. Adjustments should be made with the Vernier at its half capacity setting.

75 - AVC-DET-AF	85				-.4
41 - Output	175	185			-.45

NOTE: All control grid readings are lower than the actual applied voltage due to high series resistance in the circuit.

MODEL 651**Socket Layout****Alignment, Trimmers****COLONIAL RADIO CORP.**

In order to prevent interference from code stations when the receiver is located near the coast, a wave trap is incorporated in the antenna circuit. Although this trap is shown in the schematic as a coil with a series condenser, actually it consists of two multilayer coils wound on top of each other with one end of each coil left unconnected. The distributed capacity between the coils is the condenser shown in the schematic. The design of the coil is such that the combination of distributed capacity and inductance is resonant at about 600 meters which is the frequency used by ships and also is very near the IF frequency of the receiver.

The 75 AVC-Detector-AF Circuit:

The IF signal existing at the IF output transformer secondary is impressed between the diode plates and the cathode of the 75 tube, in series with the 500 M ohms of the volume control and the 50 M ohm resistor. Diode current flows, creating a voltage drop across these resistances. Only the drop across the volume control resistance is used for AVC voltage. The control grid returns of the 6A7 and 78 tubes are connected through filter resistors to one end of the volume control. This end is negative with respect to the other end of the control so that the voltage drop across it, due to the diode current, is impressed as negative bias on the control grids of the 6A7 and 78 tubes. Any increase in signal strength increases the 75 diode current, increases the voltage drop across the volume control, and so increases the negative bias of the 6A7 and 78 tubes with a resultant decrease in tube amplification. Since increases in signal strength are offset by decreases in tube amplification, the input to the detector tends to remain at a constant value.

Any desired portion of the audio component across the volume control may be picked up by the movable arm of the control and fed through the .02 mfd. condenser to the triode section of the 75 tube. It is there amplified and then coupled to the 41 output tube.

The IF Stages:

1. Connect the output meter (low scale) across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube, leaving the grid clip attached to the cap.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.

5. Change the test oscillator connection to the grid of the 6A7 tube and adjust the IF input transformer.

6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment: (Broadcast)

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.

2. Set the test oscillator to exactly 1640 kc.

3. Turn the dial pointer to exactly 1640 kc and adjust the broadcast oscillator trimmer for maximum output.

4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the variable condenser for maximum output.

5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.

6. Since the adjustments are interacting to an extent, it is advisable to repeat the entire operation.

Always use as low an output from the test oscillator as possible.

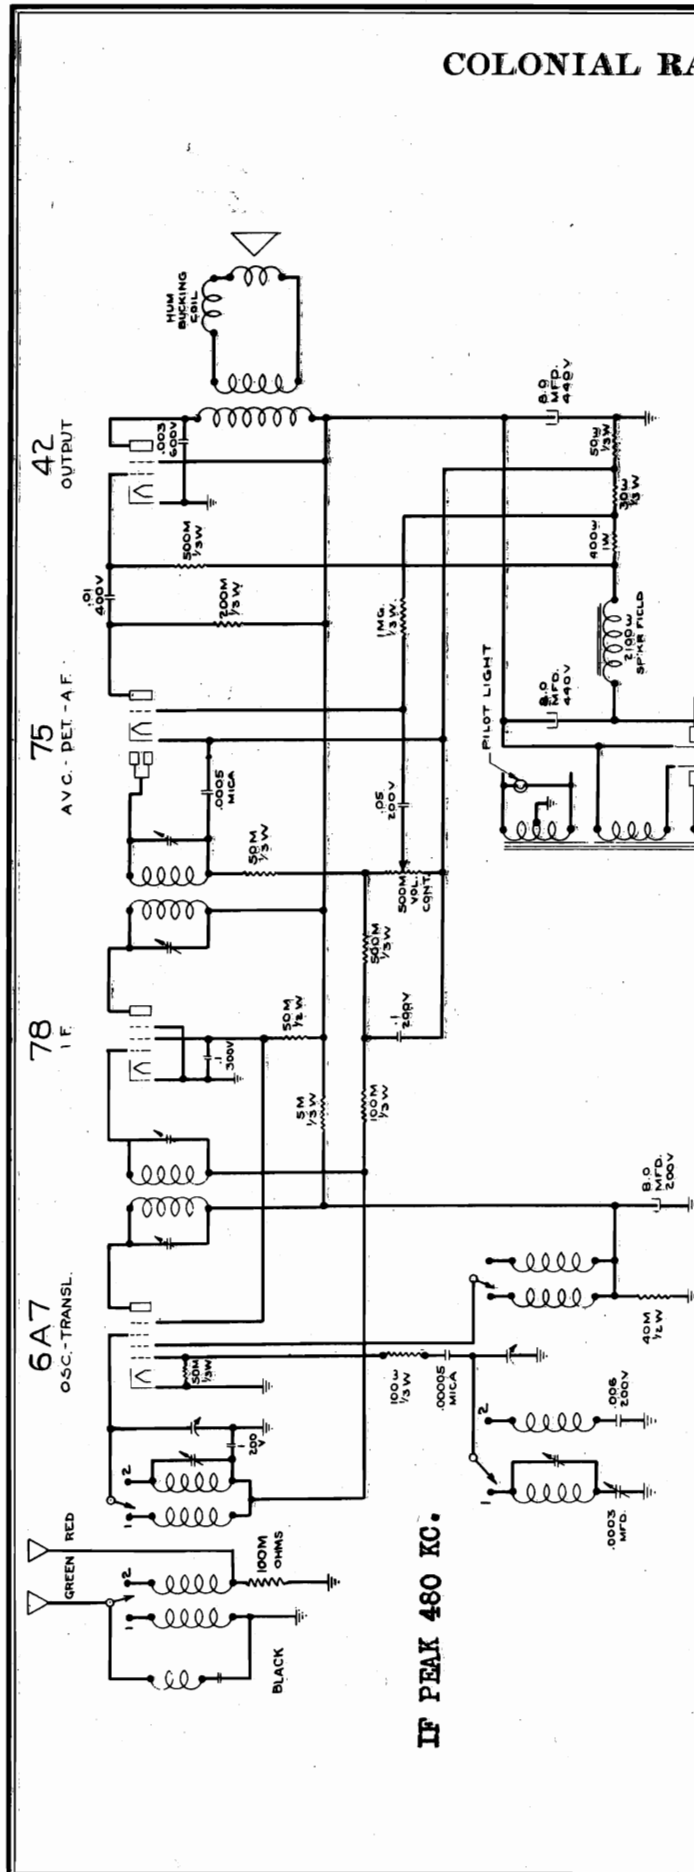

Short Wave Alignment:

Set the test oscillator to 15 megacycles and tune in its signal. Then adjust the trimmer on the short wave translator coil for maximum output.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the receiver chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube. Leave the grid clip attached to the cap and the tube shield in place.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the 6A7 tube and adjust the IF input transformer.
6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment (Broadcast):

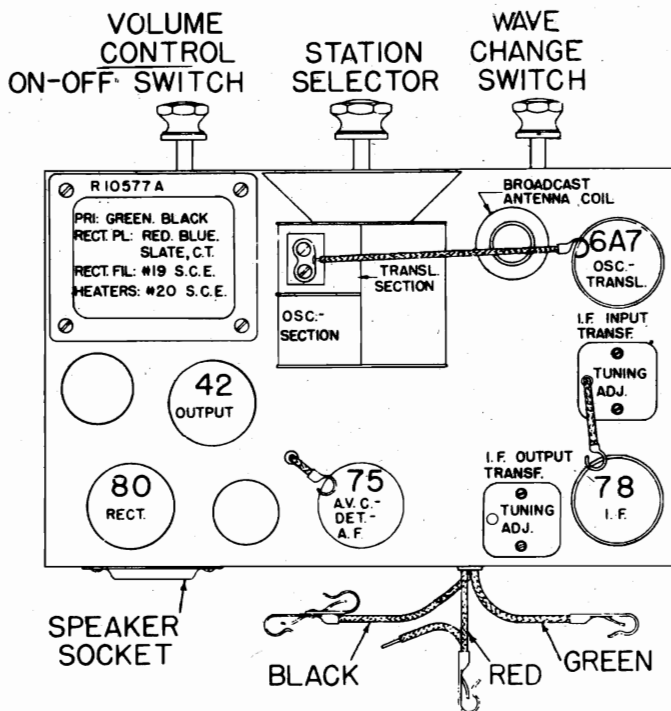

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.
2. Set the test oscillator to 1650 kilocycles.

3. Screw the oscillator padder condenser to approximately three quarters of its maximum capacity.
4. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output.
5. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the translator trimmer, mounted on the variable condenser section nearer the dial, for maximum output.
6. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.
7. Repeat the 1650 kc and 1400 kc adjustments.

Always use as low an output from the test oscillator as possible.

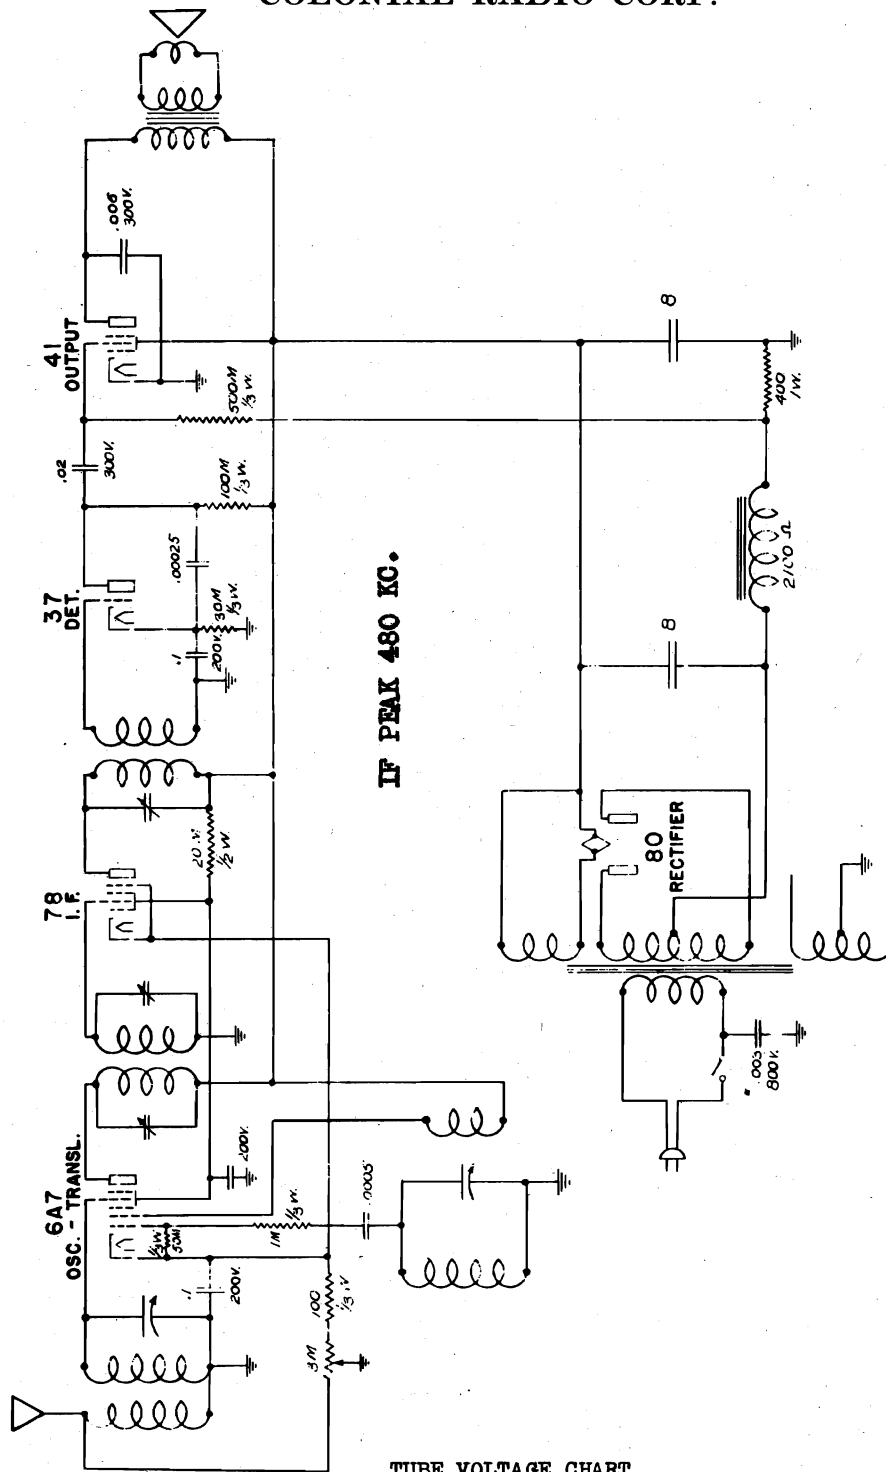

Short Wave Alignment:

1. Leave the test oscillator coupled to the green antenna lead as for broadcast alignment.
2. Set the test oscillator to 15 megacycles and tune in its signal. Then adjust the trimmer, mounted on the short wave translator coil, for maximum output.

ALIGNMENT PROCEDURE

The IF Stages:

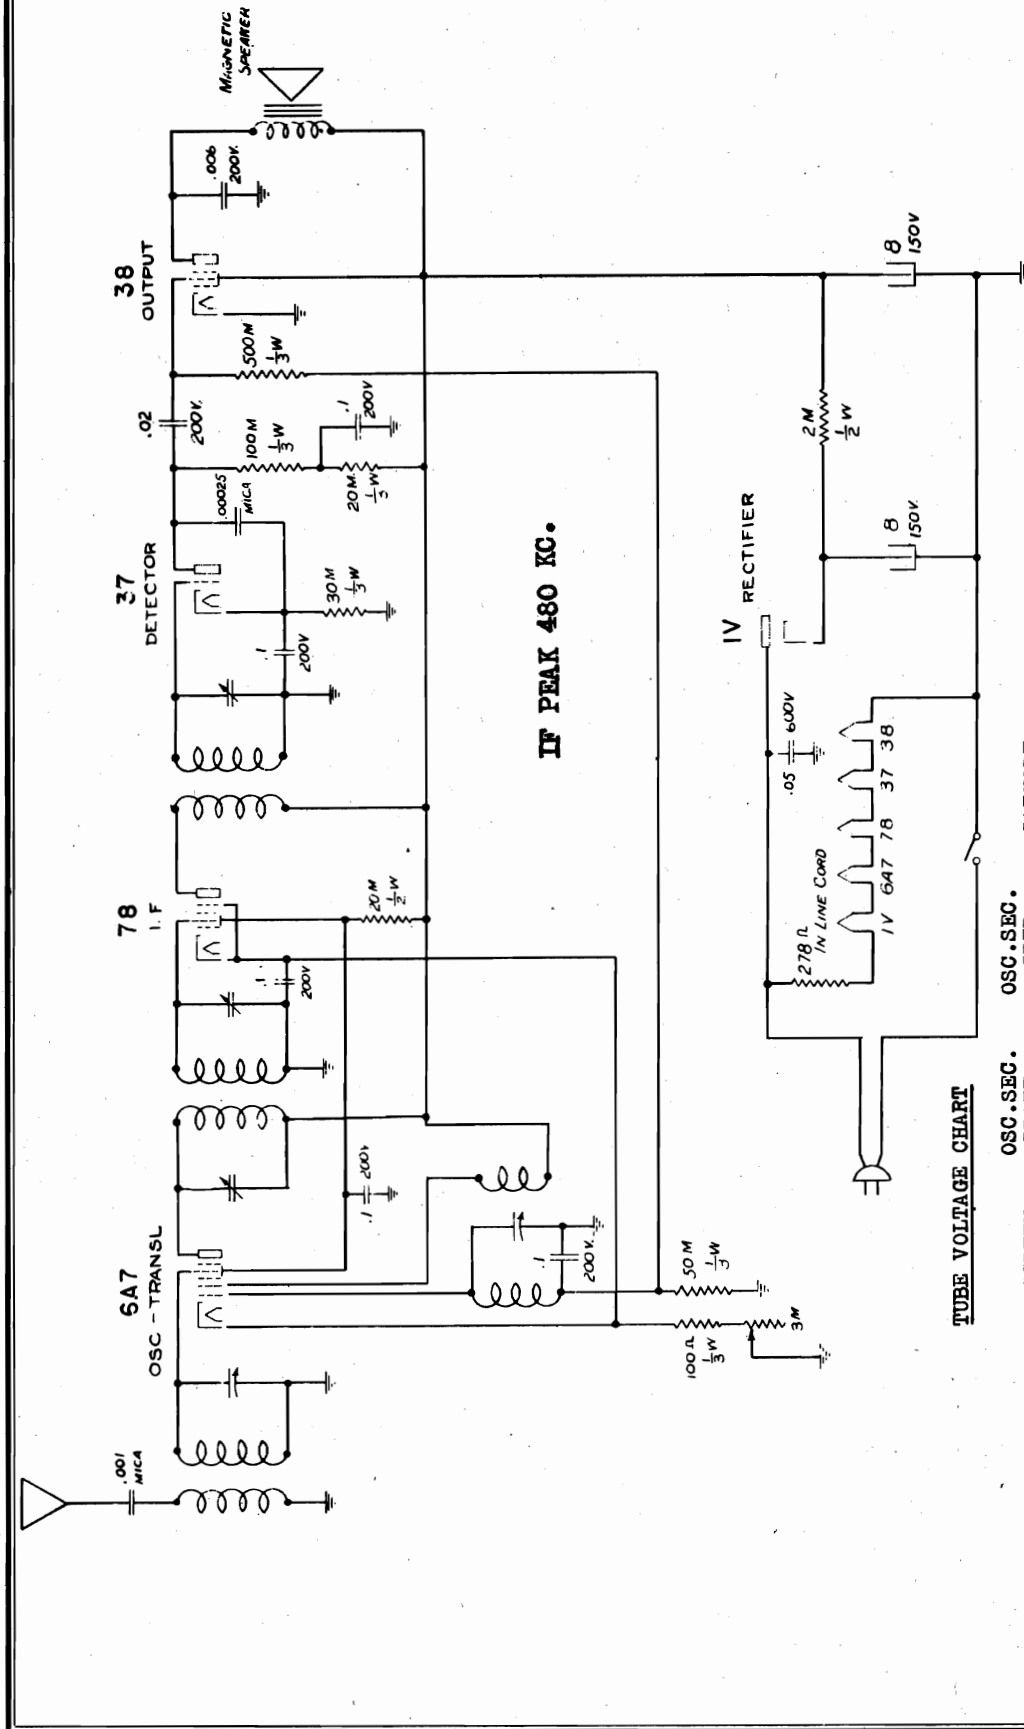

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube, leaving the grid clip attached to the cap.
4. Set the test oscillator to 480 kc, and adjust the IF output transformer tuning condenser. This condenser is mounted on the IF output transformer terminal board under the chassis, about two inches behind the variable condenser.
5. Change the test oscillator connection to the grid of the 6A7 tube and adjust the IF input transformer. The locations of its tuning adjustments are shown in the Service Illustration.
6. Repeat the adjustments to secure greater accuracy.

RF Alignment:

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.
2. Set the test oscillator to 1750 kilocycles.
3. Turn the variable condenser plates all the way out. Then adjust the trimmer on the oscillator section of the variable condenser for maximum output. The oscillator section is the one furthest from the dial, as shown in the Service Illustration.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output.

MODEL 654
Alignment, Socket
Trimmers, Parts

COLONIAL RADIO CORP.

The COLONIAL Model 654 is a five tube, broadcast superheterodyne, designed for operation from either AC or DC power supply. The tubes and their functions are:

- 6A7 - Oscillator-Translator
- 78 - IF
- 37 - Detector
- 38 - Output
- 1V - Rectifier

Since the tube heaters are in series, if any one tube burns out, none will light. However, it is necessary to replace only the burned out tube. The others then will light. The full line voltage will appear across the heater prongs of a socket in which there is a burned out tube.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the high scale (about 100 volts) of the output meter across the loud speaker terminals.
2. Connect the ground lead of the test oscillator to the chassis through a .1 mfd. condenser.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube, leaving the grid clip attached to the cap.

4. Set the test oscillator to 480 kc. and tune the IF output transformer. This transformer is mounted under the chassis and has a single bakelite base tuning condenser mounted on its terminal board. There is but one tuning adjustment for this transformer, since only the transformer secondary is tuned.

5. Change the test oscillator connection to the grid of the 6A7 tube and adjust the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.

6. Repeat the adjustments to secure greater accuracy.

RF Alignment:

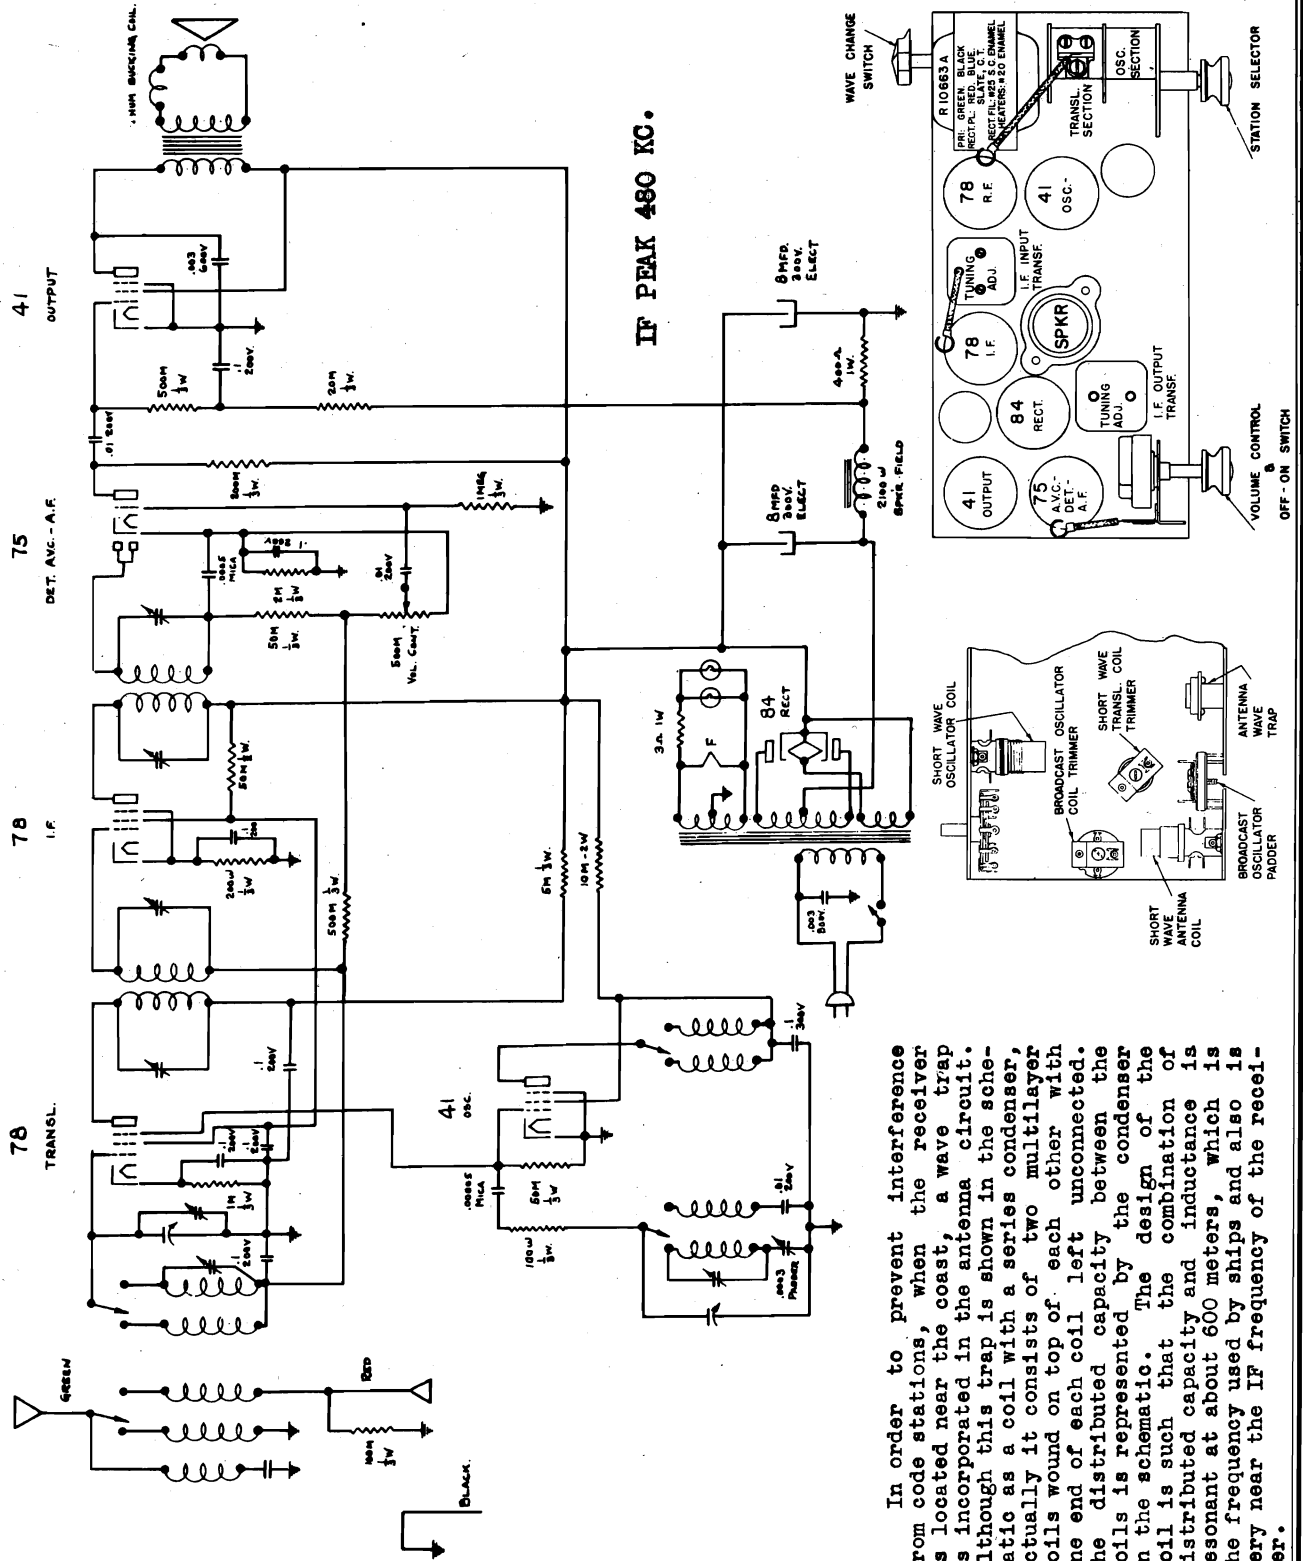

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.
2. Set the test oscillator to 1750 kilocycles.
3. Turn the variable condenser plates all the way out. Then adjust the trimmer on the oscillator section of the variable condenser for maximum output. The oscillator section is the one furthest from the dial, as shown in the Service Illustration.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output.

COLONIAL RADIO CORP.

MODEL 655 Schematic, Notes Trimmers, Socket Parts Layout,

In order to prevent interference from code stations, when the receiver is located near the coast, a wave trap is incorporated in the antenna circuit. Although this trap is shown in the schematic as a coil with a series condenser, actually it consists of two multilayer coils wound on top of each other with one end of each coil left unconnected. The distributed capacity between the coils is represented by the condenser in the schematic. The design of the coil is such that the combination of distributed capacity and inductance is resonant at about 600 meters, which is the frequency used by ships and also very near the IF frequency of the receiver.

MODEL 655
Voltage
Alignment

COLONIAL RADIO CORP.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter (low scale) across the loud speaker voice coil.

2. Connect the ground lead of the test oscillator to the chassis.

3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube, leaving the grid clip attached to the cap.

4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.

5. Change the test oscillator connection to the grid of the 78 translator tube and adjust the IF input transformer.

6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment (Broadcast):

1. Screw the oscillator padding condenser to about three quarters of its maximum capacity.

2. Couple the test oscillator to the green antenna lead, leaving the antenna connected. Set the test oscillator to 1610 kc.

3. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output. Some of these sets have a trimmer on the oscillator section of the variable condenser as well as one mounted on the broadcast oscillator coil. In others, the adjusting screw has been removed from the trimmer on the variable condenser and only the trimmer on the oscillator coil used. It will be found that in sets using both condensers, that maximum output cannot be reached even though one of the trimmers is screwed all the way in, making it necessary to use the other trimmer. In effect, both trimmers are in parallel when the Wave Switch is in the broadcast position.

4. Set the test oscillator to 1400 kc. and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output.

5. Set the test oscillator to 600 kc. and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.

6. Since the adjustments are interacting to an extent, it is advisable to repeat the entire operation.

Always use as low an output from the test oscillator as possible.

Short Wave Alignment:

Set the test oscillator to 15 megacycles and tune in its signal. Then adjust the trimmer on the short wave translator coil for maximum output.

MODEL 656

Alignment

COLONIAL RADIO CORP.

ALIGNMENT PROCEDUREThe IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.

2. Connect the ground lead of the test oscillator to the chassis.

3. Connect the other lead of the test oscillator, in series with a .1 mfd condenser, to the control grid of the 78 IF tube, leaving the grid clip attached to the cap.

4. Set the test oscillator to 175 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.

5. Change the test oscillator connection to the grid of the 78 translator tube and tune the IF input transformer.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

6. Repeat the procedure in order to secure greater accuracy.

RF Alignment (Broadcast Band):

1. Set the test oscillator to 1650 kilocycles.

2. Couple the output of the oscillator to the antenna lead of the set, with the antenna connected.

3. Turn the variable condenser plates all the way out. With the wave band selecting switch in position "A", tune the oscillator trimmer for maximum output. The position of this trimmer is shown in the Service Illustration.

4. Set the test oscillator to 1400 kc and adjust the antenna and translator trimmers. The antenna trimmer is the one on the variable condenser section nearest the dial. The translator trimmer is accessible through the hole in the top of the translator coil shield as shown in the Service Illustration.

5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the broadcast oscillator padder for maximum output. The location of this padding condenser is shown in the Service Illustration.

6. Repeat the 1650 kc and 1400 kc operations. Then repeat the 600 kc padding operation.

Always use an output from the test oscillator low enough to render the AVC action inoperative.

Short Wave (Band "B") Alignment:

1. Leave the test oscillator coupled to the antenna lead as for broadcast alignment.

2. Set the test oscillator to 5000 kc. and tune in its signal. Screw the short wave (Band "B") antenna coil trimmer all the way in (maximum capacity). Then reduce the trimmer capacity until the output reaches a peak. A second peak may be obtained when the trimmer capacity is reduced still further. However, the correct position in which to leave the trimmer is the one using the maximum capacity, that is, with the trimmer condenser plates most nearly in a closed position.

3. Set the test oscillator to 1800 kc. and tune in its signal. If necessary, turns may be shifted on the short wave antenna coil to secure maximum output. If turns are shifted, it will be necessary to repeat the trimmer adjustment at 5000 kc.

Short Wave (Band "C") Alignment:

1. Leave the test oscillator coupled to the antenna lead as before.

2. Set the test oscillator to 15 megacycles.

3. With the wave band selecting switch in position "C", tune the receiver to 15 megacycles.

4. Screw the short wave (Band "C") antenna coil trimmer all the way in (maximum capacity). Then reduce the trimmer capacity until the output reaches a peak. A second peak may be obtained, when the trimmer capacity is reduced still further. However, the correct position in which to leave the trimmer is the one using the maximum capacity, that is with the trimmer condenser plates most nearly in a closed position.

5. Set the test oscillator to 6 megacycles and tune in its signal. If necessary, turns may be shifted on the short wave (Band "C") antenna coil to secure maximum output. If turns are shifted, it will be necessary to repeat the trimmer adjustment at 15 megacycles.

As mentioned in the instructions for this receiver, either a conventional type antenna or a doublet can be used. If a doublet is used, the wave band selecting switch automatically changes connections on the broadcast band so that the doublet acts as a conventional antenna. Examination of the schematic will reveal that all three sections of the variable condenser are used only when the wave band selecting switch is in the BROADCAST position. In the short wave positions, "B" and "C", the variable condenser section nearest the dial is disconnected.

The 500 M ohms of the volume control is used to supply AVC voltage by utilizing the drop across it, due to the diode current of the 75 tube.

COLONIAL RADIO CORP.

COLONIAL RADIO CORP.

MODEL 657
Alignment

In order to prevent interference from code stations, when the receiver is located near the coast, a wave trap is incorporated in the antenna circuit. Although this trap is shown in the schematic as a coil with a series condenser, actually it consists of two multilayer coils wound on top of each other with one end of each coil left unconnected. The distributed capacity between the coils is represented by the condenser in the schematic. The design of the coil is such that the combination of distributed capacity and inductance is resonant at about 600 meters, which is the frequency used by ships and also is very near the IF frequency of the receiver.

The 75 AVC-Detector-AF Circuit:

The IF signal existing at the IF output transformer secondary is impressed between the diode plates and the cathode of the 75 tube, in series with the 500 M ohms of the Volume Control and the 50 M ohm resistor. Diode current flows, creating a voltage drop across these resistances. Only the drop across

the Volume Control resistance is used for AVC voltage. The control grid returns of the 6A7 and 78 tubes are connected through filter resistances to one end of the Volume Control. This end is negative with respect to the other end of the control so that the voltage drop across it, due to the diode current, is impressed as negative bias on the control grids of the 6A7 and 78 tubes. Any increase in signal strength increases the 75 diode current, increases the voltage drop across the Volume Control, and so increases the negative bias of the 6A7 and 78 tubes with resultant decrease in tube amplification. Since increases in signal strength are offset by decreases in tube amplification, the input to the detector tends to remain at a constant value.

Any desired portion of the audio component across the Volume Control may be picked off by the movable arm of the control and fed through the .01 mfd. condenser to the triode section of the 75 tube. It is there amplified and then coupled to the 43 output tube.

The IF Stages:

1. Connect the output meter (low scale) across the loud speaker voice coil.

2. Connect the ground lead of the test oscillator to the chassis.

3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube, leaving the grid clip attached to the cap.

4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.

5. Change the test oscillator connection to the grid of the 6A7 tube and adjust the IF input transformer.

6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment (Broadcast):

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.

2. Set the test oscillator to 1660 kilocycles.

3. Turn the variable condenser plates all the way out. Then adjust

HUM BALANCE

There is an Isolantite base condenser mounted under the chassis immediately below the volume control. This condenser is used to minimize hum.

ALIGNMENT PROCEDURE

the oscillator trimmer for maximum output. Some of these sets have a trimmer on the oscillator section of the variable condenser as well as one mounted on the broadcast oscillator coil. In others, the adjusting screw has been removed from the trimmer on the variable condenser and only the trimmer on the oscillator coil used. It will be found that in sets using both condensers, that maximum output cannot be reached even though one of the trimmers is screwed all the way in, making it necessary to use the other trimmer. In effect, both trimmers are in parallel when the Wave Switch is in the broadcast position.

4. Set the test oscillator to 1400 kc. and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output.

5. Set the test oscillator to 600 kc. and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.

6. Since the adjustments are interacting to an extent, it is advisable to repeat the entire operation.

Always use as low an output from the test oscillator as possible.

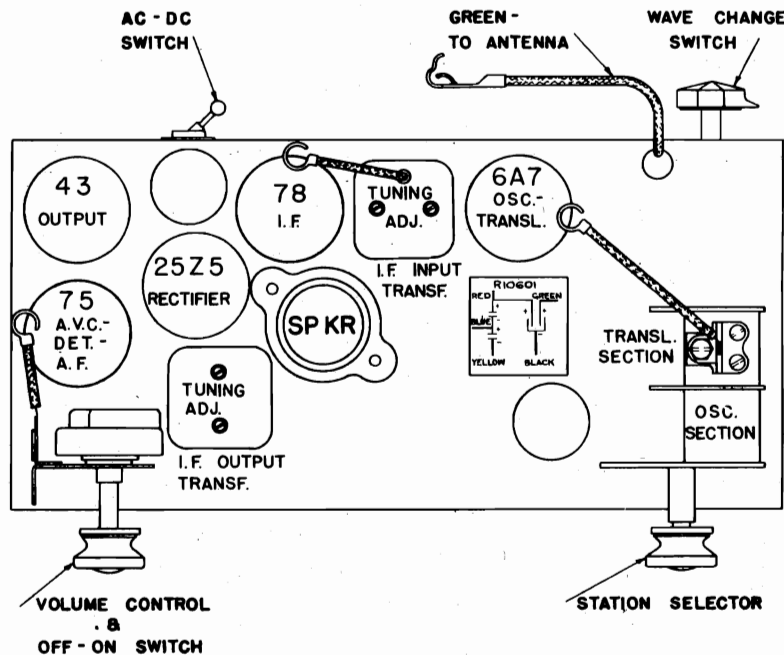

Short Wave Alignment:

Set the test oscillator to 15 megacycles and tune in its signal. Then adjust the trimmer on the short wave translator coil for maximum output.

With the set detuned and the volume control on full, adjust this condenser until the point affording minimum hum is found.

- PRIMARY: Green. Black.
- RECTIFIER PLATE: Red. Blue. Slate, center tap.
- RECTIFIER FILAMENT: #19 single cotton enamel with red tracer.
- HEATERS: #19 single cotton enamel.

The voltage drop created across the 500 M ohms of the volume control, due to the diode current of the 75 tube, is used for AVC voltage.

MODEL 658
Alignment, Trimmers
Socket Layout

COLONIAL RADIO CORP.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the receiver chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube. Leave the grid clip attached to the cap and the tube shield in place.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid of the 78 translator tube and adjust the IF input transformer.
6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment (Broadcast):

1. Couple the test oscillator to the green antenna lead, leaving the antenna connected.
2. Set the test oscillator to 1660 kilocycles.
3. Screw the oscillator padder condenser to approximately three quarters of its maximum capacity.
4. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output.
5. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the translator trimmer, mounted on the variable condenser section nearer the dial, for maximum output.
6. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the padder until maximum output is obtained.
7. Repeat the 1660 kc and 1400 kc adjustments.

Always use as low an output from the test oscillator as possible.

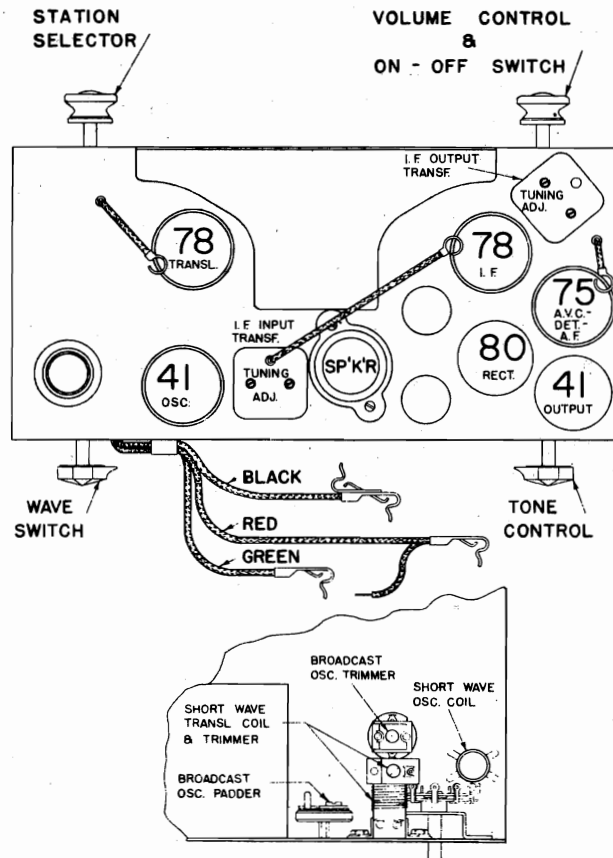

Short Wave Alignment:

1. Leave the test oscillator coupled to the green antenna lead as for broadcast alignment.
2. Set the test oscillator to 16 megacycles and tune in its signal. Then adjust the trimmer condenser, mounted on the short wave translator coil, for maximum output.

In order to reduce the distributed capacity and thereby extend the high frequency limit of the receiver, the grid and plate leads to the oscillator coil and oscillator socket must be kept out in the open and as far removed from the metal of the chassis as possible.

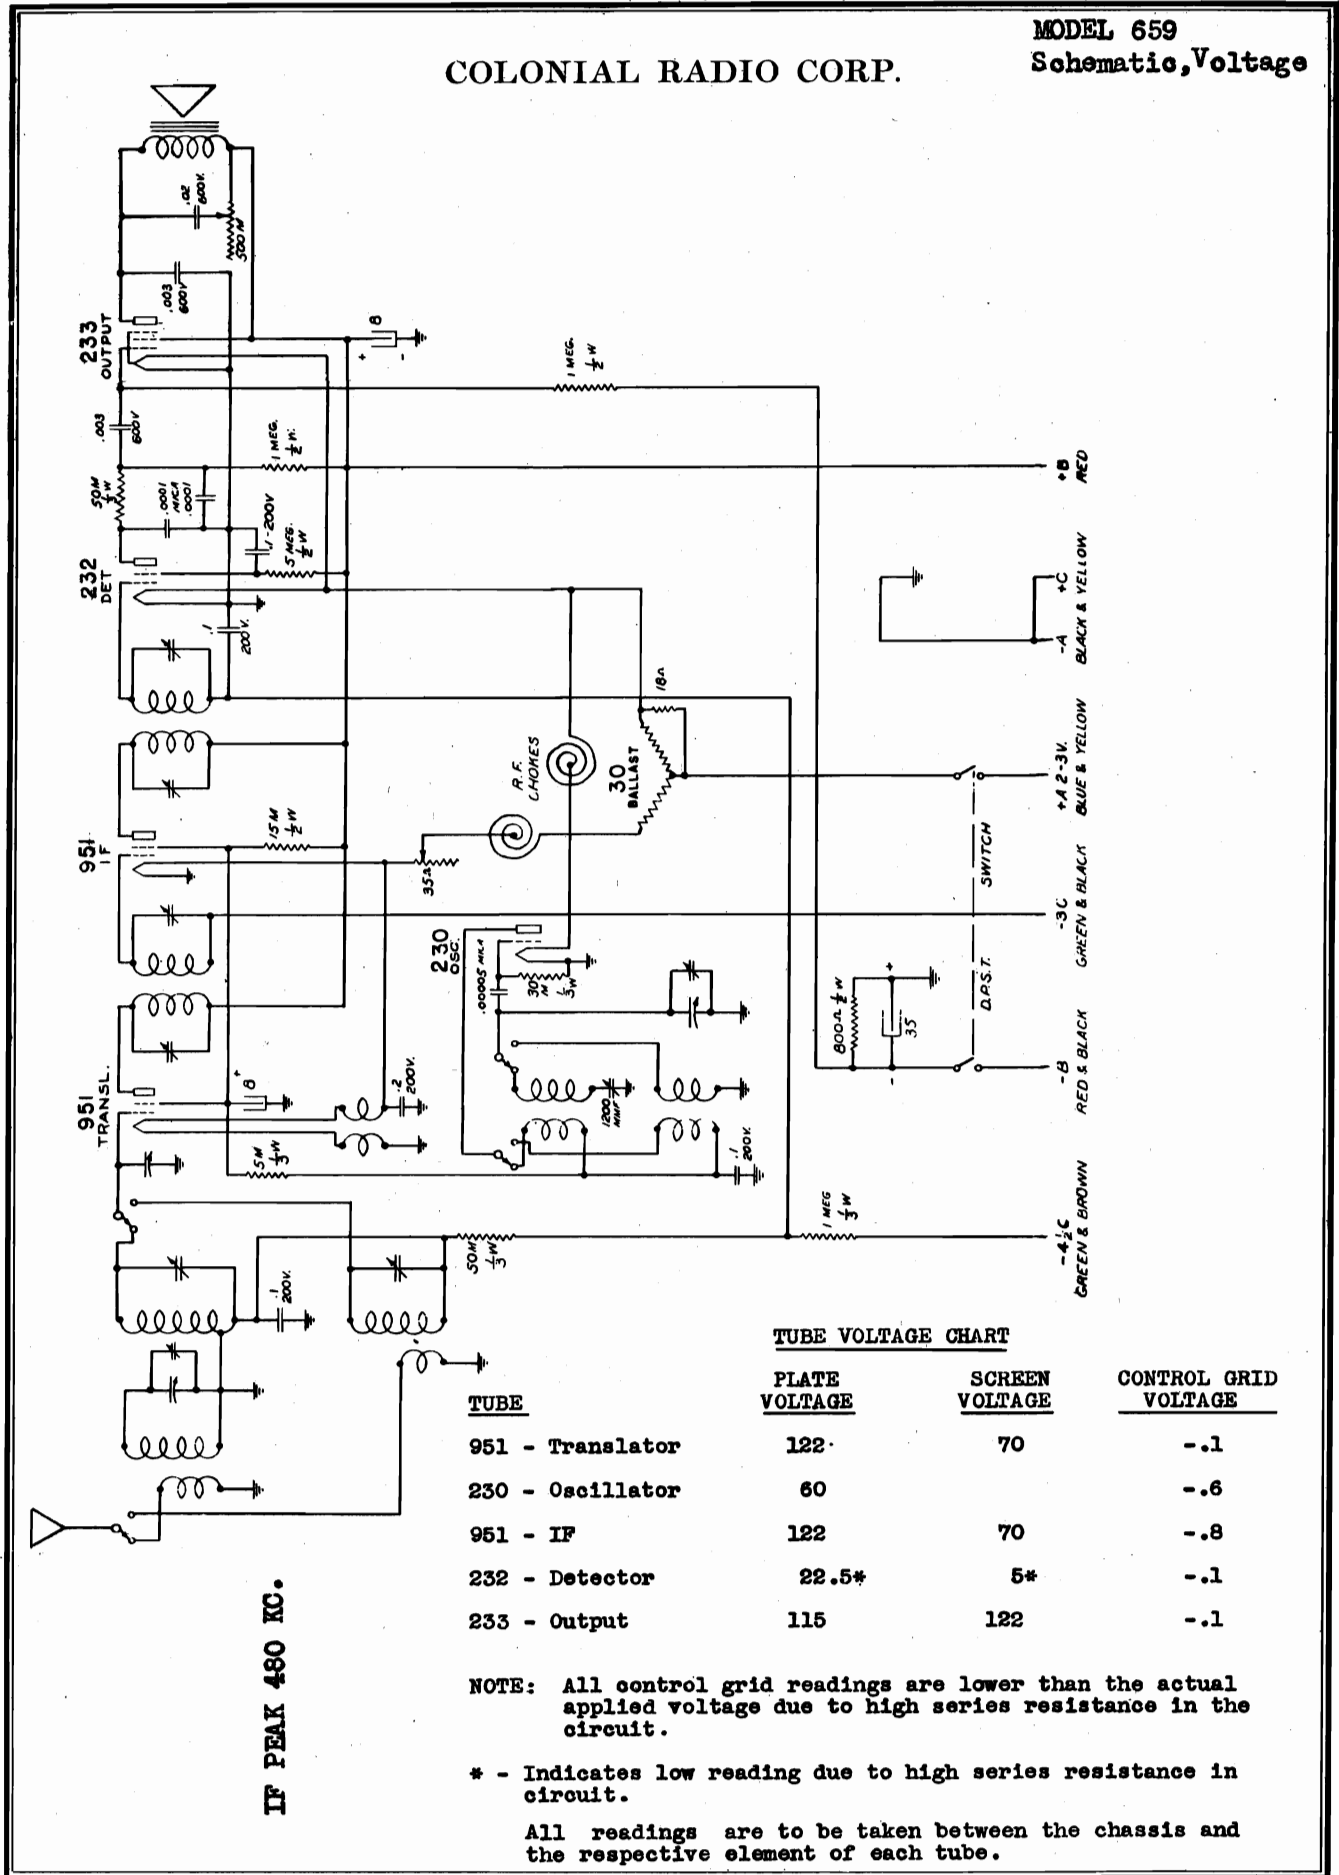

TUBE REPLACEMENT

There are two wood screws inside the cabinet, at the upper rear corners. These are used to secure the cabinet top, for shipping purposes only. They can be easily removed if the rear panel of the cabinet is taken off. Once removed, they need not be replaced. To remove the cabinet top then, for tube replacement, take out the single screw at the top center of the rear panel and push the top up and off.

Socket, Trimmers

COLONIAL RADIO CORP.

ALIGNMENT PROCEDURE

- The IF Stages:**
1. Connect the output meter, across the grid circuit of the test oscillator, to the scale (about 100 volts) of the meter should be used.
 2. Connect the ground lead of the test oscillator to the chassis.
 3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid of the IF tube, leaving the grid clip attached to the cap.
 4. Set the test oscillator to 480 kc. and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
 5. Change the test oscillator connection to the grid of the transformer tube and tune the IF input transformer.
 6. Repeat the adjustments to secure greater accuracy.
- Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.
- RF Alignment: (Broadcast)**
1. Set the test oscillator to exactly 1600 kc.
 2. Couple the output of the oscillator to the antenna lead of the set, with the antenna connected.
- Short Wave Alignment:**
1. Set the test oscillator to 15 megacycles and tune in its signal.
 2. Adjust the short wave translator trimmer for maximum output.
 3. If necessary, shift the end turns (enamel wire) of the short wave translator coil to secure the maximum and minimum output. Do this at 600 kc.
 4. Re-adjust the translator trimmer at 15 megacycles.

CROSLLEY RADIO CORP.

MODEL 103
Voltage, Parts List

Model 103

Specifications

Model 103 is a five tube superheterodyne designed for operation from a six volt automobile storage battery. The "B" voltage is furnished by a Crosley Synchronode. The intermediate frequency used is 181.5 kc.

Tubes and Voltage Limits

The following are the tubes and voltages measured with the receiver in operating condition but with no signal to the antenna, and with a battery voltage of 6.3 volts. All voltages are measured from tube contact to chassis with a 300 volt D. C. voltmeter (1000 ohms per volt).

Tube	Position	Plate	Screen Grid	Cathode	Supp. Grid	Filament
78	R. F. Amplifier	210	100	2	2	6.3
78	Oscillator Modulator	210	100	28	0	6.3
6B7	I. F. Amplifier and Diode Detector	210	100	2.5		6.3
78	Audio Amplifier	50	20	2.0	2	6.3
41	Output	195	210	16.0		6.3

Voltage limits are plus or minus 15% of values given.

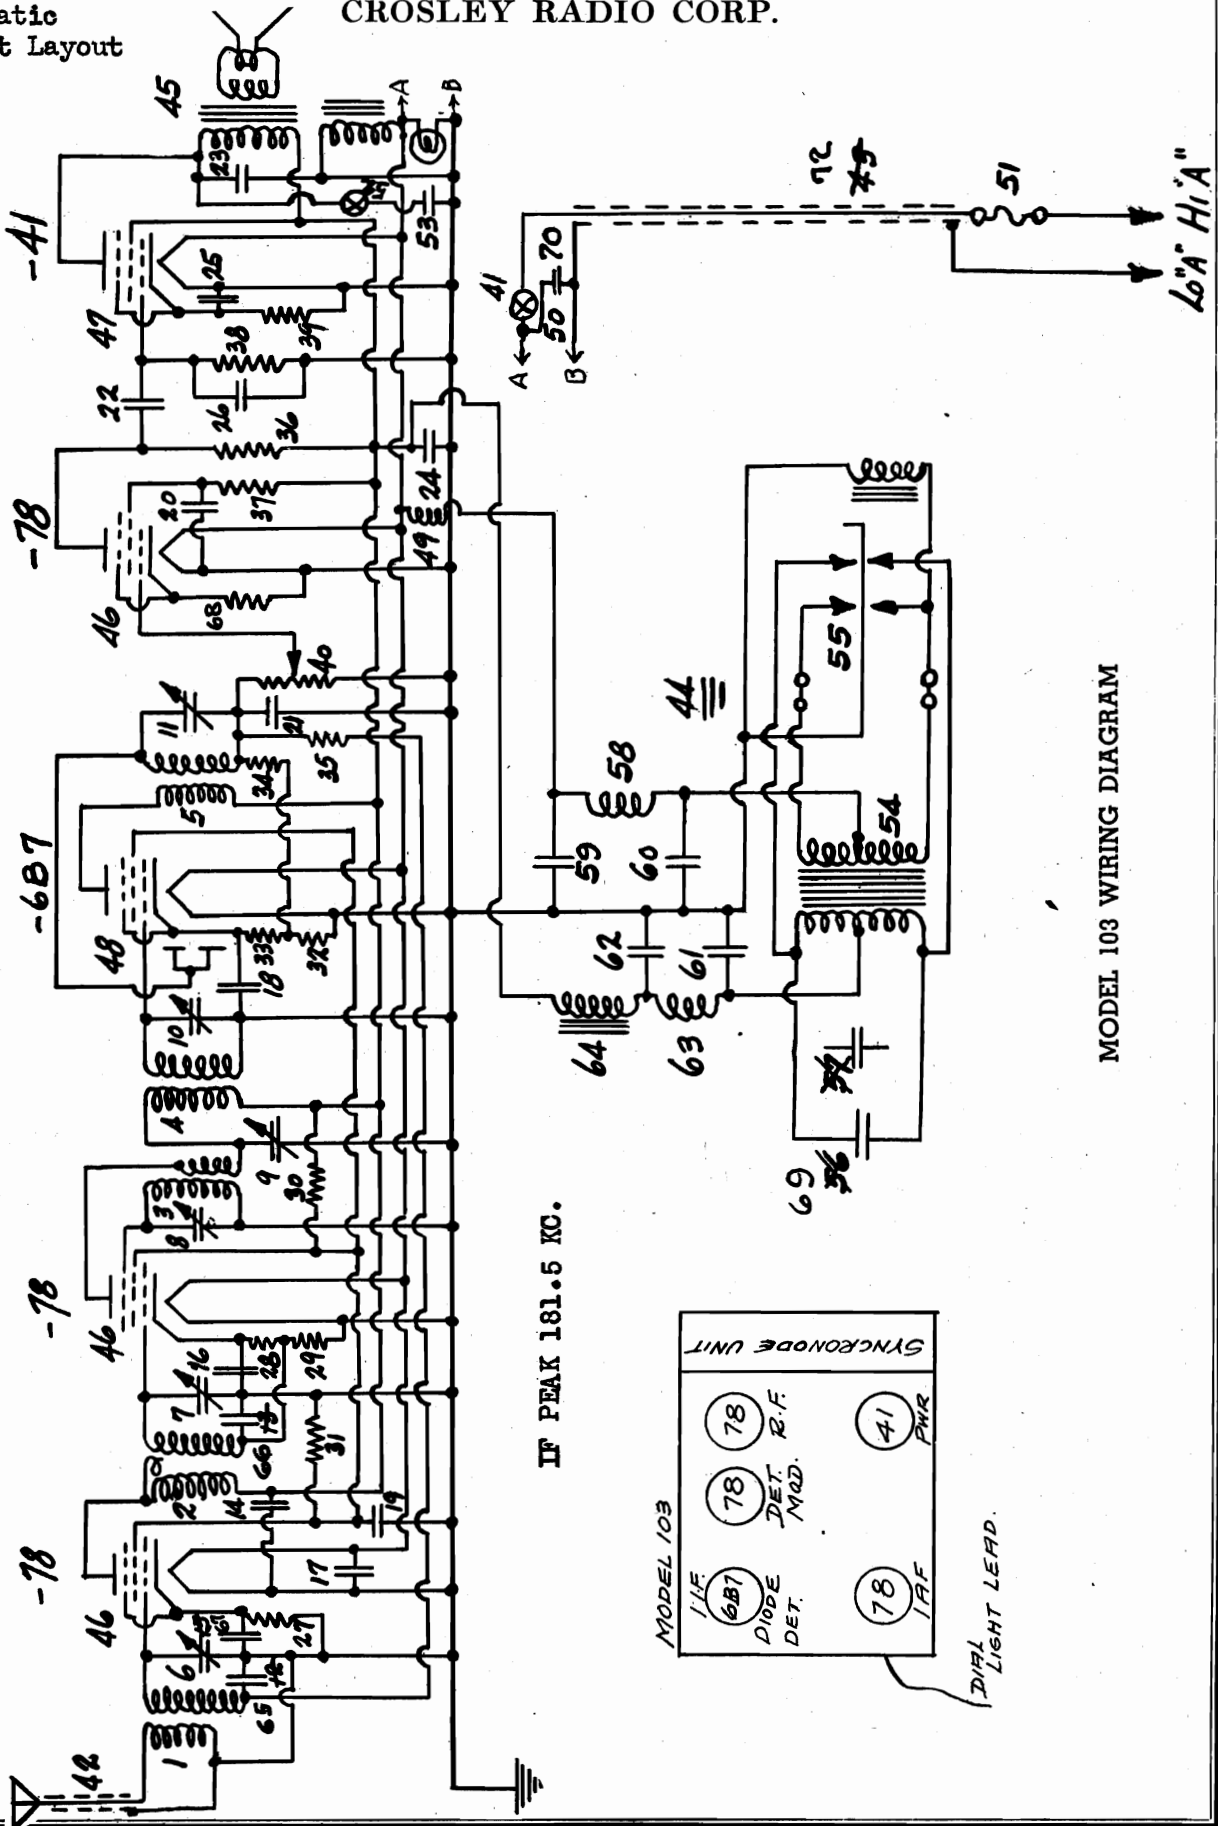

PARTS LIST—MODEL 103

INSTRUCTIONS FOR ORDERING—Give part number, description of part, and serial number of receiver on which part is to be used. If article wanted is not listed separately, then that part of complete assembly containing this article should be ordered. Goods shipped on open account to Crosley Wholesale Distributors only. Cash must accompany Dealer and Consumer orders. Prices are subject to the usual trade discounts, and are subject to change without notice.

MODEL 169
Voltage, Parts List

Model 169

Specifications

Model 169 is a four-tube superheterodyne designed for operation from AC electric circuits. It uses an intermediate frequency of 456 kc.

Tubes And Voltage Limits

The following are the tubes and voltages measured

with the receiver in operating condition but with no signal to the antenna circuit, and with a line voltage of 117.5 volts (235 for a 220 volt receiver). All voltages, except filament, are measured from tube contact to chassis with a 500 volt (1000 ohms per volt) DC voltmeter. Filament voltages are measured with a low range AC voltmeter.

Tube	Position	Plate	Screen Grid	Cathode	Supp. Grid	Filament
58	Oscillator-modulator	165	82	22	0	2.5
6F7	I. F. Detector	165	82	2	0	2.5
2A5	Output	158	165	10		2.5
80	Rectifier	295				4.9

Voltage limits are plus or minus 10% of values given.

PARTS LIST—MODEL 169

INSTRUCTIONS FOR ORDERING—Give part number, description of part, and serial number of receiver on which part is to be used. If article wanted is not listed separately, then that part of complete assembly containing this article should be ordered. Goods shipped on open account to Crosley Wholesale Distributors only. Cash must accompany Dealer and Consumer orders. Prices are subject to the usual trade discounts, and are subject to change without notice.

* Figures in 2nd last column refer to parts shown in diagram.

MODEL 178 WIRING DIAGRAM

To Be Used Only
With Air Cell Battery

Specifications

Model 178 is a five tube superheterodyne designed for battery operation. Batteries required are: 2 volt "A" battery, 135 volt "B" battery with 67 1/2 volt tap, and 22 1/2 volt "C" battery. Intermediate frequency used is 456 kc.

Model 179

Specifications

Model 179 is a seven tube superheterodyne designed for operation from AC electric circuits. The intermediate frequency used is 181.5 kc.

Tubes and Voltage Limits

The following are the tubes and voltages measured from tube contact to chassis with the receiver in operating condition but with no signal to the antenna circuit, and with a line voltage of 117.5 volts (235 volts for 220 volt receivers). All voltages, except filament, are measured with a 500 volt (1000 ohms per volt) DC voltmeter. Filament voltages are measured with a low range AC voltmeter.

ured from tube contact to chassis with the receiver in operating condition but with no signal to the antenna circuit, and with a line voltage of 117.5 volts (235 volts for 220 volt receivers). All voltages, except filament, are measured with a 500 volt (1000 ohms per volt) DC voltmeter. Filament voltages are measured with a low range AC voltmeter.

MODEL 181
Voltage, Parts List

Model 181

Specifications

Model 181 is a six tube superheterodyne designed for operation from AC electric circuits. The intermediate frequency used is 456 kc.

Tubes and Voltage Limits

The following are the tubes and voltages measured from tube contact to chassis with the receiver in operating condition but with no signal to the antenna circuit, and with a line voltage of 117.5 volts (235 volts for 220 volt receivers). All voltages, except filament, are measured with a 500 volt (1000 ohms per volt) DC voltmeter. Filament voltages are measured with a low range AC voltmeter.

Tube	Position and Use	Plate	Screen Grid	Voltages		
				Cathode	Supp. Grid	Filament
2A7	Oscillator	165		-9.5		
	Modulator	240	110	2.5		2.45
58	IF Amplifier	236	110	0		2.45
56	Diode Detector and AVC					2.45
58	AF Amplifier	52	27	0		2.45
2A5	Output	222	240	0		2.45
80	Rectifier	330				4.8

Chassis to B- 93 volts.
Bias voltages are obtained by a resistor divider shunting the speaker field which is in B- circuit, from rectifier to chassis.
IF Amplifier bias (Grid to B-) 28 volts.
AF Amplifier bias (Grid to B-) 12 volts.
Output bias (Grid to B-) 18 volts.

PARTS LIST—MODEL 181

INSTRUCTIONS FOR ORDERING—Give part number, description of part, and serial number of receiver on which part is to be used. If article wanted is not listed separately, then that part of complete assembly containing this article should be ordered. Goods shipped on open account to Crosley Wholesale Distributors only. Cash must accompany Dealer and Consumer orders. Prices are subject to the usual trade discounts, and are subject to change without notice.

* Figures in 2nd last column refer to parts shown in diagram on page 18.

MODEL 182
Parts List

Specifications

Model 182 is a five tube superheterodyne designed for operation from AC or DC electric circuits. The intermediate frequency used is 456 kc.

Tubes and Voltage Limits

The following are the tubes and voltages measured

from tube contact to negative line (B -) with the receiver in operating condition but with no signal to the antenna circuit (antenna coiled up), and with a line voltage of 117.5 volts, 60 cycle a. c. All voltages except filament, are measured with a 500 volt (1000 ohms per volt) d. c. voltmeter. Filament voltages are measured with a low range AC voltmeter.

BY-PASS & FILTER CONDENSERS

MODEL 4A1

Alignment, Voltage

CROSLLEY RADIO CORP.

Alignment Procedure . . .

To align the receiver at intermediate frequency it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator should have an attenuator so that the strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator, which has been adjusted to 456 Kc. to the control grid connection on the top of the 6F7 tube through an .02 mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I. F. transformer condensers for maximum signal output. To make this adjustment it is necessary that a standard 5/16" (across flat) hexagon socket wrench

be used for the upper condenser, and a small screw driver fitting inside of the nut hole for adjustment of the lower condenser. Always make this I. F. adjustment very carefully and go over the adjustment several times to be sure that the peak has been reached. To align a receiver at broadcast radio frequency, it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc. together with a suitable attenuator and dummy antenna be available. Set the oscillator at 1400 Kc. and connect the high side of the oscillator to the receiver antenna terminal through a .0002 mfd. (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator shunt trimmer which is located on the front section of the gang condenser until

the signal is heard best. Without changing the gang condenser setting, adjust the antenna trimmer located on the rear section of the gang condenser. It is necessary that these adjustments be gone over several times until no further improvements can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the dial until it reads 60 and set the modulated oscillator at approximately 600 Kc. The approximate sensitivity of the receiver may be checked here and it is possible that by slight bending of the gang condenser plates some improvement may be made. It is very essential, however, that this bending of plates be done with extreme care and by someone who is experienced in this operation.

Automatic Volume Control Circuit . . .

Diode voltage is developed across resistor 34 which is the level control. This voltage is fed back through isolating resistor, part No. 26, to the grid return of the antenna coil, part No. 1, thereby exerting automatic volume control voltage on the pentode section of the 6F7 oscillator modulator. No AVC voltage is impressed on the 6B7 I. F. amplifier because in so doing serious distortion might result. AVC voltage is also impressed on the 6D6 A. F. amplifier by means of coupling resistor 57.

Method of Biasing . . .

Both the pentode and triode section of the 6F7 oscillator modulator obtain their bias from the cathode resistor, part No. 22. The 6B7 I. F. amplifier section obtains its bias from the cathode resistor, part No. 25. Bias for the 6D6 A. F. amplifier is also obtained from resistor No. 25, while the bias for the output type 42 is obtained from resistor part No. 30.

Analysis of Signal Channel . . .

The signal enters at the antenna lead-in terminal through the bayonet socket and then goes to the antenna coil, part No. 1. There is optionally offered a wave trap to be used with this receiver when it is operated in the neighborhood of commercial code stations using frequencies in the region of 456. This wave trap prevents these code stations from riding on through and being amplified by the intermediate frequency amplifier. The signal is tuned by the rear section of the gang condenser, part No. 3, and then impressed on the pentode grid of the 6F7. The 6F7 triode section is equipped with a conventional oscillator circuit tuned by the front section of the gang condenser, part No. 4. The oscillator output is impressed on the cathode of the 6F7 through a pickup coil. The output therefore of the 6F7 pentode section is intermediate frequency which is impressed on the first I. F. transformer, part No. 5. This I. F.

transformer is double tuned. The signal is then fed to the grid of the pentode section of the 6B7 I. F. amplifier which tube has a double tuned output I. F. transformer, part No. 8, in its plate circuit. This amplified output is impressed on the two diodes of the 6B7 in parallel and diode voltage is developed across level control, part No. 34. The DC component of this voltage is fed forward through resistor 57 to the grid of the 6D6 A. F. amplifier, but the audio frequency component is fed from the level control contact arm through coupling condenser 56 to the grid of the 6D6 A. F. amplifier. In this way a bias depending on the strength of the signal is impressed on the grid of the 6D6 A. F. amplifier while the actual audio frequency voltage is determined by the setting of the level control. The amplified audio frequency output of the 6D6 is fed through coupling condenser No. 18 to the grid of the 42 output tube and is then amplified and fed to the speaker part No. 43. Condenser No. 19 serves to keep the impedance of the output system more nearly constant.

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Epośc	Esup
6F7	Osc. Mod.	6.0	230	0	8	100	60	—
6B7	I.F. and Diode	6.0	230	0	3	100	—	—
6D6	A.F.	6.0	60	0	3	25	—	3
42	Output	6.0	220	0	16	230	—	—

All voltages are plus or minus 10% and measured to chassis with 500 volt 1000 ohm per volt voltmeter. Battery voltage 6 volts.

CROSLEY RADIO CORP.

MODEL Fiver Jr.(5M3)
Voltage, Notes
Alignment**General Description . . .**

Chassis 5M3 is used in the Fiver Jr. It is a low-priced but highly efficient 5-tube superheterodyne receiver covering the frequency range

of 535-1750 Kc. The intermediate frequency is 456 Kc.

Tubes Used and Their Function . . .

The tubes used are 6D6 oscillator

modulator, 6D6 I. F. amplifier, 76 detector, 42 output, and 80 rectifier.

The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Esup
6D6	Osc.Mod.	6.3	235	29	32	120	0
6D6	I. F.	6.3	235	0	3	120	3
76	Detector	6.3	80	0	10	—	—
42	Output	6.3	225	0	18	235	—
80	Rectifier	4.9	—	—	310	—	—

All voltages are measured to chassis voltages and are plus or minus 10%. All DC are voltages measured to chassis at 117.5 volt line with 1000 ohms per volt, 250-volt voltmeter. Power demand 50 watts, 110 volts, 60 cycles.

Method of Biasing . . .

Referring to the circuit diagram, it will be seen that the 6D6 oscillator modulator tube has a more or less complex biasing system. This is because resistor No. 22 in the cathode circuit creates a bias for the input section of the tube, while resistors 22 and 23 in series create the bias for the suppressor grid oscillator section. The 6D6 I. F. amplifier obtains its bias from the volume control, part No. 40. There is a fixed limiting resistance in this volume control so that at the full volume position there is still the bias indicated in the voltage chart, and as the volume is reduced, the bias on the 6D6 I. F. amplifier increases. The 76 detector obtains its bias from the cathode resistor, part No. 24, while the 42 output tube obtains its bias from its cathode resistor, part No. 29.

Volume Control Circuit . . .

As explained above, as the volume control is backed off of the maximum sensitivity position, cathode bias is inserted in the 6D6 I. F. amplifier circuit. At the same time, resistor 40, being connected across the antenna and ground, tends to short circuit the antenna circuit. Thus, reduction in sensitivity is obtained simultaneously by reducing

the gain in the I. F. amplifier and reducing the effectiveness of the antenna.

Analysis of Signal Channel . . .

Starting with the antenna, the signal is fed through the antenna coil, part No. 2, and tuned by the radio frequency section of the gang condenser, part No. 6. The signal is then impressed on the control grid of the 6D6 oscillator modulator. This tube is so connected that the combination cathode, suppressor grid, and plate of the 6D6 tube form a conventional triode oscillator. The oscillator frequency is determined by the setting of the gang condenser oscillator section, part No. 6, in conjunction with oscillator coil, part No. 3. The plate shape of the oscillator section of the gang condenser is such that a constant I. F. frequency of 456 Kc. is present at the primary terminals of the first I. F. transformer, part No. 4. This I. F. transformer is double tuned and the I. F. signal is then impressed on the grid of the 6D6 I. F. amplifier. The amplified output of this tube is impressed on the second I. F. transformer, part No. 5, which is single tuned, with condenser part No. 9. To prevent overload being serious in the 76 detector circuit, resistor No. 25 is used so that when grid current is drawn the bias on the tube increases very rapidly. In the plate circuit of the 76 detector there is present in addition to the normal DC plate current, both intermediate frequency and audio frequency. The intermediate frequency is bypassed by condenser No. 16, while the audio

frequency is passed on to the output tube grid through condenser No. 17. The grid circuit of the output tube is completed through resistor No. 28. The amplified audio output of the type 40 tube is, of course, fed to the speaker in the usual manner.

Power Supply System . . .

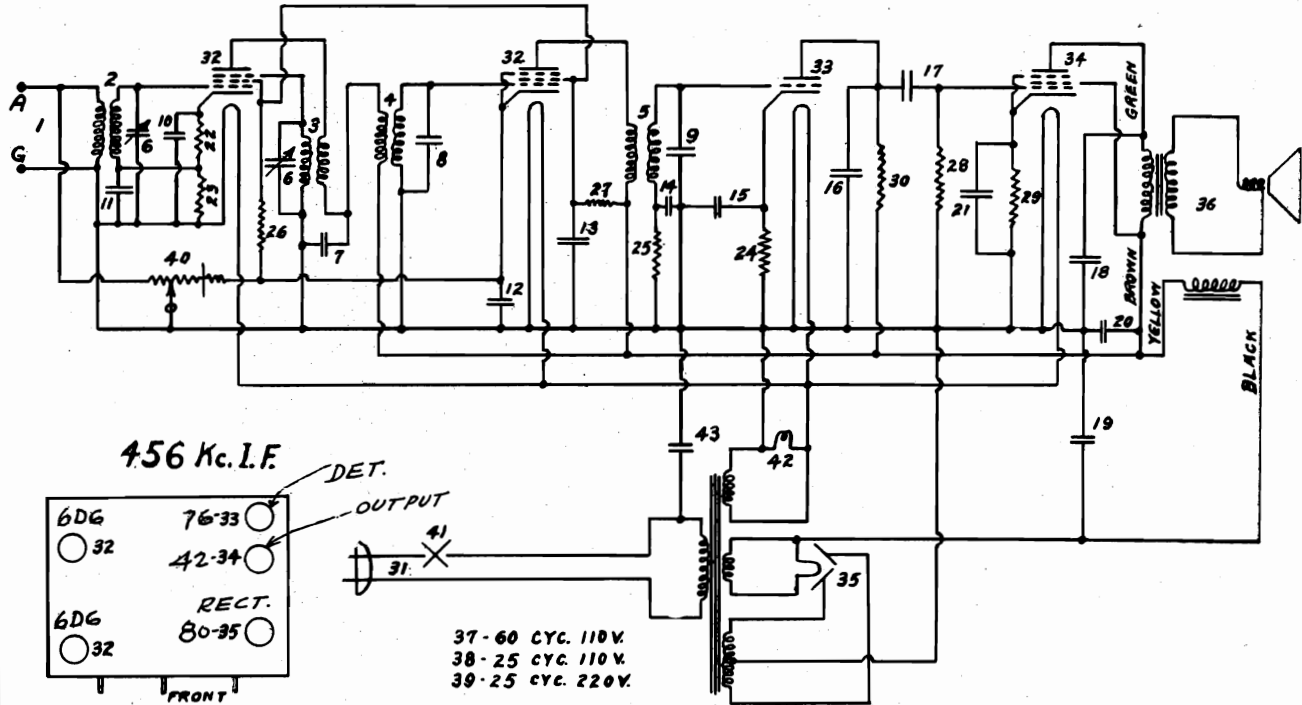

The power supply system consists of a transformer, part No. 37, for 110-volts, 60 cycles, part No. 38 for 110-volt 25 cycles, and part No. 39 for 220 volts, a type 80 rectifier tube, electrolytic condenser part No. 19, the speaker field as a filter choke, and electrolytic condenser part No. 20.

Alignment Procedure . . .

To align the I. F. amplifier, it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator should have an attenuator, so that the strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator, which has been adjusted to 456 Kc. to the control grid connection on the top of the 6D6 oscillator modulator tube through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the three I. F. tuning condensers located on the top of the chassis for maximum signal output. To make this adjustment, it is necessary that a standard $\frac{1}{4}$ " (across flats) hexagon socket wrench be used. The wrench is preferably insulated. Always make these adjustments very carefully and go over

MODEL Fiver Jr.(5M3)
Schematic,Socket
Parts List

CROSLEY RADIO CORP.

them several times to be sure that the peak has been reached.

To align the receiver at radio frequency it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc. together with a suitable attenuator and dummy antenna be available. Set the modulated oscillator to 1400 Kc. and connect the high side of the oscillator to the receiver antenna terminal

through a .0001 (dummy antenna) condenser and the low side to receiver chassis. Now, with dial set at 140, adjust the gang condenser oscillator trimmer, which is in the rear section of the gang until the signal is heard best. Then adjust the R. F. trimmer, which is in the front section of the gang condenser, for maximum signal. The set is now

aligned at 1400 Kc. and by setting the modulated oscillator to 600 Kc., the set may be rechecked at this point. It will be sometimes found that a slight bending of the gang condenser plate will help the sensitivity at 600 Kc. This operation should be done very carefully so that no short circuiting of the condenser plates result.

CROSLEY RADIO CORP.

MODEL Deluxe Fiver-L-B
(Chassis 5V1)
Voltage, Data, Parts List

General Description . . .

Chassis 5V1 is used in the DeLuxe Fiver and DeLuxe Fiver Low-boy. It is a 5-tube 3-gang automatic volume control dual band receiver. The frequency bands are 535 to 1720 Kc. and 1650 to 4500 Kc. The intermediate frequency is 181.5 Kc.,

the use of which insures adequate selectivity.

Tubes Used and Their Function . . .

The tubes used are 6A7 oscillator-modulator, 6D6 I. F. amplifier, 6B7 diode and audio frequency amplifier, 42 output, and 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esup	Eg-osc	Ep-osc
6A7	Osc-Mod.	6.5	240	0	3	0	-15	125
6D6	I. F.	6.5	240	-3.5	0	0	—	—
6B7	Diode-AF	6.5	30	-3.5	0	—	—	—
42	Output	6.5	230	-18	0	—	—	—
80	Rectifier	5.1	—	—	240	—	—	—

All voltages are plus or minus 10%. All DC voltages are measured to chassis at 117.5 line with 1000 ohms per volt 250-volt voltmeter. Power demand is 30 watts at 110 volts 60 cycles.

and second secondary in the preselector system. No automatic volume control is exerted on the I. F. amplifier stage, which is the 6D6, because in so doing there is a serious danger of introducing distortion.

F. signal is then impressed on the diode plates in parallel. In this stage there is developed across resistor 34 a DC diode voltage, an audio frequency voltage, and some intermediate frequency. The audio frequency and intermediate frequency signals pass through coupling condenser, part No. 20, but the filter resistor, part No. 35, excludes most of the intermediate frequency so that mostly audio frequency is present across resistor 29, the volume control. This audio frequency is then amplified through the pentode section of the 6B7 tube and the amplified audio output is fed through coupling condenser 18 to the grid of the output tube type 42. The output of the type 42 tube is fed to the speaker in the conventional manner. Resistor 56 in the grid circuit of the output tube acts as a further filter for whatever intermediate frequency might still be present and also tends to suppress distortion at extremely loud volume. Condenser part No. 16 is connected across the speaker transformer and tends to hold the impedance of the speaker load more constant at the higher audio frequencies.

Method of Biasing . . .

Referring to the circuit diagram, it will be seen that the input section of the 6A7 oscillator modulator obtains its bias from the cathode resistor, part No. 30, while the oscillator section of the same tube gets its bias from the grid leak and condenser combination, in which part No. 31 is the grid leak and part No. 12 is the grid condenser. Bias for the remainder of the tubes is obtained from the voltage divider network connected across the speaker field, which also is the filter choke. Resistors 41, 42 and 43 form its voltage divider network, and the bias voltage applied to the 6D6 I. F. amplifier is that voltage drop across resistor 41. The audio frequency amplifier section of the 6B7 tube obtains its bias from the drop across resistor 41. The grid circuit is completed through volume control part No. 29. The output tube bias is the drop across the combined resistors 41 and 42, completed, of course, through resistors 39 and 56.

Analysis of Signal Channel . . .

The signal enters at the antenna terminal and when the switch is thrown to the broadcast position flows through the antenna coil primary. In the first secondary circuit it is tuned by means of one section of the gang condenser, part No. 5, and then due to the inductive coupling between the first secondary and the second secondary, signal is fed over to this latter coil where it is tuned by another section of the gang condenser, part No. 5. This signal is impressed on the grid of the oscillator modulator tube. The oscillator section of this tube is tuned by the specially-shaped third section of the gang condenser, part No. 5, in conjunction with oscillator coil, part No. 2. The frequency of the oscillator is such that a constant intermediate frequency of 181.5 kilocycles is present in the plate circuit of the first detector or oscillator-modulator tube. This intermediate frequency signal is fed to the first I. F. transformer, part No. 3; which transformer is double tuned. The signal is then fed to the grid of the 6D6 I. F. amplifier and then the amplified output is fed to the second I. F. transformer, part No. 4, which transformer is also double tuned. The I.

For the high frequency band the signal channel is slightly different in that the first section of the preselector is not used. Instead the signal is fed directly over to the second secondary through coupling condenser part No. 10. The switch is now connected into the tap on the second secondary so that part of this secondary acts as an antenna primary and the balance as the high fre-

Automatic Volume Control Circuit . . .

Automatic volume control voltage is generated across resistor 34 and is fed back through filter resistor 33 to the 6A7 control grid via the switch

MODEL Deluxe Fiver, L-B
(Chassis 5V1)
Schematic, Alignment
Socket Layout

CROSLLEY RADIO CORP.

quency secondary. The oscillator coil is tapped in the usual manner simply to reduce inductance.

Power Supply System . . .

The power supply system consists of a transformer part No. 45 for 110 volts 60-cycle, part No. 46 for 110 volts 25-cycle, part No. 47 for 220 volts, a rectifier tube type 80, the speaker field as the filter choke, and filter condensers parts 24 and 25. In this circuit the filter choke is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminates the use of a large bypass condenser on the cathode of the output tube, type 42. At the same time, better audio quality for the lower notes is obtained than with the ordinary bypass condenser circuit.

Alignment Procedure . . .

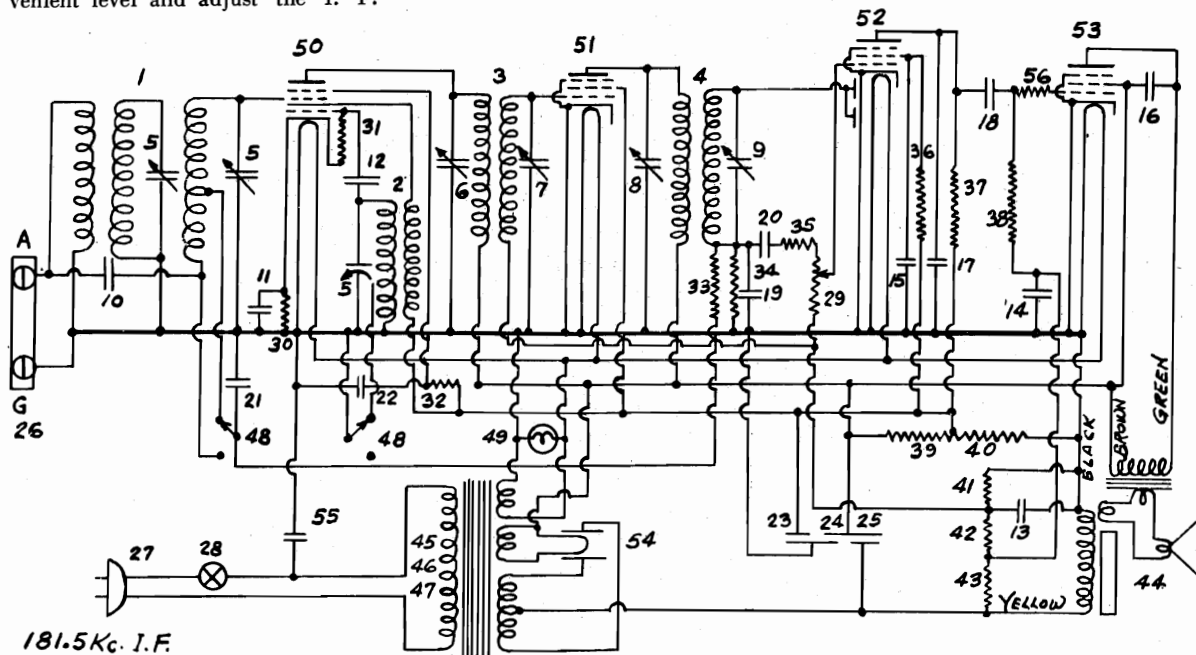

To align the I. F. amplifier, it is necessary that there be available a suitable modulated oscillator capable of adjustment to 181.5 Kc. with good accuracy. This oscillator should have an attenuator so that strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator, which has been adjusted to 181.5 Kc. to the control grid connection on the top of the 6A7 tube, through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I. F.

transformer condensers, three of which are located on top of the chassis and one in the rear of the chassis, for maximum signal output. To make this adjustment, it is necessary that a standard 1/4" (across flats) hexagon socket wrench be used. This wrench should be insulated. Always make these I. F. adjustments very carefully and go over the adjustments several times to be sure that the peak has been reached.

To align the receiver at broadcast frequencies it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc. together with a suitable attenuator and dummy antenna be available. Set the oscillator to 1400 Kc. and connect the high side of the oscillator to the receiver antenna terminal through a .0001 (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator trimmer on the gang condenser (the oscillator section is in the rear of the gang) until the signal is heard best. Without changing the gang condenser setting, adjust the remaining two sections of the gang condenser. The gang con-

denser adjustment may be accomplished with an ordinary screwdriver. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. The performance of the receiver may now be checked at 600 Kc. by setting the modulated oscillator to 600 Kc. and the receiver dial to that point around 60, which gives best reception. Sometimes it is possible to make a slight improvement in the performance at this point by bending some of the gang condenser plates slightly. This operation should be done very carefully so that no short circuiting of the condenser plates results.

The receiver may be checked in the higher frequency band if a modulated oscillator, capable of covering frequencies of 1700 to 4000 is available. It is not necessary, however, to align the receiver at these frequencies because if the receiver is properly aligned at broadcast frequencies it will be in alignment at the higher frequencies.

CROSLLEY RADIO CORP.

MODEL 50,50 LB (5H1)
Voltage, Data**General Description . . .**

Chassis 5H1 is used in the Model Fifty and Model Fifty Lowboy. It is a 5-tube short wave and broadcast chassis employing the latest superheterodyne circuit, in which has been incorporated a high efficiency tuned radio frequency stage for both short wave and broadcast. The frequency ranges covered are 535 to

1750 Kc., which is the normal broadcast band and the lower frequency police band, and 5700 to 15500 Kc., which is the short wave or high frequency band. The intermediate frequency is 456 Kc. and while there is only one intermediate frequency stage, adequate selectivity is obtained through the use of very high efficiency I.F. transformers, in addition to the three-gang condenser.

Tubes Used and Their Function . . .

The tubes used are 6F7 radio frequency amplifier and audio frequency amplifier, 6A7 oscillator, modulator, 6B7 intermediate frequency amplifier and diode detector, 42 output tube and type 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Esup	Epl	Egl
6F7	R.F.-A.F.	6.5	250	-3.5	0	125	—	35	-3.5
6A7	Osc.-Mod.	6.5	250	-3.5	0	125	—	190	-15.0
6B7	I.F.-Diode	6.5	250	-3.5	0	125	—		
42	Output	6.5	230	-18	0	250			
80	Rectifier	5.1							

All voltages are plus or minus 10%. All D.C. voltages measured to chassis at 117.5 volt line with 1000 ohms per volt, 250-volt voltmeter. Power demand 50 watts, 110 volts, 60 cycles.

Method of Biasing . . .

Referring to the circuit diagram attached, it will be seen that the bias for the pentode section of the 6F7 tube is obtained from the drop across resistor No. 52. Resistors Nos. 52, 53 and 54 form a voltage divider network across the speaker field, which field also acts as a filter choke. The tap between resistors Nos. 52 and 53 may be followed through resistors Nos. 48 and 47 and thence to the grid return of the 6F7 pentode section. The cathode of the 6F7 returns to the ground, as does also the lower end of resistor No. 52, therefore the drop across resistor No. 52 is impressed on the grid of the pentode section of the 6F7 tube. The grid of the pentode section of the 6F7 returns, of course, through the band change switch. The same condition exists for the grid section of the 6A7 tube. The 6A7 also obtains its bias from the drop across resistor No. 52 but in this case this voltage is fed through resistor No. 48 only and then to the grid return of the 6A7 tube. The oscillator section of the 6A7 obtains its bias, of course, from the grid leak and condenser combination, resistor No. 56 being the low frequency grid leak and resistor No. 57 being the high

frequency grid leak. The bias for the pentode section of the 6B7 tube is also obtained from the voltage drop across resistor No. 52 but in this case this voltage is not fed through any filter resistor. Now returning to the triode section of the 6F7, which section is an audio amplifier, it will be found that the bias for this section is also obtained from the drop across resistor No. 52 and through volume control part No. 70. The bias for the output tube type 42, must be greater than that for the other tubes and it is generated due to the drop across resistors 52 and 53 in series and is fed through the grid leak, part No. 51.

Automatic Volume Control Circuit . . .

Automatic volume control voltage is developed in the diode circuit across resistors 35, 47 and 48. Since resistor 48 returns to the junction between resistors 52 and 53, a delay voltage is supplied and this voltage is equal to the drop across resistor 52. The audio frequency diode resistor is part No. 49 and it will be noted that it returns directly to ground which is the same point that the low potential end of resistor 52 returns. Automatic volume control is exerted on the 6F7 pentode section which is the radio frequency stage. While the full diode voltage is that drop across resistors 35, 47 and 48 in series, only the voltage across 47 and 48 is impressed on the radio fre-

quency amplifier. In a similar manner automatic volume control is exerted on the 6A7 control grid and this voltage is obtained from the drop across resistor 48. No automatic volume control is exerted on the intermediate frequency amplifier stage, which is the 6B7, because in so doing there is serious danger of introducing distortion.

Analysis of Signal Channel . . .

Starting with the antenna, the signal enters switch contacts, part No. 21, at which point, depending upon the position of the switch, it will flow either to the broadcast or short wave antenna coil primary, parts Nos. 1 and 2 respectively. Tuning is accomplished by the first section of the gang condenser, part No. 20, connected in the secondary circuit of the antenna coil. The signal is then impressed on the radio frequency pentode grid of the 6F7 tube and is amplified by the tube. The output of the 6F7 tube goes into the primary of the inter-stage radio frequency transformer, part Number 3 or 4, depending on whether the switch is connected to the low or high frequency position. The secondaries of the interstage coils are again tuned by another section of the gang condenser, part No. 20, and the signal is then impressed on the control grid of the 6A7 oscillator modulator tube. The oscillator section of the 6A7 tube uses the oscillator coils 5 and 6 for the low

MODEL 50, 50 LB (5HL)

Alignment, Notes

and high frequency bands respectively, and the oscillator is tuned by the third section of the gang condenser, part No. 20. In this tube the frequency of the signal is changed from radio frequency to 456 Kc., the intermediate frequency. The signal passes from the plate of the 6A7 tube to the first intermediate frequency transformer, part No. 7, and the primary and secondary of this transformer are both tuned to obtain maximum selectivity. The output of the secondary of the transformer is impressed on the control grid of the 6B7 tube in which the intermediate frequency signal is amplified and fed to the second intermediate frequency transformer, part No. 10, which transformer is also tuned in both the primary and secondary circuits. The signal is now impressed directly on the audio frequency diode, in the 6B7 tube and through condenser No. 27 on the automatic control diode of the same tube. In the audio frequency diode the signal is converted from intermediate frequency to audio frequency which audio frequency is present across resistor 49 and condenser 46. There is also a direct current voltage and some intermediate frequency also present here. The audio frequency signal is separated from the direct current voltage by condenser 45 and whatever intermediate frequency there may be left in this circuit is filtered by resistor 50 and the remaining pure audio frequency voltage is impressed across volume control, part No. 70. Adjusting the position of the arm of this volume control applies greater or less audio frequency voltage on the grid of the triode section of the 6F7. This triode is used as an audio frequency amplifier. The plate of this tube is connected to the audio coupling resistor, part No. 58, and the audio frequency voltage is coupled to the grid of the output tube, type 42, through condenser 32. The grid circuit of the output tube is completed through resistor 51. The amplified audio output is impressed across the speaker transformer in the speaker assembly, part No. 59.

Power Supply System . . .

The power supply system consists of a transformer, part No. 67, for 110-volt 60-cycle, part No. 68 for 110-volt 25-cycle, and part No. 69 for 220-volt 25-60 cycle, a rectifier tube type 80, the speaker field

CROSLLEY RADIO CORP.

as a filter choke, wet electrolytic condenser part No. 39, and dry electrolytic condenser part No. 38. In this particular circuit the filter choke is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminate the use of a large bypass condenser on the cathode of the output tube, type 42. At the same time, better audio quality for the lower notes is obtained than with the ordinary bypass condenser circuit.

Alignment Procedure . . .

To align the I. F. amplifier it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator should have an attenuator so that the strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator which has been adjusted to 456 Kc. to the control grid connection on the top of the 6A7 tube through an .02 mfd. series condenser. The low side of the oscillator to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I. F. transformer condensers for maximum signal output. To make this adjustment it is necessary that a standard 5/16 inch (across flats) hexagon socket wrench be used for the upper condenser, and a small screwdriver fitting inside of the nut hole for adjustment of the lower condenser. Always make this I.F. adjustment very carefully and go over your adjustment several times to be sure that the peak has been reached.

To align the receiver at broadcast radio frequency it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc., together with a suitable attenuator and dummy antenna, be available. Set the oscillator at 1400 Kc., and connect the high side of the oscillator to the receiver antenna terminal through a .0002 (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator broadcast shunt trimmer indicated on the diagram attached and located under the chassis until the signal is heard best. Without changing the gang condenser setting, adjust the antenna and radio frequency broadcast trimmers for maximum signal. It is necessary that these adjustments be gone over

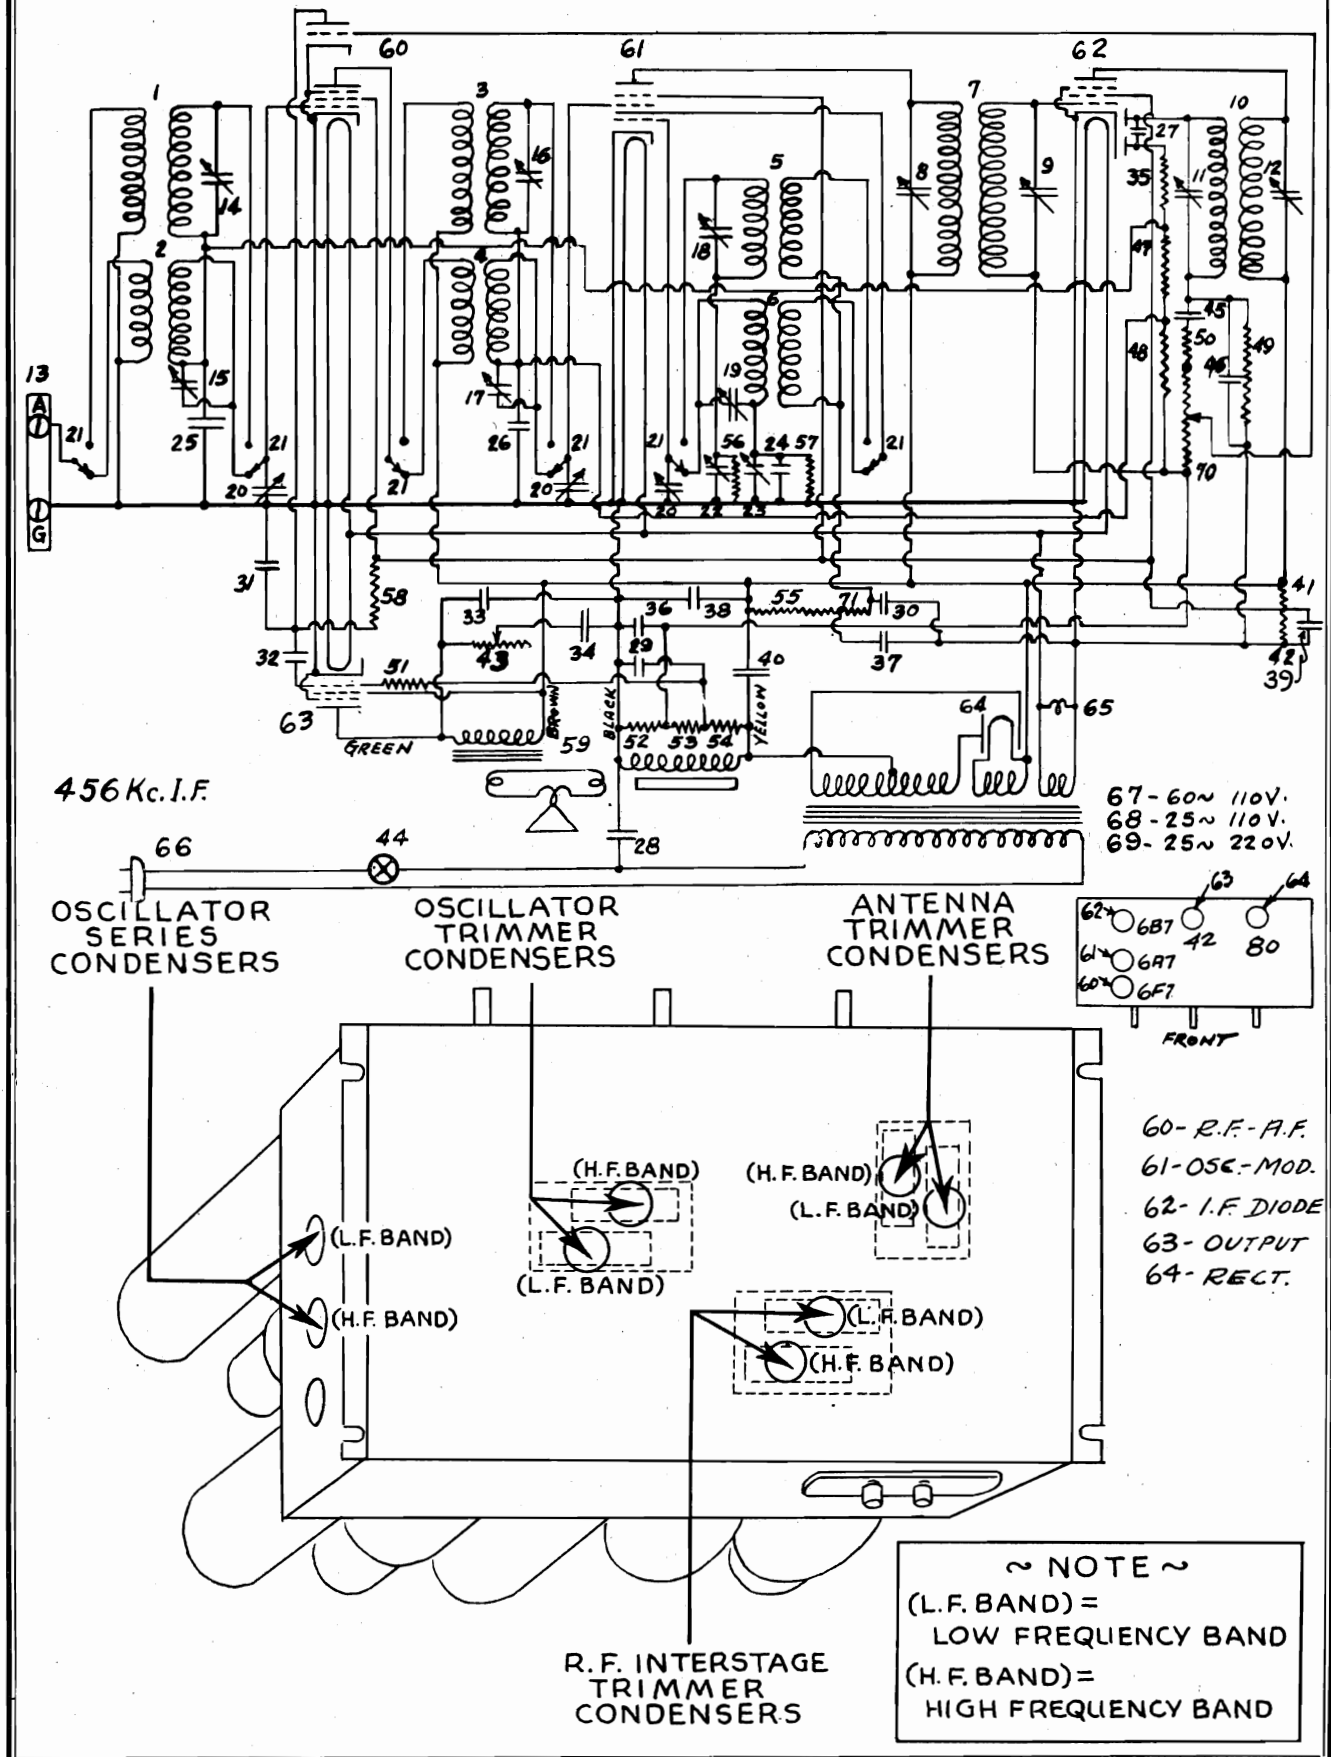

several times until no further improvements can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the dial until it reads 60 and set the modulated oscillator to approximately 600 Kc. Adjust the modulated oscillator carefully until maximum response is obtained. Now readjust the oscillator series trimmer located on the side of the chassis as shown on the diagram attached for maximum signal. It is sometimes advisable to move the main dial back and forth slightly about 60 on the dial during the course of this adjustment if a still greater signal is obtainable.

To align the set in the high frequency or short wave band, it is necessary that a modulated oscillator be available for frequencies of 6000 and 15000 Kc. The procedure for this band is similar to the broadcast band except that a 750 ohm midget carbon resistor is used for the dummy antenna instead of the .0002 condenser. Set the modulated oscillator to 15,000 Kc. and the receiver dial to 15. Adjust the oscillator shunt trimmer for the high frequency band to maximum signal. Now adjust the antenna and interstage R.F. trimmers for maximum signal, making sure to go over the adjustment several times so that no further improvement can be made. Now set the modulated oscillator to approximately 6000 Kc. and the receiver dial to 6. Readjust the modulated oscillator slightly for maximum signal and then adjust the oscillator series trimmer for the high frequency band for best signal, making whatever slight adjustments in the tuning control are necessary to bring in maximum signal.

Tuning Receiver In High Frequency Band . . .

Due to the tremendously greater number of transmitter channels covered in the high frequency band, the receiver is endowed with a much greater apparent selectivity. For this reason, if the receiver is tuned carelessly, many high frequency stations will be missed or passed over without hearing them. It is very necessary that the receiver be tuned slowly and that extreme care be exercised in final adjustment of the receiver to the center of the carrier after a high frequency station is received.

RESISTORS

MODEL 51 (5C2)
Voltage, Data

CROSLEY RADIO CORP.

General Description . . .

Chassis 5C2 is used in the Model 51. It is a 5-tube AC-DC superheterodyne receiver employing a 3-gang condenser, Automatic Volume Control and electro-dynamic speaker. The frequency range is 535-1750 Kc.

The intermediate frequency is 181.5. Use of this low intermediate frequency assures very good selectivity.

Tubes Used and Their Function . . .

The tubes used are 6F7, Oscillator-

modulator, 78 I. F. amplifier, 6B7 diode and audio frequency amplifier, 43 output, and 25Z5 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Esup	Ep-osc
6F7	Osc-Mod.	6.5	100	0	5	100	—	100
78	I. F.	6.5	100	0	3	100	3	—
6B7	Diode-AF	6.5	15	0	1	15	—	—
43	Output	27	96	-20	0	100	—	—
25Z5	Rectifier	27	—	—	100	—	—	—

All voltages are plus or minus 10%. All DC voltages are measured to -B at 117.5 volt line with 1000 ohms per volt, 250-volt voltmeter. Power demand 50 watts, 110 volts, 60 cycles. Voltages on other frequencies and DC will vary slightly from the above table.

Method of Biasing . . .

Referring to the circuit diagram it will be seen that the 6F7 Pentode section obtains its bias from the cathode resistor part No. 5. The oscillator section obtains the major portion of its bias from the grid leak and condenser combination in which part No. 55 is the grid leak and 54 the grid condenser. The 78 I. F. amplifier obtains its bias from the cathode resistor, part No. 6. Bias for the 6B7 audio amplifier is obtained from cathode resistor part No. 7. The effect of this circuit is that a slight bucking bias is applied to the diode section, but a very weak signal soon overcomes this bias and the diode then acts as though there were no bias resistor. The pentode audio amplifier section, however, makes use of this initial bias in resistor No. 7 and after signal is applied, depending on the strength of the signal, a varying amount of bias will be applied to accommodate the signal from the AVC circuit. Bias for the output tube, type 43, is obtained from the drop across the filter choke, part No. 41. and whatever hum component there is remaining is filtered through resistor 18 and bypass condenser 30.

Automatic Volume Control Circuit . . .

Automatic volume control voltage is developed in the diode circuit across resistor 10 in series with volume control, parts No. 15 or 50. This voltage is fed back through filter resistor No. 11 to the control grid return of the 6F7 modulator section. No automatic volume control is exerted on the intermediate frequency amplifier, type 78 tube, because in so doing there is a serious danger of introducing distortion.

Analysis of Signal Channel . . .

Starting with the antenna, part No. 1, which is a self-attached reel of wire in the case of this receiver, the signal flows through condenser part No. 25. The purpose of this condenser is to insulate the antenna from the balance of the set, so that if it should touch any devices having voltage on them, neither the receiver nor the device will be burned out. The signal then feeds into the primary of the first preselector coil and is transferred to the first secondary and tuned with one section of the gang condenser, part No. 20. This first secondary coil is coupled inductively to the second secondary coil, which coil is tuned by another section of the gang condenser part No. 20. The output of this double-tuned preselector circuit is fed to the grid of the 6F7 modulator section. The oscillator section of the 6F7 is tuned with the third section of the gang condenser, part No. 20, in conjunction with coil part No. 2, all of

these coils bearing the same part number, since they are mounted on one continuous core. The shape of the oscillator section of the gang condenser is such that a constant intermediate frequency of 181.5 is generated when the signal is applied and this intermediate frequency is present across the primary of the first I. F. transformer, part No. 53. This I. F. transformer is double tuned by condensers 21 and 22 respectively, and the signal is then applied to the grid of the 78 I. F. amplifier. The amplified I. F. output is then fed to the second I. F. transformer, part No. 52, which transformer is also double tuned. This then goes to the diode plates connected in parallel. As mentioned above, the diode resistor is a combination of fixed resistor part No. 10 and the volume control part No. 15 or 50. All of the diode voltage developed is used for automatic volume control, while only that portion of the combination DC diode voltage and audio frequency voltage across the volume control is fed to the grid of the 6B7 audio frequency amplifier. Due to the fact that some intermediate frequency is present in this circuit, and it is necessary to eliminate it, this is done in the plate circuit of the 6B7 amplifier with bypass condenser, part No. 34. The audio frequency voltage is fed over to the grid of the type 43 output tube thru coupling condenser 35, while the grid circuit of this tube is completed thru resistors 17 and 18. The amplified output of this tube is, of course, fed to the speaker in the usual manner. A very important part of the audio frequency amplifier

MODEL 51 (5C2)
Schematic, Alignment

CROSLEY RADIO CORP.

is resistor, part No. 13, connected between plate of the type 43 output tube and the screen of the type 6B7 audio amplifier. Naturally some audio frequency is fed through this resistor, as well as the direct current voltage which supplies the screen. However, at the screen of the 6B7 is located a bypass condenser, part No. 33, so that the higher audio frequencies do not affect the screen of this tube, while the lower audio frequencies are not bypassed, and the effect, therefore, is a regenerative one so far as the lower audio frequencies are concerned. The result of this circuit is that in spite of the very small proportions of the cabinet and speaker a desirable amount of lower notes are reproduced by the set.

Power Supply System . . .

Since this is an AC-DC receiver, no power transformer is used. To supply the filament of the tubes a series resistor, part No. 19, is used to drop the voltage to the required amount, while the plate voltage supply is obtained from the 25Z5 rectifier. This rectifier has two plates and two cathodes, all of which are separated from each other. It is therefore possible to use one plate and cathode to supply the plates of the remaining tubes and the other plate and cathode to supply the speaker field. In so doing much smoother operation is obtained and less hum results. The speaker field supply is filtered with condenser No.

38. The signal plate supply is filtered with condensers No. 39 and 40, in conjunction with choke, part No. 41.

Alignment Procedure . . .

To align the I. F. amplifier, it is necessary that there be available a suitable modulated oscillator capable of adjustment to 181.5 Kc. with good accuracy. This oscillator should have an attenuator, so that strength of the oscillator output can be regulated. Connect the high side of the output of the modulated oscillator, which has been adjusted to 181.5 Kc. to the receiver antenna wire, as close to where it enters the cabinet as possible, through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. It will be found that the best way to make this connection to the antenna wire is with a sharp, pointed prod, so that the insulation on the antenna wire is not permanently damaged. The unused dead end portion of the antenna wire should be rolled up on its reel. With the oscillator set to a convenient level, adjust the four I. F. transformer tuning condenser adjustment nuts available through the front flange of the chassis for maximum signal output. To make these adjustments, it is necessary that a standard 1/4" (across flats) hexagon socket wrench be used for the adjustment nut. The wrench should be insulated. It may be necessary to move the tuning dial slightly

for best results. Always make these I. F. adjustments very carefully and go over the adjustments several times to be sure that the peak has been reached.

To align the receiver at broadcast frequency, it is necessary that an adjustable oscillator, having frequencies of 1400 and 600 Kc. together with a suitable attenuator and dummy antenna be available. Set the oscillator at 1400 Kc. and turn the tuning control of the receiver to 140 on the dial. Connect the high side of the oscillator to the receiver antenna through a .0001 Mfd. (dummy antenna) condenser. Now adjust the oscillator section trimmer on the gang condenser (the oscillator section is the rear-most section of the gang) until the signal is heard best. Then adjust the remaining two R. F. trimmers on top of the gang condenser for best signal. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. The set is now aligned at 1400 Kc. and by adjusting the modulated oscillator to 600, the set may be rechecked at this point. It will sometimes be found that a slight bending of the gang condenser plates will help the sensitivity at 600 Kc. This operation should be done with extreme care, however, so that no short circuiting of the condenser plates results.

MODEL Dual Sixty (6V2)
Dual Sixty LB
Voltage, Data

CROSLEY RADIO CORP.

CHASSIS 6V2

General Description . . .

Chassis 6V2 is used in the Dual Sixty and Dual Sixty Lowboy. It is a 6-tube 3-gang automatic volume control dual range receiver. The chassis has a continuously variable tone control. The frequency bands

covered are 535 to 1700, and 1650 to 4500 Kc. The intermediate frequency is 181.5 Kc., the use of which insures adequate selectivity.

Tubes Used and Their Function . . .

The tubes used are type 58 R. F.

amplifier, type 2A7 oscillator modulator, type 58 I. F. amplifier, type 55 diode and A. F. amplifier, type 2A5 output, and type 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Ep-osc	Eg-osc
58	R. F.	2.5	225	0	3	120	—	—
2A7	Osc.-Mod.	2.5	225	0	3.5	120	175	-15
58	I. F.	2.5	225	-4	0	120	—	—
55	Diode-AF	2.5	40	-4	0	—	—	—
2A5	Output	2.5	210	-18	0	225	—	—
80	Rectifier	4.9	330AC	—	225	—	—	—

All voltages are plus or minus 10%. All DC voltages are measured to chassis at 117.5 line with 1000 ohms per volt, 250-volt voltmeter. Power demand is 60 watts at 110 volts 60 cycles.

Method of Biasing . . .

Referring to the circuit diagram, it will be seen that the bias for the R.F. tube is obtained from the cathode bias resistor, part No. 29. The bias for the input section of the type 2A7 oscillator modulator is obtained from cathode bias resistor, part No. 30, while the oscillator section obtains its bias from the grid leak and condenser combination in which part No. 15 is the grid condenser and part No. 35 the grid leak. The remainder of the tubes are shunt biased. The bias voltages are obtained from a voltage divider network connected across the speaker field, which field acts as a filter choke connected in the negative leg of the power supply. Referring to the diagram, it will be seen that the grid return of the I.F. amplifier tube, type 58, is connected to the junction point between resistors 34 and 46.

The other side of resistor 46 returns to ground so that the voltage drop across resistor 46 is the bias on the I.F. amplifier grid. This same bias voltage is used for the type 55 audio amplifier section, but in this case it is fed through volume control part No. 42. In the case of the output tube, type 2A5, the voltage developed across resistors 34 and 46 is fed through resistor 40 to the grid of this tube.

Automatic Volume Control Circuit . . .

In the broadcast band automatic volume control is exerted on the 58 R.F. amplifier, but in the high frequency band automatic volume control is used on the 2A7 oscillator modulator. The automatic volume control voltage is developed across resistor 36 and fed back to filter resistor, part No. 37, directly to the grid return of the high frequency antenna coil, part No. 4, and then to a switch contact in the secondary circuit of the broadcast antenna coil. When the switch is thrown to the broadcast band (down in the circuit diagram) the automatic volume control voltage goes through the switch, part No. 45, to the grid of the R.F. amplifier through the antenna coil secondary, part No. 2. With the switch thrown in the high frequency position (up in the circuit diagram), the automatic volume control voltage is fed through the secondary of the high frequency antenna coil, part No. 4, and then to the switch, part No. 45, to the grid of the oscillator modulator tube, type 2A7.

Analysis of Signal Channel . . .

The signal enters at the antenna terminal and depending on the position of the switch, part No. 45, is transferred either to the broadcast antenna coil or the high frequency antenna coil, parts No. 2 and No. 4 respectively. In the broadcast band the signal is tuned with one section of the gang condenser, part No. 8,

and fed to the grid of the 58 R. F. amplifier. The broadcast antenna coil is tapped, as indicated in the diagram, for the purpose of improving the image ratio. The effect of this tap is to produce an unsymmetrical selectivity characteristic, so that at the point of the normal image response, approximately 360 Kc. higher, this unsymmetrical selectivity curve tends to attenuate the image signal very materially. The amplified R.F. output of this tube is fed to the interstage transformer, part No. 3, the secondary of this transformer being tuned by another section of the gang condenser, part No. 8. The signal then goes to the control grid of the 2A7 oscillator modulator. The oscillator section of this tube is tuned by the third section of the gang condenser, which has specially-shaped plates, also indicated as part No. 8. The frequency of the oscillator is such that a constant intermediate frequency of 181.5 Kc. is present in the plate circuit of the 2A7 oscillator modulator tube. The I.F. output of the oscillator modulator tube is impressed on the first I.F. transformer, part No. 6, which transformer is double tuned. The output of this transformer is impressed on the grid of the type 58 I.F. amplifier. The amplified output of the type 58 I.F. amplifier is impressed on the second I.F. transformer, part No. 7, which transformer is also double-tuned. The I.F. signal is then impressed on the diode plates of the type 55 tube connected in parallel. In this stage there is developed across resistor 36, a DC diode voltage, an audio fre-

MODEL Dual Sixty (6V2)
Alignment, Trimmers
CROSLLEY RADIO CORP.

quency voltage, and some intermediate frequency. The audio and intermediate frequency signals pass through the coupling condenser, part No. 19 but the filter resistor, part No. 38, excludes most of the intermediate frequency remaining so that only audio frequency is present across the volume control, part No. 42. The audio frequency is amplified through the triode section of the 55 and then fed through coupling condenser 21 to the grid of the type 2A5 output tube. The slight amount of intermediate frequency remaining at this point is filtered through bypass condenser No. 20. The power audio output of the 2A5 is then fed to the speaker in a conventional manner. Condenser 22 is permanently connected across the speaker to hold its impedance at a more nearly constant value at higher audio frequency, while condenser 23 and variable resistor 43 form a tone control combination.

Power Supply System . . .

The power supply system consists of a transformer, part No. 51, for 110 volts, 60 cycles, part No. 52 for 110 volts 25 cycles, and part No. 53 for 220 volts, a type 80 rectifier tube, the speaker field as the filter choke, and the electrolytic filter condensers, part Nos. 25 and 26. In this circuit the filter choke (speaker field) is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminate the use of a large bypass condenser in the cathode of the output tube, type 2A5. At the same time, better audio quality for the lower

notes is obtained than with ordinary bypass condenser circuits.

Alignment Procedure . . .

To align the I.F. amplifier, it is necessary that there be available a suitable modulated oscillator capable of adjustment to 181.5 Kc. with good accuracy. This oscillator should have an attenuator so that the strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator which has been adjusted to 181.5 Kc. to the control grid connection on the top of the 2A7 tube, through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I.F. transformer tuning condenser, all four of which are accessible from the top of the chassis for maximum signal output. To make this adjustment it is necessary that a standard $\frac{1}{4}$ " (across flats) hexagon socket wrench be used. The wrench is preferably insulated. Always make these I.F. adjustments very carefully and go over the adjustments several times to be sure that the peak has been reached. To align the receiver at broadcast frequencies, it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc., together with a suitable attenuator and dummy antenna be available. Set the oscillator to 1400 Kc. and connect the high side of the oscillator to the receiver antenna terminal through a .0002 Mfd. (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial and adjust the oscillator

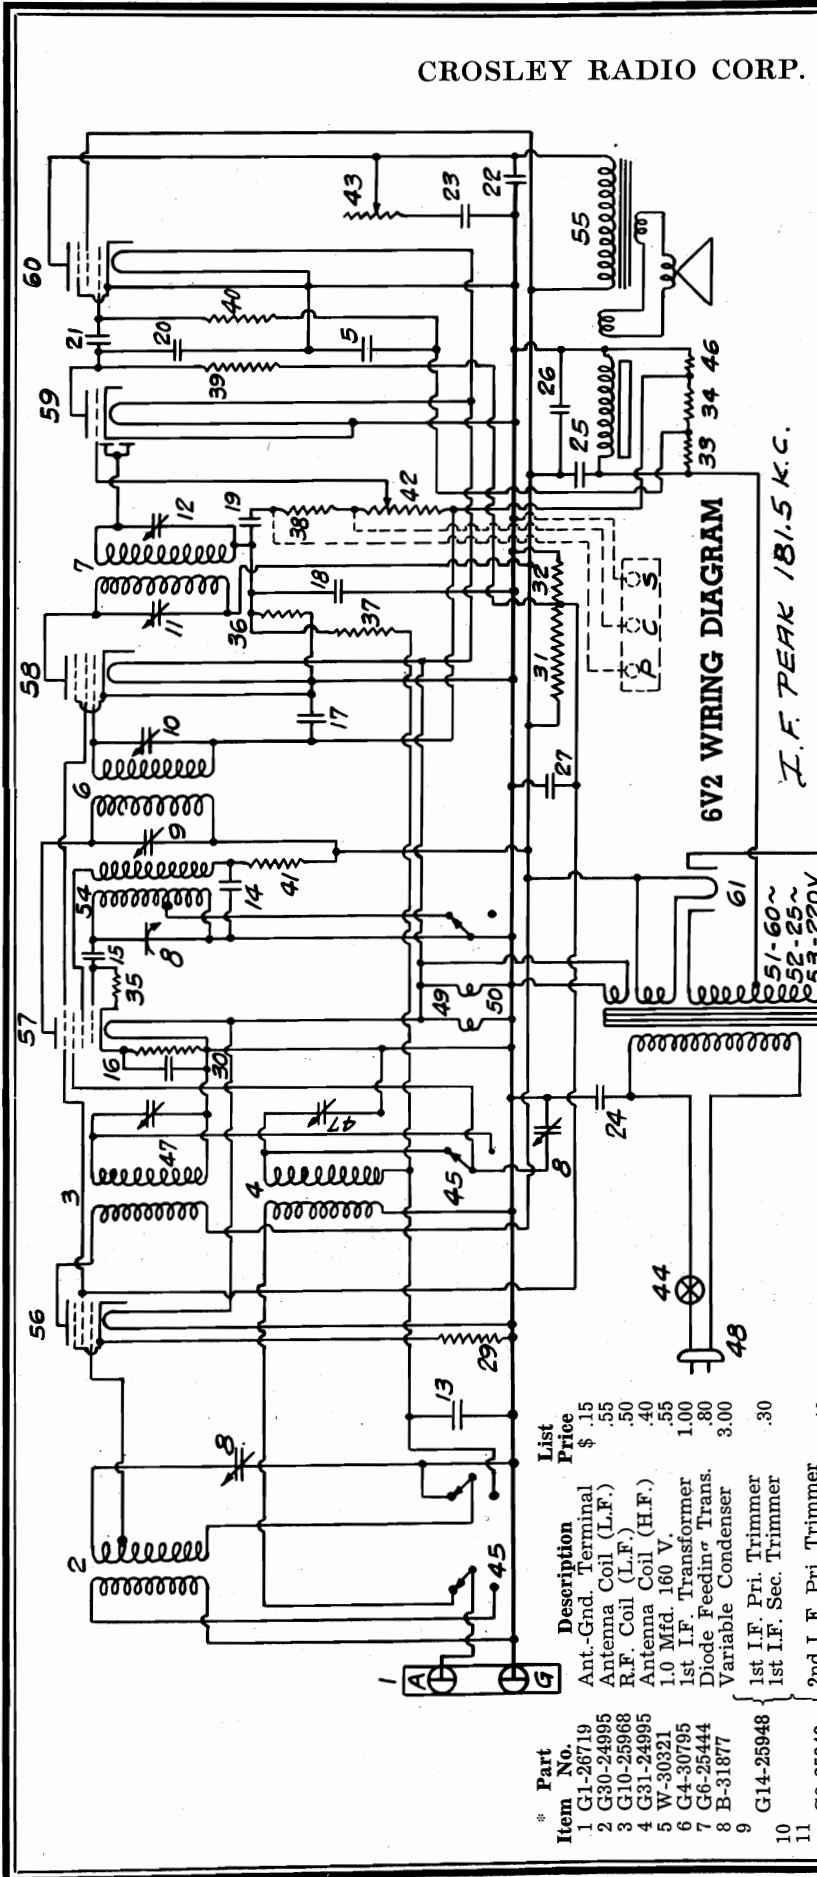

trimmer on the top of the gang condenser as indicated in the diagram until the signal is heard best. Without changing the gang condenser setting, adjust the R.F. trimmer, which is also on top of the gang, and the antenna trimmer for the broadcast band, located as indicated in the diagram on the side of the chassis, for maximum signal. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from this modulated oscillator for best accuracy. The performance of the receiver may now be checked at 600 Kc. by setting the modulated oscillator to 600 and the receiver to that point around 60 which gives best reception. Sometimes it is possible to make a slight improvement in the performance at this point by bending some of the gang condenser plates slightly. This operation should be done very carefully so that no short circuiting of the condenser plates results.

To align the receiver in the higher frequency band it is necessary that a modulated oscillator, capable of adjustment to frequencies of 1700 and 4000 Kc. be available. Set the oscillator to 4000 Kc. and throw the wave change switch to the high frequency band. Adjust the receiver in the neighborhood of 4.0 on the dial until maximum signal is heard. Now adjust the short wave antenna trimmer located on the side of the chassis as indicated in the diagram for best signal. The receiver may now be rechecked at 1700 Kc. by setting the oscillator at 1700 and the receiver dial at 1.7.

MODEL Sixty-One (6H2)
Sixty-One LB
Voltage, Notes

CROSLLEY RADIO CORP.

CHASSIS 6H2

General Description . . .

Chassis 6H2 is used in the Model Sixty-one and Model Sixty-one Low-boy. It is a 6 tube short wave and broadcast chassis employing the latest superheterodyne circuit, in which has been incorporated a high efficiency tuned radio frequency stage for both short wave and broadcast. The frequency ranges covered are

535 to 1750 Kc., which is the normal broadcast band and the lower frequency police band, and 5700 to 15500 Kc., which is the short wave or high frequency band. The intermediate frequency is 456 Kc. and while there is only one intermediate frequency stage, adequate selectivity is obtained through the use of very high efficiency I.F. transformers, in addition to the three-gang condenser.

Tubes Used and Their Function . . .

The tubes used are 6D6 radio frequency amplifier, 6A7 oscillator modulator, 6B7 intermediate frequency amplifier and diode detector, 76 audio frequency amplifier, 42 output tube and type 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Esup	Epl	Egl
6D6	R.F.	6.5	250	0	-3.5	125	—	—	—
6A7	Osc.-Mod.	6.5	250	0	-3.5	125	—	190	-15.0
6B7	I.F.-Diode	6.5	250	0	-3.5	125	—	—	—
76	A.F.	6.5	35	0	-3.5	—	—	—	—
42	Output	6.5	230	-18	0	250	—	—	—
80	Rectifier	5.1							

All voltages are plus or minus 10%. All D.C. voltages measured to chassis at 117.5 volt line with 1000 ohms per volt, 250-volt voltmeter. Power demand 60 watts, 110 volts, 60 cycles.

Method of Biasing . . .

Referring to the circuit diagram attached it will be seen that the bias for the 6D6 R.F. tube is obtained from the drop across cathode resistor No. 45. The input section of the 6A7 also obtains its bias from the drop across cathode resistor No. 41. The oscillator section of the 6A7 obtains its bias, of course, from the grid leak and condenser combination, resistor No. 42 being the grid leak. The bias for the pentode section of the 6B7 tube is also obtained from the voltage drop across resistor No. 45 but is not fed through the filter resistor. The 76 audio amplifier bias is also obtained from the drop across resistor No. 45. The bias for the output tube type 42, due to the drop across resistor 54, is fed through the grid leak, part No. 50.

Automatic Volume Control Circuit . . .

Automatic volume control voltage is developed in the diode circuit across resistors 44 and 46. A delay voltage is supplied and this voltage is equal to the drop across resistor 45. The audio frequency diode resistor is part No. 47 and it will be noted that it returns directly to re-

sistor 45. Automatic volume control is exerted on the 6D6 which is the radio frequency stage. While the full diode voltage is that drop across resistors 44 and 46 in series, only the voltage across 46 is impressed on the radio frequency amplifier. In a similar manner automatic volume control is exerted on the 6A7 control grid and this voltage is obtained from the drop across resistor 46. No automatic volume control is exerted on the intermediate frequency amplifier stage, which is the 6B7, because in so doing there is serious danger of introducing distortion.

Analysis of Signal Channel . . .

The signal enters at terminals A1, A2, and G. These three terminals are provided to permit the use of a doublet antenna with transposed lead-in and no ground if desired. With such an antenna, the two lead-in wires are connected to A1 and A2 and the strap between A2 and G is open circuited. If it is desired to operate the receiver with simply a conventional antenna and ground, connect A2 and G together and to the ground wire. The conventional antenna is connected to the A1 terminal.

The signal enters switch contacts, part No. 74, at which point, depending upon the position of the switch, it will flow either to the broadcast or short wave antenna coil primary,

parts Nos. 2 and 3 respectively. Tuning is accomplished by the first section of the gang condenser, part No. 10, connected in the secondary circuit of the antenna coil. The signal is then impressed on the 6D6 tube and is amplified. The output of the 6D6 tube goes into the primary of the inter-stage radio frequency transformer, part Nos. 4 or 5, depending on whether the switch is connected to the low or high frequency position. The secondaries of the inter-stage coils are again tuned by another section of the gang condenser, part No. 10, and the signal is then impressed on the control grid of the 6A7 oscillator modulator tube. The oscillator section of the 6A7 tube uses the oscillator coils 6 and 7 for the low and high frequency bands respectively, and the oscillator is tuned by the third section of the gang condenser, part No. 10. In this tube the frequency of the signal is changed from radio frequency to 456 Kc., the intermediate frequency. The signal passes from the plate of the 6A7 tube to the first intermediate frequency transformer, part No. 8, and the primary and secondary of this transformer are both tuned to obtain maximum selectivity. The output of the secondary of the transformer is impressed on the control grid of the 6B7 tube in which the intermediate frequency signal is amplified and fed to the second intermediate frequency transformer, part No. 9, which transformer is also tuned in both the pri-

Alignment, Trimmers

CROSLEY RADIO CORP.

mary and secondary circuits. The signal is now impressed directly on the audio frequency diode, in the 6B7 tube and through condenser No. 40 on the automatic control diode of the same tube. In the audio frequency diode the signal is converted from intermediate frequency to audio frequency which audio frequency is present across resistor 47 and condenser 26. There is also a direct current voltage and some intermediate frequency present here. The audio frequency signal is separated from the direct current voltage by condenser 27 and whatever intermediate frequency there may be left in this circuit is filtered by resistor 48 and the remaining pure audio frequency voltage is impressed across volume control, part No. 58. Adjusting the position of the arm of this volume control applies greater or less audio frequency voltage on the grid of the 76. This triode is used as an audio frequency amplifier. The plate of this tube is connected to the audio coupling resistor, part No. 49, and the audio frequency voltage is coupled to the grid of the output tube, type 42, through condenser 29. The grid circuit of the output tube is completed through resistor 50. The amplified audio output is impressed across the speaker transformer in the speaker assembly, part No. 70.

Power Supply System . . .

The power supply system consists of a transformer, part No. 71, for 110-volt 60-cycle, part No. 72 for 110-volt 25-cycle, and part No. 73 for 220-volt 25-60 cycle, a rectifier tube type 80, the speaker field as a filter choke, wet electrolytic condenser part No. 36, and dry electrolytic condenser Part No. 37. In this particular circuit the filter choke is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminate the use of a large bypass condenser on the cathode of the output tube, type 42. At the same time, better audio quality for the lower notes is obtained than with the ordinary bypass condenser circuit.

Alignment Procedure . . .

To align the I. F. amplifier it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator should have an attenuator so that the strength of the oscillator output can be adjusted. Connect the high side of the output of the modulated oscillator which has been adjusted to 465 Kc. to the control grid connection on the top of the 6A7 tube through an .02 mfd. series condenser. The low side of the oscillator to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I. F. transformer condensers for maximum signal output. To make this adjustment for I.F. transformers in a round shield it is necessary that a standard 5/16 inch (across flats) hexagon socket wrench be used for the upper condenser, and a small screwdriver fitting inside of the nut hole for adjustment of the lower condenser. A screwdriver only will adjust the I.F. transformers in a square shield. Always make this I.F. adjustment very carefully and go over your adjustment several times to be sure that the peak has been reached.

To align the receiver at broadcast radio frequency it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc., together with a suitable attenuator and dummy antenna, be available. Set the oscillator at 1400 Kc., and connect the high side of the oscillator to the receiver antenna terminal through a .0002 mfd. (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator broadcast shunt trimmer indicated on the diagram and located under the chassis until the signal is heard best. Without changing the gang condenser setting, adjust the antenna and radio frequency broadcast trimmers for maximum signal. It is necessary that these adjustments be gone over several times until no further improvements can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the

dial until it reads 60 and set the modulated oscillator to approximately 600 Kc. Adjust the modulated oscillator carefully until maximum response is obtained. Now adjust the oscillator series trimmer located on the side of the chassis as shown on the diagram attached for maximum signal. It is sometimes advisable to move the main dial back and forth slightly about 60 on the dial during the course of this adjustment if a still greater signal is obtainable.

To align the set in the high frequency or short wave band, it is necessary that a modulated oscillator be available for frequencies of 6000 and 15000 Kc. The procedure for this band is similar to the broadcast band except that a 750 ohm midget carbon resistor is used for the dummy antenna instead of the .0002 condenser. Set the modulated oscillator to 15,000 Kc. and the dial to 15. Adjust the oscillator H.F. shunt trimmer until the signal is heard best. Now adjust the antenna and interstage H.F. trimmers for maximum signal, making sure to go over the adjustment several times so that no further improvement can be made. Now set the modulated oscillator to approximately 6000 Kc. and the receiver dial to 6. Readjust the modulated oscillator slightly for maximum signal and then adjust the oscillator series trimmer for the high frequency band for best signal, making whatever slight adjustments in the tuning control are necessary to bring in maximum signal.

Tuning Receiver In High Frequency Band . . .

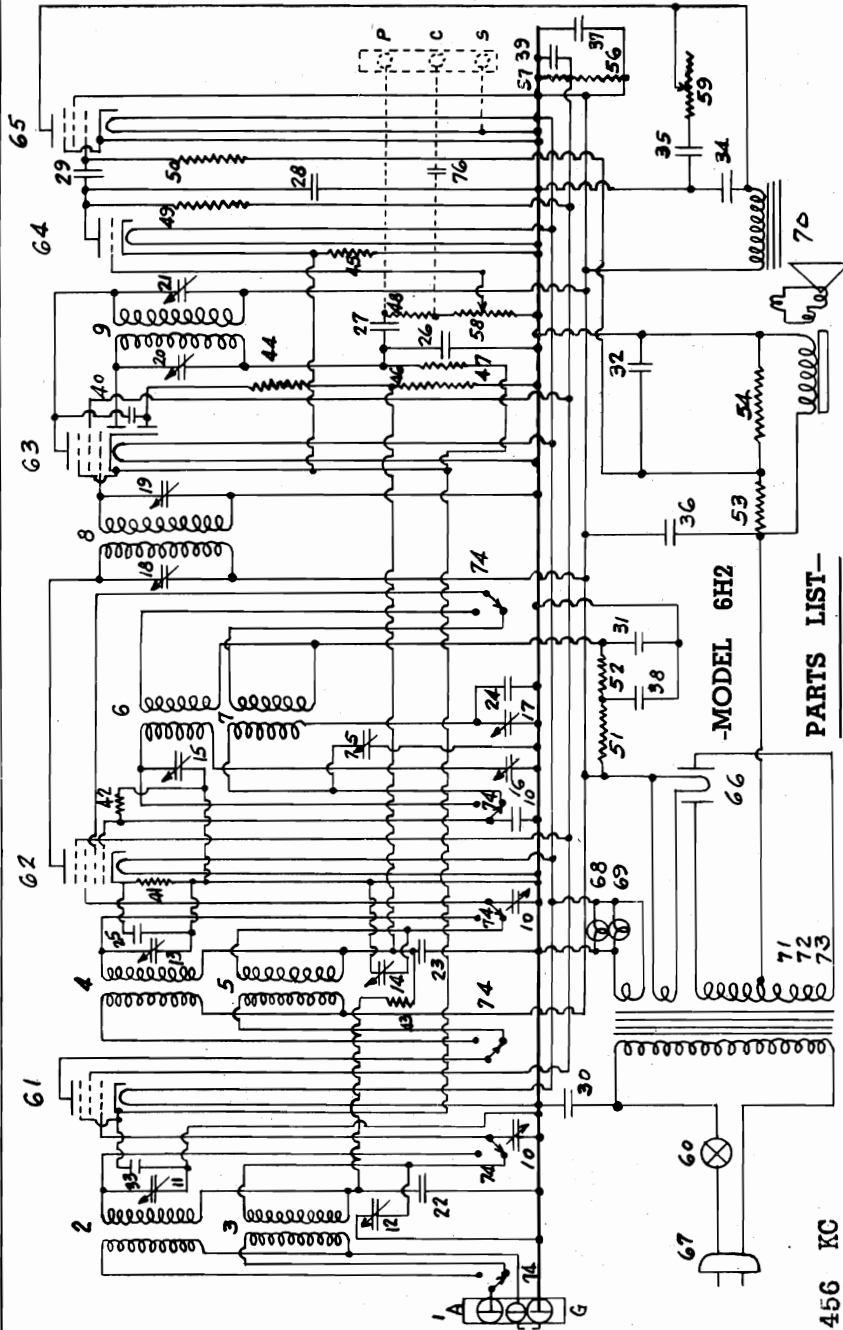

Due to the tremendously greater number of transmitter channels covered in the high frequency band, the receiver is endowed with a much greater apparent selectivity. For this reason, if the receiver is tuned carelessly, many high frequency stations will be missed or passed over without hearing them. It is very necessary that the receiver be tuned slowly and that extreme care be exercised in final adjustment of the receiver to the center of the carrier after a high frequency station is received.

CROSLEY RADIO CORP.

CHASSIS 7H2

General Description . . .

Chassis 7H2 is used in the Model 72 and 72 Lowboy. It is a seven-tube short wave and broadcast chassis employing the latest super-heterodyne circuit, in which has been incorporated a high efficiency tuned radio frequency stage for both short wave and broadcast. The frequency ranges covered are 535 to 1750 Kc., which is the regular broadcast band and lower frequency police band, and 5700 to 15500 Kc.

which is the short wave or high frequency band. The intermediate frequency is 456 Kc. Two stages of I. F. are used to assure adequate selectivity. A special friction type 80:1 drive is used to make tuning as smooth and easy as possible. Instead of the customary tuning knob, a special fishing-reel type of crank is provided so that the tuning can be spun quickly from one end of the dial to the other. With the high ratio drive employed, this would be

quite laborious if a conventional knob were used for tuning.

Tubes Used and Their Function . . .

The tubes used are type 58 R. F. amplifier, type 2A7 oscillator modulator, type 58 first I. F. amplifier, type 58 second I.F. amplifier, type 2B7 diode detector and audio amplifier, type 2A5 output tube and type 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Ep-osc.
58	RF	2.5	225	0	3	100	
2A7	Osc. Mod.	2.5	225	0	3	100	150
58	1st IF	2.5	225	0	4.5	100	
58	2nd IF	2.5	225	0	4.5	100	
2B7	Diode AF	2.5	50	0.5	0	22	
2A5	Output	2.5	215	2.0	0	225	
80	Rectifier	4.9	—	—	225	—	

Voltage Across Speaker Field, — 120.

All d. c. voltages are plus or minus ten percent. All voltages measured to chassis at 117.5 volt line with 1000 ohms per volt, 500-volt voltmeter. Power demand 75 watts at 110 volts 60-cycle.

Method of Biasing . . .

Referring to the circuit diagram attached, it will be seen that the bias for the first type 58 tube is obtained from the resistor, part No. 78, in the cathode circuit of this tube. Bias for the type 2A7 is obtained in a similar manner from cathode resistor, part No. 19. The oscillator section of the 2A7 obtains its bias, of course, from the grid leak and condenser combination, resistor 20 being for the broadcast or low frequency band and resistor 23 for the short wave or high frequency band. Bias for both I. F. tubes is obtained in the broadcast band from cathode resistor, part No. 34. In the high frequency band it is desired that the sensitivity of the set be improved, so bias resistor No. 31 is connected in shunt to resistor No. 34 so that the I. F. amplification is thereby increased when the set is switched to the short wave or high frequency band. The result of this circuit arrangement is that the set has substantially the same sensitivity in

both broadcast and short wave bands, in spite of the fact that the radio frequency coils in the short wave band cannot possibly be as efficient as they are in the broadcast band. The next two tubes employ shunt instead of self biasing. Resistors 55, 56 and 57 form a voltage divider network connected across the speaker field, which also is the filter choke. The most negative point of this voltage divider network is the end of resistor 57 which connects to the speaker field, while the positive end of the network is that end of resistor 55 which connects to the type 2B7 and 2A5 cathodes. It will therefore be seen that the negative grid bias for the type 2B7 audio frequency amplifier section is obtained at the junction point between resistors 55 and 56. The voltage obtained at this point has some hum present and it is therefore necessary that it be fed through the hum filter resistor, part No. 43, and thence through the grid circuit completing resistor, part No. 41, to the type 2B7 grid. Bias for the output tube, type 2A5 is obtained at the junction point between resistors 56 and 57 and fed through the grid circuit completing resistor to the grid of the 2A5 output tube. It is therefore seen that the bias fed

to the output tube is necessarily larger than that fed to the 2B7, since it is the drop across two resistors, while that fed to the 2B7 is the drop across only one resistor.

Automatic Volume Control Circuit . . .

Automatic volume control is developed in the diode circuit across volume control resistor, part No. 39. This voltage is picked off at the junction between resistor 38 and the volume control, part No. 39, and fed through isolating resistor, part No. 75, to the grid return circuit of the 2A7 tube. The same point is also fed to the grid return of the first type 58 I.F. amplifier. From this point there is connected an additional isolating resistor, part No. 27, and from there to the type 58 R.F. amplifier grid return. No automatic volume control is exerted on the second intermediate frequency amplifier type 58 tube because in so doing there is serious danger of introducing distortion.

Analysis of Signal Channel . . .

Starting with the antenna, the signal enters switch contact indicated as part No. 1, and depending on

MODEL 72,72 LB (7E2)**Alignment****CROSLLEY RADIO CORP.**

which position the switch happens to be in, flows either to the short wave antenna coil primary or to the broadcast antenna coil primary, parts No. 2 and No. 3 respectively. It is to be noted that a resistor, part No. 77, is connected across the broadcast antenna coil primary for the purpose of securing better alignment. The secondary of the antenna coil is tuned with a section of the gang condenser, part No. 14, and the signal is then impressed on the grid of the type 58 R.F. amplifier. The amplified output of the tube follows through the switch and into the primary of broadcast or high frequency interstage coil, depending on the switch position. The output of the secondary of the interstage coil is tuned with another section of the gang condenser, part No. 14, and fed to the control grid of the type 2A7 modulator oscillator tube. The oscillator section of this tube is automatically connected at the same time the switch is thrown so that the frequency of the oscillator is controlled by the third section of the gang condenser, part No. 14, so as to give a constant intermediate frequency of 456 Kc. in the plate circuit of the type 2A7 modulator oscillator. This intermediate frequency is now fed into the primary of the first I.F. transformer, part No. 29, and thence to the secondary of the same transformer. This transformer is tuned in both primary and secondary circuits to obtain maximum selectivity. The output of transformer No. 29 is fed to the first type 58 I.F. amplifier and the output of this tube then goes to the second I.F. transformer, part No. 33, which I.F. transformer is also double tuned. The signal then follows to the grid of the second type 58 I.F. amplifier whose output is in turn fed to the primary of a single tuned diode type I.F. transformer, part No. 35. The tuned secondary circuit of the diode transformer feeds the two diode plates of the type 2B7 connected in parallel. The diode resistor is a combination of part No. 38 and volume control No. 39 connected in series, but only that portion of the diode voltage developed across part No. 39 is used. The reason for this connection is that smoother action is obtained without regeneration. Both audio frequency and direct current are present across resistor No. 39 and, to separate out the direct current, condenser, part No. 40, is used to couple the audio

frequency over to the grid of the type 2B7 audio frequency amplifier. Resistor No. 41 completes the grid circuit of this tube. The amplified audio frequency in the plate circuit of the 2B7 is fed through coupling condenser, part No. 47 into the grid of the type 2A5 output tube, which grid circuit is completed with resistor No. 48. The plate circuit of the output tube is connected to the speaker transformer in the customary manner. Condenser No. 50 is used to match the impedance of the output tube and speaker more closely at higher audio frequencies, while condenser No. 51 and variable resistor No. 52 form the tone control.

Power Supply System . . .

The power supply system consists of a transformer, part No. 63, for 110-volt 60-cycle, part No. 64 for other uses, a rectifier tube type 80, the speaker field as a filter choke, wet electrolytic condenser, part No. 60, and dry electrolytic condenser, part No. 8. In this particular circuit the filter choke is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminate the use of a large bypass condenser in the cathode of the output tube, type 2A5. At the same time better audio quality for the lower notes is obtained than with the ordinary bypass condenser circuit. The Universal transformer, part No. 64, is a special transformer originally developed for export use, but because of its enthusiastic reception it has been incorporated in this chassis. The primary of the transformer is equipped with four voltage taps clearly marked so that the set can be made to operate from 90 to 265 volts in four steps. The transformer operates on any frequency from 25 to 100 cycles.

Alignment Procedure . . .

To align the I.F. amplifier it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator should have an attenuator so that the strength of the oscillator output can be regulated. Be sure that the band change switch is thrown to the low frequency or broadcast band position. Connect the high side of the output of the modulated oscillator, which has been adjusted to 456 Kc.

to the control grid connection on the top of the 2A7 tube through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I.F. transformer condensers for maximum signal output. The first and second I.F. transformer tuning condensers are located on the left-hand side of the chassis, while the diode tuning condenser is located under the chassis as indicated in the diagram attached. To make these adjustments, it is necessary that a standard $\frac{1}{4}$ " (across flats) hexagon socket wrench be used for the adjustment nut. The wrench is preferably insulated. Always make this I.F. adjustment very carefully and go over the adjustments several times to be sure that the peak has been reached.

To align the receiver at broadcast frequency, it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc., together with a suitable attenuator and dummy antenna be available. Set the oscillator at 1400 Kc. and connect the high side of the oscillator to the receiver antenna terminal through a .0002 (dummy antenna) condenser. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator broadcast shunt trimmer, indicated on the diagram as "oscillator trimmer condenser L.F. band" and located under the chassis, until the signal is heard best. Without changing the gang condenser setting, adjust the antenna and radio frequency broadcast trimmers, also located under the chassis and indicated in the diagram attached for maximum signal. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the dial until it reads 60 and set the modulated oscillator to approximately 600 Kc. Adjust the modulated oscillator carefully until maximum response is heard. Now adjust the oscillator series trimmer for the low frequency band located under the chassis as shown in the diagram for maximum signal. It is sometimes advisable to move the main dial back and forth slightly about 60 on the dial during the course of this adjustment if a still greater signal is obtainable.

CROSLY RADIO CORP.

MODEL 72,72 LB (7H2)
Alignment, Parts List

To align the set in the high frequency or short wave band, it is necessary that a modulated oscillator be available for frequencies of 6000 and 15000 Kc. The procedure for this band is similar to the broadcast band, except that a 750 ohm midget carbon resistor is used for the dummy antenna instead of the .0002 condenser. Set the modulated oscillator to 15000 Kc. and the receiver dial to 15. Adjust the oscillator trimmer condenser under the chassis to maximum signal. Now adjust the antenna and interstage trimmers for maximum signal, making sure to go

over the adjustment several times so that no further improvement can be made. Now set the modulated oscillator to approximately 6000 Kc. and the receiver to 6. Readjust the modulated oscillator slightly for maximum signal and then adjust the high frequency band oscillator series trimmer for best signal, making whatever slight readjustments in the tuning control are necessary to bring in maximum signal.

Tuning Receiver In High Frequency Band . . .

Due to the tremendously greater

number of transmitter channels covered in the high frequency band, the receiver is endowed with a much greater apparent selectivity. For this reason, if the receiver is tuned carelessly, many high frequency stations will be missed or passed over without hearing them. It is very necessary that the receiver be tuned slowly and that extreme care be exercised in final adjustment of the receiver to the center of the carrier after a high frequency station is located and received.

INSTRUCTIONS FOR ORDERING—Give part number, description of part, and serial number of receiver on which part is to be used. If article wanted is not listed separately, then that part of complete assembly containing this article should be ordered. Goods shipped on open account to Crosley Wholesale Distributors only. Cash must accompany Dealer and Consumer orders. Prices are subject to the usual trade discounts, and are subject to change without notice.

MODEL 72, 72 LB (7H3)
Voltage, Data

CROSLY RADIO CORP.

CHASSIS 7H3

General Description . . .

Chassis 7H3 is used in the Models 72 and 72 Lowboy. It is a 7-tube, short-wave and broadcast chassis, employing the latest superheterodyne circuit in which has been incorporated a high efficiency tuned radio frequency stage for both short wave and broadcast. The major difference between chassis 7H3 and its predecessor, chassis 7H2, lies in the addition of a broad A.V.C. Circuit to chassis 7H3 and the further use of A.V.C. on the first audio amplifier. The frequency ranges covered are

535 to 1735 Kc., which is the regular broadcast band and the lower frequency police band, and 5700 to 15,500 Kc., which is the short wave or high frequency band. The intermediate frequency is 456 Kc. Two stages of I.F. are used to assure adequate selectivity. A special friction-type 80-1 drive is used to make tuning as smooth and easy as possible. Instead of the customary tuning knob, a special fishing reel type of crank is provided so that the tuning can be spun quickly from one end of the dial to the other. With the

high ratio drive employed, this would be quite laborious if a conventional knob were used for tuning.

Tubes Used and Their Function . . .

The tubes used are—type 6D6 R.F. amplifier, type 6A7 oscillator modulator, type 6B7 first I.F. amplifier and AVC Diode, type 6D6 second I.F. amplifier, type 6F7 A.F. Diode and AVC A.F. amplifier, type 42 output, and type 80 rectifier. The tube voltages are shown in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Ep-Osc
6D6	R.F.	6.5	225	—	0	100	—
6A7	Osc.-Mod.	6.5	225	—	(10LF) (OHF)	100	150
6B7	1st I.F. & A.V.C. Diode	6.5	225	0.3	0	100	—
6D6	2nd I.F.	6.5	225	—	2.0	100	—
6F7	Diode & I.F.	6.5	30	.5	0	22	—
42	Output	6.5	215	2.0	0	225	—
80	Rectifier	4.9	—	—	225	—	—

105 volts across speaker field.

All DC voltages are plus or minus 10%. All DC voltages are measured to chassis at 117.5 volt line, with 1000 ohms per volt, 500 volt voltmeter. Power demand is 75 watts at 110 volts 60 cycles.

Method of Biasing . . .

Referring to the circuit diagram it will be seen that the 6D6 R.F. amplifier obtains its bias from the voltage drop across resistor 55. Resistors 55, 56 and 57 form a voltage divider network connected in shunt with the speaker field, which field is in the negative leg of the power supply system. The most positive point of the network is where resistor 55 is connected to chassis, and the most negative point on the network is where resistor 57 connects to the center tap on the power transformer secondary. The grid return of the 6D6 R.F. amplifier follows through isolating resistor part No. 27, and thence through a second group of resistors, parts Nos. 75, 78, 80, down to the junction point between resistors 55 and 56. The 6A7 input section obtains its bias through isolating resistor No. 7 and then through resistor 80 to the same point, namely the junction between resistors 55 and

56. The oscillator section of the 6A7 obtains its bias from the usual grid leak and condenser arrangement in which part No. 20 is the grid leak for the low frequency band and part No. 23 for the high frequency band. Bias for the 6B7 first amplifier, is obtained from the drop across resistor 55, while the bias for the 6D6 second I.F. amplifier is obtained at the same point but through resistors 75, 78 and 80. The 6F7 pentode section, which is used as an audio amplifier, obtains its fixed bias from resistor 55, but there is also a varying bias, depending on the signal strength applied due to the diode voltage drop across the level control, part No. 39. In this case, resistors 65 and 41 form a voltage divider network so that the diode voltage developed is split up in their ratio. The type 42 output tube obtains its bias from the combined drop across resistors 55 and 56 in series, this circuit being completed through grid resistor No. 48.

Automatic Volume Control Circuit . . .

Automatic Volume Control voltage is generated in the diode of the 6B7 first I.F. amplifier. This diode is fed

from the second I.F. transformer and the A.V.C. voltage is developed across resistors 78 and 80, after the signal voltage has become sufficiently large to overcome the initial bias across resistor 55. Automatic volume control voltage is fed both forward and back in the circuit of this 7H3 receiver. The full voltage is fed to the 6D6 R.F. amplifier through isolating resistor 75 and 27, while that part of the voltage developed across resistor 80 only is fed through isolating resistor No. 7 to the 6A7 input grid. The 6B7 pentode section does not have any AVC exerted on it because if this were done some distortion might result. The 6D6 second I.F. amplifier has the full voltage exerted on it through isolating resistor 75. It will be noted that in this stage the AVC voltage is sent forward instead of back through the circuit. The first audio amplifier, type 6F7 also has AVC exerted on it. In this case, the grid and plate of the 6F7 triode section are used as a diode and diode voltage is developed across resistors 38 and 39 in series. Resistors 65 and 41 form a voltage divider network so that a portion of this diode voltage is fed onto the input grid of the 6F7 pentode section.

MODEL 72, 72 LB (7H3)
Alignment, Data
CROSLLEY RADIO CORP.
Analysis of Signal Channel . . .

The signal enters at the terminals A1, A2 and G. These three terminals are provided to permit the use of a doublet antenna with transposed lead-ins and no ground connection, if desired. With such an antenna the two lead-in wires are connected to A1 and A2, and the wire strapped between A2 and G is open-circuited. If it is desired to operate the receiver with simply a conventional antenna and ground, connect A2 and G together and to the ground wire. The conventional antenna is connected to the A1 terminal.

The signal flows either to the short wave antenna coil primary or to the broadcast antenna coil primary, parts No. 2 and No. 3 respectively. It is to be noted that a resistor, part No. 77, is connected across the broadcast antenna coil primary for the purpose of securing better alignment. The secondary of the antenna coil is tuned with a section of the gang condenser, part No. 14, and the signal is then impressed on the grid of the type 6D6 R. F. amplifier. The amplified output of the tube follows through the switch and into the primary of broadcast or high frequency interstage coil. The output of the secondary of the interstage coil is tuned with another section of the gang condenser, part No. 14, and fed to the control grid of the type 6A7 modulator oscillator tube. The oscillator section of this tube is automatically connected at the same time the switch is thrown so that the frequency of the oscillator is controlled by the third section of the gang condenser, part No. 14, so as to give a constant intermediate frequency of 456 Kc. in the plate circuit of the type 6A7 modulator oscillator. This intermediate frequency is now fed into the primary of the first I. F. transformer, part No. 29, and thence to the secondary of the same transformer. This transformer is tuned in both primary and secondary circuits to obtain maximum selectivity. The output of transformer No. 29 is fed to the type 6B7 first I. F. amplifier and the output of this tube then goes to the second I. F. transformer, part No. 33, which I. F. transformer is also double tuned. The signal then follows to the grid of the type 6D6 second I. F. amplifier whose output is in turn fed to the primary of a double tuned diode type I. F. transformer, part No. 35. The tuned secondary circuit of the diode transformer feeds the triode grid and plate of the type 6F7 connected in

parallel. The diode resistor is a combination of part No. 38 and volume control No. 39 connected in series, but only that portion of the diode voltage developed across part No. 39 is used. The reason for this connection is that smoother action is obtained without regeneration. Both audio frequency and direct current are present across resistor No. 39. Condenser, part No. 40, is used to couple the audio frequency over to the pentode grid of the type 6F7 audio frequency amplifier. Resistor No. 41 completes the grid circuit of this tube. The amplified audio frequency in the plate circuit of the 6F7 is fed through coupling condenser, part No. 47 into the grid of the type 42 output tube, which grid circuit is completed with resistor No. 48. The plate circuit of the output tube is connected to the speaker transformer in the customary manner. Condenser No. 50 is used to match the impedance of the output tube and speaker more closely at higher audio frequencies, while condenser No. 51 and variable resistor No. 52 form the tone control.

Power Supply System . . .

The power supply system consists of a transformer, part No. 63, for 110-volt 60-cycle, part No. 64 for other uses, a rectifier tube type 80, the speaker field as a filter choke, wet electrolytic condenser, part No. 60, and dry electrolytic condenser, part No. 8. In this particular circuit the filter choke is included in the negative leg of the power supply system, because in so doing it is possible to use the drop across the filter choke for biasing, and eliminate the use of a large bypass condenser in the cathode of the output tube, type 42. At the same time better audio quality for the lower notes is obtained than with the ordinary bypass condenser circuit. The Universal transformer, part No. 64, is a special transformer originally developed for export use, but because of its enthusiastic reception it has been incorporated in this chassis. The primary of the transformer is equipped with four voltage taps clearly marked so that the set can be made to operate from 90 to 265 volts in four steps. The transformer operates on any frequency from 25 to 100 cycles.

Alignment Procedure . . .

To align the I. F. amplifier it is necessary that there be available a suitable modulated oscillator capable of adjustment to 456 Kc. with good accuracy. This oscillator

should have an attenuator so that the strength of the oscillator output can be regulated. Be sure that the band change switch is thrown to the low frequency or broadcast band position. Connect the high side of the output of the modulated oscillator, which has been adjusted to 456 Kc. to the control grid connection on the top of the 6A7 tube through an .02 Mfd. series condenser. The low side of the oscillator is to be connected to the receiver chassis. Set the output of the oscillator to a convenient level and adjust the I. F. transformer condensers for maximum signal output. The first and second I. F. transformer tuning condensers are located on the left-hand side of the chassis, while the diode transformer tuning condensers are located on the top of the tall I. F. transformer as indicated in the diagram attached. To make these adjustments, it is necessary that a standard $\frac{1}{4}$ " (across flats) hexagon socket wrench be used for the adjustment nuts and a small screw driver for the slot. The tools are preferably insulated. Always make these I. F. adjustments very carefully and go over the adjustments several times to be sure that the peak has been reached.

To align the receiver at broadcast frequency, it is necessary that an adjustable oscillator having frequencies of 1400 and 600 Kc., together with a suitable attenuator and dummy antenna be available. Set the oscillator at 1400 Kc. and connect the high side of the oscillator to the A1 receiver antenna terminal through a .0002 (dummy antenna) condenser. Be sure that there is a connection between A2 and G. Turn the tuning control of the receiver to 140 on the dial. Now adjust the oscillator broadcast shunt trimmer, indicated on the diagram as "oscillator trimmer condenser L. F. band" and located under the chassis, until the signal is heard best. Without changing the gang condenser setting, adjust the antenna and radio frequency broadcast trimmers, also located under the chassis and indicated in the diagram attached for maximum signal. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the dial until it reads 60 and set the modulated oscillator to approximately 600 Kc. Adjust the modulated oscillator carefully until maximum response is heard. Now adjust the oscillator series trimmer for the low frequency band located

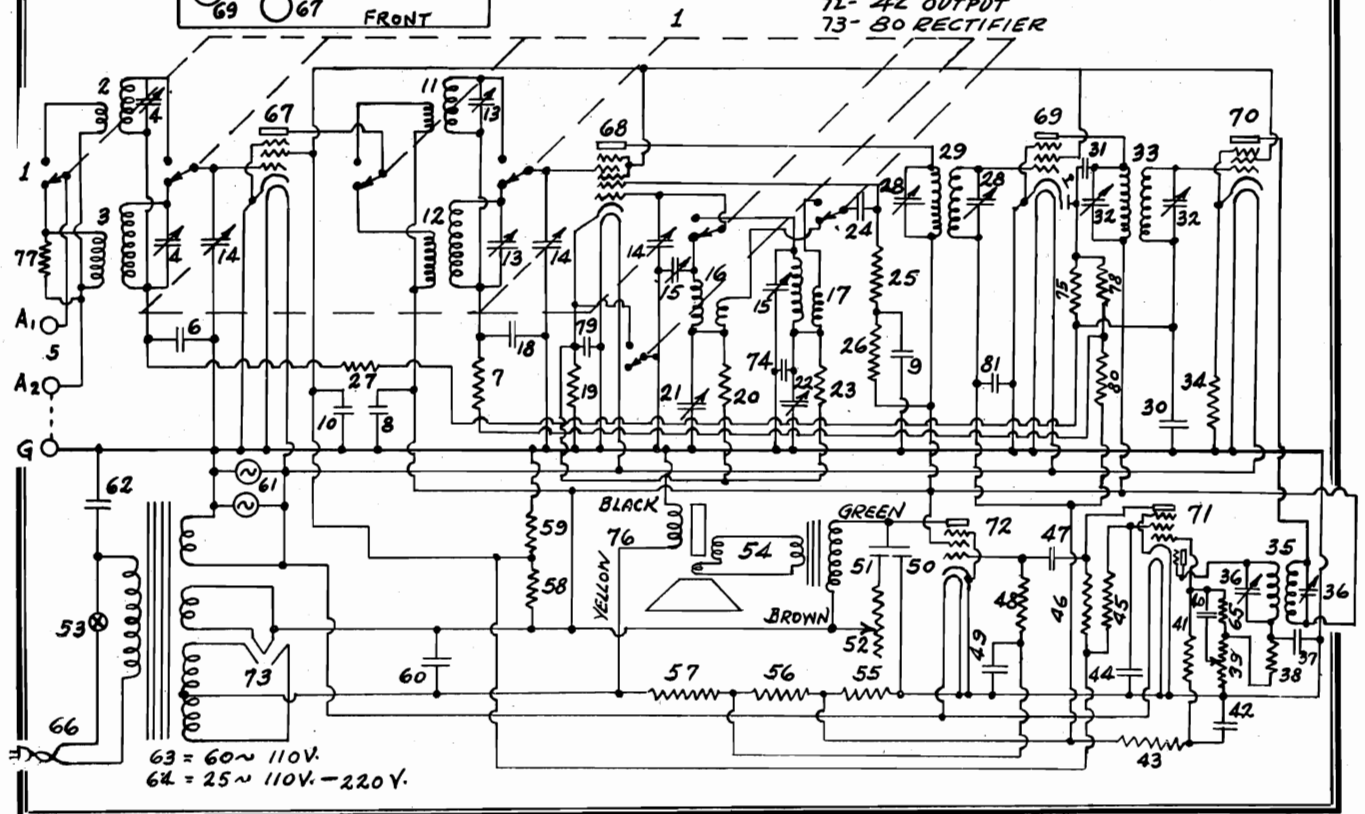

CROSLLEY RADIO CORP.

under the chassis as shown in the diagram for maximum signal. It is sometimes advisable to move the main dial back and forth slightly about 60 on the dial during the course of this adjustment if a still greater signal is obtainable.

To align the set in the high frequency or short wave band, it is necessary that a modulated oscillator be available for frequencies of 6000 and 15000 Kc. The procedure for this band is similar to the broadcast band, except that a 750 ohm midget carbon resistor is used for the dummy antenna instead of the .0002 condenser. Set the modulated oscillator to 15000 Kc. and the receiver

dial to 15. Adjust the oscillator trimmer condenser under the chassis to maximum signal. Now adjust the antenna and interstage trimmers for maximum signal, making sure to go over the adjustment several times so that no further improvement can be made. Now set the modulated oscillator to approximately 6000 Kc. and the receiver to 6. Readjust the modulated oscillator slightly for maximum signal and then adjust the high frequency band oscillator series trimmers for best signal, making whatever slight readjustments in the tuning control are necessary to bring in maximum signal.

Tuning Receiver In High Frequency Band . . .

Due to the tremendously greater number of transmitter channels covered in the high frequency band, the receiver is endowed with a much greater apparent selectivity. For this reason, if the receiver is tuned carelessly, many high frequency stations will be missed or passed over without hearing them. It is very necessary that the receiver be tuned slowly and that extreme care be exercised in final adjustment of the receiver to the center of the carrier after a high frequency station is located and receiver.

CROSLEY RADIO CORP.

MODEL 80AW, 80AW LB (8H1)
Voltage, Data

TECHNICAL DATA PERTAINING TO CHASSIS 8H1

General Description . . .

Chassis 8H1 is used in the Model 80-AW and Model 80-AW Lowboy. It is an 8-tube all-wave receiver, covering the band of 540-24000 Kc., in four steps. Other features are an 80 to 1 ratio drive mechanism with special fishing reel type of control, airplane type dial, push-pull pentode output, doublet antenna terminals,

and tone control. Two stages of double-tuned I. F. amplification, making a total of six tuned I. F. circuits are used to insure adequate selectivity. A tuned radio frequency stage is used in all frequency bands. The automatic volume control is of the broad type to obtain smoothest possible operation.

Tubes Used and Their Function . . .

The tubes used are type 6D6 R. F. amplifier, type 6A7 oscillator modulator, type 6D6 first I. F. amplifier, type 6B7, second I. F. amplifier, AVC diode and AF diode, type 6F7 first AF pentode amplifier, and triode phase inverter, two type 42 push-pull output and type 80 rectifier. The normal tube voltages are as indicated in the table below:

Type	Where Used	Ef	Ep	Eg	Ek	Esg	Epx	Egx
					SW-BC			
6D6	R.F.	6.3	250	0	3	100	—	—
6A7	Osc.-Mod.	6.3	250	0	3	100	220	0 to -10
6D6	1st I. F.	6.3	250	0	7-21	100	—	—
6B7	2nd I. F. and Diode	6.3	250	0	3	100	—	—
6F7	A.F. and Phase Inv.	6.3	140	0	4	35	70	0
42	Output	6.3	240	0	16	250	—	—
80	Rectifier	5.0	—	—	350	—	—	—

All voltages are plus or minus 10%. All DC voltages are measured with 117.5 volts AC line and with a 500-volt 1000-ohms-per-volt DC voltmeter. Power demand is 100 watts.

Method of Biasing . . .

The type 6D6 R. F. amplifier obtains its normal bias from the cathode resistor, part No. 39. The bias for the input section of the 6A7 oscillator modulator is obtained from the cathode resistor, part No. 40. The oscillator bias is obtained from the grid leak and condenser combination in which part No. 29 is the grid leak and part 50 the grid condenser. The type 6D6 first I. F. amplifier obtains its bias from the cathode resistor, part No. 41, for all bands except No. 4, the broadcast band. When the switch is thrown to the band No. 4 position, auxiliary resistor, part No. 95, is inserted in series with part No. 41. It is the purpose of this auxiliary resistor to reduce the gain of the receiver at broadcast frequencies, because if full sensitivity were used the receiver would be entirely too sensitive in the broadcast band. The bias for the 6B7 second I. F. amplifier input section, is obtained from the cathode resistor, part No. 42, which resistor also furnishes the delay voltage for the AVC system. The variable mu

pentode AF amplifier and phase inverter, type 6F7, obtains its bias from resistor No. 36, while the output tubes obtain their bias from the resistor No. 43.

Automatic Volume Control Circuit . . .

The automatic volume control diode in the 6B7 is fed from the plate of this tube through coupling condenser, part No. 51. Diode voltage is developed across resistors 32 and 33 after the signal has become sufficiently strong to overcome the initial bias generated in resistor 42. The voltage across resistor 32 is that part which is used for AVC purposes. Following the circuit diagram, it will be seen that the AVC voltage flows through isolating resistor No. 27 to the grid return of the high frequency interstage coil, part No. 8, and then to the input grid of the 6A7 oscillator modulator. In the other three bands, the AVC voltage is fed through the additional isolating resistor, part No. 26, to the grid return and then to the input grid of the 6A7. AVC voltage is also fed from resistor 27 through isolating resistor 24 to the grid return of the highest frequency antenna coil, part No. 4, and then to the grid of the 6D6 R. F. amplifier. For the other bands the AVC voltage is fed

through additional resistor 25 to the grid returns. At this point AVC voltage is also fed to the grid return of the 6D6 first I. F. amplifier. This receiver also has AVC on the audio system, but this AVC voltage is obtained from the audio diode, which diode is also in the 6B7 tube. In this case, the diode is fed from the secondary of the last I. F. transformer, part No. 20, and diode voltage is developed across resistors 28, 46 and 34 in series. That portion across resistors 34 and 46 is fed to the input grid of the pentode section of the 6F7 tube. This voltage will vary in magnitude, depending on the setting of the level control, part No. 46, but there is always a residual amount which is that voltage developed across resistor 34.

Analysis of Signal Channel . . .

The signal enters at the terminals A1, A2 and G. These three terminals are provided so that it is possible to use either a doublet or a conventional type of antenna with the receiver. When a doublet antenna is used, connect the two lead-in wires to A1 and A2 respectively, and a ground may or may not be connected to the G terminal, as desired. With this connection it is important that the strap between A2 and G termin-

MODEL 80AW, 80AW LB
Alignment (8H1)
Trimmers

CROSLEY RADIO CORP.

tor is somewhat affected by the R. F. adjustment. It is necessary that these adjustments be gone over several times until no further improvement can be made. Always work with the weakest possible signal from the modulated oscillator for best accuracy. Now rotate the dial until it reads 60 and set the modulated oscillator to approximately 600 Kc. Adjust the modulated oscillator carefully until maximum response is heard. Now adjust the oscillator series trimmer condenser for the broadcast band, located in the third hole from the front on the chassis end flange, indicated in the diagram, until maximum response is heard. It is sometimes advisable to move the main dial back and forth slightly about 60 on the dial during the course of this adjustment if a still greater signal is obtainable.

The same procedure is used for the remaining three bands except that the dummy antenna condenser is replaced by a 750-ohm midget carbon resistor. The shunt padding condensers for band No. 3 are located in the middle row on the end of the coil assembly, while the series padding condenser for band No. 3 is the second from the front on the receiver end flange. To align the receiver in band No. 3 it is necessary that a modulated oscillator and suitable attenuator be available, with frequencies of 1700 and 4000 Kc. Set the dial at 4 and the modulated oscillator to 4000 Kc. Adjust the oscillator shunt trimmer, which is the front condenser on the coil shield assembly in the middle row for maximum signal. Then adjust the remaining two condensers in the middle row for maximum signal, making what slight adjustments may be necessary if the oscillator is slightly detuned by the R. F. adjustment. Then set the modulated oscillator to approximately 1700 Kc., and the receiver dial to 1.7. Adjust the modulated oscillator slightly until the signal is heard best and then adjust the oscillator series trimmer located on the receiver end flange (the second from the front) for maximum signal. Make whatever slight readjustments are necessary in the dial to bring this signal in best.

To align the receiver in band No. 2, the bottom row of trimmer condensers on the coil shield assembly are used. An oscillator capable of adjustment to 4500 and 10,000 Kc. is necessary. Set the oscillator at approximately 10,000 and the receiver dial to 10. Adjust the oscillator shunt trimmer condenser, which is the front condenser in the lower row, for maximum signal. Then adjust the remaining two condensers in the lower row, making whatever slight readjustment of the dial is necessary to bring the signal in best. Set the dial of the receiver to 4.5 and the modulated oscillator to 4500 Kc. Now adjust the oscillator series trimmer condenser for this band, which is the frontmost one on the receiver on the chassis end flange, for maximum signal, making whatever slight dial readjustments are necessary.

The aligning condensers for band No. 1 are located directly under and

to the right of the gang condenser. To align the receiver in this band, it is necessary that a modulated oscillator and attenuator for a frequency of 22,000 Kc. be available. Set the modulated oscillator to 22,000 Kc. and the receiver dial to 22. Adjust the oscillator shunt trimmer, which is the frontmost of the three trimmer condensers available from the top of the chassis, for maximum signal. Now adjust the remaining two trimmer condensers also available from the top of the chassis, and make whatever slight dial adjustments are necessary to bring the signal in best. There is no series trimmer condenser for this band but the alignment may be checked by setting the modulated oscillator to approximately 11,000 Kc. and tuning it in on the receiver dial. It should come in at about 11 on the dial.

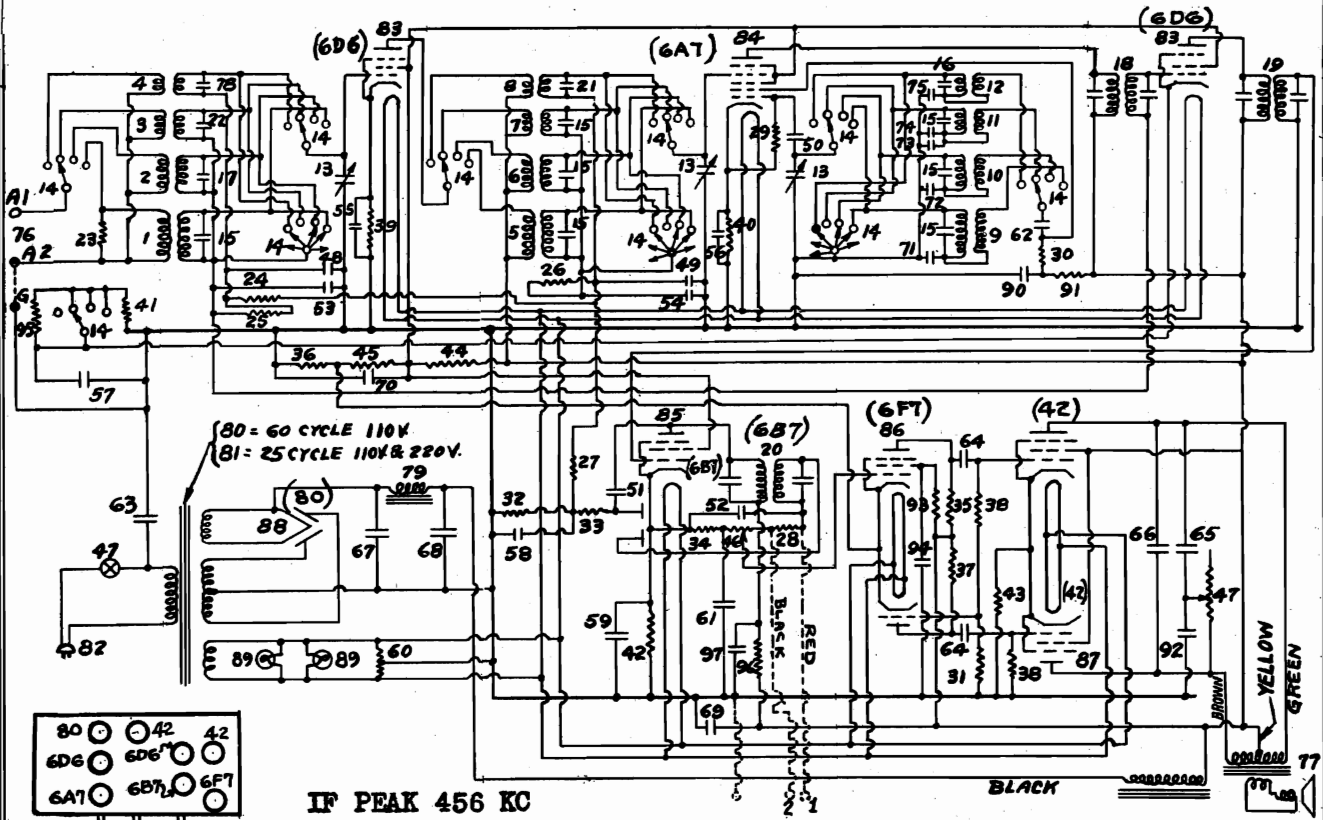

Tuning Receiver In High Frequency Band . . .

Due to the tremendously greater number of transmitter channels covered in the high frequency band, the receiver is endowed with a much greater apparent selectivity. For this reason, if the receiver is tuned carelessly, many high frequency stations will be missed or passed over without hearing them. It is very necessary that the receiver be tuned slowly and that extreme care be exercised in final adjustment of the receiver to the center of the carrier after a high frequency station is located and received.

PROCEDURE FOR ALIGNMENT:

Apply a modulated 456-kc. signal to modulator grid and align the four dual trimmers in the top of the I-F. cans for maximum output from the set.

Apply a 600 kc. signal at the antenna and track the oscillator by varying the nut adjustment on the oscillator padding condenser until maximum response is obtained, by rotating the dial. Disregard calibration when making this adjustment.

At all steps in the above procedure the output should be kept only as high as is necessary for good align-

ment, but the output should be lowered always by decreasing the input to the receiver, never by reducing the setting of the volume control. This control should be set at maximum throughout any adjustments of the R-F. or I-F. circuits. Use a suitable output meter across the voice coil of the speaker for indicating the correct adjustment for maximum response.

MODEL 1200

**Voltage
Alignment**

DETROLA RADIO CORP.

1. Apply a modulated 175 Kilocycle signal to the grid of the modulator (1st detector) tube and align the four dual trimmer adjustments in the top of the IF transformer cans for maximum output from the receiver.
2. With the band switch knob in the 530-1500 Kilocycle or clockwise position, and the tuning dial set to 1400 Kilocycles, apply a 1400 Kilocycle signal at the antenna and adjust the three trimmer screws on the gana condenser for maximum output from the receiver.
3. Apply a 600 Kilocycle signal at the antenna and track the oscillator by varying the nut adjustment on the oscillator padding condenser and returning the dial until maximum response is obtained. This adjustment should be made disregarding calibration.
4. With the band switch in the short wave or counter-clockwise position and the dial set to 3.6 Megacycles, apply a 3600 Kilocycle signal at the antenna and align the three trimmers in the top of the short wave coil cans for maximum response.
5. Apply a 1600 Kilocycle signal at the antenna and track the oscillator as at 600 Kilocycles in the broadcast band by adjusting the slotted screw adjustment on the oscillator padding condenser.

Suitable harmonics of a broadcast oscillator may be used for alignment purposes in the short wave band.

At all steps in the aligning procedure, the output should be kept only as high as is necessary for good alignment but the output should always be lowered by decreasing the input to the receiver, never by reducing the volume control setting. The volume control should be at maximum setting during any adjustments of the RF and IF circuits. A suitable output meter should be connected across the speaker voice coil to indicate the correct adjustment for maximum response.

TABLE OF VOLTAGES

Line Voltage - 115 Volts - 60 Cycles AC
Interchannel Noise Suppressor Set for Maximum Sensitivity

Position	Tube	Plate	Screen	Cathode

 MODEL 128
 Schematic, Data

Model 128

To balance set, first remove chassis from cabinet; second, tune condenser to about 1720 kc and align trimmer condenser on detector stage, then do same to antenna stage until loudest noise level is obtained.

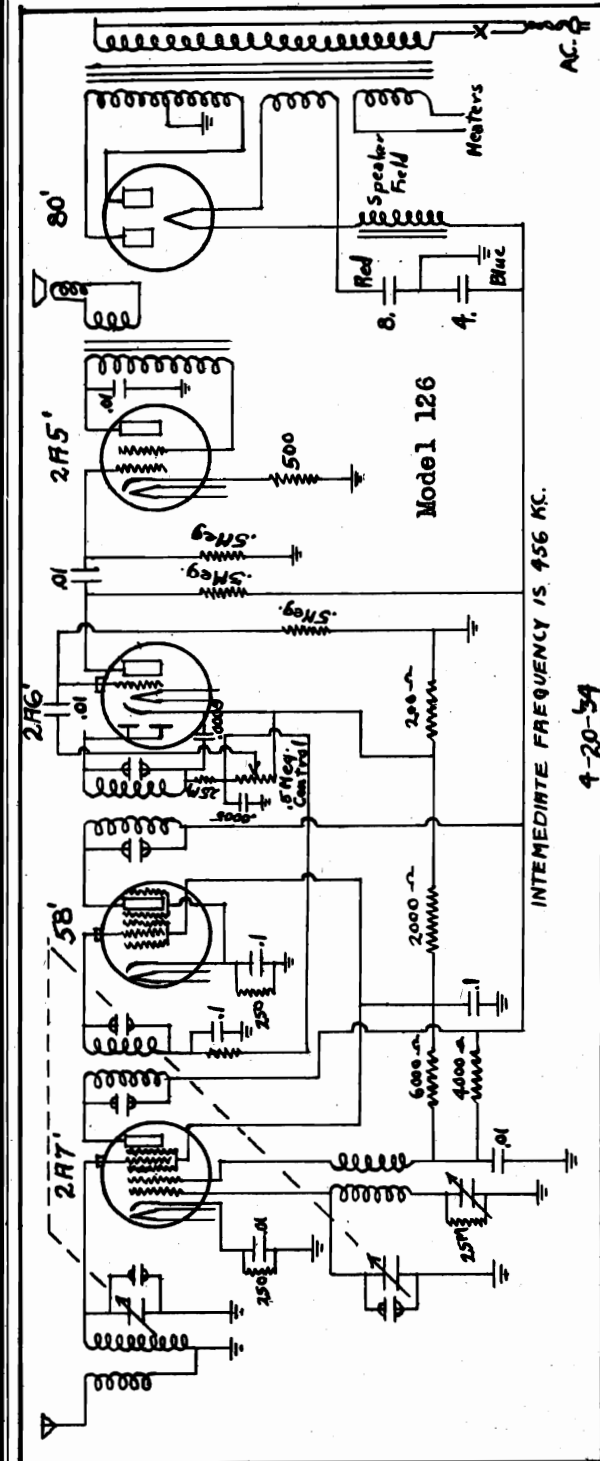

Model 111

This set is designed to oscillate across a major portion of the broadcast band. This regeneration is controllable by reducing the volume of the set. Oscillation in a set of this type increases the sensitivity from ten to twenty times.

Schematic, Alignment

Model 126

To balance set, first align the IF transformers at 456 kc with gang condenser closed, next turn condenser all way open and align at 1720 kc, then adjust padder condenser at 600 kc, then go back and check at 1720 kc.

Model 124
This set is designed to operate on 105-120 volts, A.C. The regular band covers from 1712 KC-550 KC and short wave from 15-55 meters.

Model 124

105 TO 120 VOLTS A.C.
5.25 WATTS
ALL RESISTORS NOT MARKED
ARE 1/2 WATT
-571394

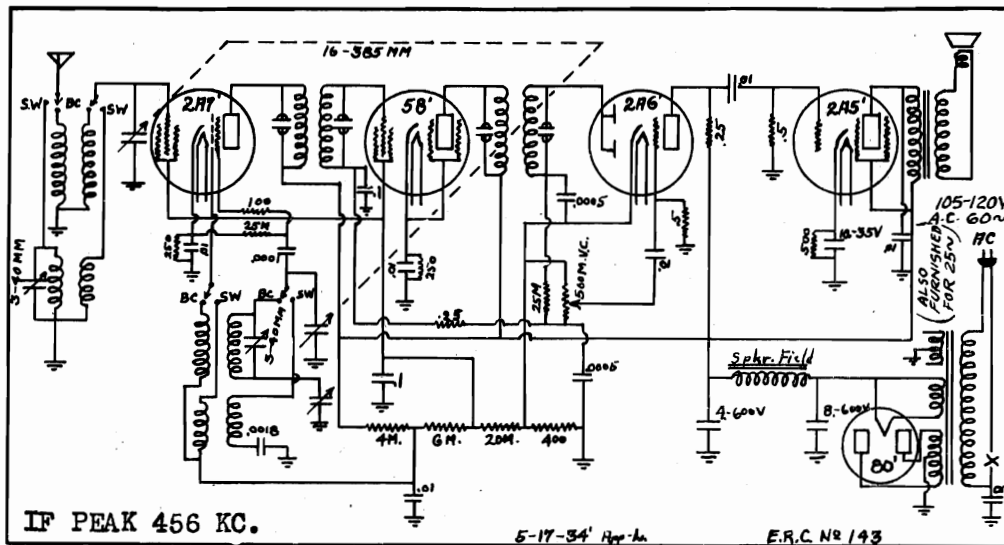

Model 124

To align set on broadcast, remove 56 oscillator tube, trim Intermediate Frequency Transformer at 456 KC from an oscillator, feeding same into 57, first detector grid. Secondly, open gang condenser wide open and adjust trimmer condensers on top to maximum noise level, then adjust low frequency padder at approximately 600 KC; after doing this go back and recheck at 1700 KC.

To adjust short wave, turn switch left and tune gang condenser to 31 meters on dial and trim small padders underneath to maximum noise level or some station, checking oscillator coil padder with gang condenser tuned at different points.

Parts List

ECHOPHONE RADIO MFG. CO.

IF PEAK 456 KC.

5-17-34 Rev. 1

E.R.C. No. 143

PARTS LIST

This set covers from 1720 KC to 540 KC regular broadcast including 1712 KC police and 15 - 55 meters short wave which covers major foreign stations.

The circuit uses 1-2A7 1st detector and oscillator; 1-58 IF; 1-2A6 second detector and first audio; 1-2A5 power output and 1-80 rectifier.

To align receiver proceed as follows:

1. Peak the two IF transformers, applying a 456 note at the 2A7 grid.
2. Turn variable condenser wide open, peaking oscillator stage at 1712 KC- then peak RF and antenna stage.
3. Adjust low frequency with gang tuned to 600 KC, to maximum peak.
4. Go back and check trimmers on gang condenser at 1400 KC.

If radio stops playing turn off immediately - check tubes. For-

- Hum - check for
- Open resistor
 - Bad Filter condenser
 - Open by pass condenser
 - Defective tube or tubes.

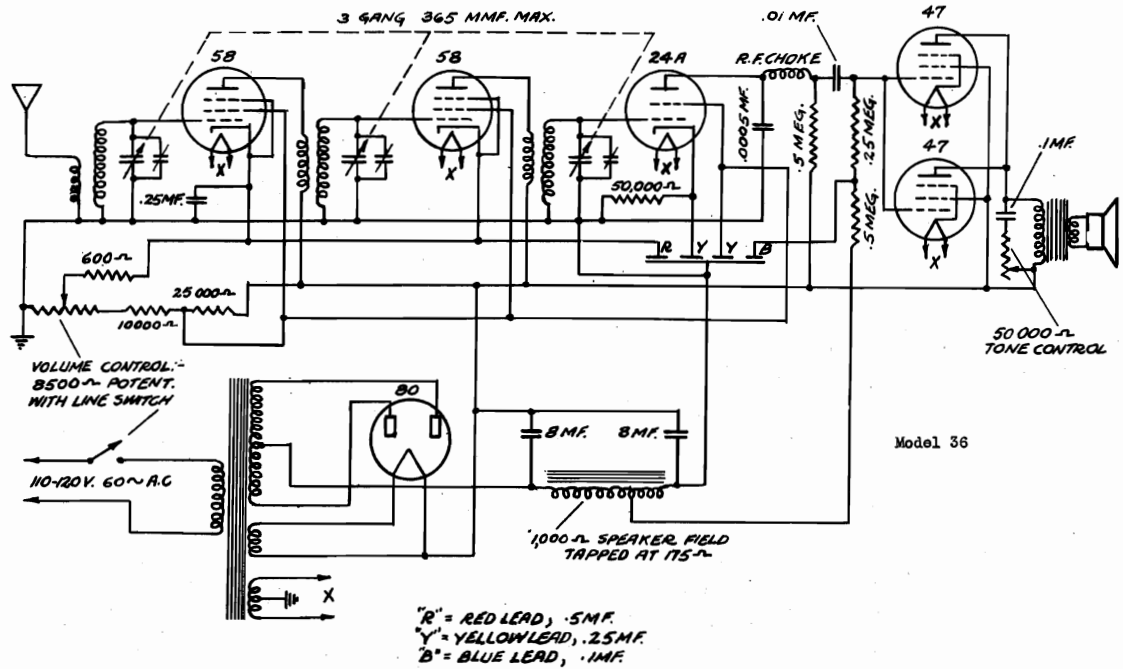

- Poor tone- check for
- Bad resistor
 - Voice coil in speaker rubbing
 - Defective by pass condenser
 - Defective filter condenser

Voltage, Alignment
Parts List

ELECTRICAL RESEARCH LABS.

ALIGNMENT PROCEDURE: For properly aligning either the intermediate transformer or the variable condenser it is necessary that an accurately calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the control grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.
2. Set the oscillator frequency at 265 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter, and then adjust the other trimmer screw of the intermediate transformer for maximum sensitivity.
4. Adjust the second intermediate transformer in the same manner.

NOTE: Two types of intermediate transformer trimmers have been used in this model receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one intermediate trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is not necessary to remove the receiver chassis from the set housing to align the gang condenser. Regardless of whether or not the receiver is or is not mounted in the set housing the alignment procedure is the same. Three holes are provided in the left hand side of the set housing for the gang condenser trimmers and one in the front of the set housing for the 600 kilocycle padding condenser.

1. Properly connect the remote control head and shafts and adjust the dial needle on the dial face so that the dial calibration is correct.
2. Connect the high output side of the oscillator to the antenna and the ground to the receiver chassis.
3. Tune the receiver to exactly 1400 kilocycles on the dial and adjust the oscillator to this frequency. BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE OSCILLATOR GANG CONDENSER TRIMMER. Looking at the side of the receiver and reading from top to bottom the trimmer condensers are the antenna, R. F. and oscillator sections. Next, adjust the R. F. and antenna sections of the gang condenser for maximum sensitivity.
4. Tune the receiver to approximately 600 kilocycles on the dial and set the oscillator to this frequency. Then adjust the 600 kilocycle padding condenser, which is located on and accessible through the hole in the front of the chassis for maximum output. Always rock the condenser slightly to the right and left when making this adjustment using the position of greatest output.

MODEL 5700, 5721

Alignment

ELECTRICAL RESEARCH LABS.

NOTE: It may be found that stations on the short wave band are received at a slightly different dial setting than formerly received after changing the aerial dimensions. Using one of the antenna transmission systems designed for man-made static elimination may prove beneficial for very difficult locations. Care must be taken in using this type aerial system as an improperly designed transmission system will decrease the range of the receiver, particularly on short wave reception. Simply using a transmission system will not eliminate the noise unless the flat top of the aerial can be erected outside of the field of disturbance. A shielded lead-in is not recommended as the signal loss on short waves will be excessive. The antenna should be connected to the red lead coming out at the rear of the chassis and for best results it is recommended that a good ground be connected to the black lead coming out at the rear of the chassis.

BAND SELECTOR SWITCH: Two different frequency bands are available, the frequency range being:

1715 to 535 Kilocycles- 175 to 560.75 Meters
16 to 5.2 Megacycles- 18.7 to 57.7 Meters

Selection of the desired frequency band is made with the band selector switch knob, which is located on the lower right front of the cabinet. When the band selector switch is placed in the maximum left hand position the receiver is operating on the 5.2 to 16 megacycle band. For operation on the 1715 to 535 kilocycle band place the band selector switch knob in the maximum right hand position. Both bands are calibrated on a single dial, one section of which is calibrated in kilocycles, 1715 to 535 kilocycles, and the other section is calibrated in megacycles, 16 to 5.2 megacycles.

ALIGNMENT PROCEDURE: Only when an IF transformer, antenna or oscillator coil is replaced should it ever be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is absolutely necessary that a good accurate calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 tube leaving the grid cap disconnected. The ground side of the oscillator should be connected to the receiver chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the intermediate transformer brass hex adjusting nut located on top of the intermediate transformer can up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside the brass hex nut for maximum output.
4. Adjust the second I. F. transformer in the same manner as the first I. F. transformer.

VARIABLE CONDENSER ALIGNMENT: It is essential that the following instructions be carefully adhered to in the order given otherwise the receiver will be insensitive and the dial calibration will be inaccurate.

1. Connect the high side of the oscillator output to the set antenna lead and the oscillator ground to the receiver chassis.
2. Place the band selector switch for operation on the 16 to 5.2 megacycle band.
3. Set the oscillator frequency to exactly 15 megacycles and adjust the receiver dial to exactly 15 megacycles. Then BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE trimmer condenser of the oscillator gang condenser section. The oscillator trimmer condenser is mounted on top of the rear section of the variable condenser. The front section of the variable condenser tunes the antenna stage.
4. Place the band selector switch for operation on the 1715 to 535 kilocycle band, set the oscillator to

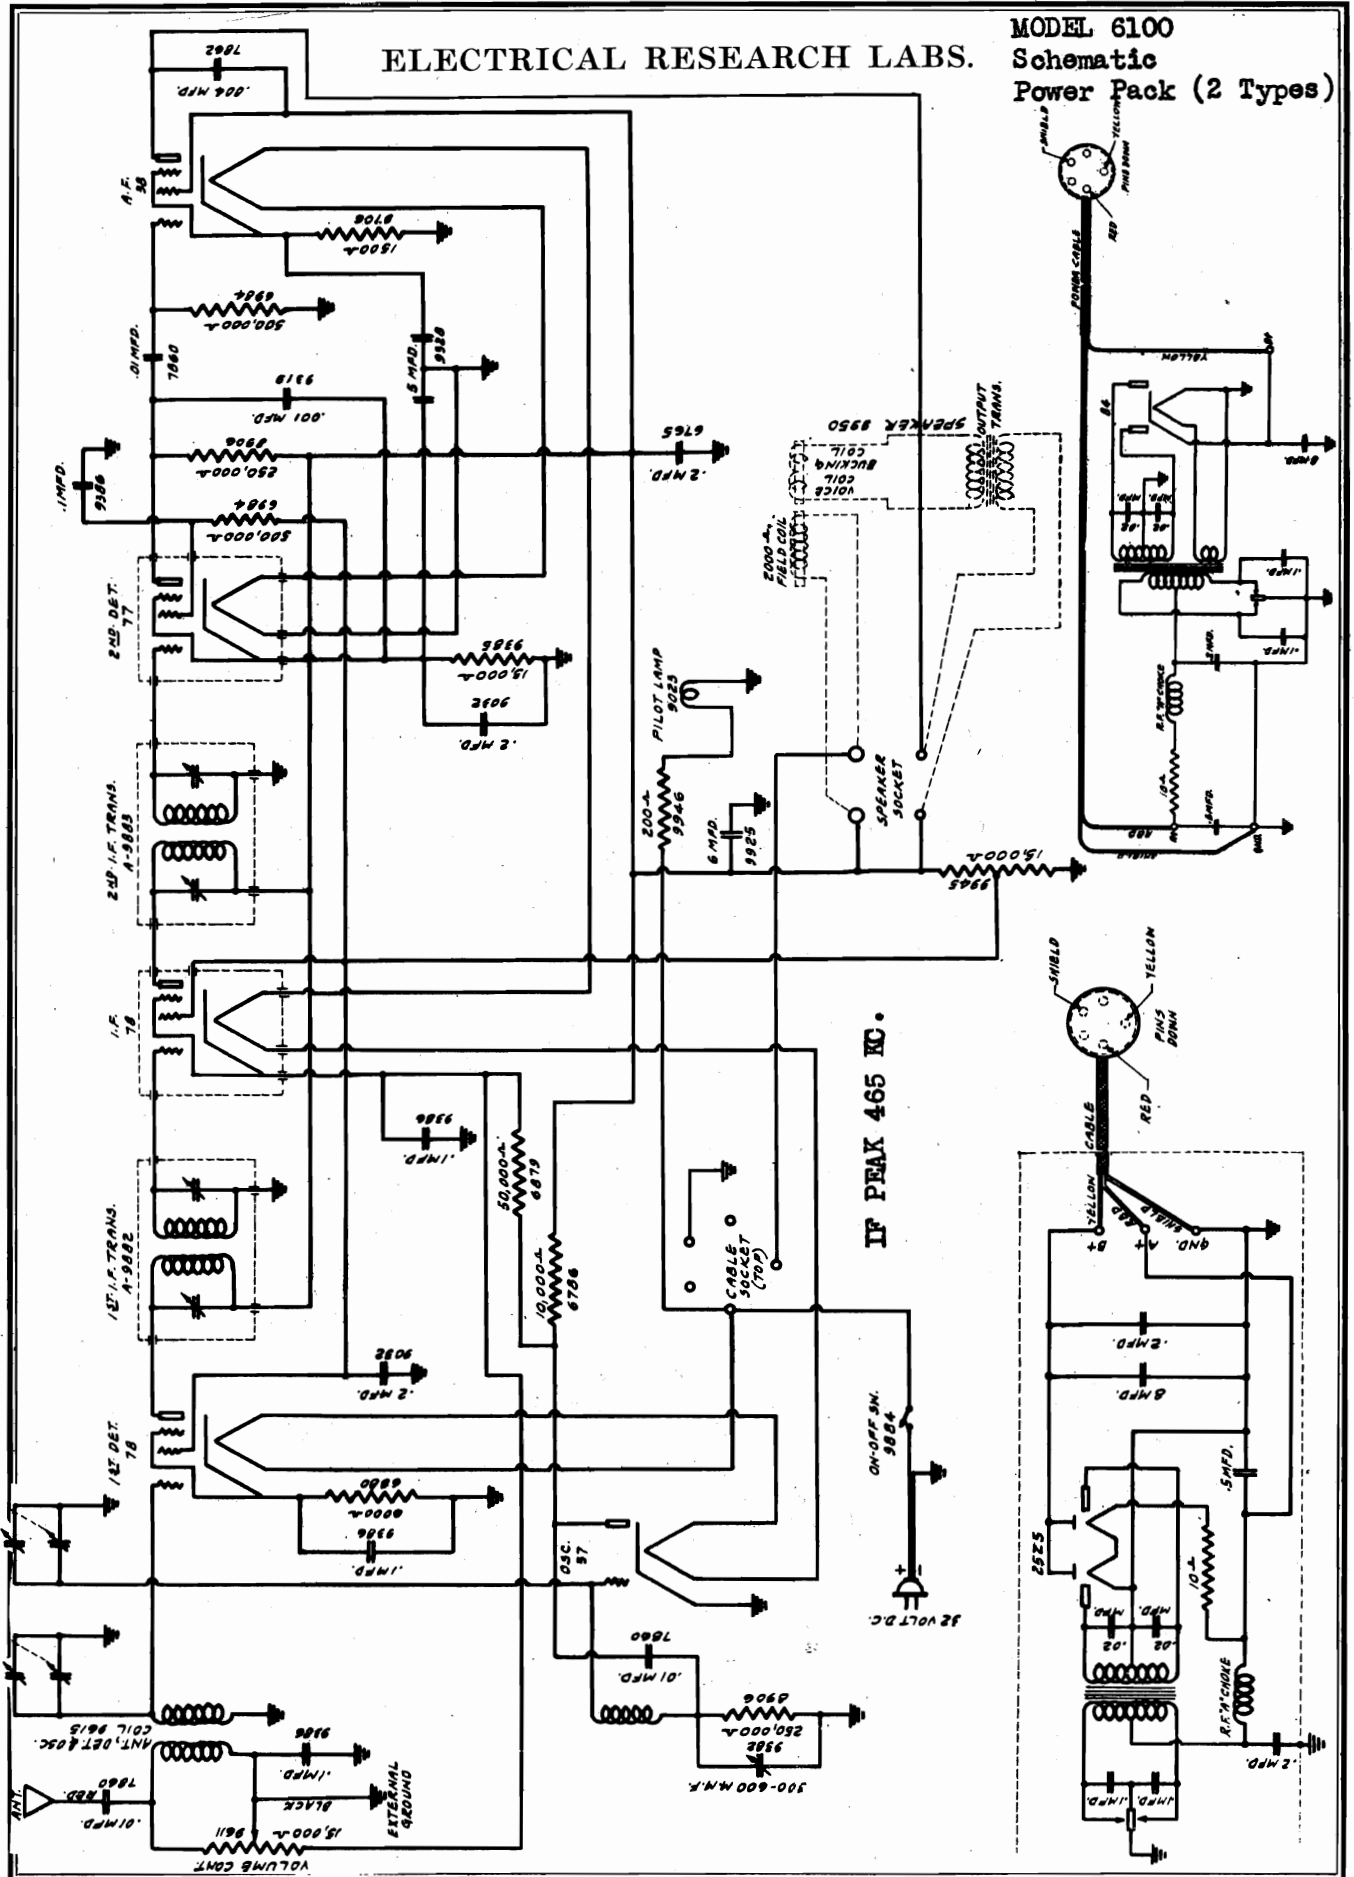

exactly 1400 kilocycles and tune the receiver dial to 1400 kilocycles. BRING IN THIS 1400 KILOCYCLE SIGNAL BY ADJUSTING THE SMALL TRIMMER CONDENSER which is located underneath near the center and towards the front of the chassis.

5. Next adjust the antenna variable gang condenser section trimmer condenser for maximum output (front section).
6. Leave the receiver operating on the same band and set the oscillator frequency to approximately 600 kilocycles and adjust the dial to approximately 600 kilocycles. Then while rocking the variable condenser slightly to the right and left, adjust the 600 kilocycle padding condenser which is located below the speaker and accessible through the front of the chassis for maximum output.
7. Recheck the 1400 kilocycle adjustment.
8. Place the band selector switch for operation on the 16 to 5.2 megacycle band and tune the dial to exactly 15 megacycles and set the oscillator frequency to 15 megacycles. Then adjust the trimmer condenser which is located underneath and toward the center of the right hand side of the chassis for maximum output.

This completes the alignment procedure and it is suggested that all the adjustments be rechecked.

 Read voltage from socket to receiver chassis.

32 VOLT SIX TUBE SUPERHETERODYNE RECEIVER.

This receiver is designed to operate on 32 volt battery plants only and must not be used on 36 volt battery plants without a voltage regulator. Generally, it is not advisable to operate the receiver while the generator is charging the battery due to the fact that considerable radio interference (static noise) may be encountered. This is not a reflection on the receiver, but is due to interference caused by the power plant generator, itself. Some generators have built-in traps to eliminate this interference and when so constructed this particular type of plant generator will not cause interference. If excessive static noise is encountered be sure that it is not caused by the 32 volt plant generator.

THIRTY-TWO VOLT POWER UNIT: Two power units have been furnished with the six tube 32 volt receiver, one unit utilizes a 25Z5 tube and the other an 84 tube. Diagrams for both of these units are shown on the receiver circuit diagram. It will be noted from the parts and price list that all parts with the exception of the power transformer and tube sockets are interchangeable. When ordering these parts be sure to order by part number.

NOTE: The dynamotor type unit supplied with the five tube 32 volt receiver cannot be used with the six tube receiver nor can the power units (utilizing the 84 or 25Z5 tube) furnished with the six tube receiver be used with the five tube 32 volt set.

The 32 volt power unit is shipped unmounted and must be placed in the sound-proof celotex compartment. In the console models this is located below the receiver mounting board and in the table models it is located above the chassis. To install the power unit in the sound-proof box remove the wood screws which hold the celotex back to the box, then place the power unit on the rubber mounting blocks provided inside of this box so that the unit is floating free on these rubber insulators. It is very important that the unit does not touch the side of the box. If excessive vibration is noticed be sure to check the power unit installation, as excessive vibration will result if it is not properly mounted on all of the rubber supports or if it is permitted to touch the side of the celotex housing.

PILOT LIGHT: A type T-3 $\frac{1}{2}$ #40 6.3 volt pilot light is used. The pilot light is readily accessible for removal from the rear of the cabinet.

ANTENNA AND GROUND: Under ordinary conditions an aerial from twenty-five to seventy-five feet in length including lead-in will prove ample. In some locations which are located a considerable distance from broadcast stations it may be necessary to use a longer aerial than this to obtain satisfactory daylight reception. Never place the aerial lead-in in close proximity to the 32 volt lighting lines, as considerable static noise may be picked up if the antenna lead-in is run parallel to the 32 volt power lines for any distance.

INTERMEDIATE ALIGNMENT: Only when an intermediate transformer has become defective due to an open or burned out winding should it be necessary to readjust the intermediate transformer. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device. To align the intermediate transformer:

1. Connect the high side of the oscillator output to the control grid of the #36 modulator tube. The ground side of the oscillator should be connected to the ground lead.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the intermediate transformer trimmer screws up and down until maximum reading is obtained on the output meter. Then adjust the other trimmer screw in the same manner.
4. The second I. F. transformer should next be adjusted in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

To align the variable condenser:

1. Connect the high output side of the oscillator to the set antenna lead and the ground side of the oscillator to the ground lead.
2. Tune the receiver to 1400 kilocycles on the dial and set the oscillator to this frequency.
3. Adjust the variable condenser trimmer screws for maximum output reading.
4. Tune the set to approximately 600 kilocycles on the dial and adjust the oscillator frequency to 600 kilocycles. Adjust the padding condenser located on the rear of the chassis adjacent to the antenna and ground leads and accessible through the hole in the chassis for maximum output reading.

When making this adjustment be sure to rock the variable condenser to the right and left using the position where the greatest reading is obtained.

ELECTRICAL RESEARCH LABS.

Alignment, Voltage

SHORT WAVE TRIMMER: A short wave trimmer control is incorporated in the receiver and is used for a fine tuning adjustment when tuning for short wave reception from 1.5 megacycles to 24 megacycles. The band selector switch knob consists of two sections. The small front section knob is used for adjusting the short wave trimmer and the large rear section is the band selector switch knob. When tuning for short wave reception always rotate the tuning control slowly until a station is heard with maximum volume. Don't hurriedly skim over the dial or pass up any weak signals. After adjusting the tuning control so as to bring the station in at its loudest point adjust the short wave trimmer control by turning the trimmer knob first in the clockwise and then in the counter-clockwise direction to the position of greatest volume. Occasionally after tuning in this manner still better results may be obtained by readjusting the tuning control, and then further fine adjustment should be made with the short wave trimmer for maximum volume. It may be found that when adjusting the short wave trimmer that the signal will disappear, indicated by the elimination of signal, static and background noises. Rotating the short wave trimmer control slightly either clockwise or counter-clockwise will bring the signal in again. When operating the receiver on the broadcast band (1500 K.C. to 540 K.C.) the trimmer is inoperative.

Triode Plate. Comparative voltage only. The voltmeter is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis unless otherwise specified.

ALIGNMENT PROCEDURE: Only when an antenna, oscillator or I. F. transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 First Detector tube, leaving the grid clip disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter, then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.
4. The second and third I. F. transformers should next be adjusted in the same manner as the first I.F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the variable condenser and padding condensers to follow the procedure given carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.
2. Place the band selector switch for operation on the 1.5 to 4 megacycle band. Tune the receiver to exactly 1.7 megacycles on the dial, set the short wave trimmer about half the distance between maximum clockwise and counter-clockwise rotation and adjust the oscillator frequency to exactly 1.7 megacycles.

Next, bring this 1.7 megacycle signal in to maximum output by adjusting the padding condenser accessible through the hole in the right hand side and closest to the rear of the chassis.

3. Leave the band selector switch for operation on the 1.5 to 4 megacycle band and tune the receiver to exactly 3.4 megacycles on the dial.

Next, set the test oscillator to exactly 3.4 megacycles and tune the signal in by adjusting the oscillator variable condenser trimmer mounted on top of the variable condenser. The middle section of the variable condenser is the oscillator section. Recheck the 1.7 megacycle adjustment after making the adjustment at 4 megacycles. For best results it is always advisable to check each adjustment several times. **NOTE:** This completes the short wave adjustment.

4. Adjust the band selector switch for operation on the broadcast band (1500 to 540 kilocycles) and tune the receiver to exactly 1400 kilocycles on the dial and set the oscillator to this frequency. Turn the receiver on end and bring this 1400 kilocycle signal in to maximum output by adjusting the trimmer screw on the small trimmer, which is located adjacent to the short wave switch underneath the chassis.

Next, adjust the antenna and preselector variable condenser section trimmers mounted on top of the variable condenser for maximum signal output. (These are the front and rear gang sections).

5. Leave the band selector switch for operation on the broadcast band (1500 to 540 kilocycles) and tune the receiver and oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser which is located on the right hand side and towards the front of the chassis for maximum output reading. This adjustment is quite critical and it is necessary to rock the condenser slightly to the right and left to obtain maximum sensitivity.

Always recheck the 1400 kilocycle alignment after making the adjustment at 600 kilocycles.

MODEL 6300,6315

Parts List,Notes

ELECTRICAL RESEARCH LABS.

SIX TUBE SUPERHETERODYNE RECEIVER
24 Megacycles to 540 Kilocycles

- Band No. 1 - from 10 Megacycles to 24 Megacycles
- Band No. 2 - from 4 Megacycles to 10 Megacycles
- Band No. 3 - from 1.5 Megacycles to 4 Megacycles
- Band No. 4 - from 1500 Kilocycles to 540 Kilocycles

Selection of the desired frequency band is made with the band selector switch knob (large rear knob of double knob) which is located on the lower right front of the cabinet below the tuning control knob. When the band selector switch is placed in the maximum left hand position the receiver is operating on Band No. 1, 10 megacycles to 24 megacycles. Rotating the band selector knob in the clockwise direction the three other positions are in the order named, Band No. 2, 4 megacycles to 10 megacycles, Band No. 3, 1.5 to 4 megacycles and Band No. 4, 1500 kilocycles to 540 kilocycles. All four frequency bands are calibrated on a single dial. The calibrated section of the dial for the band that the receiver is adjusted to operate on is indicated by the dial indicator which is automatically adjusted by the band selector switch knob.

SHORT WAVE RECEPTION: The usual careless tuning that is sufficient to bring in the long wave length regular broadcast stations will fail in tuning in short wave reception. In tuning for short wave stations, great care must be taken so that the stations are not passed over, as the tuning is very sharp and quite critical. Many times a lack of results when tuning for short wave stations is due not only to the operator tuning the receiver incorrectly, but also to the operator trying to pick up foreign and North American short wave stations when the stations are not broadcasting. An important consideration is the time difference between the United States and European Countries; i.e., at 10:00 P.M. Central Standard Time it is 4:00 A. M. in England and 5:00 A. M. in most other countries in Europe and, as a rule, no stations are broadcasting at that time. While short wave reception presents a varied and more thrilling entertainment than we have been accustomed to hearing on the broadcast band, the many peculiarities and difficulties of short wave reception have been minimized and the possibilities over-emphasized, which has resulted in the erroneous belief that reception of foreign short wave stations is an easy accomplishment. To the contrary, short wave stations are not tuned in with the ease we have been accustomed to in tuning in local broadcast stations, but requires patience, extreme care in tuning, an understanding of the proper procedure and favorable conditions. Reception of short wave stations, as a rule, is not comparable to the clear, static-free programs received from the local broadcast stations, but is more erratic and is generally accompanied by fading and static although occasionally reception may be as good as local programs.

Reception of short wave stations varies from season to season and between daylight and after sunset.

Band No. 4 (regular broadcast band) from 1500 to 540 kilocycles varies also in that the range of the station is materially increased after dark and fading of distant stations becomes more pronounced. In some locations stations that are received during daylight occasionally fade so badly after sundown that it is impossible to receive good reception after dark. Other stations which cannot be heard during daylight provide good reception after darkness.

Band No. 3, 1.5 to 4.0 megacycles permits reception of police calls and some amateur phone stations. The range of the stations broadcast within this band is increased after sundown.

Band No. 2 from 10.0 to 4.0 megacycles includes the 49 meter band, the 31 meter band and some amateur stations. Stations broadcast within this band include many of the foreign short wave stations and North American Stations. Reception of stations transmitting on the 49 meter band is most reliable during the Summer months when located approximately 300 miles or more during daylight which increases to 1,500 miles or more when a large portion of the signal path lies in darkness. The Winter range is approximately 600 miles during daylight and 2,000 miles or more after sundown. Stations operating on the 31 meter band are most reliable when the receiver is located about 800 miles away during daylight in the Summer months increasing to 2,500 miles after sundown.

Band No. 1, from 24 megacycles to 10.0 megacycles includes the 25, 19 and 16 meter bands. Reception of stations in the 25 meter band is best during daylight when the receiver and transmitter are located 1,000 miles or less than 2,000 miles apart. After sundown reception may be expected only from stations located a distance of 2,000 miles or more away from the receiver. Stations operating on the 19 meter band provide satisfactory reception generally during daylight hours only. After nightfall or when any appreciable portion of the transmission path is in darkness signals are rarely heard. Stations operating below 19 meters are generally useful only when transmitting during daylight and over a distance of 2,000 miles or more. Ordinarily they cannot be received after sunset.

PART NO. 7700

SERVICE NOTES
for the
BATTERY OPERATED
SEVEN TUBE SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE: For properly aligning either the intermediate transformer or the gang condenser it is necessary that an accurately calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 106 tube leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the first intermediate transformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter, and then adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the second intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning to follow the procedure carefully, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the receiver antenna lead and the ground to the chassis.
2. Place the band selector switch for operation on the short wave band, tune the receiver to exactly 15 megacycles on the dial and set the test oscillator frequency to exactly 15 megacycles. THEN TUNE IN THE 15 MEGACYCLE SIGNAL BY ADJUSTING THE TRIMMER MOUNTED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER TO MAXIMUM OUTPUT.

Looking at the front of the receiver the oscillator section is the rear section of the gang condenser.

3. Set the band selector switch for operation on the broadcast band, adjust the test oscillator frequency to 1400 kilocycles and set the receiver dial to exactly 1400 kilocycles. NEXT, BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED UNDERNEATH AND NEAR THE CENTER FRONT OF THE CHASSIS.
4. After making this adjustment tune the dial to 1720 kilocycles and set the oscillator frequency to 1720 kilocycles. If the 1720 kilocycle signal cannot be received reduce the 1400 kilocycle trimmer capacity until the 1720 kilocycle signal is brought in.
5. Next, set the receiver dial and test oscillator to exactly 1400 kilocycles, and adjust the trimmer located on the front section of the gang condenser for maximum sensitivity.

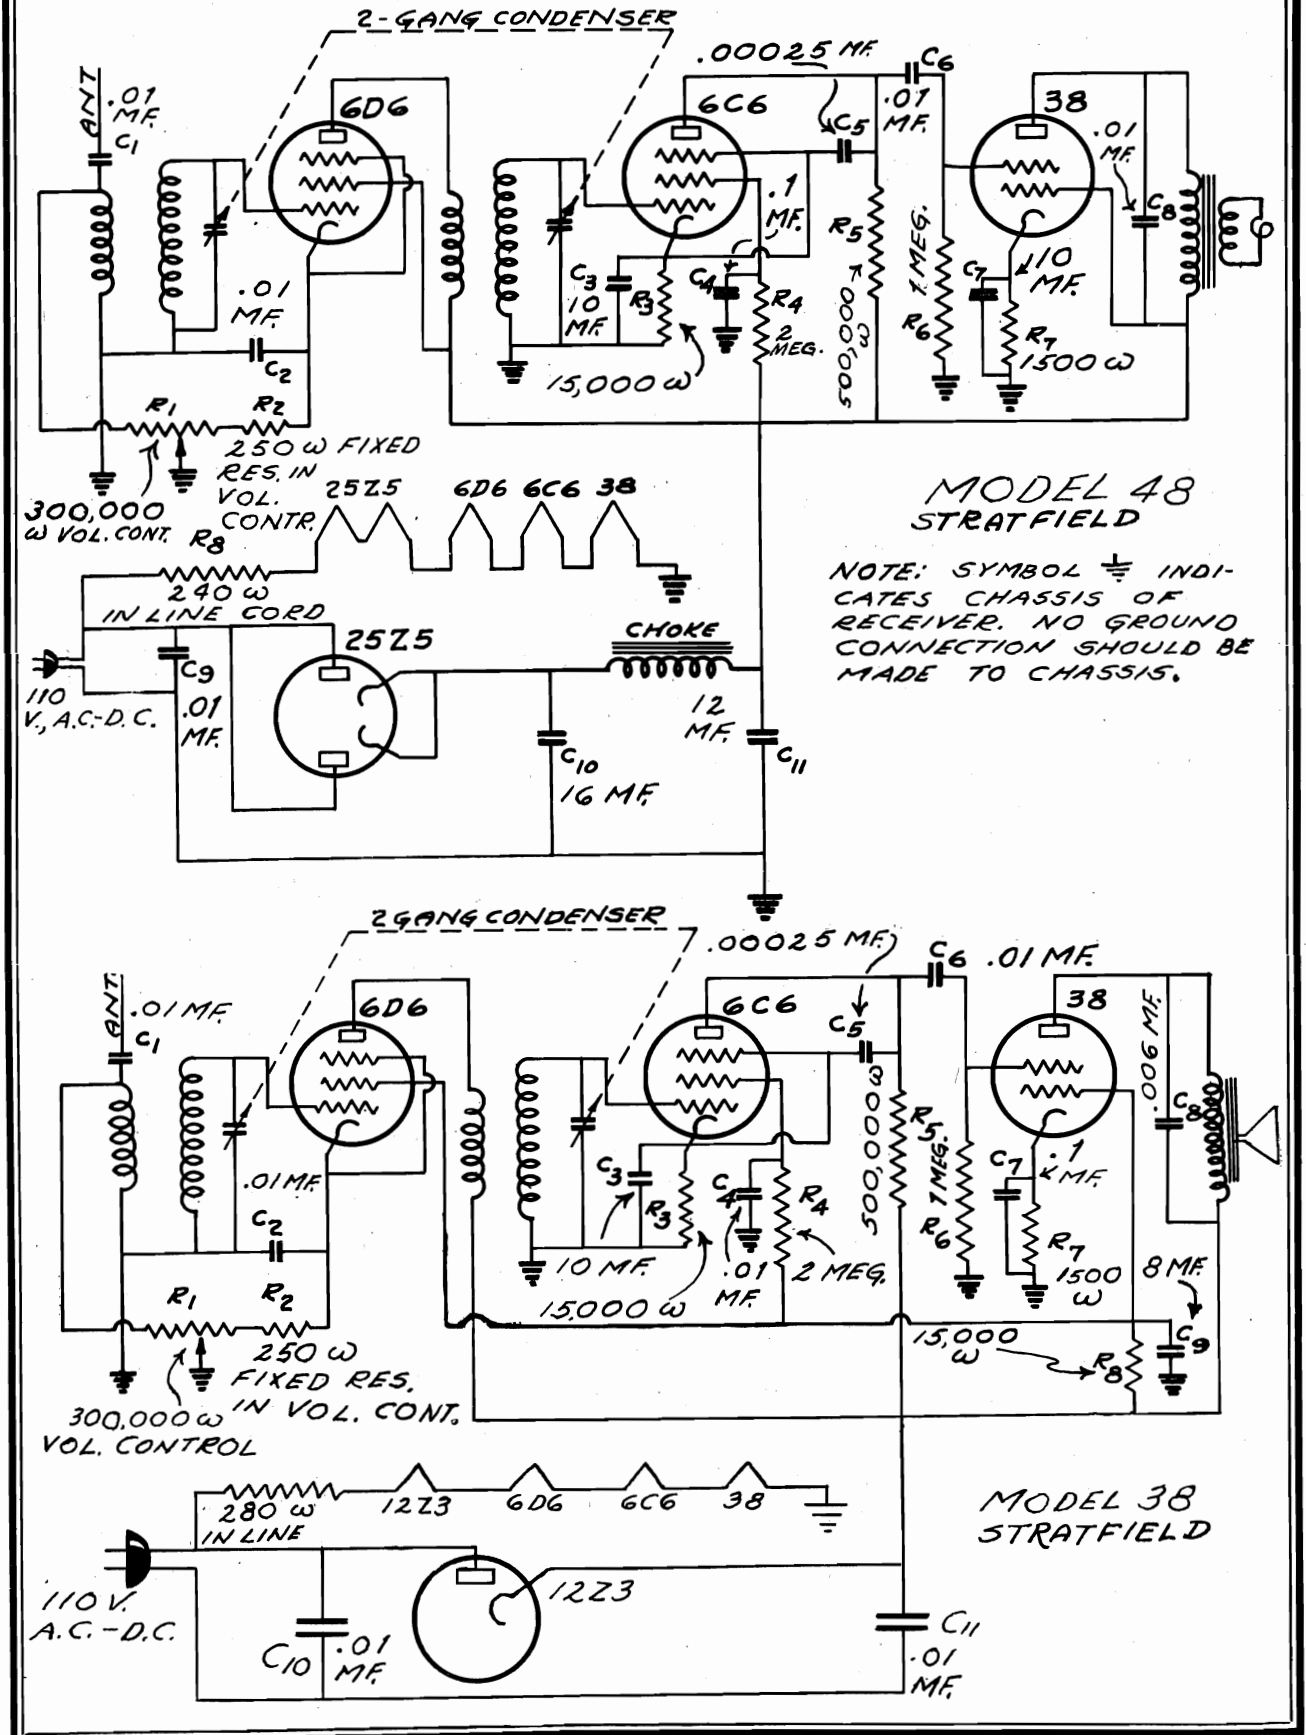

6. Leave the band selector switch for operation on the broadcast band, tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser, which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity. As this adjustment is quite critical it is necessary to rock the condenser slightly to the right and left to find the point of greatest sensitivity.

7. Place the band selector switch for operation on the short wave band, adjust the test oscillator frequency to exactly 15 megacycles and set the receiver dial to 15 megacycles. Turn the receiver on its back with the dial up and adjust the trimmer, which is mounted on the top of the coil underneath and near the right hand side of the chassis, for maximum output. Be sure to rock the condenser slightly to the right and left when making this adjustment.

This completes the alignment procedure. It is recommended that all of the adjustments be gone over again. Generally it will be found that improved results can be obtained if this is done.

Voltage Readings:

For the convenience of servicemen, a table giving the voltage readings for this receiver is included in these instructions. Readings should be taken with the volume control turned on fully (all the way to the right) and a high resistance voltmeter (1000 ohms per volt) must be used for the d-c measurements. An a-c voltmeter must be used on the a-c circuits. D-c voltages measured from point indicated to ground.

Tube	Plate	Anode Grid	Control Grid	Osc. Grid	Screen Grid	Suppressors	Cathode
6A7	214	214	—	—	62	—	2
77	70	—	—	—	62	4	4
42	194	—	*-13	—	215	—	—
80	—	—	—	—	—	—	—

*Measured from ground to tap on speaker field winding.

Voltage across field—100 volts d-c.

Voltage across 80 filament—5 volts a-c.

Voltage across all other filaments or heaters—6.2 volts a-c.

The above voltages, with slight variations, should be obtained with an a-c input line voltage of 117.5.

MODEL 38,42 (U-6-D)
Parts List, Alignment EMERSON RADIO AND PHONOGRAPH CORPORATION

Alignment procedure:

1. Short circuit oscillator stator of the variable condenser to ground.
2. Introduce the 456 kc signal on the grid of the 6D6 i-f tube.
3. Adjust the single tuned i-f transformer for maximum response on the output meter.
4. Remove the 456 kc signal from the 6D6 grid and put it on the 6A7 grid.
5. Adjust both trimmers on first i-f transformer for maximum response.
6. Remove 456 kc signal from 6A7 grid.
7. Remove the short circuit from the stator of the oscillator section of the gang condenser.
8. Set the range changing switch to the broadcast band.
9. Make sure that the needle on the dial reaches its extreme position at both ends of the broadcast band when the gang condenser is at maximum and minimum. If the needle does not do this, loosen the set-screw on the hub of the dial and rotate the gang condenser to maximum capacity. Then rotate the needle of the dial (by means of the selector knob) to its extreme position at the 550 kc end of the broadcast band. Tighten the set-screw securely and proceed to realign the set.
10. Set the needle on the dial to 1600 kc.
11. Introduce a 1600 kc signal into the antenna.
12. Adjust oscillator trimmer (the one farthest from the chassis on the oscillator coil) for maximum response.
13. Introduce a 600 kc signal into the antenna. Rock the gang condenser back and forth around the 600 kc dial reading and at the same time adjust the series padding condenser for maximum output. Leave the series padder set to the point of maximum sensitivity. The series padder is on the front of the chassis.
14. Check alignment on 1600 kc.
15. Now throw the range switch to short-wave position and introduce a 15 megacycle (mc) signal into the antenna.
16. Set the dial needle to 15 mc.
17. Adjust oscillator trimmer for maximum output. The short-wave oscillator trimmer is the one nearest the oscillator coil.
18. Connect the antenna to the set and adjust the interstage coil for maximum noise at 15 mc. The interstage coil is the one with only one trimmer on it. Before starting the adjustment turn the trimmer out so as to have minimum capacity and gradually increase it. A peak will be noticed and then as the capacity is increased the noise diminishes and disappears. When the capacity is increased further, the noise may increase again. The peak with the trimmer having less capacity than it has when the noise disappears is the proper peak.

ADJUSTMENTS

This instrument was carefully aligned and adjusted at the factory. *No one but an experienced serviceman should make an attempt at re-aligning the receiver.* If it becomes necessary, the following procedure should be accurately executed: :

A good accurate oscillator should be used with frequencies of 456 k.c., 600 k.c., 1425 k.c., and 15,000 k.c. In addition, an output meter across the voice coil should be used for the precise results necessary.

Alignment procedure:

1. Short circuit oscillator stator of variable condenser to ground.
2. Introduce 456 k.c. on the grid of the 58 tube.
3. Adjust the trimmer on the single tuned i.f. coil for maximum response on the output meter.
4. Adjust the two trimmers on the double tuned i.f. coil following the 58 tube.
5. Remove the oscillator signal from the 58 grid and introduce it on the grid of the 2A7 tube.
6. Adjust the two trimmers on the first i.f. coil.
7. Re-align all i.f. trimmers for maximum response on the output meter.
8. Remove the 456 k.c. signal from the 2A7 grid. It will not be used again.
9. Remove the short circuit from the stator of the oscillator section of the condenser.
10. Rotate the range changing switch to the left for the short-wave range.
11. Make sure that the needle on the dial reaches its extreme position at both ends of the broadcast scale when the condenser is at maximum and minimum. If this condition is not obtained, loosen the set-screw on the hub of the dial and rotate the condenser plates to maximum capacity. Then rotate the needle of the dial (by means of the selector knob) to its extreme position at the 550 k.c. end of the broadcast scale. Tighten the set-screw securely once again and re-alignment may proceed.
12. Set the pointer of the dial to a little above the higher wave length edge of the 19-meter, brown segment, on the dial.
13. Introduce a strong 15,000 k.c. signal into the antenna.
14. Adjust the short-wave oscillator trimmer, (the trimmer nearest the chassis on the oscillator coil), until the signal comes to maximum. Attenuate the signal.
15. Adjust the short-wave antenna trimmer (the one on the free end of the antenna coil) until the signal again comes to maximum. When these conditions are fulfilled the receiver is aligned on the short-wave range. Remove the 15,000 k.c. signal from the antenna.
16. Rotate the range switch to the right (broadcast position) and set the pointer of the dial to 1425.
17. Introduce the 1425 k.c. signal into the antenna. Adjust the oscillator trimmer (the trimmer on the oscillator coil, furthest from the edge of the chassis) for maximum response. Attenuate this signal.
18. Adjust the broadcast antenna trimmer for maximum response (the trimmer on the end of the antenna coil closest to the chassis). Remove the 1425 k.c. signal from the antenna.
19. Introduce 600 k.c. into the antenna. Rock the gang condenser back and forth around the 600 k.c. dial reading, and at the same time, adjust the series padding condenser for maximum output. Leave the series padder set to the point of maximum sensitivity. (Series padder is on side of oscillator coil can). Broadcast alignment is now complete.

MODEL 45 (6BD)

**Alignment
Voltage**

**EMERSON RADIO AND PHONOGRAPH
CORPORATION**

1. Short circuit oscillator stator of the variable condenser to ground.
2. Introduce the 456 kc signal on the grid of the 6D6 I-f tube.
3. Adjust both trimmers of the second stage I-f transformer for maximum response on the output meter.
4. Remove the 456 kc signal from the 6D6 grid and put it on the 6A7 grid.
5. Adjust both trimmers on first I-f transformer for maximum response.
6. Remove 456 kc signal from 6A7 grid.
7. Remove the short circuit from the stator of the oscillator section of the gang condenser.
8. Set the range changing switch to the broadcast band.
9. Make sure that the needle on the dial reaches its extreme position at both ends of the broadcast band when the gang condenser is at maximum and minimum. If the needle does not do this, loosen the set-screw on the hub of the dial and rotate the gang condenser to maximum capacity. Then rotate the needle of the dial (by means of the selector knob) to its extreme position at the 550 kc end of the broadcast band. Tighten the set-screw securely and proceed to re-align the set.
10. Introduce a 1600 kc signal into the antenna.
11. Rock the gang condenser back and forth around the unmarked cardinal division at the bottom of the high frequency end of the dial and at the same time adjust oscillator trimmer (the one farthest from the chassis on the oscillator coil) for maximum response.
12. Introduce a 600 kc signal into the antenna. Rock the gang condenser back and forth around the 600 kc dial reading and at the same time adjust the series padding condenser for maximum output. Leave the series padder set to the point of maximum sensitivity. The series padder is on the front of the chassis.
13. Check alignment on 1600 kc.
14. Now throw the range switch to short-wave position and introduce a 15 megacycle (mc) signal into the antenna.
15. Set the dial needle to 15 mc.
16. Adjust oscillator trimmer for maximum output. The short-wave oscillator trimmer is the one nearest the chassis on the oscillator coil.
17. Connect the antenna to the set and adjust the interstage coil for maximum noise at 15 mc. The interstage coil is the one with only one trimmer on it. Before starting the adjustment turn the trimmer out so as to have minimum capacity and gradually increase it. A peak will be noticed and then as the capacity is increased the noise diminishes and disappears. When the capacity is increased further, the noise may increase again. The peak with the trimmer having less capacity than it has when the noise disappears is the proper peak.

Voltage Analysis:

Readings should be taken with a 1000 ohms per volt meter.

Voltages listed below are from the point indicated to ground. With volume control on full.

	<i>Plate</i>	<i>Screen</i>	<i>Suppressor</i>	<i>Cathode</i>
6D6 R-f.	100	45	3.0	3.0
6A7 Oscillator-Modulator	100	50	—	3.0
6D6 I-f.	250	80	4.0	4.0
75 A-f.	85	—	—	1.5
42 Output	230	250	—	0

The pilot lights used are Mazda No. 40, 6-8 volts and .15 ampere.

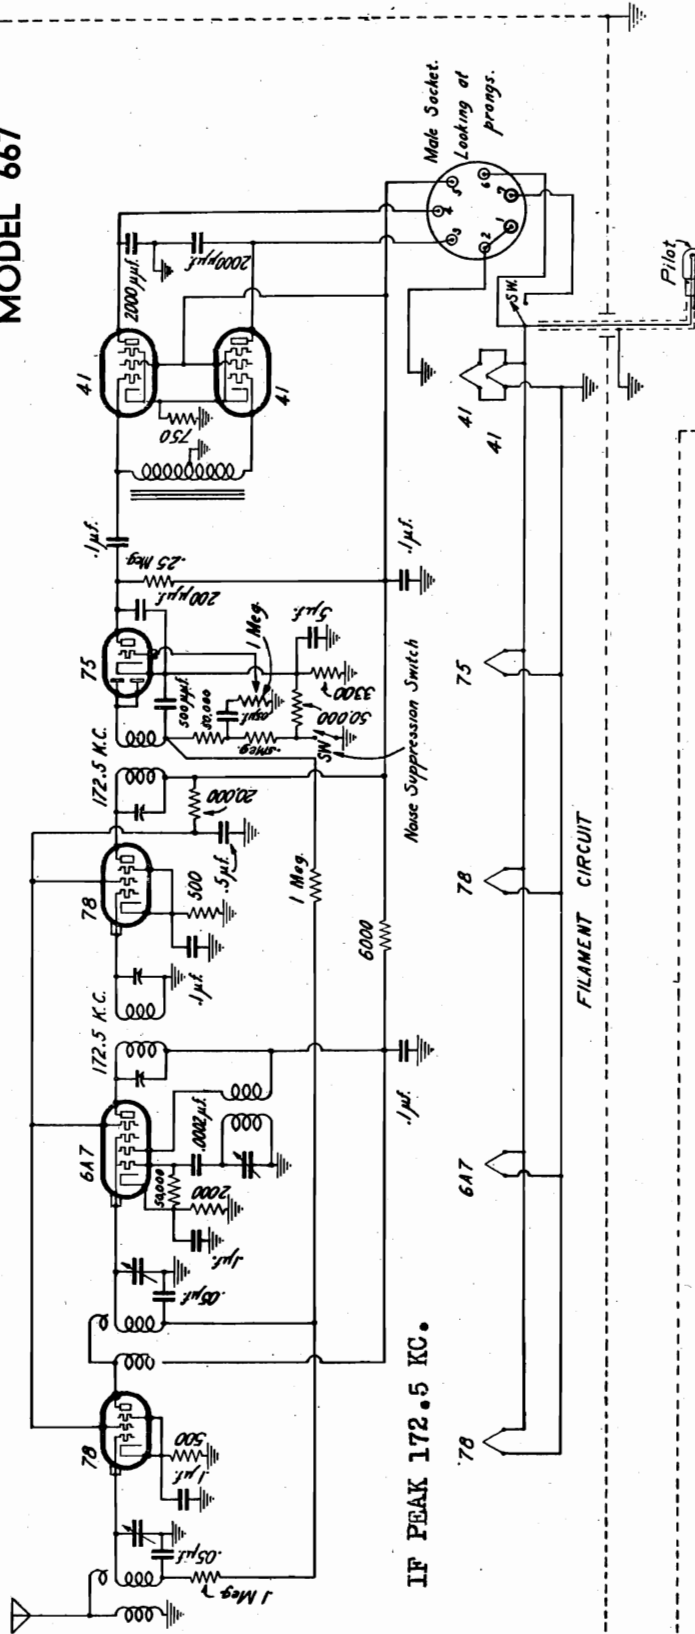

Voltage across field 100 volts. Line voltage—117.5 volts a.c.

**Voltage, Alignment
Installation Data**

**EMERSON RADIO AND PHONOGRAPH
CORPORATION**

After unpacking the receiver and before starting to install it, a careful check of the parts furnished should be made.

The following is a list of the items:

1. The receiver proper, complete with six tubes in their places inside, and with front cover intact.
2. Receiver mounting bracket with plate, nut, and lockwasher.
3. Remote control head.
4. Two drive cables.
5. Speaker-eliminator complete with vibrator, tube, mounting bracket, battery cable and receiver connector cable with plug.
6. One distributor suppressor.
7. Six spark plug suppressors.
8. One generator condenser.
9. One ammeter condenser.
10. Four screws and four lock washers for securing bracket to receiver.
11. Two bolts, two nuts and two lockwashers for mounting speaker.

Make a general examination of the receiver. See that the tubes are pushed down in their sockets and that the grid caps are in place on the proper tubes. In order to do this it will be necessary to remove the top nuts from the front cover plate and slide the receiver out of its housing by pulling out on the cover plate.

Mounting the receiver—while the receiver may be mounted in any available location, three recommended positions are listed below—

1. Mounted so that the control cables face right.
2. Mounted so that the control cables face front.
3. Mounted so that the control cables face left.

Positions 2 and 3 will be found best for most cars. It should be borne in mind that the controls will operate more smoothly if the cables are bent as little as possible. Select a position for the receiver that will allow the cables to fall in an easy sweep. There should be no sharp bends or kinks.

Hold the receiver up against the dash in the desired location with the cables in the direction chosen. Mark around it with a pencil, and in the center of the area bounded by the pencil lines drill a $\frac{1}{8}$ " hole through the dash.

Mount the bracket on the receiver using the four screws and lockwashers. Put a lockwasher under the head of each screw and insert the screws through the bracket holes and into the tapped holes in the case. Screw up tightly.

Now lift the receiver into place, pushing the bracket bolt through the hole in the dash. On the engine side of the dash put the mounting plate on the bolt, then the lockwasher and nut. After making certain that the receiver is straight, tighten the nut securely.

Mount the control head on the steering column and connect the cables to control head, following instructions given on the red tag.

To attach the control cables to the receiver insert the free end of the right hand cable into the upper chuck on the receiver. Push the cable in tightly while turning the right hand knob back and forth until the tongue on the drive cable engages with the slot in the condenser shaft. While holding the cable in place tighten the set screw in the chuck enough to prevent turning or withdrawal of the cable housing. If the set screws are too tight the cables will bind.

Proceed in the same manner to connect the other drive cable, inserting the key or key knob into the key hole at the left on the control head, and turning back and forth as before. On turning all the way to the left, the switch will snap to the "off" position.

Connect the pilot light leads to the control head, the black wire going to the insulated post.

Tie the control cables and pilot light lead to the steering column and the dash, using friction tape. Do this at as many points as is necessary to prevent swaging and vibration, always bearing in mind the fact that smooth operation of the controls depends on the manner in which the cables are run.

Now line up the dial pointer, following the instructions furnished on the red tag.

Install the speaker in any convenient location that the length of cable will allow. Drill two $\frac{3}{8}$ " holes and mount the bracket, using the $\frac{3}{8}$ " bolts.

Two cables extend from the speaker. On one of these cables is the female end of a detachable six prong plug, the male end of which is on the receiver. Connect the speaker to the receiver by means of this plug, observing that the two large pins on the male half of the plug engage with the two large holes in the female half of the plug. Do not try to force the plug together in any other manner.

A 10 ampere fuse is located in a small tubular holder in the battery lead. To replace the fuse, remove the cap, insert the fuse and replace the cap. The fuse is intended to protect the receiver, and in no case should one larger than 10 amperes be used.

The other cable terminates in a clip, designed for connection to the ammeter binding post. Before attaching this clip the remote control should be tested. See that the knob for the volume control and switch operates properly. When turned all the way to the left the switch should be heard to snap to the "off" position. On turning the knob to the right the switch first snaps on and then operates as the volume control.

The clip on the battery cable may now be attached. Squeeze the sides of the clip together so that the holes are in line, then push it over the battery post of the ammeter and release. If uncertain as to which post is on the battery side of the ammeter, connect the clip to either post and switch on the set by turning the left hand control knob to the right. The dial will immediately light up. Now notice the reading on the ammeter as the set is turned on and off. If when the set is on the ammeter shows discharge, turn off the set and move the clip to the other post.

At this point the antenna should be connected. Proceed as follows:

Assuming that the car is already equipped with a suitable antenna, see that the lead-in is shielded and kept away from the motor compartment and high tension ignition wires.

Check the antenna for a possible ground and if found satisfactory connect it to the inner wire extending through and beyond the shield of the antenna lead on the receiver. Be careful to make a good splice, soldering if possible. Make the splice close enough to both shields so that the portion of wire left unshielded will be short.

Cover the splice with several layers of friction tape and then connect both shields together, again soldering if possible. Ground the shield at one or more points to the dash or car body.

For installations in cars not equipped with built-in antennae, see the instructions given under "Antenna".

The installation of the receiver may now be considered complete, provided all the foregoing instructions were faithfully carried out. A preliminary test can now be made, after which the suppression of any motor noises that are present may be undertaken.

Intermediate Frequency.

To align the intermediate frequency transformers use a good modulated oscillator set for 172.5 k.c. Set the volume control for maximum volume and short circuit the rear section of the variable condenser.

Connect the oscillator output across the grid of the 6A7 tube and ground. Connect an output meter across the primary of the speaker transformer or across the voice coil. Using the smallest output from the test oscillator that will give a small reading on the meter, adjust the two i.f. transformers for the largest reading obtainable. Use a non-metallic screw driver if possible.

Radio frequency and oscillator stages.

To align the r.f. and oscillator sections, remove the short from the variable condenser, and couple the oscillator through a standard dummy antenna to the antenna lead and ground of the receiver. Set the test oscillator to some frequency between 1350 and 1450 k.c. Set the dial to the frequency selected, following the pointer alignment instructions on the red tag. Adjust the trimmers on the variable condenser, beginning with the oscillator trimmer. Reduce the output of the test oscillator and repeat. In the absence of an oscillator, the r.f. sections may be aligned by tuning in a weak station between 1350 and 1450 k.c. and aligning as before. If an output meter is not available, adjust for maximum volume from the speaker.

Voltage analysis:

Note: All "B" and "C" voltages should be measured on a high resistance voltmeter of 1000 ohms per volt or over. Voltages are measured from the chassis (ground) to the point indicated. Ground the antenna to the shield when taking readings.

Voltage across battery—6 volts scant.

Voltage across speaker field—6 volts scant.

Voltage across all heaters—6 volts scant.

Tube	Plate	Screen	Cathode	Suppressor	Osc. Plate
78 R.f.	135	90	3.5	3.5
6A7	135	90	12.5	140
78 I.f.	180	90	3.	3.
75	75	1.
41	185	192	16.5
41	185	192	16.5

**MODEL 965
Voltage, Alignment**

**EMERSON RADIO AND PHONOGRAPH
CORPORATION**

Tubes and their functions:

1-78	Radio frequency amplifier.	1-75	{ Diode second detector. Audio frequency amplifier. Automatic volume control.
1-6A7	{ Electron coupled oscillator. First detector.	1-41	Output power tube.
1-78	Intermediate frequency amplifier.	1-84	Full-wave rectifier.
		1-	Non-synchronous vibrator inverter.

Voltage Analysis:

Note: All "B" and "C" voltages should be measured on a high resistance voltmeter of 1000 ohms per volt or over.

The voltages are measured to ground from the points named. Ground the antenna to its shield when taking readings.

Battery volts—6. Volts across heaters—6 scant. Volts across speaker field—6 scant.

<i>Tube</i>	<i>Plate</i>	<i>Screen</i>	<i>Cathode</i>	<i>Suppressor</i>	<i>Osc. plate</i>
78	110.....	110.....	6	6	—
6A7	170.....	110.....	6	—.....	170
75	110.....	—.....	1.3.....	—.....	—
78	110.....	110.....	3.5.....	3.5.....	—
41	210.....	220.....	15	—.....	—

If the set fails to operate look for some minor cause which might be one of the following:—

1. No "A" supply—"A" lead to set not making contact with ammeter post. Fuse blown.
2. Low "A" supply—The car battery needs recharging.
3. Tubes not in place in their sockets.
4. Grid caps not in place.
5. Defective tubes.
6. Antenna lead shorted to shield at splice, or otherwise grounded.

A 10-ampere fuse is located in a small tubular holder in the battery lead. To replace the fuse, unscrew the threaded cap, insert the fuse and replace the cap, screwing up firmly. The fuse is intended to protect the receiver and in no case should one larger than 10 amperes be used.

ADJUSTMENTS

Intermediate Transformers

To align the intermediate frequency transformers, use a good modulated oscillator set for 172½ k.c. Set the volume control for maximum volume and turn the dial to a point where little or no signal is received; then ground the antenna.

Connect the oscillator output between the grid of the 6A7 tube and ground. Connect an output meter across the primary of the speaker transformer or across the voice coil. Using the smallest output from the test oscillator that will give a small reading on the meter, adjust the two I.F. transformers for the largest reading obtainable. Use a non-metallic screw driver if possible.

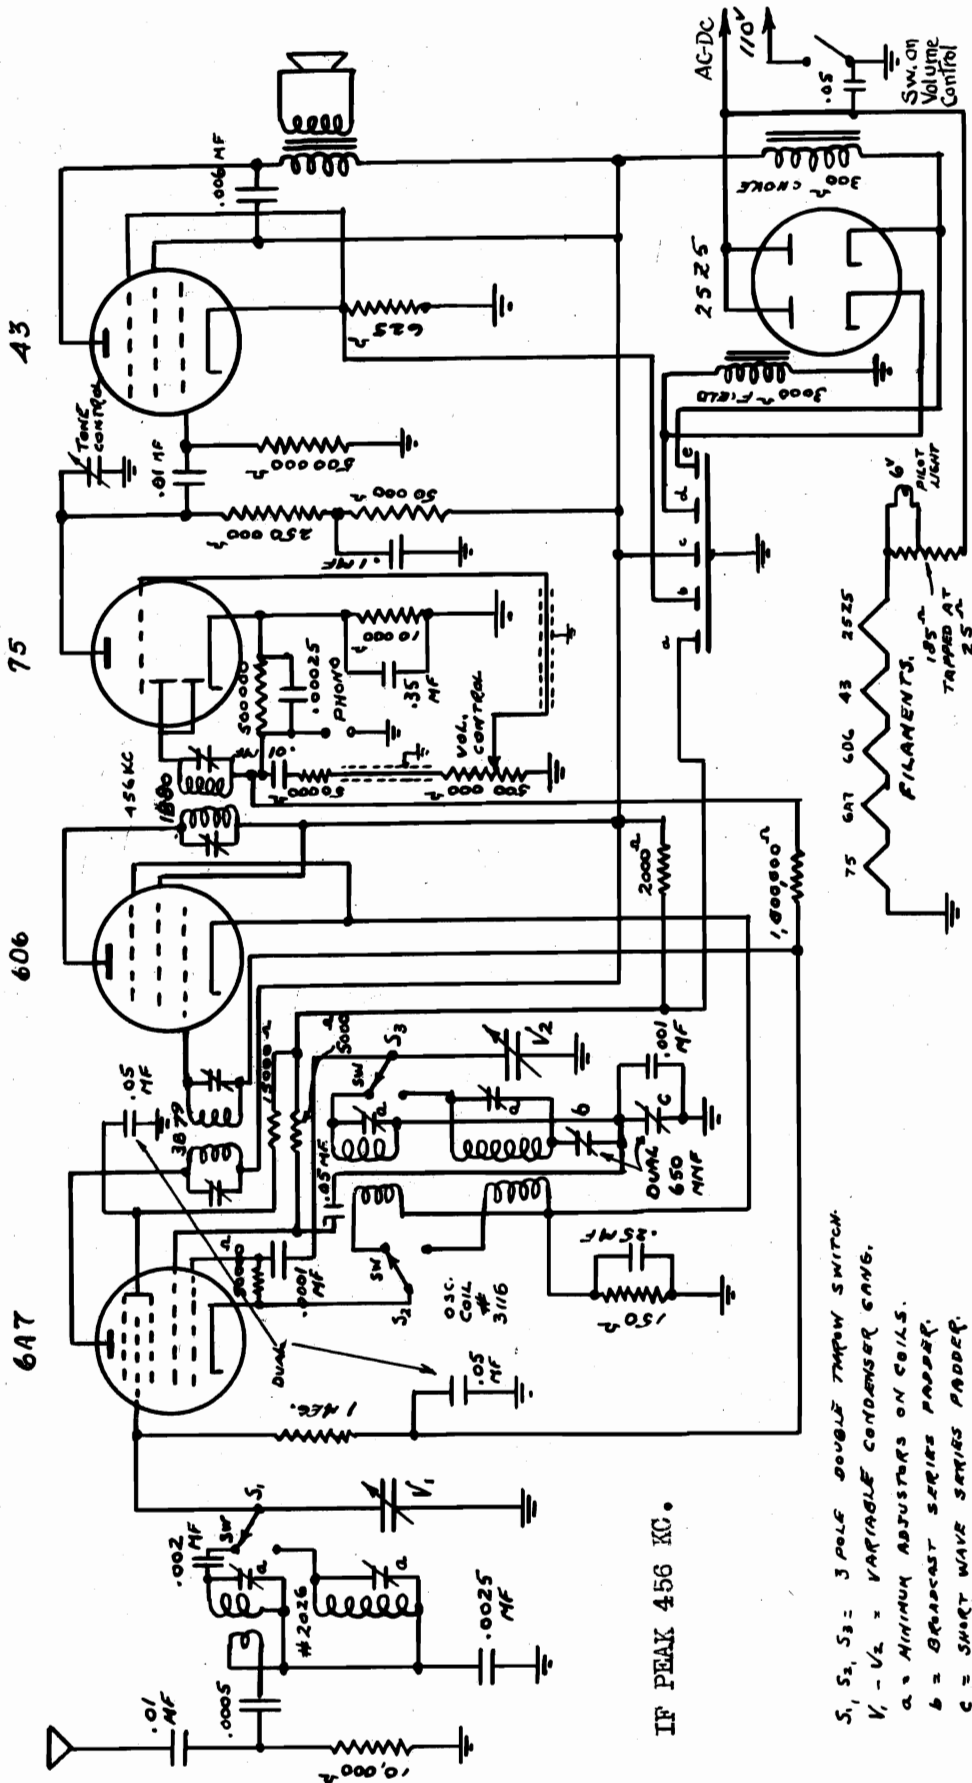

Radio Frequency and Oscillator

To align the R.F. and oscillator sections, couple the oscillator through a standard dummy antenna to the antenna lead and ground of the receiver. Set the test oscillator to some frequency between 1350-1450 k.c. Set the dial to the frequency selected. Adjust trimmers on the variable condenser beginning with the oscillator trimmer. Reduce the output of the test oscillator and repeat. In the absence of an oscillator, the R.F. sections may be aligned on broadcast.

Tune in a weak station between 1350 and 1450 k.c. and align as before. If an output meter is not available, adjust for maximum volume, then reduce the input and repeat.

"RV" CHASSIS (60-25 CYCLES)

NOTE: The wave band switch is to be in the normal wave (550 to 1500 KC) position for the following adjustments.

ADJUSTMENT OF I. F. CONDENSERS

The four (4) I. F. condensers are located as indicated in the sketch.

ADJUSTMENT OF THE GANGED VARIABLE CONDENSER COMPENSATORS

There are three holes (see sketch) in the overall condenser shield housing which permit the insertion of a screw driver for compensating purposes.

- 1st - Place F-37 oscillator tube in socket.
- 2nd - Remove the lead wire which is connected to both the control grid of the first detector tube and to the dummy antenna system of the signal generator. Replace the shield cap on the first detector tube shield.
- 3rd - Connect the antenna (red) wire of the receiver to the dummy antenna system of the signal generator. The ground (slate) wire should remain connected to the ground post of the signal generator.
- 4th - Adjust the carrier frequency output of the signal generator to 1400 KC.
- 5th - Set the calibrated dial of the receiver to read 1400 KC.
- 6th - Starting with the compensator nearest the rear of the receiver, adjust each compensator (as indicated on sketch) in turn for maximum signal output. Do not disturb the setting of the ganged variable condenser during these operations. Leave the volume control on full and regulate the signal output with the attenuator control of the signal generator.

1st - Disconnect the outside antenna system from the receiver.

2nd - Remove the shield cap from the first detector tube shield. Connect a lead wire from the dummy antenna system of the signal generator to the control grid of the first detector tube. Do not disconnect the control grid connector from the tube, nor remove the tube shield. Connect the ground (slate) lead of the receiver to the ground post of the signal generator. In the event that the signal generator being used does not have a dummy antenna system, connect a 250 mmfd. condenser in series with the lead wire.

3rd - Remove the F-37 oscillator tube from the receiver socket.

4th - Place an output meter across the secondary of the receiver output transformer (which is mounted on the speaker) so that the variations in signal output can be noted. Output meters (with a multi-range scale) are generally supplied with good quality commercial signal generators.

5th - Place the signal generator in operation and adjust the frequency output to 265 KC. Regulate the attenuator control so that the output signal is low enough to insure accuracy in adjusting the I. F. condensers of the receiver.

6th - With the aid of a #4 socket wrench, adjust the four (4) I. F. condensers to resonance as indicated by the greatest deflection on the output meter.

ADJUSTMENT OF OSCILLATOR SERIES COMPENSATOR

The oscillator series compensator can be adjusted through the hole near the input push-pull transformer (see sketch)

- 1st - Adjust the carrier frequency output of the signal generator to 800 KC.
- 2nd - Set the calibrated dial of the receiver to read 800 KC.
- 3rd - With the aid of a #4 socket wrench adjust the oscillator series compensator until a maximum output signal is indicated on the output meter. To insure perfect adjustment it is necessary to "rock" the ganged variable condenser in order to follow the maximum signal output.

MODEL 141,141-Z (NA)
Alignment, Trimmers FADA RADIO & ELECTRIC CORP.
Voltage, Socket Layout

COMPENSATING INSTRUCTIONS FOR MODELS 141 & 141-Z
"NA" CHASSIS (60-25 CYCLES)
ADJUSTMENT OF OSCILLATOR SERIES COMPENSATOR

This receiver is equipped with an automatic volume control which necessitates setting the manual volume control of the receiver to its maximum position to ensure accuracy in alignment. To control the signal output of the receiver it will be necessary to use the attenuator control of the signal generator.

ADJUSTMENT OF I.F. CONDENSERS

- The four (4) I.F. condensers are located as indicated in the sketch.
- 1st - Disconnect the outside antenna system from the receiver.
 - 2nd - Connect a lead wire from the dummy antenna system to the control grid of the 6A7 first detector tube. Do not disconnect the control grid connector from the tube nor remove the tube shield. Connect the ground (plate) lead of the receiver to the ground post of the signal generator. In the event that the dummy antenna system does not have a condenser in series with the lead wire.
 - 3rd - Place an output meter across the secondary of the receiver output transformer (which is mounted on the speaker) so that the variations in signal output can be noted. Output meters (with a multi-range scale) are generally supplied with good quality commercial signal generators.
 - 4th - Place the signal generator in operation and adjust the carrier frequency output to 265 KC. Regulate the attenuator control, so that the output signal is low enough to ensure accuracy in adjusting the I.F. condensers of the receiver.
 - 5th - With the aid of a #4 socket wrench, adjust the four (4) I.F. condensers to resonance as indicated by the greatest swing of the needle on the output meter.

ADJUSTMENT OF THE GANGED VARIABLE CONDENSER COMPENSATORS

- The compensators are located at the top of their respective tuning condenser section and can be adjusted with the aid of a screw driver in the order indicated on the attached sketch.
- 1st - Remove the lead wire which is connected to both the control grid of the first detector tube and to the dummy antenna system of the signal generator.
 - 2nd - Connect the antenna (red) wire of the receiver to the dummy antenna system of the signal generator. The ground (plate) wire should remain connected to the ground post of the signal generator.
 - 3rd - Adjust the carrier frequency output of the signal generator to 1400 KC.
 - 4th - Set the calibrated dial of the receiver to read 1400 KC.
 - 5th - Starting with the compensator nearest the rear of the receiver, adjust each compensator (as indicated on sketch) in turn for maximum signal output. Do not disturb the setting of the ganged condenser during these operations. Leave the volume control on full and regulate the signal output with the attenuator control of the signal generator.

The oscillator series compensator can be adjusted through the hole in the right hand side of chassis (see sketch).

- 1st - Adjust the carrier frequency output of the signal generator to 600 KC.
- 2nd - Set the calibrated dial of the receiver to read 600 KC.
- 3rd - With the aid of a #4 socket wrench adjust the oscillator series compensator until a maximum output signal is indicated on the output meter. To insure perfect adjustment it is necessary to "rock" the ganged variable condenser in order to follow the maximum signal output.
- 4th - After the oscillator series compensator is properly adjusted, set the calibrated dial of the receiver to 1400 KC and adjust the signal generator to the same frequency. Then readjust all variable condenser compensators as outlined in the foregoing instructions.

Alignment, Color Code, Notes

MODELS 51, 52, AND 53

THE CIRCUIT

Models 51, 52, and 53 are 5 tube superheterodynes. The circuits are very similar, the only differences being those made necessary in order to cover different wave bands. These sets are in many ways a radical departure from conventional design. Maximum performance with a minimum number of tubes is accomplished thru the use of new multi-purpose tubes and new type, high efficiency, I. F. transformers. Due to the use of a high impedance primary, a litz wire secondary, and a wave trap, very good pre-selection and high gain are obtained in the tuned antenna stage. The antenna circuit is fed into a 2A7 which serves the triple purpose of R. F. amplifier, electron coupled oscillator, and first detector. The I. F. output of this tube is fed into the double tuned, first I. F. transformer and from there into the 58 I. F. amplifier. The output of this tube is fed into the second, double tuned, I. F. transformer. The output of this transformer is fed into the 2A6 where three functions are accomplished. Detection, automatic volume control, and audio amplification. The A. F. output of this tube is resistance coupled to the grid circuit of the 2A5, high gain, output tube from where it is transferred to the loudspeaker. A familiar type 80 rectifier is used in a conventional power supply circuit.

WAVE BANDS

The model 51 chassis is a standard broadcast receiver covering a frequency range of 540 to 1725 kilocycles. The model 52 is a dual band chassis covering frequency ranges of 540 to 1700 kilocycles and 1600 to 3500 kilocycles. The model 53 is a split band chassis covering frequency ranges of 540 to 1725 kilocycles and 5 to 16.5 megacycles.

SUGGESTED SERVICE PROCEDURE

If the set does not operate test all tubes. If no tube tester is available replace the tubes in the set, one by one, with tubes known to be good. A noisy tube cannot always be found by checking in a tube tester, however by sharply tapping each of the tubes in the set the bad tube can usually be located.

If, after replacing any defective tubes, the set is still inoperative follow the instructions given under Resistance and voltage analysis.

ALIGNMENT PROCEDURE

Proper adjustment of the tuned circuits will only be possible thru the use of a good service oscillator and output meter.

The gang condenser plates are properly adjusted in the factory and under no condition should it be necessary to bend them.

All adjustments should be made with the volume control full "on". The wave band switch on models 52 and 53 should be in the broadcast position.

1. Supply a 456 kilocycle signal to the grid of the 2A7 thru a .00005 Mfd. condenser. Carefully adjust both trimmers on the first I. F. transformer. The center screw will peak the grid side and the hexagon nut will peak the plate side. Next adjust the second I. F. transformer in the same manner. Since these adjustments are very critical it is advisable to go back over them to make sure they are correct.

2. Turn the gang condenser until it is fully meshed. The dial should read 540 kilocycles, if it is incorrect loosen the set screw and move the dial until the reading is correct.

3. Supply a 1500 kilocycle signal from the test oscillator to the antenna of the set. Tune the set until the dial reads 1500 kilocycles. Adjust the trimmer on the oscillator section of the gang condenser (front section) until the signal comes in at 1500 on the dial. Adjust the trimmer on the R. F. section, of the gang condenser, for maximum output with minimum input from the service oscillator. Some sets do not have a trimmer on the oscillator section and in this case it will only be necessary to adjust the R. F. trimmer for maximum output with the set tuned to the correct frequency reading.

4. On the model 53 a low frequency padding condenser will be found located on the front of the chassis. To adjust this condenser tune the set and the service oscillator to 600 kilocycles. Adjust the padding condenser for maximum output at the same time tune the set back and forth across the 600 kilocycle signal to make sure the correct peak is obtained.

5. If all adjustments have been carefully made the dial readings will be approximately correct on all frequencies. If not it will be necessary to go over the entire procedure again.

6. On models 51 and 53 it will sometimes be necessary to make high frequency adjustments at 1200 kilocycles rather than 1500 in the event police calls do not come in properly after alignment.

7. On the model 53 a small trimmer condenser will be found under the chassis and connected across the secondary of the short wave R. F. coil. This condenser should be peaked at 16 megacycles. Turn the band selector to the short wave position and tune the set to 16 megacycles. Supply a 16 megacycle signal to the antenna and adjust the trimmer for maximum output. If no oscillator, supplying a 16 megacycle signal, is available it may be possible to pick up the tenth harmonic of the 1500 kilocycle signal (15 megacycles) from a standard service oscillator. If neither is available it will be necessary to use the signal from a short wave station, near 16 megacycles, or adjust for maximum noise level.

RESISTORS

The body color represents the first figure of the resistance value.

The end color represents the second figure of the resistance value.

The dot color represents the number of ciphers following the first two figures.

MICA CONDENSERS

The first dot on the condenser represents the first figure of the capacity.

The second dot on the condenser represents the second figure of the capacity.

The third dot on the condenser represents the number of ciphers following the first two figures.

MODEL 51,52,53 Series
Voltage

FAIRBANKS-MORSE HOME APP., INC.

RESISTANCE AND VOLTAGE ANALYSIS

The following chart gives detailed information regarding the resistance from various points to various other points on the chassis. The measured voltage from the various tube socket contacts to ground is also given. When this chart is faithfully followed little difficulty should be experienced in finding almost any fault that may develop.

Resistance Tests. These tests should be made with an accurate ohm-meter. The speaker should be connected. All tubes should be removed from the set. The volume and tone controls should be full "on". The A. C. line plug must be removed from the A. C. outlet.

Voltage Tests. These readings should be taken with all tubes in their sockets. The volume and tone controls should be full "on". The antenna should be disconnected. Tune the set to a point where no signal is received.

DISTORTIONLESS AUTOMATIC VOLUME CONTROL

Full automatic volume control, detection, and audio amplification are obtained through the use of a 6E7 tube. The diode plates of the tube are connected together to form a half wave rectifier. Due to the characteristics of this portion of the tube, current flows from the cathode to the diode plates and through the secondary of the second I.F. transformer through resistors R-14 and R-15 to ground, and back to the cathode to form a complete circuit. A voltage drop is produced across resistor R-15. The D. C. component of this drop is added to the fixed bias on the 6A7 and two of the 6D6 tubes to produce automatic volume control. The magnitude of this voltage is dependent on the strength of the incoming signal carrier. This circuit has been carefully designed so that no delay is present. This avoids any possibility of audio distortion. R-8, R-10, and R-13 are decoupling resistors. C-7, C-9, and C-15 are R.F. by-pass condensers, to provide a direct path to ground for signal currents. Resistor R-14 and condensers C-20 and C-22 form a filter circuit to remove extraneous noises from the rectified current.

The audio component of the voltage drop across resistor R-15 is taken off through condenser C-23 and is applied to the grid of the pentode section of the 6E7.

ALIGNMENT PROCEDURE

To insure the performance this set is capable of delivering the following instructions should be carefully studied before any alignment adjustments are attempted.

Proper adjustment of the tuned circuits will only be possible through the use of a reliable, all wave, service oscillator and an output meter. Two types of service oscillators have been tested in our laboratories and found satisfactory for use in aligning the model 70. The new Clough-Brengle, continuously variable Model C-9 manufactured by the Clough-Brengle Company, 1134 West Austin Avenue, Chicago, Illinois, was very satisfactory. The Triumph Universal, Model 100 built by the Triumph Manufacturing Co., 4017 West Lake Street, Chicago, Illinois, was also satisfactory.

All adjustments should be made with the volume control full "on". Any desired variations in signal strength should be obtained by adjusting the output of the service oscillator.

I. F. ALIGNMENT

All Intermediate Frequency alignment adjustments must be made with the band selector switch in the broadcast position (Band Number One).

1. Supply a 456 Kilocycle signal, from an accurate service oscillator, to the grid of the 6A7 tube. A small condenser, about .0005 Mfd. (50 Mmfd.), should be connected in series with the oscillator lead to prevent the characteristics of the oscillator circuit from affecting the I. F. transformer.

2. Adjust the grid side (the center screw, Figure 3) of the first I. F. transformer, carefully, for maximum output with minimum input from the service oscillator.

3. Adjust the plate side (the hexagon nut, Figure 3) of the first I. F. transformer, carefully, for maximum output with minimum input from the service oscillator.

4. Repeat steps 2 and 3 on the second I. F. transformer.

5. Much of the sensitivity and selectivity of the receiver depend upon the proper setting of these critical adjustments, for this reason it is advisable to go back over them to make sure they are correct.

ANTENNA, R.F. FIRST DETECTOR, AND OSCILLATOR

The adjustment condensers for the antenna, R.F. first detector, and oscillator stages are located in the same shields that house the coils for these stages. These coils are contained in the three large aluminum shield cans located to the right of the gang condenser, on the chassis. Four holes are located in the side of each of these cans through each of which a condenser adjusting screw is accessible.

On each coil the upper screw is for band number one (530-1500 kilocycles). The second screw, from the top, is for band number two (1500-4200 Kilocycles). The third screw, from the top, is for band number three (4.17-12 Megacycles). The fourth screw, from the top, is for band number four (9.5-24 Megacycles).

The first shield, from the front of the chassis, contains the oscillator coil. The second shield from the front of the chassis, contains the R.F. first detector coil. The third or rear shield contains the antenna coil.

The adjustment condensers located in these three coil cans serve the same purpose as the small trimmers usually found on the gang condenser of a strictly broadcast receiver. Since this set covers four wave bands, four separate trimmers are necessary for each stage. A non-metallic tool must be used for making adjustments on these condensers.

**BAND NUMBER ONE
(530-1500 Kilocycles)**

1. Supply a 1500 Kilocycle signal to the antenna of the set. Turn the gang condenser all the way out of mesh. Adjust the oscillator trimmer condenser for maximum output with minimum input from the service oscillator.

2. Supply a 1400 Kilocycle signal to the antenna of the set. Tune the gang condenser to 1400 Kilocycles. Adjust the R.F. first detector trimmer for maximum output with minimum input from the service oscillator. Adjust the antenna trimmer for maximum output with minimum input from the service oscillator.

3. Supply a 600 Kilocycle signal to the antenna of the set. Tune the gang condenser to 600 Kilocycles. Adjust the upper section (C-47, Figure 4) of the low frequency padding condenser for maximum output with minimum input from the service oscillator. At the same time rock the gang condenser back and forth across the signal to make sure the correct peak is obtained. The low frequency padding condensers are located on the right front side of the chassis.

**BAND NUMBER TWO
(1500-4200 Kilocycles)**

1. Supply a 4200 Kilocycle signal to the antenna of the set. Turn the gang condenser all the way out of mesh. Adjust the oscillator trimmer condenser for maximum output with minimum input from the service oscillator.

2. Supply a 3900 Kilocycle signal to the antenna of the set. Tune the gang condenser to 3900 Kilocycles. Adjust the R.F. first detector trimmer for maximum output with minimum input from the service oscillator.

Adjust the antenna trimmer for maximum output with minimum input from the service oscillator.

3. Supply a 1650 Kilocycle signal to the antenna of the set. Tune the gang condenser to 1650 Kilocycles. Adjust the lower section (C-46, Figure 4) of the low frequency padding condenser for maximum output with minimum input from the service oscillator. At the same time rock the gang condenser back and forth across the signal to make sure the correct peak is obtained. The low frequency padding condensers are located on the right front side of the chassis.

**BAND NUMBER THREE
(4.17-12 Megacycles)**

1. Supply a 12 Megacycle signal to the antenna of the set. Turn the gang condenser all the way out of mesh. Adjust the oscillator trimmer condenser for maximum output with minimum input from the service oscillator.

2. Supply an 11 Megacycle signal to the antenna of the set. Tune the gang condenser to 11 Megacycles. Adjust the R.F. first detector trimmer for maximum output with minimum input from the service oscillator.

Adjust the antenna trimmer for maximum output with minimum input from the service oscillator.

**BAND NUMBER FOUR
(9.5-24 Megacycles)**

1. Supply a 24 Megacycle signal to the antenna of the set. Turn the gang condenser all the way out of mesh. Adjust the oscillator trimmer condenser for maximum output with minimum input from the service oscillator.

2. Supply a 22 Megacycle signal to the antenna of the set. Tune the gang condenser to 22 Megacycles. Adjust the R.F. first detector trimmer for maximum output with minimum input from the service oscillator.

Adjust the antenna trimmer for maximum output with minimum input from the service oscillator.

GANG CONDENSER PLATES

The adjustment of the various plates of the gang condenser is very critical since it must be accurate on four bands. These adjustments are made in the factory with precision equipment and under no condition should it be necessary to change them by bending plates.

DIAL CALIBRATION

Tune in a weak station of known frequency, on the low frequency end of the broadcast band. If the reading on the dial scale is incorrect, loosen the set screw on the hub of the dial. Turn the dial carefully until the correct reading is obtained. This should be done in such a manner as not to disturb the setting of the gang condenser. After the station comes in at the correct frequency tighten the set screw.

Resistors

The Body Color represents the first figure of the resistance value.
The End Color represents the second figure of the resistance value.

The Dot Color represents the number of eighths following the first two figures.

Mica Condensers

(Capacity in Micro-Microfarads)

The First Dot on the condenser represents the first figure of the capacity.

The Second Dot on the condenser represents the second figure of the capacity.

The Third Dot on the condenser represents the number of eighths following the first two figures.

The colors on the condensers should be read from left to right with the condenser in an upright position.

HUM

A ground is made to the A. C. line through a .01 Mfd. condenser, connected to the primary of the power transformer. If a hum is noted in the set the A. C. plug should be reversed to connect the grounded side of the line to the grounded side of the set. In most cases the line ground is some distance from the wall outlet to which the set is connected, for this reason an external ground should be used.

FIGURE 3

WAVE BANDS

The Model 70 is an all wave chassis covering a frequency range from 530 Kilocycles to 24 Megacycles in four bands. Band selection is accomplished by means of a dial four gang switch, controlled by a knob located on the right side of the front panel. The counter-clockwise (extreme left) position is Band Number One (530—1500 Kilocycles); turning in the clockwise direction, the next position is Band Number Two (1500—2000 Kilocycles); the next position is Band Number Three (3.17—12 Megacycles); and the next position (extreme right) is Band Number Four (3.5—24 Megacycles). One Megacycle is 1000 Kilocycles.

TUBES AND CIRCUIT

New multi-purpose tubes are employed thereby giving performance equal to the ordinary ten tube set. Two type 6D6 tubes are used as first and second radio frequency amplifier. A 6A7 is used as a combined oscillator and first detector. A 6D6 is used as the intermediate frequency amplifier. A 6B7 tube is employed and performs three functions: second detector, discriminator, automatic volume control, and first audio amplifier. A 42 is used as the audio output tube. A familiar type 80 rectifier is used in a full wave power supply circuit. Several unique features will be found in this chassis. The most unusual is that two radio frequency amplifier stages are employed on both of the higher frequency bands. Special low loss coils are used. Each coil has a separate high frequency trimmer for each band. A total of eight tuned circuits are brought into use on each band. A new type, high gain, intermediate frequency transformer is used.

25Z5	Rect.	-	-	-	-	-

ALIGNMENT PROCEDURE

If the set is weak or broad it is possibly out of alignment and the following adjustments should be made.

1. A 177.5 kilocycle signal, from a good service oscillator, should be supplied to the grid of the 39 first detector tube thru a small condenser (.00005 MFD). The trimmers on the first and second I. F. transformers should be adjusted for maximum output with minimum input from the service oscillator. The first I. F. transformer is located at the left of the chassis and the second I. F. at the right of the chassis, viewed from the front. These trimmers may be reached from the bottom of the chassis.
2. Supply a 1500 kilocycle signal to the antenna of the set. Tune the dial to 1500 kilocycles. Adjust the trimmer on the oscillator section of the gang condenser (the rear section) for maximum output with minimum input from the service oscillator.
3. Adjust the trimmers on the R. F. and first detector sections of the gang condenser for maximum output with minimum input from the service oscillator.

ALIGNMENT PROCEDURE

Should it ever become necessary to realign the RF and IF circuits, the procedure outlined below should be followed.

1. Apply a modulated 175 Kilocycle signal to the grid of the modulator (1st detector) tube and align the four dual trimmer adjustments in the top of the IF transformer cans for maximum output from the receiver.
2. With the band switch knob in the 530-1500 Kilocycle or clockwise position, and the tuning dial set to 1400 Kilocycles, apply a 1400 Kilocycle signal at the antenna and adjust the three trimmer screws on the gana condenser for maximum output from the receiver.
3. Apply a 600 Kilocycle signal at the antenna and track the oscillator by varying the nut adjustment on the oscillator padding condenser and returning the dial until maximum response is obtained. This adjustment should be made disregarding calibration.
4. With the band switch in the short wave or counter-clockwise position and the dial set to 3.6 Megacycles, apply a 3600 Kilocycle signal at the antenna and align the three trimmers in the top of the short wave coil cans for maximum response.
5. Apply a 1600 Kilocycle signal at the antenna and track the oscillator as at 600 Kilocycles in the broadcast band by adjusting the slotted screw adjustment on the oscillator padding condenser.

Suitable harmonics of a broadcast oscillator may be used for alignment purposes in the short wave band.

At all steps in the aligning procedure, the output should be kept only as high as is necessary for good alignment but the output should always be lowered by decreasing the input to the receiver, never by reducing the volume control setting. The volume control should be at maximum setting during any adjustments of the RF and IF circuits. A suitable output meter should be connected across the speaker voice coil to indicate the correct adjustment for maximum response.

FEDERATED PURCHASER

Alignment

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER, AND TURN THE VOLUME & TONE CONTROLS TO THEIR MAXIMUM POSITIONS (clockwise).

The I.F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I.F. amplifier to be at fault, in that event:-

- (1) Attach the output meter from plate to screen of 2A5 tube.
- (2) Feed the signal from the local oscillator tuned to exactly 485 kc. into the receiver at the control grid of the first detector, providing a D.C. path from the point to ground.
- (3) Adjust the I.F. trimmers to give maximum indication on the output meter. There are three I.F. transformers, each with two screw adjustments. On the early models these adjustments are on the bottom of the transformers, accessible from the under side of the chassis. On the later models these adjustments are on the top of the transformers.
- (4) NEXT-feed the 485 kc. signal in at the antenna post, replace the first detector grid cap, and adjust the wave trap condenser for MINIMUM indication on the output meter. This adjustment is a $\frac{1}{4}$ " hex nut on a two plate trimmer under the chassis, below the gang condenser, near the band switch.

(1) Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc., should come in.

(A) Set Band switch to band 1 (top scale).

(B) Adjust oscillator trimmer (screw adjustment, top-rear of gang condenser) until desired signal is heard. There will be two peaks in adjusting this trimmer. The peak obtained with the loosest trimmer setting is correct.

(2) Repeat operation 1 at, or near, 550 kc., using band 1.

(A) Adjust oscillator pad (fourth adjustment from right, on rear of chassis pan) until desired signal is heard.

(3) Repeat operation 1 at, or near, 1450 kc., using band 2.

(A) Adjust oscillator pad (third adjustment from right on rear of chassis pan) until the desired signal is heard.

(4) Repeat operation 1 at, or near, 3500 kc., using band 3.

(A) Adjust oscillator pad (second adjustment from right on rear of chassis pan) until the desired signal is heard.

(5) Repeat operation 1 at, or near, 8500 kc., using band 4.

(A) Adjust oscillator pad (extreme right adjustment on rear of chassis pan) until the desired signal is heard.

TO ALIGN (or gang) THE R.F. CIRCUITS

(1) Set the dial to 1400 kc., using band 1.

(A) Attach oscillator, tuned to set, to antenna post.

(B) Attach output meter from screen to plate of 2A5 tube.

(C) Adjust R. F. trimmer (screw adjustment, top-front-of gang condenser) for maximum output. KEEP SIGNAL INPUT LOW!

(2) Set the dial to 3700 kc., using band 2.

(A) Tune the oscillator to the receiver and adjust R.F. trimmer (extreme left adjustment on rear of chassis pan) for maximum output. KEEP SIGNAL INPUT LOW!

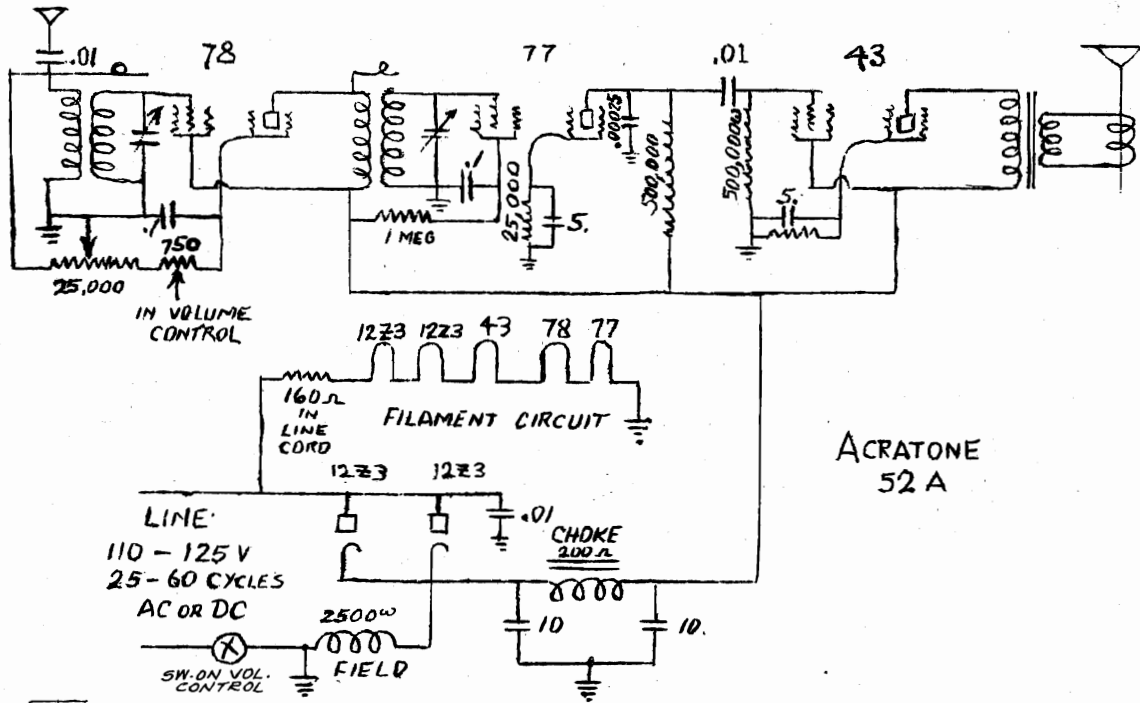

(3) Set the dial to 9000 kc., using band 3.

(A) Tune the oscillator to the receiver and adjust R.F. trimmer (second adjustment from left on rear of chassis pan)

Note 1-In case the local oscillator will not reach the higher alignment frequencies, harmonics of lower frequencies may be used.

Alignment

FEDERATED PURCHASER

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER, and TURN ALL CONTROLS TO THEIR MAXIMUM POSITIONS (CLOCKWISE).

The I. F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier to be at fault. In that event:-

- (1) Attach the output meter from plate to plate of the 46 tubes.
- (2) Feed the signal from the local oscillator tuned to exactly 175 kc. into the receiver at the control grid of the 57 first detector, providing a D. C. path from this point to ground
- (3) Adjust the I. F. trimmers to give maximum indication on the output meter. The 4 I. F. trimmers are mounted under the chassis pan, adjustable through holes in the chassis pan under the gang condenser, accessible when the rotor plates of the gang condenser are completely engaged with the stator plates. The adjustments are $\frac{1}{4}$ " hex nuts. A recheck of each adjustment to insure perfect alignment of the I. F. stages is recommended.

(1) Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc., should be received.

(A) Adjust the oscillator trimmer (screw adjustment, top front end of gang condenser) until desired signal is heard.

(2) Set the dial to the point where a station (or oscillator) of known frequency, about 1100 kc., should be received.

(A) Bend rotor plates of front section of gang condenser to correct the calibration. If the dial reading for resonance with the desired signal is higher than the true frequency bend the rotor plates out, and vice versa.

(3) Repeat operation 2 at, or near, 750 kc.

(4) Repeat operation 2 at, or near, 600 kc.

This completes the alignment procedure, and this (front) section of the gang condenser is NOT TO BE DISTURBED during the alignment of the R. F. circuits.

TO ALIGN (or gang) THE R. F. CIRCUITS

(1) Set the dial to 1400 kc.

(A) Attach the output meter from plate to plate of the 46 tubes.

(B) Attach the local oscillator to the antenna post of the receiver and adjust to resonance with the receiver.

(C) Adjust the R. F. trimmers (screw adjustments, top of gang condenser, ALL EXCEPT FRONT SCREW, for maximum indication on the output meter. KEEP SIGNAL INPUT LOW!

(2) Set the dial to 1100 kc.

(A) Adjust local oscillator to resonance with receiver.

(B) Bend rotor plates on ALL EXCEPT FRONT SECTION for maximum indication on the output meter. KEEP SIGNAL INPUT LOW!

(3) Repeat operation 2 at 750 kc.

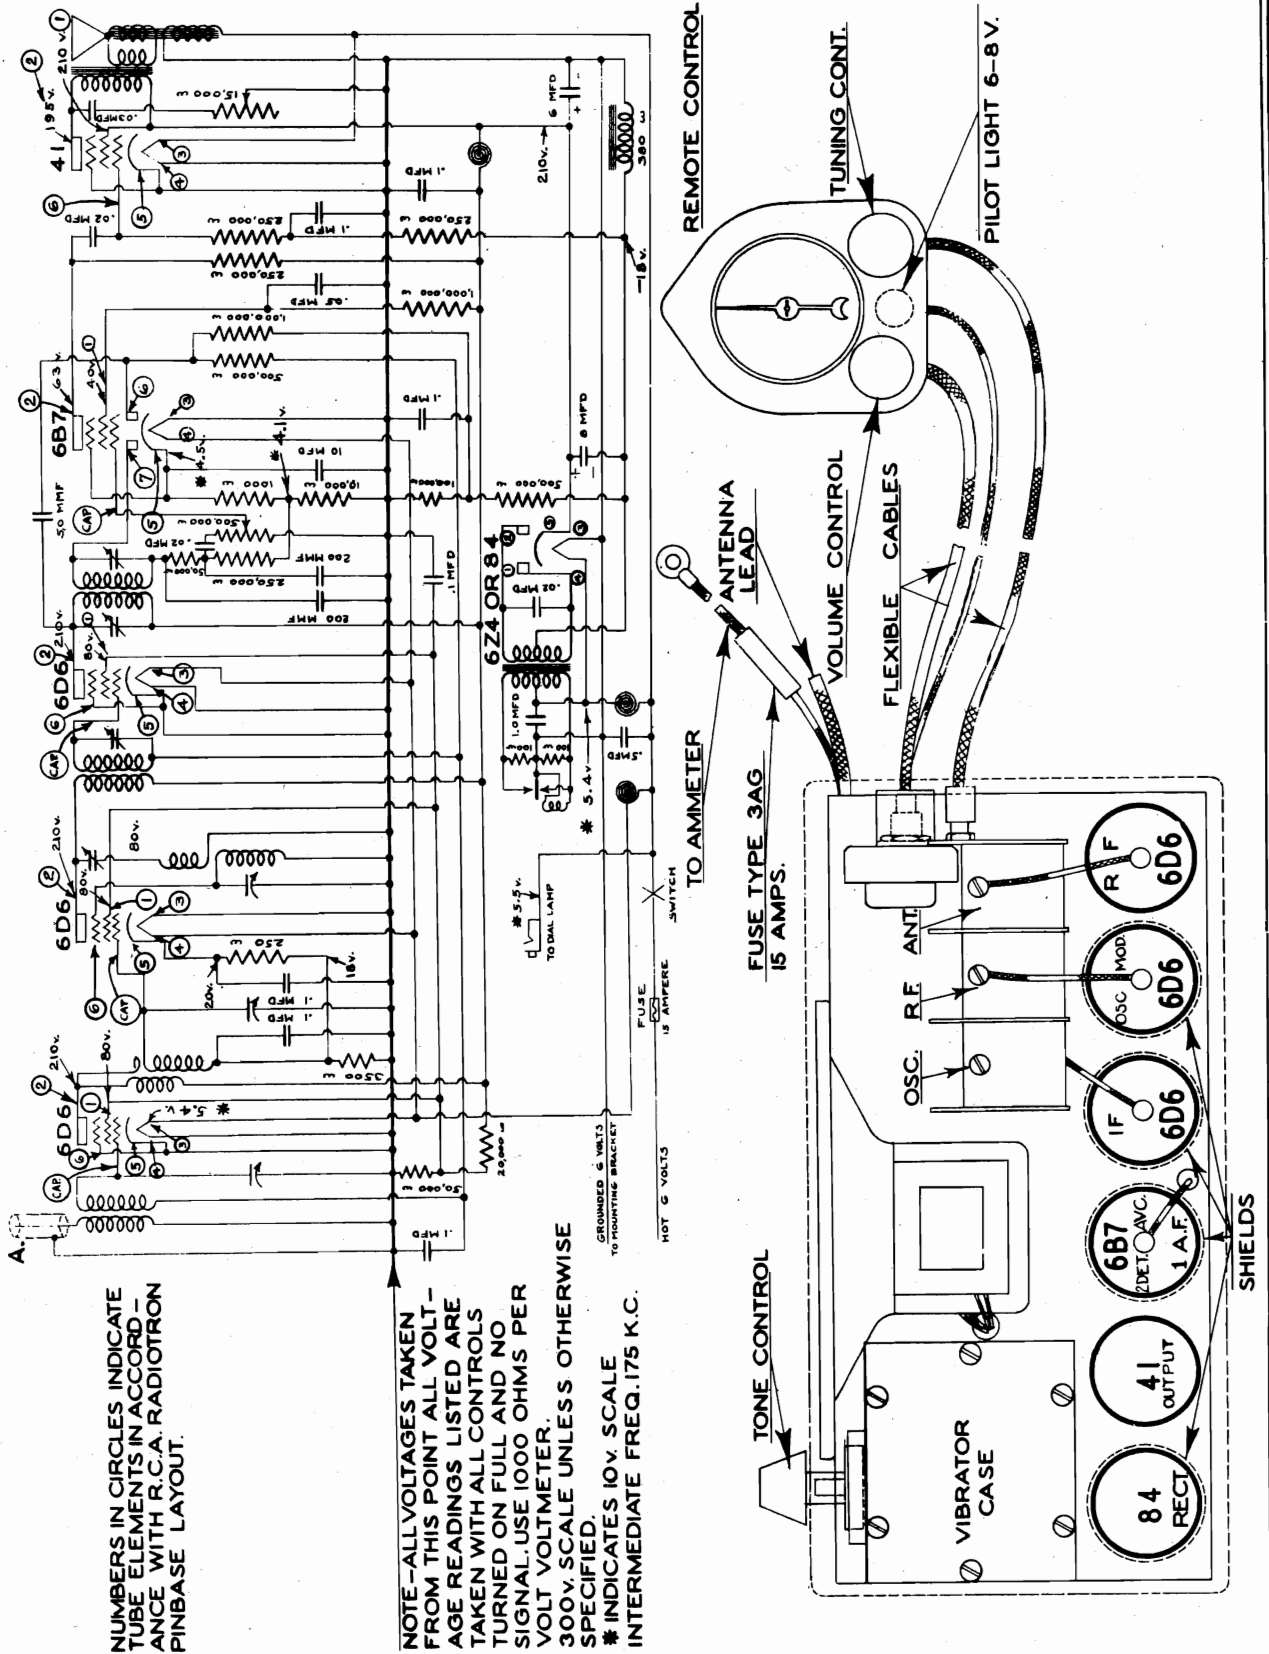

(4) Repeat operation 2 at 600 kc.

This completes the alignment of the R. F. circuits.

The alignment operations involving plate bending should be performed with utmost care if maximum results are to be obtained.

MODEL FP 32 V
(350001 up)
MODEL FR (189001 up)
Schematic, Alignment

FORDSON RADIO, INC.

CAUTION: Do not attempt to operate on current other than that noted on instrument.

INSTALLATION: The Built-in Antennas in the back of set is usually satisfactory. If more sensitivity is required attach same to a good out-door aerial. A .5 mfd condenser connected across the 32 volt line near generator to eliminate generator noise and a spark-plug-resistor connected in lead to spark plug to eliminate ignition noise may sometimes be required for satisfactory reception while batteries are charging.

USE NO GROUND CONNECTION ON SET. SHORT WAVE: Use single pole toggle switch mounted as near as possible to socket marked "75". Connect one side to green resistor with yellow dot found shunted by .00025 mica condenser and connected to black wire coming from coil can adjacent to 75 tube, connect other side of switch in series with phonograph pickup to ground.

SERVICE NOTES: Intermediate stage is carefully phased to 466 K. C. at the factory. Should rephasing be necessary feed 467 K. C. signal into grid cap of 6A7 tube and adjust double trimmers in top of coil cans to loudest signal. Phase tuning condenser by setting dial to 1400, carefully remove chassis from cabinet, feed 1400 K. C. signal into "ANT" lead and adjust trimmers on tuning condenser to loudest signal.

CAUTION: Do not attempt to operate on current other than that noted on instrument.

INSTALLATION: "Ant" lead may be fed from "BLT-IN-ANT" lead, indoor or outdoor aerial, radiator, bed springs or any large metal object, if desired.

SHORT WAVE: Left hand knob when clear to the left is on Short Wave. A one-quarter inch movement to the right and it is on regular broadcast. Beyond this point it functions as a tone control.

PHONOGRAPH: Use a single pole switch mounted as near as possible to detector socket; connect in series with lead from ground end of grid coil of detector tube. Solder phonograph pickup leads to switch terminals.

SERVICE NOTES

1934 Motorola Auto Radio

Twin "8" — Dual "6"

To assist you in gaining an understanding of the operation and servicing of the Dual "6" and Twin "8" we are outlining herein a brief description of the circuits employed together with the function of various units. For general installation instructions see the sheet enclosed with each Motorola set.

TWIN "8" — The signal is fed into the primary of the antenna coil, which is of the aperiodic type and is induced into its associated secondary circuit, tuned by the 1st gang of the variable condenser. The signal is then fed to the 78 tube used as the first RF amplifier.

Reference to the circuit diagram (Fig. 3) will show that the 2nd RF stage is impedance coupled, feeding its energy into the grid of the 77 autodyne. In the aperiodic type of antenna coil the gain drops slightly near the 500 K.C. end, while in the impedance type coupling used in the 2nd RF coil rises slightly at this point. It will be seen then that by using these two in combination an overall flat sensitivity curve is obtained.

The type 77 autodyne tube is used because of its simplicity, performance and ability to withstand the vibration to which an auto set is subjected. The use of the padder system in the oscillator is used to allow greater accuracy in dial calibration.

In the 85 tube full wave rectification is used and A.V.C. bias is obtained by voltage drop across the 200M ohm resistance connecting the secondary of the diode feeder to ground. Full A.V.C. voltage is applied to the grids of the RF stage and IF stage and to the grid of the 85 tube. The audio component is amplified in the triode section of the 85, which is resistance coupled to the #37, 2nd audio used as a driver and is impedance coupled to the L.A. tubes operating in Push-Pull Class A Prime.

THE DUAL "6" — For all ordinary servicing of the RF section of the Dual "6" the above description will be sufficient.

Reference to the circuit diagram (Fig. 4) will show that a #75 is used as a diode detector resistance coupled to a single 42 output tube.

The manual volume control is in the grid of the 75 whereas in the Twin "8" it is in the grid circuit of the 37 tube.

Fixed bias is used on the 75 grid obtained through the voltage drop across the screen network.

SERVICING

In shooting trouble in an auto radio it is well to endeavor to isolate it to one particular section of the set.

The set may be divided into four parts for servicing. (1) Outer housing. (2) Power supply. (3) Speaker. (4) Set chassis.

The audio end of the chassis may be easily checked by removing the grid cap of the 85 or 78 tube and, if normal, a loud hum will occur.

Check the autodyne circuit by tuning the variable condensers to the minimum position and touching the oscillator stator plates. If a click is heard when touching them and also when removing the finger, it indicates that the autodyne is oscillating properly.

ALIGNMENT OF VARIABLE CONDENSERS

Because of the necessity of aligning the variable condensers with the chassis out of the housing it is important to use a definite point. Unless this is done the dial calibration will be incorrect when replacing the chassis in its housing. This point we may take as 1400 KC which is exactly 32° of angular rotation from minimum condenser setting.

Connect the oscillator feeder to the antenna pin of the chassis and set the oscillator to 1400 KC.

Carefully adjust the trimmers of the oscillator and RF variable condensers for maximum reading of output meter.

Next set the service oscillator to 600 KC rotating the variable condensers to a point 155 degrees 30 min. from minimum condenser setting.

Adjust the 600 KC padder condenser (accessible from the front of the chassis) for highest output reading.

The 600 KC setting may also be found by setting the service oscillator to 600 KC. Tune in the oscillator signal and rotate the variable condensers back and forth while adjusting the 600 KC trimmer condenser for highest reading of the output meter. The variable condensers should now track perfectly and coincide with the dial calibration.

ALIGNMENT OF THE IF TRANSFORMERS

The IF transformers and diode feeder in the Twin "8" and Dual "6" should always be aligned with a good calibrated service oscillator or signal generator.

Connect the feeder from the oscillator to the grid of the 77 autodyne tube. Remove the grid connection and connect a 500M ohm resistor from grid of the tube to the ground.

Rotate the variable condensers to the full open position.

Set the oscillator to a frequency of 262 KC and adjust the IF and diode feeder trimmers to obtain maximum reading on the output meter.

PART REPLACEMENTS

In the design of the Twin "8" and Dual "6" interchangeability of parts has been accomplished wherever possible. This greatly simplifies service. In these sets the complete power packs and their various parts along with the RF oscillator, IF coils and variable condenser are interchangeable.

Volume Control — (1) Remove rear set cover. (2) Disconnect volume control and switch leads. (3) Remove hex head screws holding volume control mounting plate and remove complete assembly. (4) Replace with standard Motorola replacement control.

By-Pass Condensers — (1) Disconnect condenser and push upwards from bottom of chassis. (2) Insert new condenser from bottom of chassis and reconnect.

Tube Sockets — (1) Disconnect all wires at socket contacts, insert tube in socket, press down firmly and turn in counter-clockwise direction until released. (2) Place new socket on tube base, press it down firmly into chassis hole and turn in clockwise direction.

Coil and IF Transformer — (1) Each coil may be removed without disturbing any other units. (2) Remove mounting screws, disconnect its respective wires and insert new coil.

MODEL Twin "8"
 MODEL Dual "6"
 Control Adjustment

GALVIN MFG. CO.

Fig. 6

ADJUSTMENT OF MOTOROLA UNIVERSAL AIR-PLANE TYPE CONTROL

The general construction of the control head is shown in the cut away view. (Fig. 6).

In connecting the flexible shafts to the control head:

1. Insert the volume control shaft into the control head to its limit then release the shaft housing about 1/32 inch to relieve any binding. Tighten set screw (D) Fig. (7) against housing.

2. Insert condenser drive shaft into control head so that the shaft extends into the tuning knob. Tighten knob set screws A and B. Release shaft housing about 1/32 inch to relieve binding.

Tighten set screw (C) against housing. The tuning knobs may be removed by completely removing the set screws E and F, Fig. (7). This is necessary when mounting control in instrument panel.

To adjust indicator arrow, tune in a station of known frequency preferably between 1000 KC and 1300 KC, then insert screw driver in rear center of control head and adjust indicator to correct frequency setting.

Special lengths of flexible shafts may be secured from your Motorola distributor or from the factory.

GALVIN MFG. CO.

GALVIN MFG. CORP.
CHICAGO, ILL.
CIRCUIT DIAGRAM MODEL #34
4-11-34 **REV. 17**

ADJUSTMENT OF TUNING CONDENSER GEAR

The tuning condenser gear may be adjusted against its drive pinion by simply turning the cam screw, reaching through a hole in the left side of front cover. This hole is covered by button, easily pried upward with screwdriver. Turn screw to the left until slight drag is felt on the station selector knob, then back off slightly until free movement is obtained. After adjustment has been made tighten small locking screw located on face of cam screw.

BALANCING THE SET TO THE ANTENNA

After the set is installed ready for operation, it may be necessary to balance the set to the antenna. This is done by adjustment of the antenna trimmer, located under a 3/8" hole in the TOP of the set. This hole is covered by a button which is removed by simply prying upward with a screw driver.

In making this adjustment tune in a very weak station around 120 to 140 on the dial. Adjust the trimmer with a screw driver until the point of maximum volume is reached.

ADJUSTING THE STATION SELECTOR INDICATOR

Tune in a station of known frequency preferably between 1000KC and 1300 KC.

Insert a screw driver in the center rear of the control head and adjust indicator to the frequency of the station being received. (See Fig. 4).

ALIGNMENT PROCEDURE CHASSIS 4A

1. Equipment

A - Test Oscillator

A - A modulated oscillator capable of producing signals at 282 K.C., 455 K.C., 1400 K.C., 3700 K.C. (10 M.C. and 20 M.C. used on 7B & 11A only) is necessary for alignment of the 1934 Grunow Receivers.

B - Out-put Meter

This may be any of the standard out-put meters on the marked but should be sufficiently sensitive to provide a good deflection at low signal strength, it should also incorporate an adjustable shunt so that extremely strong signals may be read.

C - Coupling Means

Coupling condensers of .25 Mfd. and 200 Mmf. should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. Dial Setting

Turn dial pointer so that end mark of dial is directly under fully meshed.

It will be necessary to simulate the dial plate during alignment when Chassis is removed from cabinet.

3. I.F. Alignment

A - Connect signal lead of oscillator through .25 Mfd. condenser to grid of 6F7 (1st Detector Tube) located on rear right hand corner of Chassis as you face same. Connect the ground lead to the Chassis.

B - Place oscillator in operation at 455 K.C. and turn receiver volume control to maximum. (Volume Control should remain at maximum during entire alignment procedure and signal should be attenuated at oscillator to lowest

6. 3700 K.C. Alignment

A - Throw Range Switch to S.W. position.

B - Set oscillator in operation at 3700 K.C.

C - Turn Dial pointer to 3700 K.C. or 3.7 M.C.

Model 450
Chassis 4A - Speaker 8B1

D - Adjust 3700 K.C. Trimmer (A8) located on top of Chassis near variable condenser.

7. Recheck Dial Calibration and 1400 K.C. Alignment.

ALIGNMENT PROCEDURE CHASSIS 4B

1. Equipment

A - Test Oscillator

A - A modulated oscillator capable of producing signals at 455 K.C., 600 K.C., 1400 K.C. and 1700 K.C. is necessary for alignment of the 4B Grunow Receivers.

B - Out-put Meter

This may be any of the standard out-put meters on the market but should be sufficiently sensitive to provide a good deflection at low signal strength, it should also incorporate an adjustable shunt so that extremely strong signals may be read.

C - Coupling Means

Coupling condensers of .25 Mfd. and 200 Mmf. should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. Dial Setting

Turn dial pointer until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

3. I. F. Alignment

A - Connect signal lead of oscillator through .25 Mfd. condenser to grid of 6A7 (1st Detector Tube) located on front right hand corner of Chassis. Connect the ground lead to the Chassis.

B - Place oscillator in operation at 455 K.C. and turn receiver volume control to maximum. (Volume Control should remain at maximum during entire alignment procedure and signal should be attenuated at oscillator to lowest value consistent with obtaining a readable indication on out-put meter).

C - Align three I.F. trimmers (A1-A2-A3) located on top of Chassis. Two on top of 1st I.F. Can and 1 on Chassis between 42 and 6F7 tube.

4. 1700 K.C. Alignment

A - Connect signal lead of oscillator to antenna lead, (the blue wire leading from rear of chassis) through 200 Mmf. Condenser.

B - Set dial pointer at 1700 K.C. and place oscillator in operation at 1700 K.C.

C - Align oscillator trimmer (A4) which is the first of the two on the variable condenser.

5. 1400 K.C. Alignment

A - Place oscillator in operation at 1400 K.C.

B - Set dial pointer at 1400 K.C.

C - Align antenna trimmer (A5). This operation may require rocking the variable condenser back and forth through resonance. The object of this operation is to be sure that the receiver will reach 1712 K.C. and at the same time have maximum sensitivity on the rest of the broadcast band.

Alignment

CHASSIS 5B
MODEL 550

ALIGNMENT PROCEDURE CHASSIS 5B

1. Equipment

A - Test Oscillator
A modulated oscillator capable of producing signals at 455 K.C., 600 K.C. and 1400 K.C. is necessary for alignment of the 5B Chassis.

B - Out-put Meter

This may be any of the standard output meters on the market but should be sufficiently sensitive to provide a good deflection so that extremely strong signals may be read.

C - Coupling Means

Coupling Condensers of 200 Mmf., 25 Mfd., should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. I. F. Alignment

A - Connect signal lead of oscillator through .25 Mfd. condenser to grid of 78 tube. (1st Detector Tube). The ground lead to ground post on rear of Chassis.

B - Place oscillator in operation at 455 K.C. and turn receiver volume control to maximum. (Volume Control should remain at maximum during entire alignment procedure and signal should be attenuated at oscillator to lowest value consistent with obtaining a readable indication on out-put meter).

C - Align three I. F. trimmers (A1-A2-A3) located on under side of Chassis at base of I.F. Coils.

3. Dial Calibration

A - With condensers fully meshed dial pointer should be directly over end mark on dial.

B - When Chassis is removed from cabinet it will be necessary to simulate dial escutcheon which incorporates dial pointer.

4. 1400 K.C. Alignment

A - Connect signal lead of oscillator through 200 Mmf. Condenser to antenna leading from Chassis.

B - Turn dial to 1400 (1400 K.C.) and align 1400 K.C. oscillator trimmer (A4), located forward on variable condenser.

C - Align Antenna Trimmer (A5) which is the second trimmer on variable condenser.

5. 600 K.C. Alignment.

A - Place oscillator in operation at 600 K.C. Tune in signal (this does not have to be exactly on 600 Dial Setting).

B - Adjust 600 K.C. trimmer (A6) located on under side of Chassis directly under variable condenser in direction of signal through resonance until maximum output is obtained.

C - Recheck dial calibration: Over several points on dial.

4. 3700 K.C. Alignment

- A - Throw range switch to position "B". (Right)
- B - Connect signal lead of test oscillator to Antenna post on Chassis through 200 Mmf. Condenser.
- C - Turn dial pointer to 3700 K.C.

D - Place Oscillator in operation at 3700 K.C.

E - Align Oscillator Trimmer (A5), (front trimmer located on top of variable condenser.

5. 1400 K.C. Alignment

- A - Throw range switch to position "A". (Left)
- B - Turn Dial pointer to 1400 K.C.
- C - Place Oscillator in operation at 1400 K.C.

D - Align the 1400 K.C. Trimmer (A6), (located on the front left face of the Chassis, the lower of the two at this location).

- E - Align the second and third trimmers (A7 & A8) on the top of the variable condenser.
- F - Repeat the 1400 K.C. alignment at least twice.

6. 600 K.C. Alignment

A - Place Oscillator in operation at 600 K.C.

B - Tune in 600 K.C. signal (this does not have to be exactly on 600 K.C. dial setting).

C - Adjust 600 K.C. trimmer (A9), (located on the front left face of the Chassis, the upper of two at this location), in direction of signal increase. At the same time, rock the tuning condenser back and forth through resonance. Continue this procedure until maximum signal is obtained on output meter.

Alignment, Parts

GENERAL HOUSEHOLD UTILITIES CO.

ALIGNMENT PROCEDURE

1. Equipment

A - Test Oscillator

A modulated oscillator capable of producing signals at 262 K.C. - 600 K.C. - 1400 K.C. - 16 M.C.

B - Output Meter

This may be any of the standard output meters on the market, but should be sufficiently sensitive to provide a good deflection at low signal strength, and should also incorporate an adjustable shunt so that extremely strong signals may be read.

C - Coupling Means

Coupling condensers of 200 Mmf., 25 Mfd. and a 400 ohm resistor should be used when coupling test oscillator to receiver during alignment as specified in the following paragraphs.

2. Dial Setting

Turn dial knob until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

3. I. F. Alignment

A. Connect signal lead of test oscillator to grid of the 6A7 (first detector tube) through a .25 Mfd. condenser. Connect the ground lead to the chassis.

B - Set dial pointer to 1400 K.C. and range switch on counter-clockwise (broadcast) position.

C - Place test oscillator in operation at 262 K.C. Turn receiver volume control and tone control to maximum.

5. 1400 K.C. Alignment

A - Turn range switch counter-clockwise to broadcast position.

B - Connect signal lead of test oscillator through 200 Mmf. condenser to antenna binding post.

C - Place test oscillator in operation at 1400 K.C. and set dial pointer on 1400 K.C.

D - Adjust the lower of the two trimmers (A11) located at the left front end of chassis and trimmers on 2nd(A8) and 5rd(A9) section of variable condensers to maximum output.

6. Recheck Operation No. 4 (16 M.C. Alignment)

7. 600 K.C. Alignment

A - Place test oscillator in operation at 600 K.C.

B - Tune in signal to maximum. (This point does not have to be exactly at 600 K.C. dial setting)

C - Adjust the 600 K.C. padding condenser (A10) (this is the upper of the two trimmers located at the left front end of chassis), in direction of signal increase, at the same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

D - Attenuate test oscillator output to lowest value consistent with obtaining a readable indication on output meter.

E - Adjust the four I.F. trimmers (A1-A2-A3-A4) located on the under-side of the chassis, until maximum output is obtained. During alignment maintain as low a value of signal as will allow obtaining of accurate adjustment.

4. 16 M. C. ALIGNMENT

A - Connect signal lead of test oscillator through 400 ohm resistor to antenna binding post of chassis.

B - Connect the ground lead to ground terminal of chassis.

C - Set range switch to S.W. range (clockwise position).

D - Place test oscillator in operation at 16 M.C. and set dial pointer on 16 M.C.

E - Adjust trimmer (A5) on front section of variable condenser (oscillator) --, trimmer (A6) on top of detector coil and A7 on top of the antenna coil - to maximum output - (the detector and antenna coils are located on left-hand side on top of the chassis).

F - On oscillator alignment use the lower of the two images for the oscillator alignment point. It will be noted that there are two settings at which the signal will be received. Use the setting giving most capacity, that is, the setting at which the trimmer screw is farthest in. While adjusting the detector and antenna coil trimmers rock the variable condensers back and forth until maximum output is obtained.

LOCATION OF TRIMMER CONDENSERS.

MODEL 670, 671 (6D)

Alignment Temporary

GENERAL HOUSEHOLD UTILITIES CO

- Oscillator through 400 ohm resistor to Antenna binding post of Chassis.
- B - Connect the ground lead to ground terminal of Chassis.
- C - Set Range Switch to range "C".
- D - Place test Oscillator in operation at 12 M.C.
- E - Adjust the following "C" range trimmers: Oscillator (A13), Detector (A14), Antenna (A15).
- F - When adjusting the Detector Trimmer (A14) on the "C" range it is necessary to rock the tuning condenser in a manner similar to that required when setting the 600 K.C. Padding Condenser.
- G - When adjusting the Oscillator Trimmer on the "C" range with a 12 M.C. signal it will be noted that there are two settings at which the signal will be received. Use the higher frequency setting, that is, the setting at which the trimmer screw is farthest out. On the "A", "B" and "C" range the Oscillator operates at a higher frequency than the incoming signal, and consequently the trimmer capacity will be lower when adjustment is completed.
8. 21 M.C. Alignment
- A - Set Range Switch on range "D".
- B - Place test Oscillator in operation at 21 M.C.
- C - Turn Dial Pointer to 21 M.C.
- D - Adjust the following "D" range trimmers: Oscillator (A16), Detector (A17), Antenna (A18).
- E - When adjusting the Detector Trimmer (A17) on the "D" range it is necessary to rock the tuning condenser back and forth through resonance in the same manner as required when setting the 600 K.C. Padding Condenser.
- F - When adjusting the Oscillator Trimmer on the "D" range with a 21 M.C. signal it will be noted that there are two settings at which the signal will be received. Use the lower frequency setting, that is, the setting at which the trimmer screw is farthest in. On the "D" range the Oscillator operates at a lower frequency than the incoming signal, and consequently the trimmer capacity will be higher when adjustment is completed.
- control and tone control to maximum.
- C - Attenuate test Oscillator output to lowest value consistent with obtaining a readable indication on output meter.
- D - Adjust five I.F. Trimmers, (A1, A2, A3, A4, A5), located on the I.F. transformers on top of the Chassis. (2 Trimmers are on top of each transformer and the fifth is at the lower side of the 1st I.F. transformer, (this is the Bi-Selector I.F. stage), until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.
4. 4500 K.C. Alignment
- A - Connect signal lead of test Oscillator through 200 Mmf. Condenser to Antenna binding part.
- B - Connect the test Oscillator ground lead to the ground post of Chassis.
- C - Turn Range Switch to range "B" and set Dial Pointer to 4500 K.C.
- D - Align the following "B" range trimmers: Oscillator (A6), Detector (A7) Antenna (A8).
5. 1400 K.C. Alignment
- A - Place test Oscillator in operation at 1400 K.C.
- B - Turn Dial to 1400 K.C.
- C - Turn Range Switch to range "A".
- D - Adjust the following "A" range trimmers: Oscillator (A9), Detector (A10) Antenna (A11).
6. 600 K.C. Alignment
- A - Place test Oscillator in operation at 600 K.C.
- B - Tune in signal to maximum (this point does not have to be exactly at 600 K.C. setting).
- C - Adjust the 600 K.C. Padding Condenser, (A12) in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting Padding Condenser until maximum output is obtained.
7. 12 M.C. Alignment
- A - Connect signal lead of test

- oscillator through 400 ohm resistor to Antenna binding post of Chassis.
- B - Connect the ground lead to ground terminal of Chassis.
- C - Set Range Switch to range "C".
- D - Place test Oscillator in operation at 12 M.C.
- E - Adjust the following "C" range trimmers: Oscillator (A13), Detector (A14), Antenna (A15).
- F - When adjusting the Detector Trimmer (A14) on the "C" range it is necessary to rock the tuning condenser in a manner similar to that required when setting the 600 K.C. Padding Condenser.
- G - When adjusting the Oscillator Trimmer on the "C" range with a 12 M.C. signal it will be noted that there are two settings at which the signal will be received. Use the higher frequency setting, that is, the setting at which the trimmer screw is farthest out. On the "A", "B" and "C" range the Oscillator operates at a higher frequency than the incoming signal, and consequently the trimmer capacity will be lower when adjustment is completed.
8. 21 M.C. Alignment
- A - Set Range Switch on range "D".
- B - Place test Oscillator in operation at 21 M.C.
- C - Turn Dial Pointer to 21 M.C.
- D - Adjust the following "D" range trimmers: Oscillator (A16), Detector (A17), Antenna (A18).
- E - When adjusting the Detector Trimmer (A17) on the "D" range it is necessary to rock the tuning condenser back and forth through resonance in the same manner as required when setting the 600 K.C. Padding Condenser.
- F - When adjusting the Oscillator Trimmer on the "D" range with a 21 M.C. signal it will be noted that there are two settings at which the signal will be received. Use the lower frequency setting, that is, the setting at which the trimmer screw is farthest in. On the "D" range the Oscillator operates at a lower frequency than the incoming signal, and consequently the trimmer capacity will be higher when adjustment is completed.
- control and tone control to maximum.
- C - Attenuate test Oscillator output to lowest value consistent with obtaining a readable indication on output meter.
- D - Adjust five I.F. Trimmers, (A1, A2, A3, A4, A5), located on the I.F. transformers on top of the Chassis. (2 Trimmers are on top of each transformer and the fifth is at the lower side of the 1st I.F. transformer, (this is the Bi-Selector I.F. stage), until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.
4. 4500 K.C. Alignment
- A - Connect signal lead of test Oscillator through 200 Mmf. Condenser to Antenna binding part.
- B - Connect the test Oscillator ground lead to the ground post of Chassis.
- C - Turn Range Switch to range "B" and set Dial Pointer to 4500 K.C.
- D - Align the following "B" range trimmers: Oscillator (A6), Detector (A7) Antenna (A8).
5. 1400 K.C. Alignment
- A - Place test Oscillator in operation at 1400 K.C.
- B - Turn Dial to 1400 K.C.
- C - Turn Range Switch to range "A".
- D - Adjust the following "A" range trimmers: Oscillator (A9), Detector (A10) Antenna (A11).
6. 600 K.C. Alignment
- A - Place test Oscillator in operation at 600 K.C.
- B - Tune in signal to maximum (this point does not have to be exactly at 600 K.C. setting).
- C - Adjust the 600 K.C. Padding Condenser, (A12) in direction of signal increase. At same time rock the tuning condenser back and forth through resonance while adjusting Padding Condenser until maximum output is obtained.
7. 12 M.C. Alignment
- A - Connect signal lead of test

TEMPORARY SERVICE NOTES & PARTS LIST

CHASSIS TYPE 6D
RECEIVER MODELS 670 & 671
SPEAKER TYPES 8C6 10A5

GENERAL HOUSEHOLD UTILITIES CO.
CHICAGO U.S.A.

31561-1

LITHO U.S.A.

ALIGNMENT PROCEDURE CHASSIS 6D

GENERAL

The Type 6D Chassis is used in conjunction with the 806 speaker in receiver model 670 and with the 10A5 speaker in the model 671 receiver.

This chassis is a 6 tube all wave (550 to 21800 K.C.) superheterodyne, using 1 - 6D6 tube as an R.F. Amplifier, 1 - 6A7 tube as first Detector and Oscillator, 1 - 6D6 tube as a Bi-Selector I.F. Amplifier, 1 - 75 tube acting as a second Detector, Automatic Volume Control and Audio Amplifier, 1 - 42 tube as the Audio Output and an 80 tube for the Rectifier.

The intermediate frequency is 455 K.C. An efficient range switch controls the four ranges in which the receiver operates.

ALIGNMENT

1. Equipment

A - Test Oscillator
A modulated Oscillator capable of producing signals at 455 K.C., 600 K.C., 1400 K.C., 4500 K.C., 12 M.C. and 21 M.C. is necessary for alignment of the Type 6D Chassis.

B - Output Meter
This may be any of the standard output meters on the market but should be sufficiently sensitive to provide a good deflection at low signal strength, and should also incorporate an adjustable shunt so that extremely strong signals may be read.

C - Coupling Means
Coupling Condensers of 200 Mmf., .25 Mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in following paragraphs.

2. Dial Setting

Turn dial knob until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

3. I. F. Alignment

Connect signal lead of test Oscillator to grid of the 6A7 (1st Detector Tube) through .25 Mfd. Condenser. Connect the ground lead to the Chassis:

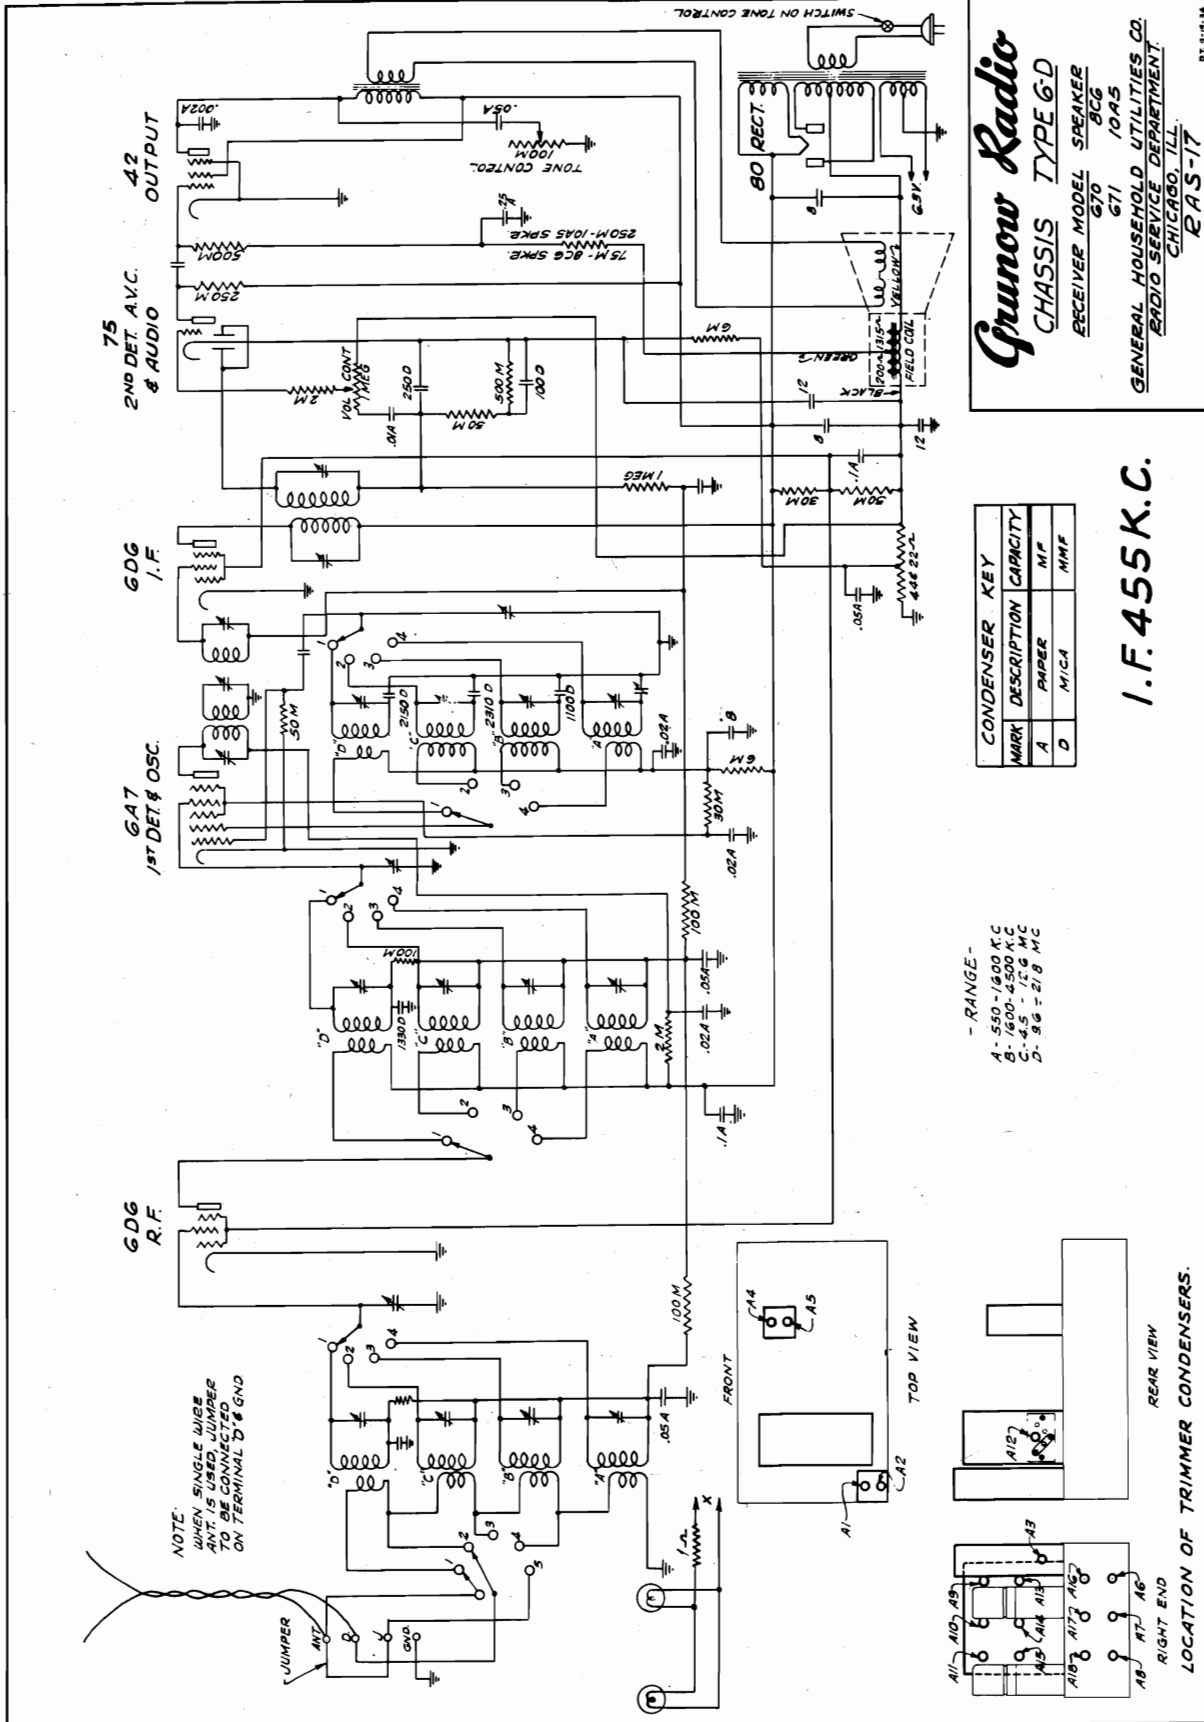

A - Set Dial pointer to 1400 K.C. and range switch on position "A". (Broadcast).

B - Place test Oscillator in operation at 455 K.C. Turn receiver volume

SERVICE DATA

The Range Switch
 In servicing the 7-B Receiver, consider the radio frequency end as four different and distinct radios:

- One working from 550 to 1500 k.c. (D Range)
 - One working from 1500 to 4200 k.c. (C Range)
 - One working from 4100 to 10,000 k.c. (B Range)
 - One working from 8500 to 21,500 k.c. (A Range)
- These four radios are put into operation as desired by means of the Range Switch.

When on position "A" the short wave coils covering the range from 8,500 to 21,500 k.c. are connected into the three tuned circuits of the receiver, one coil as an R.F. Transformer, one as the Detector Coupler, and one as the Oscillator Transformer.

On position "B" the 4100 to 10,000 k.c. coils are put into operation.

On "C" position, the 1500 to 4200 k.c. coils are shunted across the 550 to 1500 k.c. coils in such a manner as to lower the total inductance of the combined coils and reduce the losses caused by open end coils.

On both the "C" and "D" positions, four coil sets are put into the circuit and the receiver operates as a four tuned circuit radio. On all four ranges the receiver works at maximum sensitivity and selectivity. All coils and condensers are of such construction that atmospheric and temperature changes have minimum effect.

Each circuit is completely shielded from each other, and the complete range switch and coil assembly may be removed for inspection or repair.

Fig. 1

The chassis frame is built in such a way that the end plates may be disconnected allowing easy inspection of the underside of the chassis assembly. (Fig. 6).

The range switch and coil assembly is made up in a unit and may be removed for inspection or repair. (Fig. 7). The removal of this assembly necessitates the unsoldering of 13 wire leads. These leads and the positions to which they are connected are marked on the illustrations with letters. The leads A-B-C on the Coil Assembly (Fig. 7) are attached to the points marked A-B-C on the Chassis Assembly (Fig. 5). The leads marked D-E-F-G on the Coil Assembly (Fig. 7) are attached to the points of corresponding letters on the Chassis Assembly (Fig. 6). Leads H-I-J-K-L-M on Coil Assembly are connected as follows:

Lead "H" connects the ground side of the short wave antenna transformer (Red) to the rotor ground of the variable condenser.

Lead "I" connects Arm 2 of Deck 5 to the No. 1 stator of the variable condenser.

Lead "J" is the shielded lead connecting the bi-selector transformer to the No. 2 stator of the variable condenser.

Lead "K" connects Arm 2 of Deck 3 to the No. 3 stator of the variable condenser.

Lead "L" connects the switch assembly ground to the variable condenser rotor ground.

Lead "M" connects Arm 2 of Deck 2 with No. 4 stator of the variable condenser. Care should be exercised in making these connections. (A soldering iron with a bent point should be used in this operation).

Continuity and Voltage

Continuity and voltage readings should be taken from the underside of the Chassis. The values given on the schematic diagram are average and allow the service man to make a quick check of the chassis constants. The socket layout given on the schematic diagram show each socket from the underside.

INTRODUCTION

The following characteristics apply to the Grunow Radio—Chassis Type 7B:

This model is a 7 tube Super-Heterodyne All Wave (540 to 21,500 KC) Receiver using 1-6D6 tube as an R. F. Amplifier, 1-6A7 tube as a 1st Detector or mixer—being electronically coupled to a 76 oscillator tube, 1-6F7 tube the pentode section of which is used as an I.F. amplifier with a frequency of 262 K.C. and the Triode section being used as a Signal Beacon or beat oscillator. Plate Voltage of the Signal Beacon being applied by closing the switch on the tone control. A 75 tube (double diode—high mu Triode) is used as a diode detector or signal rectifier, delayed automatic volume control (AVC) and high-gain audio amplifier. The 42 output tube is a power amplifier pentode and is capable of producing large power output with a relatively small input signal. This tube receives its bias through the voltage drop produced in the tapped speaker field. The rectifier tube is an 80, the output of which is well filtered through the choke action of the speaker field and the 16 and 18 mfd. electrolytic condensers.

The broadcast section of the receiver consists of the following 4 tuned circuits: R.F. input, bi-selector, mixer input and oscillator. These circuits are tuned with a 4-gang variable condenser of rugged construction.

The short wave section of the receiver consists of 3 tuned circuits, the bi-selector being cut out to prevent losses when the receiver is working at the higher frequencies.

The Signal Beacon is a beat oscillator using the triode section of the 6F7 tube, and is a feature of the 7B Chassis. When this section of the tube is brought into operation it acts as a local oscillator and beats against the incoming signal. The presence of a station's signal will be indicated by a high pitched "whistle", becoming lower in pitch as a "resonance", or exact tuning, is approached. The Signal Beacon note becomes very low and finally reaches zero; at this point the receiver is said to be tuned to "zero beat", which indicates that it is tuned exactly to the station. The Signal Beacon is also used to receive telegraph or continuous wave signals.

The remainder of the circuit is typical and has been designed along the lines of what is considered the best engineering practice to date. Parts are all oversize and of the finest quality.

ALIGNMENT PROCEDURE

D—Align Set Oscillator or front trimmer A6, Fig. 4, on variable condenser. It may be necessary to approximate adjustment of the other three trimmers on variable condenser to obtain sufficient sensitivity to make 3700 K.C. adjustment.

5. 1400 K.C. ALIGNMENT.
A—Place test oscillator in operation at 1400 K.C.
B—Turn dial pointer to 1400 K.C.
C—Turn Range Switch to range D.
D—Adjust 1400 K.C. padding condenser, A7, Fig. 4, which is the first hand side as you face it.

E—Adjust 1st Det. Trimmer A8, Fig. 4, which is the second hand side on top of variable condenser.
F—Adjust Bi-selector trimmer A9, Fig. 4, which is the third hand side on top of variable condenser.
G—Adjust Antenna Trimmer A10, Fig. 4, which is the fourth hand side on top of variable condenser.

6.—600 K.C. ALIGNMENT.
A—Place test oscillator in operation at 600 K.C.
B—Tune in signal to maximum (this point does not have to be exactly at 600 K.C. dial setting).
C—Adjust the 600 K.C. Padding Condenser A11, Fig. 4, (which is on top of Chassis on right hand side third from front as you face Chassis), in direction of signal increases. At same time rock the tuning condenser back and forth through resonance while adjusting padding condenser until maximum output is obtained.

7. 10 M.C. ALIGNMENT.
A—Connect signal lead of test oscillator through 400 Ohm resistor to Antenna binding post of Chassis.
B—Connect the ground lead to ground terminal of Chassis.
C—Set Range Switch to Range "B" and turn dial pointer to 10 M.C.
D—Place test oscillator in operation at 10 M.C.
E—Adjust set oscillator trimmer A12, Fig. 4, (located on front face of Chassis).
F—Adjust detector trimmer A13, Fig. 4, (located on right hand side on top of Chassis second from front).
G—Adjust antenna trimmer A14, Fig. 4, (located on rear face of Chassis).

8. 20 M.C. ALIGNMENT.
A—Set Range Switch on Range A.
B—Place Test Oscillator in operation at 20 M.C.
C—Turn Dial Pointer to 20 M.C.
D—Adjust set Oscillator trimmer A15, Fig. 4, (located on top of Chassis on left of gang condenser, first from front).
E—Adjust Detector trimmer A16, Fig. 4, (located second from front on top of Chassis on left hand side).
F—Adjust Antenna trimmer A17, Fig. 4, (located third from front on top of Chassis on left hand side).

EQUIPMENT

A—Test Oscillator.
A modulated oscillator capable of producing signals at 262 K.C.—600 K.C.—1400 K.C.—3700 K.C.—10 M.C. and 20 M.C. is necessary for alignment of the 7B chassis.
B—Insulated screw driver—(All bakelite or fibre) about 6" long.
C—Output Meter.
This may be any of the standard output meters on the market but should be sufficiently sensitive to provide a good deflection at low signal strength, and should also incorporate an adjustable shunt so that extremely strong signals may be read.

D—Coupling Means.
Coupling Condensers of 200 mmf., .25 Mfd., and a 400 Ohm resistor should be used when coupling oscillator to receiver during alignment as specified in the following paragraphs.

E—The receiver should be aligned in a location free from local interference (man made static)—as high frequency disturbances will cause difficulties when the short wave section is being adjusted. (A screen room is to be recommended).

2. DIAL SETTING.
Turn dial knob until condensers are fully meshed. The dial pointer should be on the horizontal line of the dial.

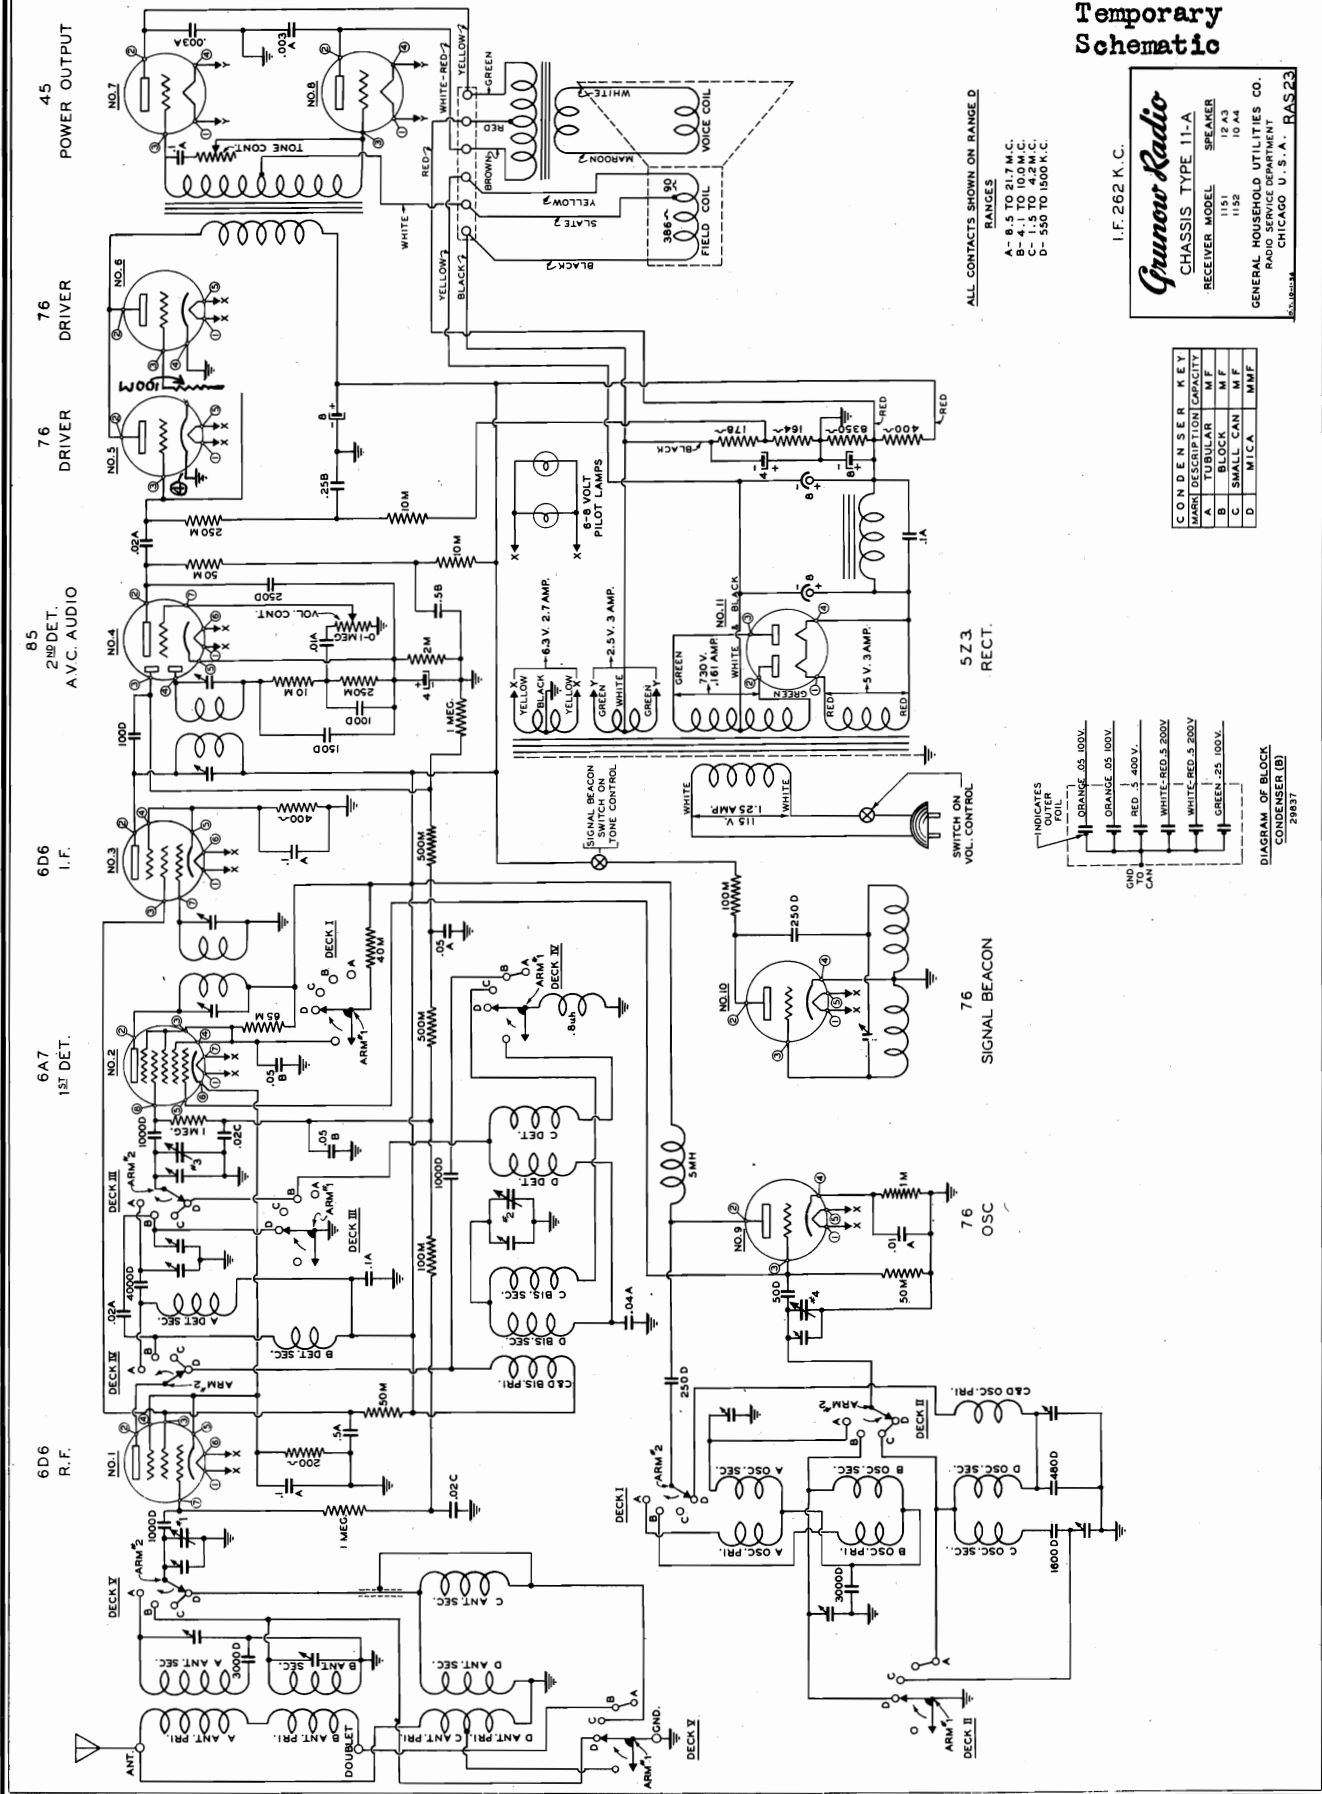

3. I. F. ALIGNMENT.
Connect signal lead of test oscillator to grid of the 6A7—(1st Detector Tube) through .25 Mfd. Condenser. Connect the ground lead to the Chassis.
A—Set Dial pointer to 1400 K.C. and range switch on position D.
B—Place test Oscillator in operation at 262 K.C. Turn receiver volume control and tone control to maximum.
C—Attenuate test oscillator output to lowest value consistent with obtaining a readable indication on output meter.
D—Adjust four I. F. Trimmers, A1-A2-A3-A4 Fig. 6, located on under side of chassis, until maximum output is obtained. During alignment, maintain as low a value of signal as will allow obtaining of accurate adjustment.
E—Turn the tone control counter clockwise until the Signal Beacon switch snaps on.
F—Adjust Signal Beacon Trimmer, A5, Fig. 5, which is located on left hand face of Chassis to zero beat with the 262 K.C. incoming signal.

4. 3700 K.C. ALIGNMENT.
A—Connect signal lead of test oscillator through 200 Mmf condenser to Antenna binding post.
B—Connect the test oscillator ground lead to the ground post of Chassis.
C—Turn range switch to range "C" and set dial pointer to 3700 K.C.

MODEL 292,293
 Changes
 MODEL 253,254,255,
 256,257,258
 Changes

GENERAL MOTORS RADIO CORP.

The grid return of the 10 tube Superhet chassis has been changed on chassis beginning with serial numbers approximately as follows:

Chassis model	Serial #	Note: For original circuit refer to:
S-3-A	3429	Rider Manuals
S-3-B	1069	Early 346-I
S-4-A	1296	Revised 2-11 & 2-12
S-4-B	1001	Radiotron 1101-1102

The change in the circuit also involves changes in parts numbers of two parts as follows:

	Part # below serial listed above	Part # above serial listed above.
245 bias resistor	1203535	1205259
Bypass cond. pack	1205971	1204162 or 1205971

Note if it should be necessary to replace the bypass cond. pack on models which use the original circuit, use part # 1205971.

if it should be necessary to replace bypass cond. pack on models which use the new circuit (shown above) with the tone control in the 2nd det. plate circuit, use part # 120597 by cutting off the red lead.

To replace bypass cond. pack on models having revised circuit, as above, with tone control in 45 plate circuit, use cond. pack part # 1204162.

The two bypass cond. packs can be distinguished by the number of leads, as follows:

- # 1204162 = 7 leads
- # 1205971 = 8 leads

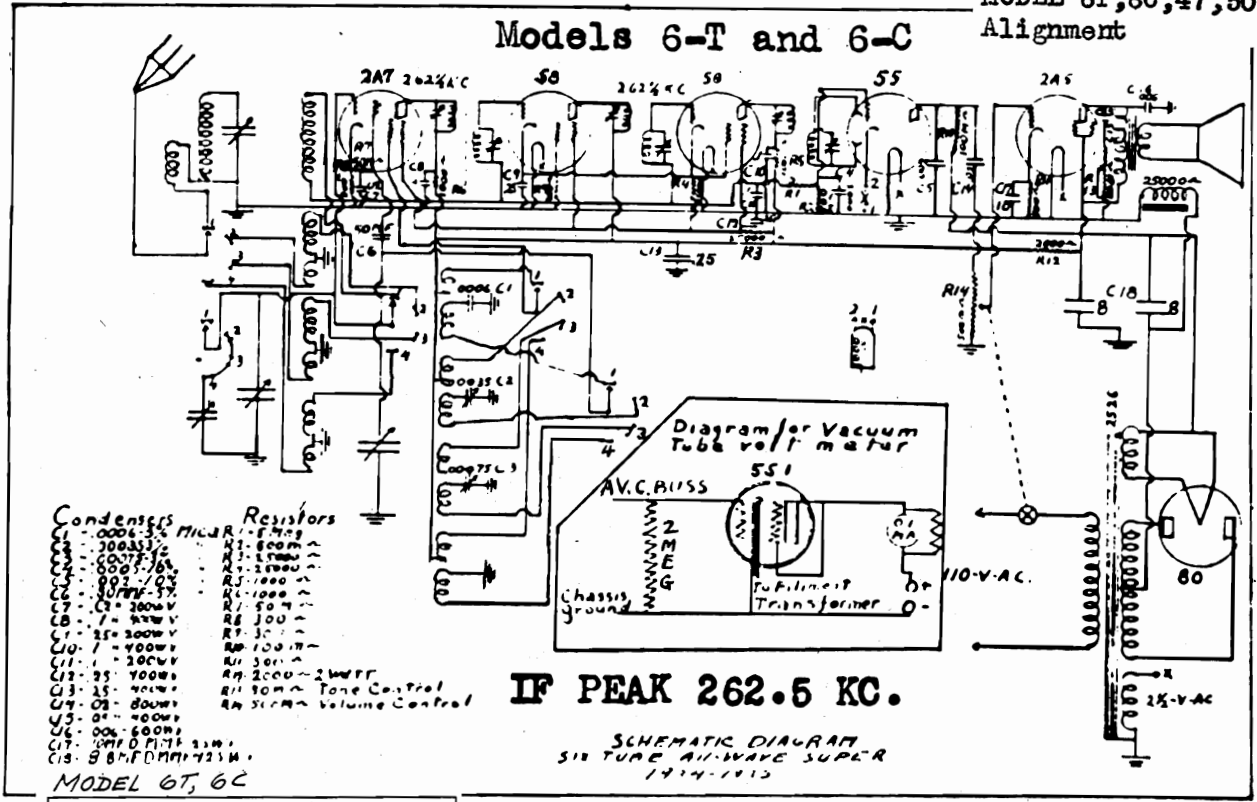

The 245 bias resistors can be distinguished by their length, color and number of sections, as shown on the diagram here.

SERVICE DATA (SIX TUBE ALL-WAVE SUPER HETERODYNE 1934-1935)

SERVICE DATA EIGHT TUBE ALL-WAVE SUPER HETERODYNE 1934-1935)

All models have automatic volume control of the diode type, controlling the first detector as well as the high frequency amplifier tubes. This A.V.C. makes it impossible to service and rebalance without a meter of the type to be described. This meter will work on any make or type of A.V.C., provided care is used. It can not be damaged by improper connection of the leads.

PARTS REQUIRED FOR VACUUM TUBE VOLT METER

- O to 1 or 0 to 1.5 milliammeter.
- Bell ringing transformer with secondary of 6-10 volts.
- 5 prong socket.
- 551 tube.
- 2 megohm grid leak.
- 10 ohm rheostat.
- 45 volt B battery.
- Clips, Box, Cord, Hookup Wire.

USING VACUUM TUBE VOLT METER

The cathode clip is connected to the cathodes of the tubes controlled by the A.V.C. The buss clip is connected to the A.V.C. buss in front of the isolating resistor. Adjust rheostat shunt until meter shows full scale reading. All balancing is done with maximum peak indicated by the meter swing toward O. Sensitivity of various receivers can be checked by the swing of meter from a known station. Short Wave fading can be seen by tuning in the station with meter connected to set.

REBALANCING

Do not rebalance a set until you are sure it requires it. 99 per cent of the sets do not need it. We do not find one case in one hundred that really should be rebalanced.

INTERMEDIATES

Connect a 262½ K. C. oscillator to the first detector grid (No. 2-A 7 tube) leaving grid cap in place. Set dial at 1400 K.C. Hook up vacuum tube meter as described and carefully adjust 3 screws on top of intermediates for maximum gain (minimum reading of meter). Don't flat top any stages. Have all shields in place. Keep volume control at lowest level.

CONDENSER GANG

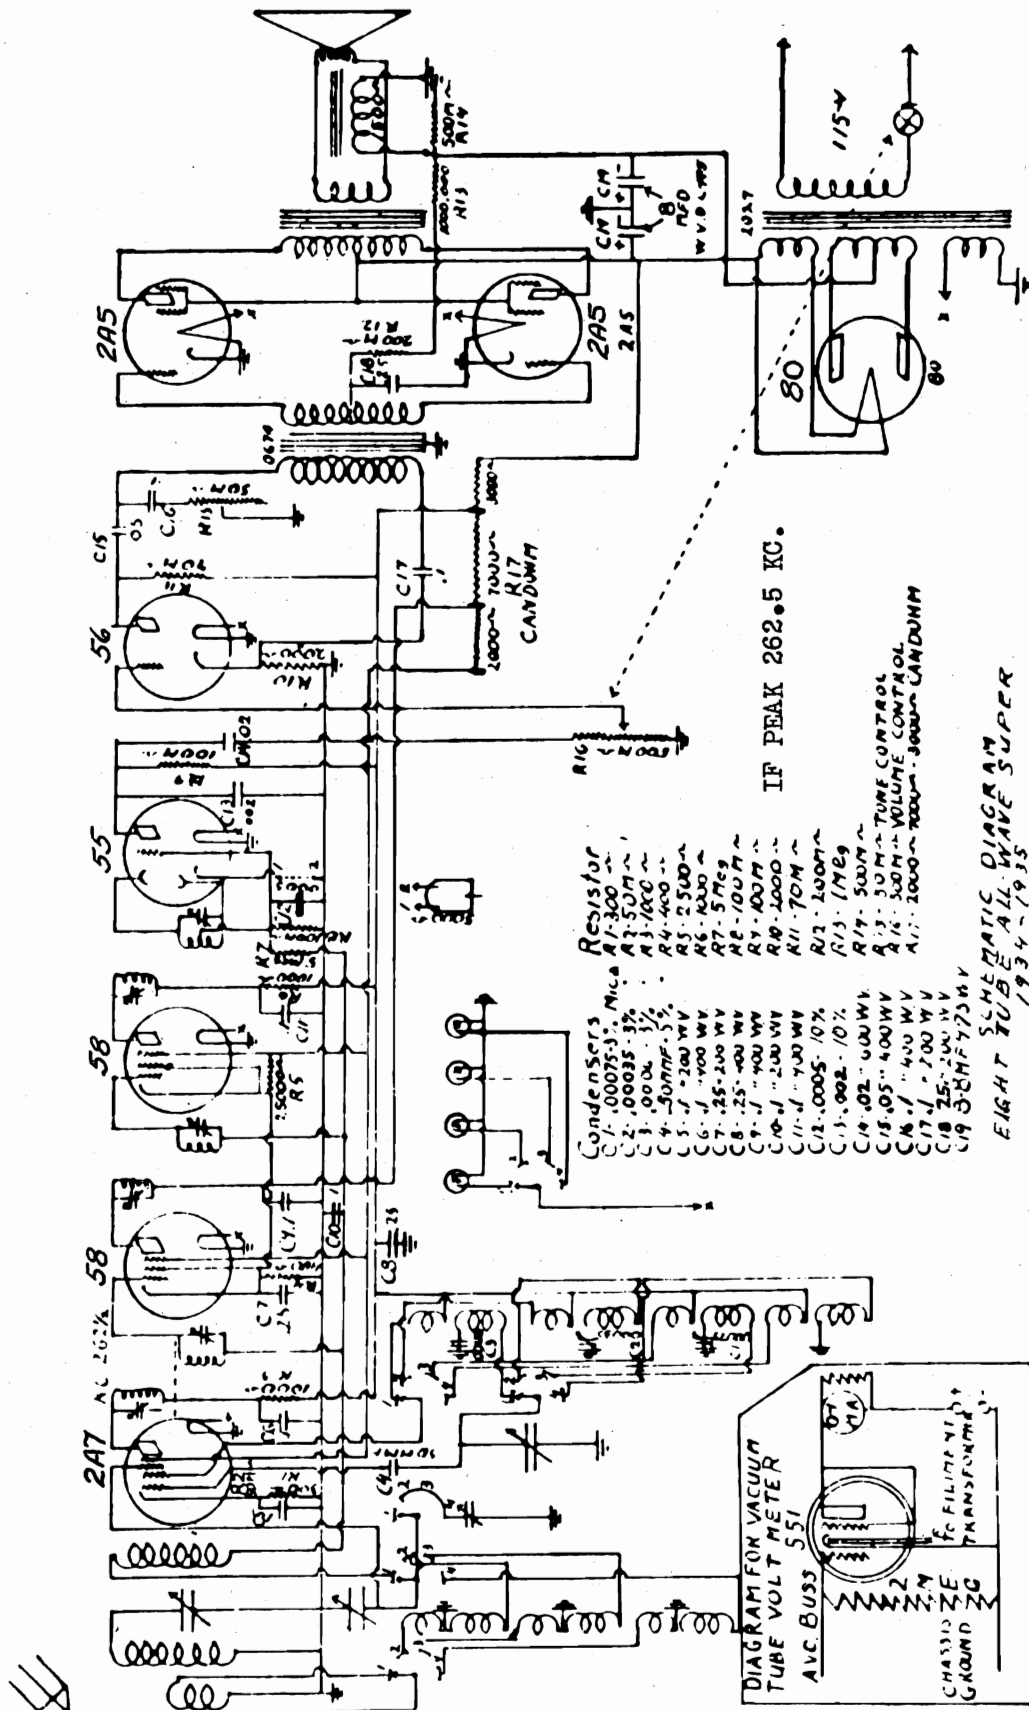

Set dial at 1400 K.C. when gang is at minimum position and tighten dial set screws. Tune in a station (or use an oscillator) to a known frequency signal around 1400 K.C. Carefully adjust oscillator section of gang until frequency is correct on dial.

If the intermediates are balanced on 262½ K.C., the dial will now track within 5 K.C. over the entire dial.

Adjust first detector section for maximum gain and follow by adjusting band pass trimmers. Don't bend any condenser plates unless absolutely necessary.

FRONT

SERVICE DATA, FIVE TUBE SUPER-HETERODYNE, 1934-1935

All models have automatic volume control of the diode type, controlling the first detector as well as the high frequency amplifier tubes. This A.V.C. makes it impossible to service and rebalance without a meter of the type to be described. This meter will work on any make or type of A.V.C., provided care is used. It can not be damaged by improper connection of the leads.

USING VACUUM TUBE VOLT METER

The cathode clip is connected to the cathodes of the tubes controlled by the A.V.C. The buss clip is connected to the A.V.C. buss in front of the isolating resistor.

Adjust rheostat shunt until meter shows full scale reading.

All balancing is done with maximum peak indicated by the meter swing toward O. Sensitivity of various receivers can be checked by the swing of meter from a known station. Short Wave fading can be seen by tuning in the station with meter connected to set.

REBALANCING

Do not rebalance a set until you are sure it requires it. 99 per cent of the sets do not need it. We do not find one case in one hundred that really should be rebalanced.

INTERMEDIATES

Connect a 175 K.C. oscillator to the first detector grid (No. 57 tube) leaving grid cap in place. Set dial at 1400 K.C. Hook up vacuum tube volt meter as described and carefully adjust 3 screws on top of intermediates for maximum gain (minimum reading of meter). Don't flat top any stages. Have all shields in place. Keep volume control at lowest level.

CONDENSER GANG

Set dial at 1400 K.C. when gang is at minimum position and tighten dial set screws. Tune in a station (or use an oscillator) to a known frequency signal around 1400 K.C. Carefully adjust oscillator section of gang until frequency is correct on dial.

If the intermediates are balanced on 175 K.C., the dial will now track within 5 K.C. over the entire dial.

Adjust first detector section for maximum gain and follow by adjusting band pass trimmers.

Don't bend any condenser plates unless absolutely necessary.

GULBRANSEN CO.

MODEL 872
Schematic, Changes
Socket Layout

Change in Later Models

In the first models of this chassis, resistors R-1 and R-3 were carbon resistors of the values as shown in Fig 1. Resistors R-12 and R-14, were in one vitreous enamel unit. The voltages for the sets with these resistors are shown in the voltage chart on Page 4 at the left.

In later models the four above mentioned resistors were replaced by one armored wire wound resistor unit. New values are used as follows

Code	Resistance
R-12	220 ohms
R-14	40 ohms
R-1	9,540 ohms
R-3	10,650 ohms

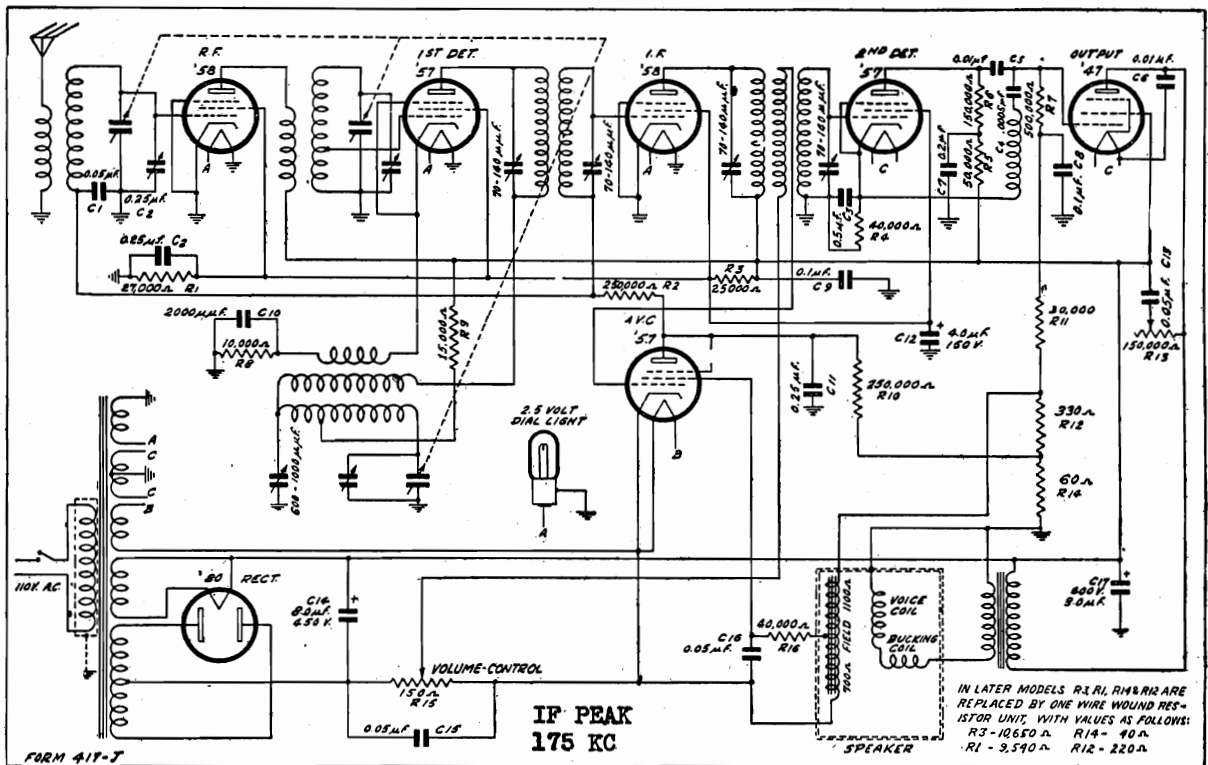

The voltages for the sets with the four-section wire wound resistor are shown in the second voltage chart on Page 4 at the right.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer and an additional filter condenser are used. Also, a slight change is made in the power unit wiring. In the twenty-five cycle set, condenser C-17 the dry electrolytic unit is put in parallel with condenser C-14. An 8.0 mfd wet electrolytic condenser is put in place of condenser C-17.

The twenty-five cycle chassis can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true that is the sixty cycle chassis cannot be operated from a twenty-five cycle power supply.

A 110-220 volt 40-60 cycle power transformer is also available for this model.

MODEL 872
Alignment, Voltage
Parts List

GULBRANSEN CO.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 175 K.C. and accurately calibrated signals over the broadcast band, and an output indicating meter are necessary. The procedure is as follows:

Set the signal generator for 175 K.C. Connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. Then adjust the four intermediate frequency condensers for maximum output. The adjusting

screws for these condensers are reached from the bottom of the chassis.

Next set the signal generator for a signal of exactly 1400 K.C. The antenna lead from the signal generator, is, in this instance, connected to the antenna lead of the receiver. Set the dial pointer on the 1400 K.C. mark on the dial scale and adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator trimmer first.

Next set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The adjusting screw for this condenser is reached from the top of the chassis and is between the I.F. and oscillator coil cans.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K.C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

MODEL "Comet Pro" AVC
Schematic, Voltage

HAMMARLUND
"COMET PRO"
A.V.C. MODEL

VOLTAGE READINGS MADE ON 1000 OHM PER VOLT METER USING 40 V. AND 500 V. RANGES, NEGATIVE TO CHASSIS. GAIN CONTROL "OFF"

DECEMBER, 1933

MODEL "Comet Pro" AVC
Alignment, Socket

HAMMARLUND MFG. CO.

Should it be necessary to remove the Comet "Pro" chassis from its shield cabinet it is easily accomplished by removing the four machine screws which extend through the bottom of the cabinet and the twelve screws around the edge of the front panel. The entire panel and chassis assembly may then be slipped out of the cabinet by drawing it forward. When thus removed all parts and wiring located beneath the chassis are exposed for examination or test. The shield cans found under the chassis may be removed if necessary by pulling them off.

First remove the chassis from the cabinet and prop it up on its rear edge so that both the top and bottom are accessible. Then connect the 10 ohm range of a 1000 ohm per volt voltmeter across the 25,000 ohm resistor between the cathode of the second detector and ground. This resistor is marked "R" in the schematic diagram.

This meter will function as a resonance indicator, showing maximum deflection when exact resonance is obtained.

Next provide a signal source. If an oscillator is available, tune it to 465 kc. and couple it to the receiver. If such an oscillator is not at hand the carrier of a fairly powerful station may be employed provided the station selected is one which is free from fading and interference. This signal should be tuned in on the receiver in the usual way and the gain control adjusted to cause an increase of about 2 volts in the voltmeter reading.

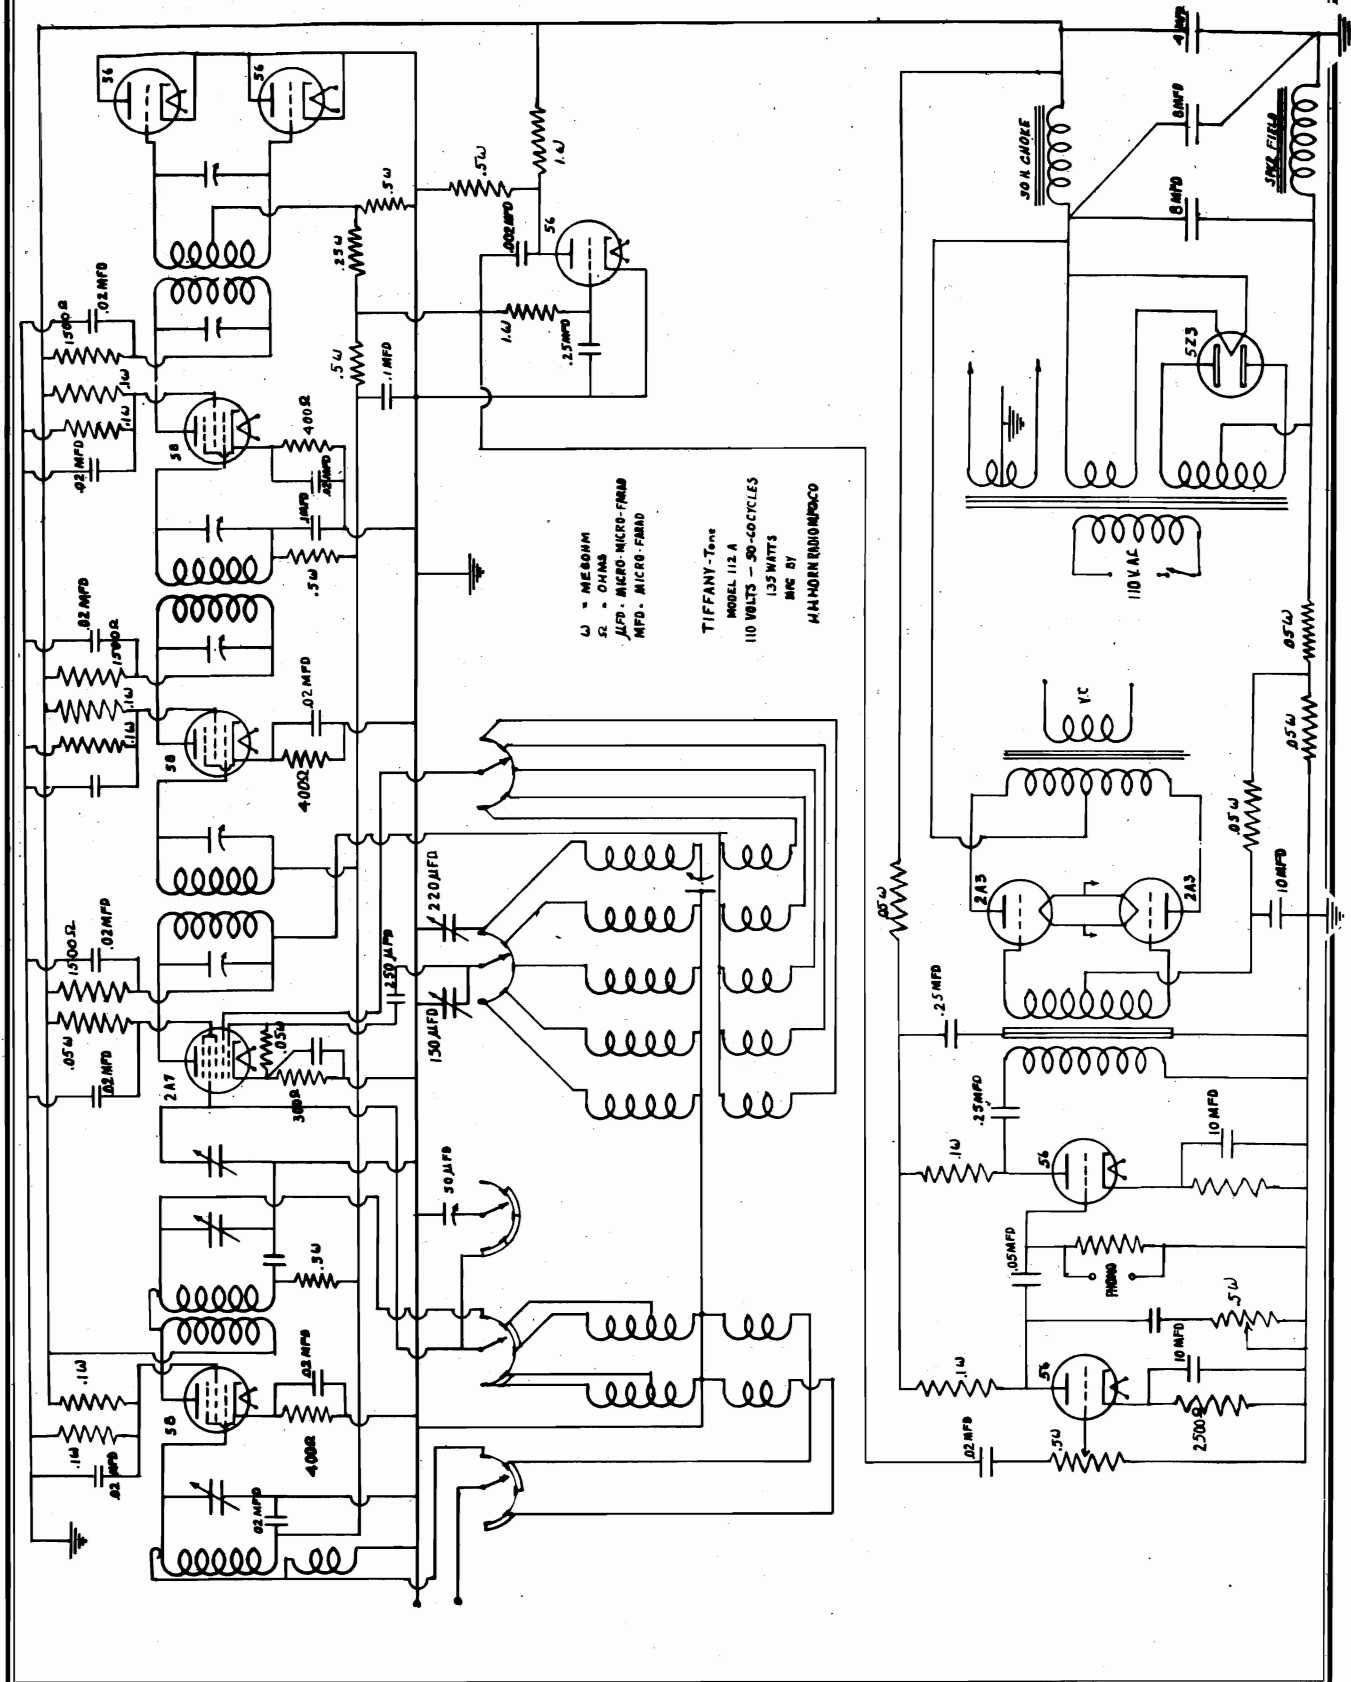

The actual alignment can now proceed. First adjust the bottom condensers of the three i.f. transformers. These are accessible from the under side of the chassis. Adjust them one after the other until maximum deflection of the resonance indicating meter is obtained. If the meter reading increases mate-

rially during this process retard the gain control to bring it back to the original plus 2 volts reading. Then make a similar adjustment of the condensers at the tops of the three i.f. transformers. Finally repeat this whole process, readjusting each condenser a second time to insure exactness of resonance.

After the i.f. stages are thus accurately lined up, turn on the heterodyne-beat oscillator and set its top lever so that it points diagonally away from the rear right-hand corner of the chassis. Then adjust the bottom adjustment screw on this transformer for exact zero beat. When this has been accomplished the receiver is in accurate alignment.

HOWARD RADIO CO.

MODEL R-9
AlignmentNOTES

- (1) One of the sections of the gang condenser is not used.
- (2) The two lower pilot light bulbs may be changed when necessary by loosening the screw holding the light bracket and it will pull out to the side. It is not necessary that the chassis be taken out of the cabinet.
- (3) It is important that the chassis is made to float as freely as possible within the cabinet.
- (4) When adjusting the oscillator circuits be sure to start on the right signal. The best procedure is to turn the trimmer all the way out and then pick the strongest signal when tuning in. If the oscillator happens to be on the wrong side, the set will be very insensitive around the center of the band.
- (5) Keep the input low from the signal generator when making the various adjustments, to prevent overloading.

The alignment of the I.F.'s; the intermediate frequency is 465 KC and the stages are aligned in the customary manner by adjusting the trimmers in the top of the IF cans for the maximum deflection with 465 KC input.

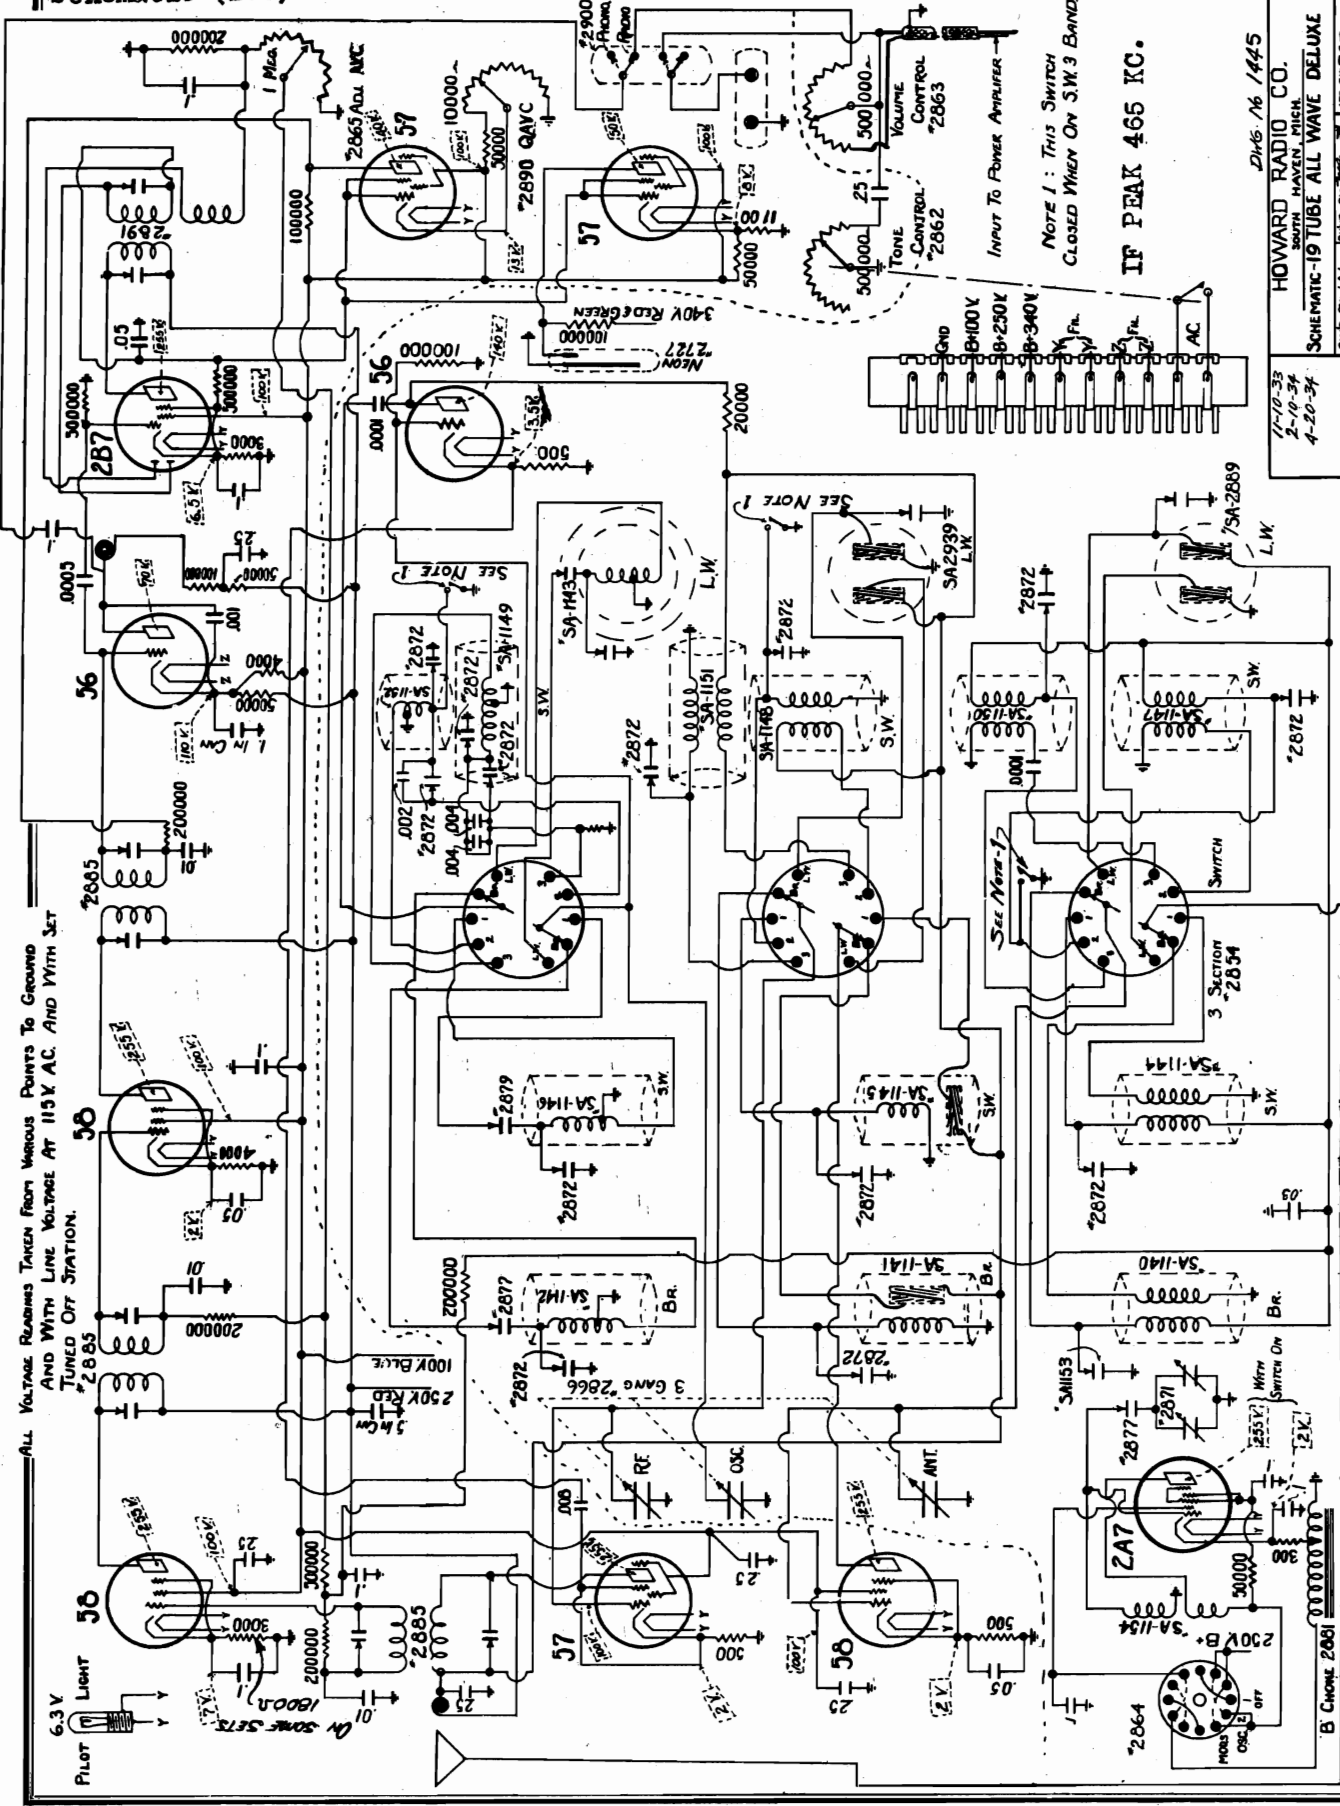

The Alignment of the Oscillator Circuits;

Before making any adjustments be sure that the hand is directly over the first line above 550 (which would be about 540) when the variable condenser is turned to maximum capacity.

- I Starting with the 1st Short Wave Band (1.6 to 4 Megacycles)
 - (1) Set your signal generator to 4 MC.
 - (2) Set dial to 4 MC.
 - (3) Then peak oscillator Trimmer (lettered "F" on the pictorial diagram) to the signal.
 - (4) Set generator to 1.6 MC.
 - (5) Set dial to 1.6 MC.
 - (6) Peak Oscillator Padding Condenser lettered "D" to signal.
 - (7) Reset generator and dial back to 4 MC and check any variation.
- II Second (2) S.W. Band, 4 to 12 MC.
 - (1) Set Generator and dial to 12 MC. Peak Oscillator trimmer lettered "G" for 12 MC.
 - (2) Cut down the signal generator to a very weak input in to the set, and adjust the RF trimmer lettered "J" at 12 MC.
- III The 3rd S.W. Band 10 to 22 MC.
 - (1) Set generator and dial to 20 MC.
 - (2) Peak Oscillator trimmer lettered "H" at 20 MC.
- IV The Broadcast band is aligned by;
 - (1) Adjusting trimmer "E" at 1400 KC.
 - (2) Peak Padding Condenser "A" at 600 KC.
 - (3) Adjust trimmer "B" across secondary winding of RF coil to peak at 1400 KC.
- V The wave trap (Trimmer "C") is adjusted to a minimum setting with 465 KC fed in to the Antenna.

MODEL W
Notes, Alignment

In the top of the coil can assembly in upper right hand corner (facing rear of tuner) will be found an adjustment. This adjustment is the one located in top next to neon adjustment.

Watching voltmeter, set the above adjustment with insulated screw driver until a maximum reading is obtained on voltmeter.

The AVC circuit has been fundamentally adjusted by the above procedure and should be set for the locality in which set is to be operated, in accordance with adjustment number 8.

8. AVC ADJUSTMENT FOR VARIOUS LOCALITIES

In certain localities especially close to a broadcast station, it may be necessary to readjust the AVC (slotted shaft) control.

In order to properly make this adjustment, tune the receiver in exact resonance with the most powerful station to be received. Then if the station's signals sound "fringy" or rough, turn the control to the right until this condition stops. Do not turn this control beyond this point.

9. NEON TUNING INDICATOR

Facing the back of tuner chassis, extending through one of the tall shielded assemblies in the upper right hand corner, will be found a small black knurled knob. This knob is used to adjust the neon resonance indicator. Due to the fact that in some localities the signal strength from certain stations varies somewhat, it is advantageous to be able to set this adjustment.

At the time of day during which the station signals are the most powerful (usually in the evening) adjust the receiver dial to a powerful station, then turn the neon adjustment until the light just fills the opening in arrow of dial. Then readjust the tuning dial of receiver. Should the light become more brilliant, leave the dial at point of highest brilliancy and again readjust neon indicator until it just fills the arrow opening.

A little practice will enable the user to set this indicator to meet the individual requirements.

When once adjusted for the locality in which the receiver is to be used, it should not have to be readjusted.

Since the inter-station silent tuning system is a proportional function of the neon light, the inter-station silent tuning system will be correctly adjusted.

The neon light system is not intended to work on the short wave stations. However, on the more powerful signals it will generally give an indication of resonance.

There are two important things to keep in mind when adjusting this receiver.

1. Since all adjustments are made with AVC inactive, extreme care must be used to attenuate the input signal low enough so that there will be no overloading of tube amplifiers while making adjustments. If the input signal voltage is attenuated to the point where the speaker voice coil power does not exceed 50 or 75 milliwatts no trouble will be experienced from this source.

2. After the high frequency adjustments have been made on short wave bands, the test oscillator or generator should be advanced to 930 KC higher in frequency - the output voltage of generator advanced considerably and notice of the image signal of receiver oscillator falls at this point. In case this signal is not heard, the adjustment of the receiver oscillator has been incorrectly made. An example:

After the third shortwave band has been adjusted at 20 m.c. it should be possible to move the test oscillator to 20, 930 KC and hear the signal.

6. THE ALIGNMENT OF THE FREQUENCY METER

- (a) Turn main dial to where 4800 KC comes in. This may be checked by your signal generator. The signal generator is not used, however, in aligning the Frequency Meter.
- (b) Make certain the hand on the Frequency Meter falls on 1.5 when the 2-gang condenser is at full capacity.
- (c) Turn the oscillator switch all the way to the right to the Modulator position.
- (d) Turn frequency dial to 4 and adjust the trimmer on the two-gang variable condenser to resonance with the main dial setting.
- (e) Turn band indicator switch to first short wave band (1.5 to 3.5)
- (f) Set the main dial to where 1500 KC comes in, which is at the .55 figure (as mentioned before).
- (g) Turn frequency dial to 1.5 and adjust trimmer No. 15 for maximum signal.

7. AVC ADJUSTMENT

Looking at the bottom view drawing #416, there will be noted a terminal of the AVC control marked "Z". Connect the negative terminal of a high resistance voltmeter (1000 ohms per volt at least, using a medium voltage scale) to this terminal marked "Z". Connect the positive side of voltmeter to chassis ground.

Adjust the receiver to a signal having approximately two or three thousand microvolt intensity (Note: a fairly powerful local station may also be used for this).

MODEL W
I-F Alignment
R-F, Osc. Align'm't.

HOWARD RADIO CO.

2. THE BROADCAST BAND

It is necessary on the broadcast band only that a metal bottom with holes in line with the trimmer nuts be used so that the circuits will not be detuned when the regular bottom plate is screwed back on.

- (a) Turn band indicator to Broadcast .55 to 1.5
- (b) Set dial to 1.4
- (c) Feed in 1400 KC and adjust trimmer No. 14 (see pictorial diagram, bottom view) for resonance.
- (d) Adjust RF and antenna stages. The RF is No. 7, and the Antenna Trimmer consists of the knurled knob extending from the top of the Antenna Coil Can.
- (e) Rotate dial to .55 and adjust trimmer No. 10 for resonance with 550 KC.
- (f) Recheck the settings at 1400 and bend plates of variable condenser at 950 or other points where necessary for KC reading on dial.

3. THE FIRST SHORT WAVE BAND

- (a) Turn band indicator to 1.5 to 3.5.
- (b) Set dial to 3.5
- (c) Feed in a 3500 KC signal and adjust Trimmer No. 13 for resonance.
- (d) Adjust RF and Antenna stages, Trimmers Nos. 3 and 6
- (e) Rotate dial to where the hand points to .55 on the broadcast band. The dial calibration may be found to be slightly off at this point and the .55 figure corresponds to 1.5 on the First Short Wave Band. Feed in 1500 KC and adjust Trimmer No. 9 for resonance.
- (f) Recheck setting at 3500 KC.

4. THE SECOND SHORT WAVE BAND

- (a) Turn band indicator to 3.5 to 9
- (b) Set dial to about 8.9. The calibration is slightly off at this point and the 8.9 figure corresponds to 8.5
- (c) Feed in 8500 KC and adjust Trimmer No. 12 for resonance
- (d) Adjust RF and Antenna stages with Trimmers Nos. 3 and 2
- (e) Rotate dial to 3.5 and adjust Trimmer No. 8 for resonance with 3500 KC
- (f) Recheck setting at 8.5 (8.9).

5. THE THIRD SHORT WAVE BAND

- (a) Turn band indicator to 9 to 21
- (b) Set the dial to 20
- (c) Feed in 20000 KC signal and adjust oscillator trimmer No. 11 for resonance
- (d) Adjust RF and Antenna stages, trimmers Nos. 1 and 4
- (e) The alignment at 9 is obtained by use of the fixed condensers. This should not require any change.
- (f) In order to make the band more sensitive where most of the foreign reception is obtained, it is advisable to turn the dial to 12 on the third band and readjust the Antenna coil trimmer (No. 1) to peak at 12000 KC.

THE PROCEDURE TO ALIGN THE I.F. STAGES

The IFs are aligned in the usual system of feeding the intermediate frequency of 465 KC into the grid of the 57 1st Detector tube.

Make certain that the AVC adjustment (which is the slotted shaft extending from the back of the chassis) is turned all the way to the left when gaining the IF, RF or oscillator circuits.

The two trimmers in each of the three IF Coil Cans should be very carefully tuned to resonance as they are very critical and will greatly affect the performance of the receiver.

The sensitivity of the IF stages should be between 10 and 20 Microvolts.

ALIGNING THE R.F. AND OSCILLATOR CIRCUITS

After the IFs are aligned, the various circuits may be aligned in the order given below.

Keep the AVC adjustment all the way off to the left as before.

It is not necessary that the oscillator be taken out of its socket when aligning any of the RF circuits.

Always adjust the oscillator stage before the RF in any particular band.

Be sure to start on the right signal when adjusting the oscillator trimmer. The best procedure is to turn the trimmer all the way out and then pick the strongest signal when turning in. If the oscillator happens to be on the wrong side, the set will be very insensitive around the center of the dial.

The plates on the variable condenser should be bent to make the KC readings on the dial line up ONLY on the Broadcast Band.

Before adjusting any bend, make certain that the pointer of the station indicator is set on the last black line when the dial is turned all the way to the left on the broadcast band just above .55 -- at this point the variable condenser should be all the way in to maximum capacity.

1. THE LONG WAVE

- (a) Turn the band indicator to .15 to .35
- (b) Set dial to .35
- (c) Feed 350 KC into the antenna post and adjust the trimmer in the long wave oscillator can for resonance. The correct trimmer for this adjustment is the one that is not green coded on the trimmer washer. (Refer to pictorial diagram, top view).
- (d) Adjust RF and antenna stages. There is only one trimmer for each.
- (e) Rotate dial to just above .17 and adjust the oscillator trimmer that is coded green, for resonance with 175 KC.
- (f) Recheck the 350 KC setting.

REPLACEMENT PARTS LIST OF "W" (EXPLORER) TUNER

10. THE POWER AMPLIFIER
The power amplifier schematic diagram will clearly give all information that is needed from a servicing standpoint.
The tuner is coupled to the audio by the 56 tube, resistance coupled to two 56 drivers into the four push-pull parallel 2A5s.
The rectifier circuit uses the 83V tube for the B supply.
However, the bias voltage for the 2A5s is obtained by an additional rectifying circuit comprising the 56 tube and additional choke and filter.

11. VARIOUS MECHANICAL ADJUSTMENTS

(a) The adjustment of the white fabric drive belt is very easily made tighter or looser by use of a socket wrench to turn the nut holding the idler pulley stud which is adjustable in the slot (see pictorial diagram). Pushing the stud upward tightens the belt, and downward loosens the tension of the belt. There is no necessity for making this belt real tight, as the belt is under no load -- only the dial disc -- it is advisable to just take out the slack.

(b) Adjustment of the rubber tread drum against the knurled drive shaft is accomplished by loosening the screws holding the variable condenser spacers (see pictorial diagram). It is advisable to loosen and reset the fabric belt as mentioned above after making this adjustment, since the changing of one will affect the other.
The right tension between the drum and the knurled shaft can be easily determined by turning the condenser to one extreme rotation and adjusting the space just so it will pull the drive mechanism. Too much pressure will cause too much work between the rubber and shaft, resulting in slippage of the drive on slow speed. Too little pressure of course will result in slippage at any speed.

(c) For other drive adjustments, remove the Escutcheon Plate three screws on top, five along bottom -- to adjust the drive discs, if necessary.

12. NOTES:-

- (1) The replacement parts list is given on the last sheet of this manual.
- (2) On some of the models the dual speed is accomplished by use of a push-pull knob instead of a double knob.
- (3) The first terminal lug next to the ground terminal on the 11 terminal strip is not used.
- (4) The resistance value of the resistor marked "X" on the pictorial diagram may be of different values, since it is placed there to reduce tendency of oscillations in the Third Short Wave Band.
- (5) On one series of sets a single shielded wire is used to couple tuner to amplifier. The later sets use a double shielded wire. The red wire is the feed wire to the amplifier, and the black is ground and connects directly from the volume control to the ground lug within the power pack. This provides a better ground connection in addition to the shielding.
- (6) Should the receiver blow fuses easily the 83V tube should be checked the first thing.

Balancing and Aligning

Each automobile radio is carefully balanced on accurate oscillators before leaving the factory. If it is necessary to rebalance because of part changes or other causes a good test oscillator capable of delivering modulated signals at 262½, 1500 and 600 Kc. will be needed. The customary audio out-put meter may be used IF the out-put of the test oscillator is weak enough to get below the A.V.C. action. Otherwise a microammeter will be needed to measure the A.V.C. voltage developed. It should be connected from ground to the junction of two 100M resistors and one condenser in the center bottom of the chassis.

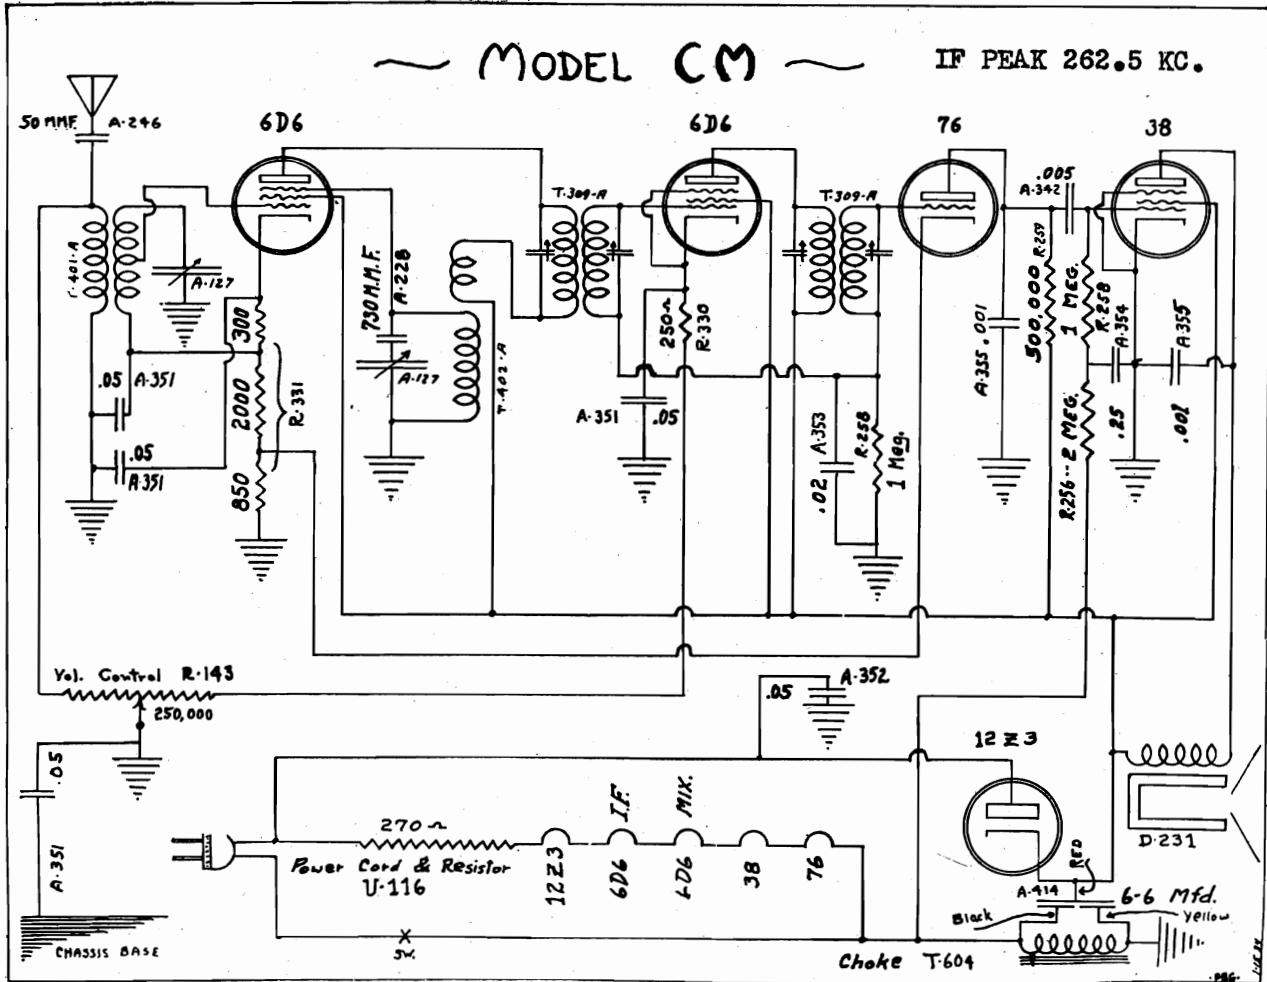

To balance the I.F. circuits, attach the antenna wire to the test oscillator. Short out the oscillator section of the tuning condenser in the radio by inserting a thin piece of metal between the plates. Set the test oscillator to 262½ Kc. and adjust the trimmers on the I.F. transformers for maximum output. Go over all four adjustments at least twice for accuracy.

Next set the test oscillator at 1500 Kc. and open the tuning condenser until it is tuned to the test signal as indicated by maximum output. Adjust the small trimmers on top of the condenser gang for maximum output.

Set the test oscillator at 600 Kc. and, while rocking the tuning condenser slowly back and forth across this setting, adjust the padder condenser for maximum output. Go over the adjustments at least twice for accuracy.

Instructions for Balancing and Aligning

Adjustments have been carefully made at the factory and should not need to be changed unless it has been necessary to replace an IF transformer or coil or the adjustments have been tampered with. Later in this bulletin, when the different chassis are taken up one by one, reference will be made to the following operations.

OPERATION NO. 1 Adjustment of IF transformers. When adjusting the IF units the oscillator section of the 2 gang variable condenser must be shorted out. This is easily accomplished by inserting a thin strip of metal between the plates. Set the test oscillator to 262½ kilocycles and connect its output to the antenna wire of the set. Using a No. 4 fibre spintite socket wrench adjust the 4 nuts at the ends of the IF units until exact resonance is obtained. It is advisable to go over them more than once as when one nut is adjusted it may throw the adjustment on the other end of the unit, slightly out of resonance.

OPERATION NO. 2. Adjusting trimmers on 2 gang condenser at 1500 kilocycles. Set the test oscillator to 1500 kilocycles and connect its output to the antenna wire of the set. If the output of the oscillator is too strong connect through a very small fixed condenser or place the output wire of the oscillator near the antenna wire without making any direct connection. Open the variable condenser until maximum signal is indicated by the meter. Then adjust the trimmer on the antenna section of the condenser until maximum signal is indicated on the meter. See "Recommended Service Department Equipment" for instructions regarding meter.

OPERATION NO. 3. Aligning 2 gang condenser on 1000 kilocycles. Test oscillator set at 1000 kilocycles and coupled to antenna wire of set. Insert a thin bakelite, celluloid or mica feeler strip between the plates of the variable condensers to determine whether the circuits are properly matched. The action is this—the dielectric constant of the celluloid feeler strip being higher than that of the air it displaces, results in an increase of capacity. Open the variable condenser just enough to indicate two or three points below maximum signal. As the feeler is inserted the meter reading should indicate increasing signal and then decreasing as the feeler is inserted farther. This procedure should be followed on both sections. Should the meter fail to show an increase in signal as the strip is inserted in either section this indicates too great a capacity for that section. This may be corrected by bending the outside rotor plates out at the point where they begin to mesh with the stator.

OPERATION NO. 4 Aligning 2 gang condenser at 550 kilocycles. Instructions same as for operation 3 except test oscillator and set tuned at 550 kilocycles.

CHASSIS' D & DSP

Chassis DSP is the same as chassis D except that an external 6" dynamic type speaker is used.

To adjust IF units and align condensers follow these operations in the order given—Operations 1 (oscillator section of 2 gang condenser nearest front of chassis), 5 (given below), 6 (given below), 3, 4 and 7 (given below). Use microammeter or DC milliammeter as previously described.

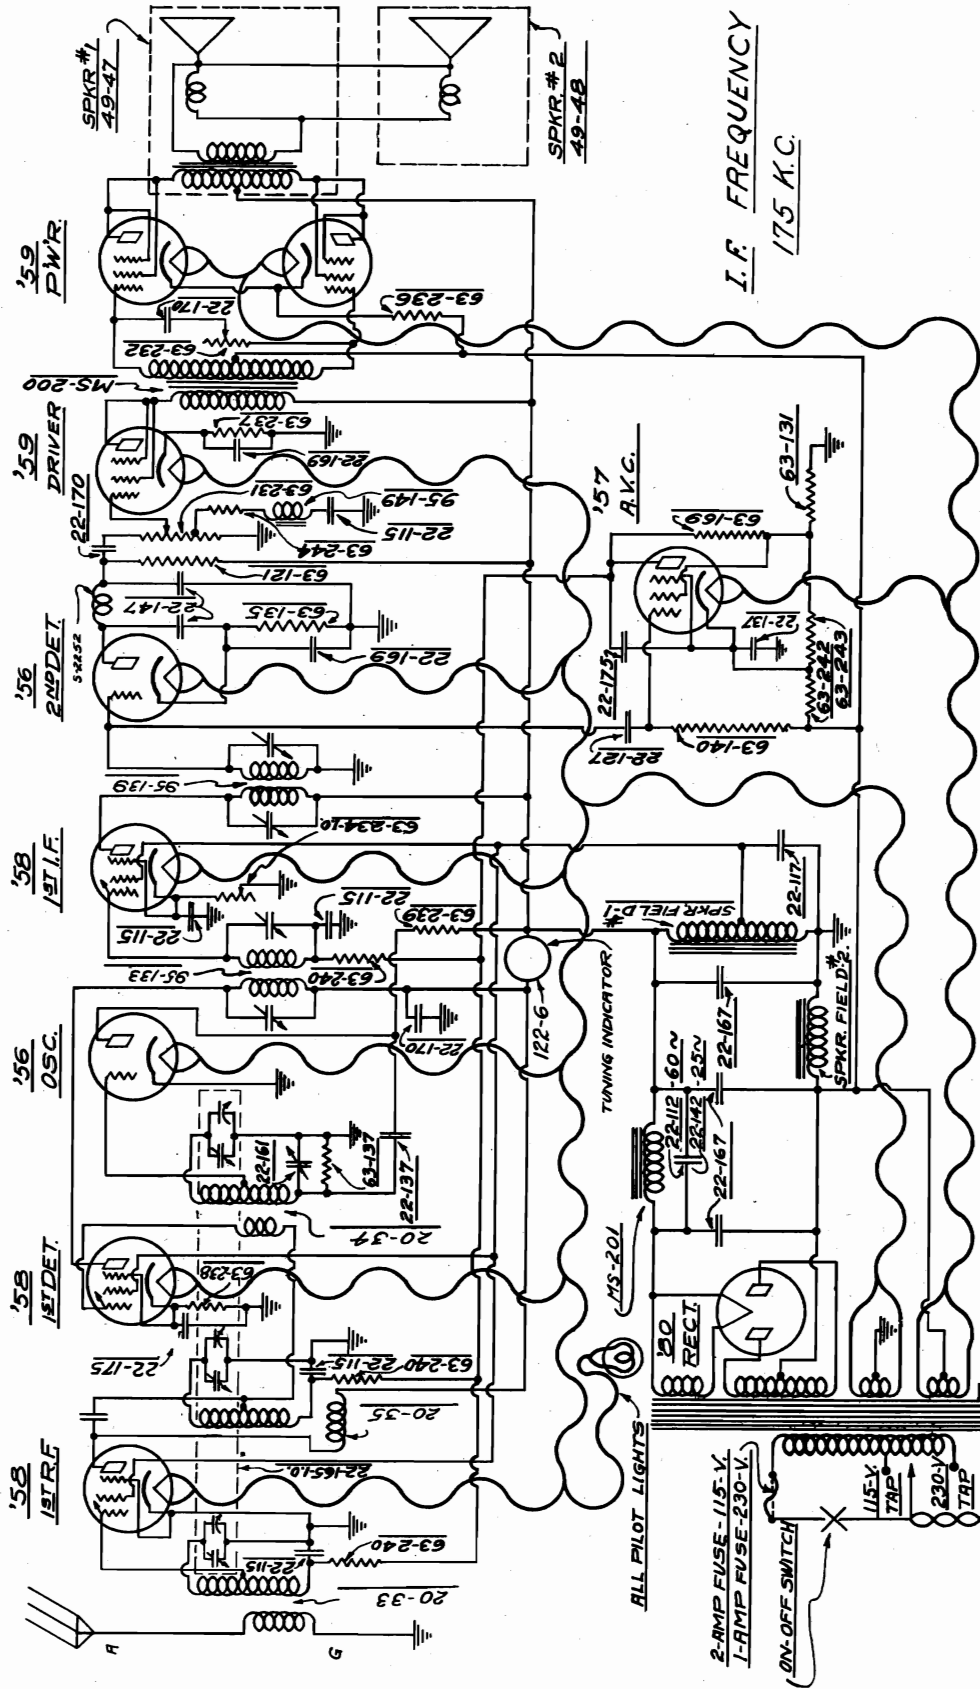

OPERATION NO. 5 Be sure the switch on the rear of the chassis is turned to the short wave position. Remove short from the oscillator section of the 2 gang condenser and proceed as follows. Turn the small two plate vernier condenser so that it is only about 1/5 meshed. If the test oscillator is to be coupled direct to the antenna wire it should be attached close to the chassis. The coiled up antenna wire acts as an RF choke and high frequency signals will not go through it. A pin pushed through the insulation of the antenna wire will allow connection close to the chassis. Set the test oscillator so that it is radiating a signal on approximately 22 meters and rotate the condenser gang very slowly until this signal is picked up. Alternately change the setting of the trimmer on the oscillator section of the 2 gang and retune the 2 gang until the maximum signal is indicated.

OPERATION NO. 6 Turn the switch on the rear of the chassis to the broadcast position. Tune in the 1500 kilocycle signal from the broadcast test oscillator. It will have been noted that there is no trimmer in the customary location on the antenna section of the 2-gang condenser. The trimmer is mounted externally near the 2 plate vernier condenser. This trimmer is used only on the broadcast band, the 2-plate vernier being in the circuit on the short wave position. Adjust the broadcast antenna trimmer for maximum signal.

OPERATION NO. 7. Turn the switch on the rear of the chassis to the short wave position. Set the two plate vernier condenser so that it is about 4/5 meshed. Pick up the 45 meter signal from the short wave test oscillator. Test for resonance with the feeler strip as described in operation 3 but do not bend any plates. If the antenna section of the condenser gang has insufficient capacity it will be necessary to crowd together two or three turns of wire on the short wave antenna coil. If too much capacity, they must be spread somewhat. The short wave antenna coil is the space wound coil on the bottom of the chassis.

"C" preceding the number signifies 1.0 watt

Set the signal generator for 175 K. C. Connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. Then adjust the 3rd I. F. primary condenser for maximum output. The adjusting screw for this condenser is reached from the top of the sub-panel and will be seen in back of the tuning condenser.

Next set the signal generator for a signal of exactly 1400 K. C. The antenna lead from the signal generator is, in this instance, connected to the antenna lead of the receiver. Set the dial pointer on the 1400 K. C. mark on the dial scale and adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator trimmer first.

MODEL B-60

**Alignment
Parts List**

LAFAYETTE RADIO & TELEVISION CORP.

Batteries

The batteries and voltages required are shown in Figs. 2 and 3.

The majority of potential complaints on short "B" battery life can be prevented if proper instructions are given to the customer at the time the receiver is installed. The average "B" drain of this receiver under no signal conditions is 18 milliamperes. **A milliammeter in the negative "B" line will quickly determine whether the "B" drain is excessive or normal.**

Two factors directly affect the "B" battery consumption. One is the strength of the station signal. When the signal is weak, little or no automatic volume control action is obtained, and the 34 tubes draw high plate current. As the strength of the incoming signal increases, plate current in these tubes is reduced with a corresponding reduction in total "B" battery current. The other factor is the volume used. As the volume is increased, the "B" battery drain of the output tubes is increased.

As this receiver does not have a pilot lamp, it is easy to forget to turn it off. When this happens, the receiver may be on as long as 24 hours or more. A continuous drain of this kind for a long period will shorten the life of the "B" batteries considerably. **Caution the customer regarding this.**

The "A" Battery consists of any direct current power supply source delivering from 2 to 3 volts. An air cell, 3 volt dry cell bank, and 2 volt storage cell are some of the units which can be used. **Caution—do not use a 6 volt storage battery.**

For the "C" battery a special 22½ volt "C" battery with 9, 10½ and 16½ volt taps, as indicated in Fig. 2, may be used. If such a battery is not available, two standard 4½ volt "C" batteries and a standard 7½ volt "C" battery can be connected as shown in Fig. 3 to supply the necessary voltages.

If the receiver does not operate satisfactorily test the batteries under load. A high resistance meter is required for the "B" and "C" voltages. If any of the batteries are considerably below their rated voltage, new ones should be used. When the "B" batteries are replaced the "C" batteries should also be replaced. The reason for this is that the "C" drain is such that the "C" batteries are run down in about the same time as the "B" batteries.

Tubes

The tubes used in this receiver are all of the 2 volt series. The 34's are R. F. Pentodes with the suppressor grid tied internally to the cathode. The 30 tube is a general purpose triode. All of these tubes are of the filament or directly heated cathode type. All of them have a 2 volt filament and should not be connected to a power supply not intended for this type of tube. The filaments of both types of tubes take 60 milliamperes at 2 volts and the total "A" drain is therefore 9 times .06 or .54 amperes. The average "B" drain of the receiver under no signal conditions is 18 milliamperes. The tube marked 10AB is a voltage regulator which keeps the filament voltage within safe operating limits over a battery range of 2 to 3 volts.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 175 K. C. and accurately calibrated signals over the broadcast band, and an output indicating meter are desirable. The procedure is as follows:

Set the signal generator for 175 K. C. Connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. Then adjust the four intermediate frequency condensers for maximum output. The adjusting screws for these condensers are reached from the bottom of the chassis.

Next set the signal generator for a signal of exactly 1400 K. C. The antenna lead from the signal generator is, in this instance, connected to the antenna lead of the receiver. Set the dial pointer on the 1400 K. C. mark on the dial scale and adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator trimmer first.

The tuning condensers are all adjusted at the factory for the correct relative capacity between the oscillator section and the other two sections. As a rule no adjustment other than at 1400 K. C., as mentioned above, is required. If, after the receiver has been aligned at 1400 K. C., the sensitivity is still low at some portion of the band, adjust the signal generator to that setting and tune for maximum output with the station selector knob on the receiver. Then, without readjusting the trimmers, bend the slotted rotor plates on the **front two sections** of the gang to obtain maximum output. Care should be taken not to bend these plates too far in an inward direction as the condenser may short as a result.

After any adjustment of this nature, set the signal generator again for a signal of 1400 K. C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

LAFAYETTE RADIO & TELEVISION CORP

MODEL L-16, L-17
L-18, L-19
Schematic
Socket, Changes

Change in Later Models

In the first models of this chassis, resistors R-1 and R-3 were carbon resistors of the values as shown in Fig 1. Resistors R-12 and R-14, were in one vitreous enamel unit. The voltages for the sets with these resistors are shown in the voltage chart on Page 4 at the left.

In later models the four above mentioned resistors were replaced by one armored wire wound resistor unit. New values are used as follows

Code	Resistance
R-12	220 ohms
R-14	40 ohms
R-1	9,540 ohms
R-3	10,650 ohms

The voltages for the sets with the four-section wire wound resistor are shown in the second voltage chart on Page 4 at the right.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer and an additional filter condenser are used. Also, a slight change is made in the power unit wiring. In the twenty-five cycle set, condenser C-17 the dry electrolytic unit is put in parallel with condenser C-14. An 8.0 mfd wet electrolytic condenser is put in place of condenser C-17.

The twenty-five cycle chassis can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true that is the sixty cycle chassis cannot be operated from a twenty-five cycle power supply.

A 110-220 volt 40-60 cycle power transformer is also available for this model.

(1) Read Across R-14.

(2) If I.F. readings are made with a cord and plug, ground the control grid through a condenser to prevent oscillation.

(3) Read Across R12 and R14.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 175 K.C. and accurately calibrated signals over the broadcast band, and an output indicating meter are necessary. The procedure is as follows:

Set the signal generator for 175 K.C. Connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. Then adjust the four intermediate frequency condensers for maximum output. The adjusting

screws for these condensers are reached from the bottom of the chassis.

Next set the signal generator for a signal of exactly 1400 K.C. The antenna lead from the signal generator is, in this instance, connected to the antenna lead of the receiver. Set the dial pointer on the 1400 K.C. mark on the dial scale and adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator trimmer first.

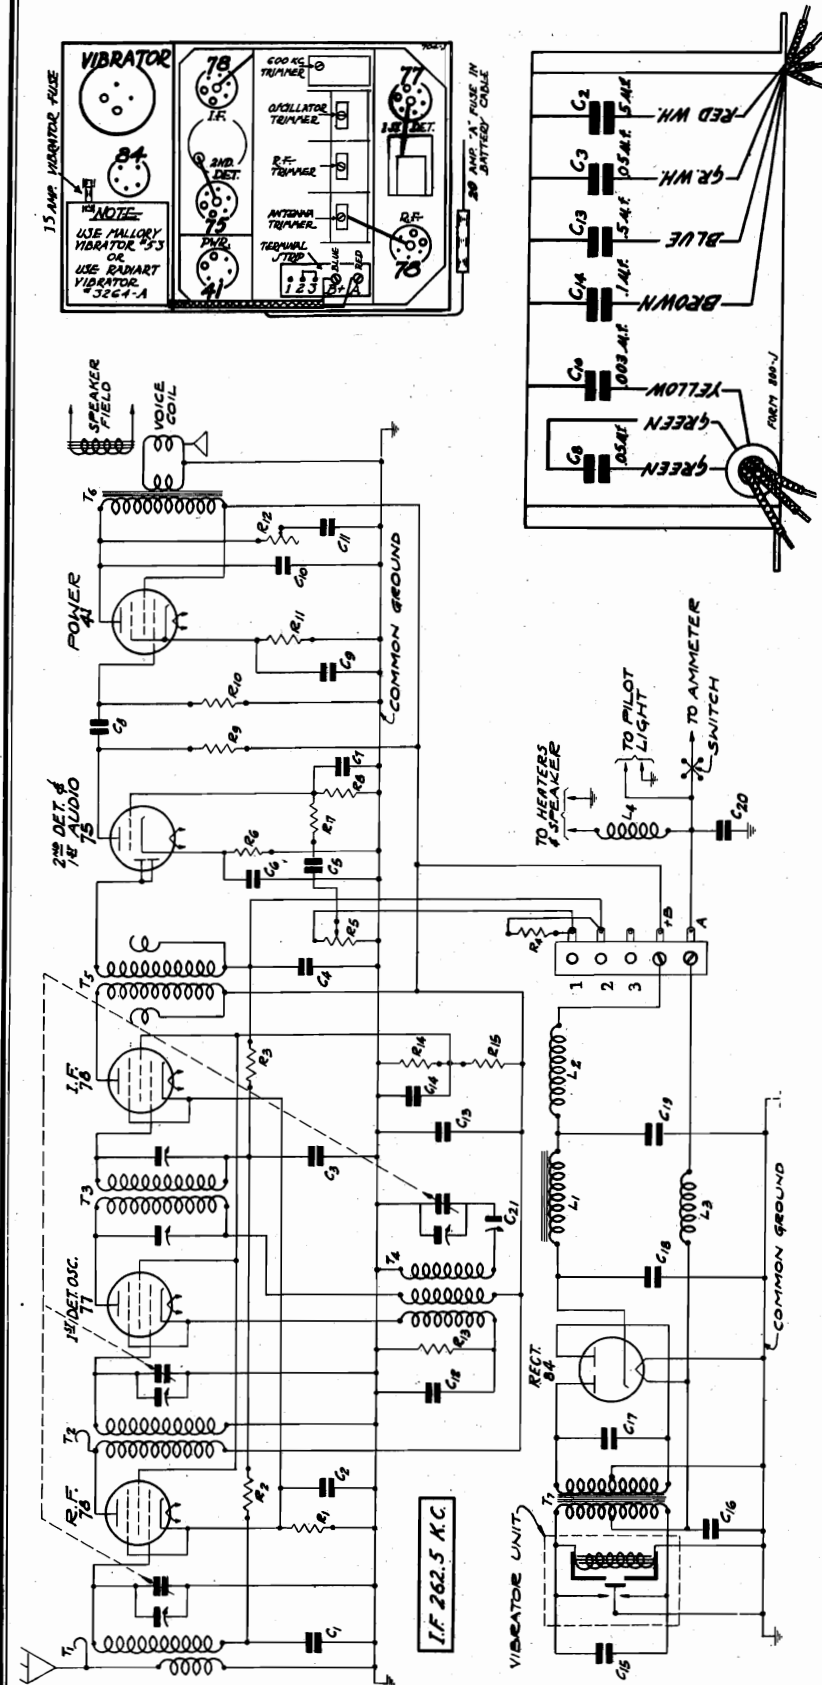

Next set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The adjusting screw for this condenser is reached from the top of the chassis and is between the I.F. and oscillator coil cans.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K.C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

Voltages At Sockets

On the following chart are given the voltages at the sockets with all tubes in and the set in operating condition. The antenna should be disconnected.

The voltages can be read with the chassis in the box, by means of an analyzer plug.

If the chassis unit is taken out of the box all of the socket terminals can easily be reached under the chassis with test prods.

If the chassis is taken out, the power unit must also be taken out. Connect a jumper from chassis base to the metal wall of unit to complete the ground circuit.

Connect the Hot side of battery to the battery cable on the chassis and the ground side of the battery to the metal chassis base.

The reading at the battery should be 6 volts with the set operating.

June, 1934

(2) Triode Plate to Cathode—as read with 1,000,000 ohm meter.

MODEL L-30

Alignment

LAFAYETTE RADIO & TELEVISION CORP.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and accurately calibrated signals at and around 262.5 K. C., the intermediate frequency and an output indicating meter are desirable.

Do not take the chassis out of the box. First set the signal generator at approximately 262.5 K. C. Connect the antenna lead from the generator to the control grid of the I. F. 78 tube, through a .05 mfd. condenser. The ground lead of the generator goes to the ground of the receiver. Turn the rotor plates of the tuning condenser completely out and keep the signal weak enough to prevent A. V. C. action. Note from Fig. 1 that the second I. F. transformer is self tuned and cannot be adjusted. Adjust the frequency of the signal generator until the output meter shows maximum output. The intermediate frequency setting of the generator is then correct, although it may be a very small percentage higher or lower than 262.5 K. C.

Next connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Do not change the signal generator setting. Then adjust the 1st I. F. trimmer condenser screws for maximum output. There are 2 holes at one end of the chassis box. The 2 trimmer screws can be reached through these holes. **CAUTION**—use an insulated screwdriver to prevent short circuiting to ground.

Now disconnect the signal generator and adjust it to exactly 1400 K. C. The antenna lead from the generator is then connected to the antenna lead of the receiver. Connect the tuning condenser flexible drive shaft to the chassis if it has been disconnected. Turn the station selector knob until the rotor plates are completely in mesh. Then with a screwdriver turn the calibration screw on the back of the control unit, until the pointer is at the lowest frequency mark. This is the large point, 5 points below the 55 mark. Then turn the station selector knob until the pointer on the dial scale is at 1400 K. C.

Then adjust the oscillator R. F. and antenna trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator section first. See Fig. 2.

Next, set the signal generator for a signal of 600 K. C. and adjust the oscillator 600 K. C. trimmer. This condenser is mounted on the end of the gang condenser. See Fig. 2.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K. C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

If the control unit or flexible shaft is moved after the set has been aligned, the setting of the dial pointer may change. This can be adjusted by turning the control unit calibration screw until the pointer is at the correct setting.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 K. C. with the volume control about three-fourths on. Remove the cover of the chassis box. The antenna trimmer is the trimmer condenser closest to the terminal strip—see Fig.

2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. **CAUTION**—Do not turn any of the other trimmer adjusting screws for this adjustment.

Removing "B" Unit From Box

Disconnect the "A" and "B+" leads at the terminal strip. On the end of the box at which the "B" unit is located will be found 9 screws around the edge. Remove these 9 screws. The "B" unit and end plate can then be lifted out.

Replacing the Vibrator

Note that vibrator unit is of the plug-in type. This unit can be inserted and removed in the same manner as a tube.

Replacing Chassis Unit

In replacing the chassis unit be sure that the ground spring near the output transformer makes a good contact with the chassis box. Reverse the procedure as given above for removing this unit.

Replacing "B" Unit

When replacing the "B" unit be sure that the ground spring makes a good contact to the partition wall in the chassis box. Reverse the procedure as given above for removing this unit.

Removing Speaker

If service work is required on the chassis, it is advisable in some cases to remove the speaker, as this will permit ready access to all of the units and wiring.

The pot magnet is secured to the vertical walls of the chassis base by means of 3 screws, 2 on one side and 1 on the other. Remove these screws. Then carefully lift out the speaker as far as the leads will permit. The yellow field lead and the black secondary lead may then be unsoldered.

**Trouble Shooting and Service
Vibrator Unit**

When servicing this receiver a new vibrator unit should be tried out in the same manner as a new set of tubes would be tried out. These units are plugged in in the same manner as a tube. One or more vibrator units should be kept on hand for replacement purposes.

"B" Unit

In case of failure in the "B" unit try out a new vibrator. If this does not remedy the difficulty and the "B" unit cannot be repaired locally it is not necessary to return the entire chassis. Remove the "B" unit from the chassis box as per the instructions in this manual after which this unit may be carefully packed and returned separately.

Weak Reception

Defective Tubes—Try out a new set of tested tubes and note any difference in performance.

Poor Antenna—To try out the effectiveness of the antenna used, check the volume against the volume when using a straight length of wire about 15 feet long, run out of the car through one of the windows. If, upon test, the external wire is found to be much superior as far as volume is concerned, the antenna is not satisfactory and will have to be re-wired or a new one installed. The antenna or lead-in may be too near grounded metal portions of the car frame or body resulting in a high capacity to ground. There may be grounded metal mesh in the car roof. There may be a poor soldered connection between the antenna, lead-in, or antenna lead from the set. The antenna system may be partially grounded at some point.

Antenna Trimmer not Adjusted—See Article "Adjusting Antenna Trimmer."

MODEL S-17762

Socket
Alignment
Trimmers

LAFAYETTE RADIO & TELEVISION CORP.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equip-

and keep the signal weak enough to prevent A.V.C. action. Note from Fig. 10 that the second I.F. transformer is self tuned and cannot be adjusted. Adjust the frequency of the signal generator until the output meter shows maximum output. The intermediate frequency setting of the generator is then correct, although it may be a very small percentage higher or lower than 262 K.C.

Fig. 12—Location of Trimmers

Next connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Then adjust the two intermediate frequency condensers for maximum output. The location of the adjusting screws for these condensers is shown in Fig. 12.

Now set the signal generator for a signal of exactly 1400 K.C. The antenna lead from the generator is, in this instance, connected to the antenna lead of the receiver. Connect the flexible drive shaft to the chassis if it has been disconnected. As explained previously, the dial scale should be at the low frequency end stop when the rotor is completely in mesh. Then turn the station selector knob until the dial scale is at 1400 K.C.

Then adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator section first (section farthest from drive gear).

Next set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The location of this condenser is shown in Fig. 12.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K.C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

ment. A signal generator that will provide accurately calibrated signals over the broadcast band and accurately calibrated signals at and around 262 K.C., the intermediate frequency and an output indicating meter are desirable.

First set the signal generator at approximately 262 K.C. Connect the antenna lead from the generator to the control grid of the I.F. 78 tube, through a .05 mfd. condenser. The ground lead of the generator goes to the ground of the receiver. Turn the rotor plates of the tuning condenser completely out

Condenser Block—Internal Wiring

Location of Tubes

Trying Out the Set and Adjusting

After the wiring has all been completed and before the chassis is permanently installed, try out the set and adjust the antenna trimmer condenser. The location of the tubes is shown in Fig. 8. Do not start the engine of the car yet.

To adjust the antenna trimmer, tune in a weak signal between 1200 and 1400 KC with the volume control about three-quarters on. On one end of the

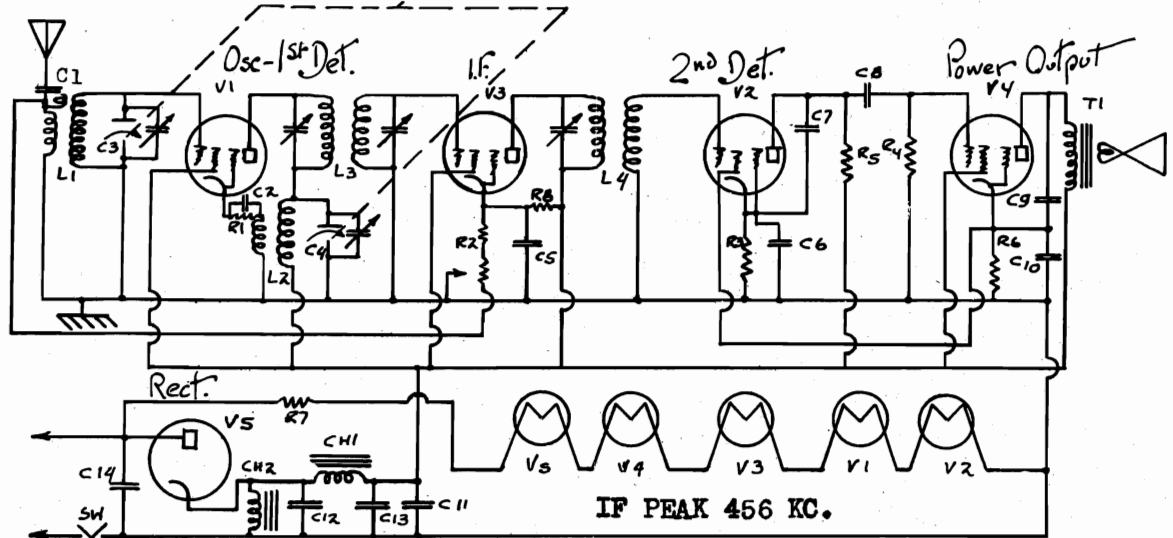

chassis box is a small metal plate. Remove the two screws which hold this plate in place. Directly under the hole in the chassis box is the antenna trimmer condenser screw. Turn this adjusting screw up or down until maximum output is obtained.

If the receiver fails to operate, check the items as given under the article by that name.

To align receiver: Turn band switch to broadcast—short C2—apply 456 K.C. to grid of V2 and adjust L6—apply 456 K.C. to grid of V1 and adjust L5—remove short from C2—apply 1400 K.C. to antennae and adjust trimmers on C1, C2—apply 600 K.C. and adjust C3.

540 to 1550 K.C.

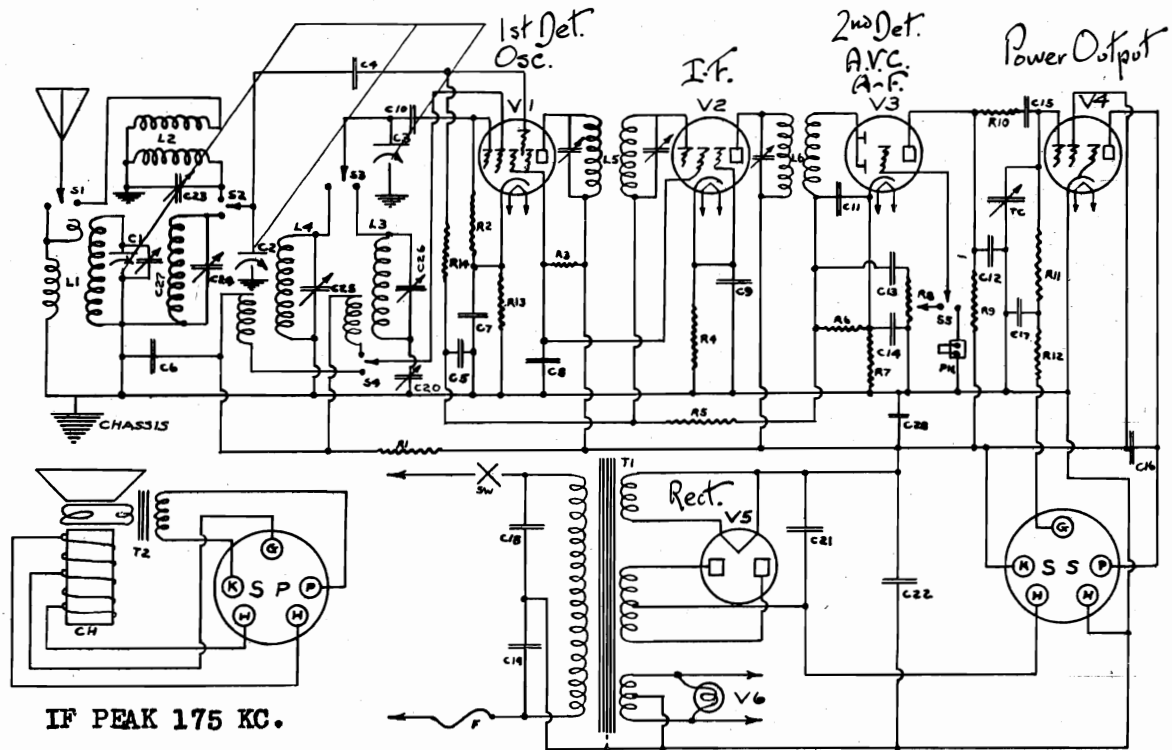

502 US

5,900 to 15,400

This receiver is a five tube Universal dual wave receiver. One band covers the usual broadcasting 540 to 1550 kilocycles, and the other takes in the high frequency broadcasting 5900 to 15400 kilocycles. The high frequency range includes the important international broadcast bands 19, 25, 31 and 49 meters. Tuning and selection of bands are facilitated by the use of colors on the dial. The broadcast band is calibrated in kilocycles, and the high frequency bands are indicated in tan, amateur in red, airplane in blue, and unclassified in white. 49 meter band is from 6.01 to 6.15 megacycles; 31 meter is from 9.5 to 9.6 megacycles; 25 meter is from 11.7 to 11.9 megacycles, and 19 meter is from 15.1 to 15.34 megacycles.

- SW—Power switch on tone control
- CH—Speaker Field 1800—Tapped at 300 Ohms

To align the receiver: Turn the band selector switch to broadcast—Short C3—Apply 175 K.C. to grid of V2 and adjust L6—Apply 175K.C. to grid of V1 and adjust L5—Remove short from C3—Apply 1400 K.C. to antennae and adjust C27, C24, C26—Apply 600K.C. and adjust C20—Shift band switch to shortwave—Apply 15 megacycles and adjust C25 to low peak then adjust C23.

540 to 1550 K.C.

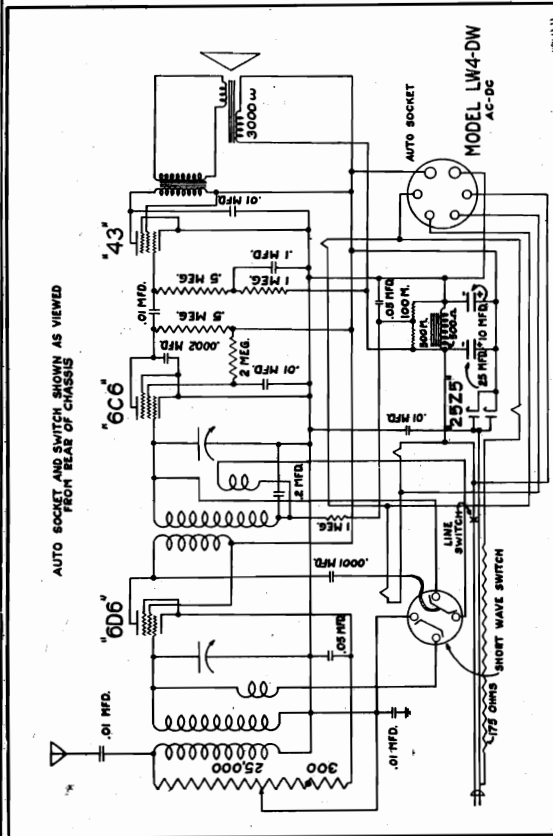

503 AS

5.5 to 17.0 megacycles

This receiver is a five tube A.C. dual wave receiver. One band covers the usual broadcasting 540 to 1550 K.C., and the other takes in the high frequency broadcasting 5500 to 17000 K.C. The high frequency range includes the important international broadcast bands 19, 25, 31, and 49 meters. Tuning and selection of bands are facilitated by the use of "Select-Ur-Band" dial. Movement of the selector switch automatically shifts the mask on dial, so that only proper band can be seen. The broadcast part is calibrated in kilocycles, and the high frequency in megacycles. Broadcast bands are indicated in tan, amateur in red, airplane in blue, and unclassified in white. 49 meter band is from 6.01 to 6.15 megacycles; 31 meter is from 9.5 to 9.6 megacycles; 25 meter is from 11.7 to 11.9 megacycles; and 19 meter is from 15.1 to 15.34 megacycles.

SERIES "63"
All Wave

TRACKING

Peak IF transformer at 262.5 kc.

Next, align condenser trimmers on broadcast range with switch turned all of the way to the left and dial set at 1500 kc., with a signal of the same frequency. Turn dial to 550 kc., and track with a signal of that frequency by means of a series pad for the broadcast range (inside screw on isolantite base at rear of set).

Turn the frequency change switch to the right one position and turn dial to 4000 kc. Put in a signal of approximately 4000 kc. and move dial, if necessary to maximum response. Adjust the RF and antenna trimmers to resonance for the second band. These are located as follows: with the set inverted and the rear of the chassis nearest the operator, the two trimmers in the furthest right-hand corner are for the antenna coil. The nearer one is for the second band and the further one for the third band. The RF coil trimmers are located toward the center of the rear of the chassis, the left one being the second band and the right being the third band. Oscillator pad is tracked at 1750 kc. (external nut on isolantite base at rear of set).

Again turning the switch one more position to the right which is the third band, track the oscillator trimmer with the dial set at 14,000 kc. and a corresponding signal. Check the alignment at 6000 kc., and if necessary bend the tuning condenser plates slightly. No pad is used here.

80	Rectf.	5.0	260	--	--	--	--	--	--

The above readings taken with a 300 volt 1000 ohm per volt DC voltmeter.

Line voltage 115 volts, 60 cycles AC. All DC voltages taken with respect to chassis ground with switch in first position.

P. R. MALLORY & CO.

**MODEL 1932 Type
Single Reed
Elkonodes**

Directions for Servicing 1932 Type Mallory 'Single-Reed' Elkonodes

The 1932 type Mallory Elkonode is a half-wave, single-reed converter used with a BR Raytheon tube for rectification. This Elkonode is supplied in six standard types—from 1 to 6 inclusive—and modifications are supplied for special requirements, such as S101, S102, S103, T112, and S111. 12-volt single-reed Elkonodes are supplied in types G1 to G6 inclusive, and 32-volt Elkonodes in types from F1 to F6 inclusive.

The mechanical construction of the single-reed Elkonode is the same in all types with the exception of the size and number of turns of wire on the Elkonode coil. Following is a table of characteristics indicating the output obtainable from these standard Elkonodes:

Milli-amperes	12	15	17	20	22	25	27	30	32	35	37	40	42	45	47	50
Volts																
220	2	3	4	4	5	6	6									
210	2	3	3	4	5	5	6	6								
200	2	3	3	4	4	5	5	6								
190	2	3	3	4	4	5	5	6	6							
180	1	2	3	3	4	4	5	5	6	6						
170		2	3	3	4	4	5	5	6	6	6					
160		2	2	3	3	4	4	5	5	6	6					
150		2	2	3	3	4	4	4	5	5	6	6	6			
140		1	2	3	3	3	4	4	4	5	5	6	6	6		
135		1	2	2	3	3	3	4	4	5	5	5	6	6	6	

The following reproductions picture the Mallory single-reed Elkonode in two positions:

No. I
1. Reed Assembly
2. Stop Post mntg. block
3. Stop Post locking-screw
7. Air-gap

No. II
4. Stop-Post
5. Contact Spring Assm.
6. Cam-nut adjustment

(1) is a side view showing the Elkonode with cover and rubber cushion removed. (2) is a front view with can and cushion removed. Numbered arrows clearly indicate the position of the Elkonode parts involved in installing new contact spring assemblies and new reed assemblies.

Routine for Dismantling Elkonodes for the Purpose of Replacing Contact and Reed Springs

- (a) Remove screws which fasten outer housing or can to base.
- (b) Hold can in upright position and tamp gently against hand permitting base and rubber housing inside of can to drop out gently. (CAUTION: Do not attempt to remove Elkonode assemblies from cans by pulling on the base.)
- (c) Remove rubber cushion from Elkonode assembly in the same manner as entire assembly was removed from can.

TO REMOVE SPRINGS:

- (d) Remove contact spring assembly by extracting screws at point marked "A" on above diagram.
- (e) Remove reed assembly by extracting screws at point marked "B" on above diagram.
- (f) Install reed assembly, using care to insure that metal blocks in which this reed is mounted are squarely aligned. NOTE: Use only Kester Resin Core Solder.
- (g) Install contact spring assembly using care to properly align metal blocks in which this spring assembly is mounted.
- (h) Inspect alignment of contact points to insure that contacts on both reed and contact springs are in proper alignment, and that their surfaces engage squarely and evenly. Alignment of these points is controlled by the position of the springs, and the screws mounting these springs should not be tightened firmly until the points are in alignment.
- (i) With points in proper alignment, the air-gap or clearance between pole-piece of the coil and reed should be adjusted to approximately 1/32 inch. This adjustment is provided for by the cam nut and locking screw at point marked "6" in diagram 2. The reed should be in a perfectly perpendicular plane, and the surface of the pole-piece or core of the coil should be exactly parallel with surface of reed.

**MODEL 1933-34 Type
Dual Reed Elkonodes**
P. R. MALLORY & CO.

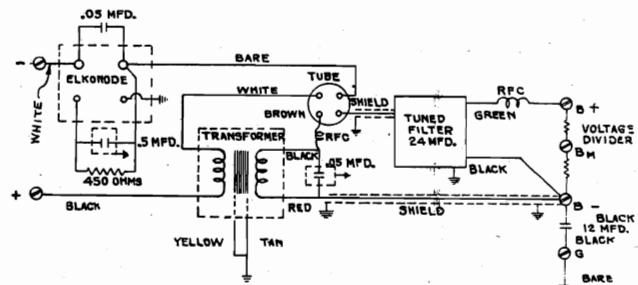

- (j) Loosen the locking screw of the stop post (identified at point 3, on diagram 1) and adjust the stop post (identified at point 4, diagram 1) so that the tip of contact spring assembly engages screw-side of stop post head, allowing contacts to meet with a light pressure. This stop post is easily adjusted by turning to left until head of contact post pulls contact on left, or contact spring, away from contact on right, or reed contact. Then turn stop post screw to right about $\frac{1}{8}$ to $\frac{1}{4}$ turn, until contact points meet the light pressure. At this point, stop post locking screw should be firmly tightened down to hold stop post in this position.
- (k) If the foregoing mechanical adjustment has been carefully followed out the Elkonode is now ready for Electrical Tests. These tests should be conducted with a master Eliminator, into which the Elkonode can be inserted while the can and rubber cushion are still removed, and with a "dummy" load on the Eliminator which will require 180 volts at 35 m.a. for Elkonode types 6, S101, S102, S103, S111, and T112. The output of the Elkonode is adjusted by increasing or decreasing the air-gap clearance between pole-piece of coil and surface of the armature reed. A cam nut and locking screw arrangement provide a flexible adjustment which sometimes must be supplemented by inserting thin metal shims between coil and bracket. NB—Shims are required only where construction of the unit will not permit air-gap clearance being decreased to point required, by adjustment of cam nut.
- (l) Electrical adjustment for other types of Elkonodes, from 1 to 5 inclusive, must be conducted with "dummy" load to equal maximum output available from whichever type Elkonode is involved per characteristics shown in the foregoing table.
- (m) Extreme care must be exercised to insure that no dirt or foreign matter is allowed to accumulate on contact points and that entire Elkonode assembly is kept thoroughly dry.
- (n) Excessive sparking usually results from improper pressure between and alignment of contact points. If it is found necessary to bend the reed to secure a flat alignment of points, this should be done very carefully, using a pair of thin flat-nosed pliers, to grasp the reed firmly *at the base where it is mounted*. A very slight pressure at this point will be required to change the angle of contact for vibrator points. *No sparking* whatever results from improper adjustment of stop post, permitting contact springs to follow reed springs past the center of cycle of amplitude or arc of vibration. Contacts should be lightly touching when at rest so there is about .014 inch clearance between stop post and contact spring. Stop post will then break this contact at the center of cycle of amplitude.

If the foregoing instructions are followed carefully, and if reliable instruments are used to measure the output of the Elkonode when electrical adjustments are being completed, you should be able to install contact and reed spring assemblies without difficulty. When adjustments have been completed to your satisfaction, place vibrator assembly inside rubber cushion by holding cushion in inverted position, and allowing assembly to drop into place. Next, place entire assembly inside can, in same manner, and fasten can to base, using screws provided for that purpose.

Thorough instructions for servicing other parts of the Mallory Elkon "B" Eliminator are provided in the service and installation bulletin accompanying each unit,—copies of which may be had upon request.

The following equipment is recommended as being extremely useful in conducting repairs on Mallory-Elkon "B" Eliminators and Elkonodes:

1. High resistance volt-meter. Scale: 0 to 300. Resistance: Not less than 1000 ohms per volt.
2. One good quality milliammeter. Scale: 0 to 50.
3. One set feeler gauges.
4. One small screw-driver.
5. One pair thin, flat-nosed pliers (duck-bill type).
6. One 1932 Mallory-Elkon "B" Eliminator chassis.
7. One variable resistor—"dummy" load arrangement to duplicate maximum load for which each of six standard types of Elkonodes is designed.

Directions for Servicing 1933-34 Type Dual-Reed Mallory 'Self-Rectifying' Elkonodes

The 1933 Mallory Self-Rectifying Elkonode is a dual-reed converter which within itself sets up the essentially alternating current required, and likewise rectifies it to the form of direct current required for radio receiver plate supply. No rectifying tube is used with the 1933 Mallory Self-Rectifying Elkonode.

This Elkonode is supplied in five standard types—from 10 to 14 inclusive—and modifications are supplied for special requirements under such designations as Nos. 30, 31, 34, 35 (for Motorola Receivers), and Nos. 36 and 37. 12-volt types are supplied in types G10 to G14 inclusive, and 32-volt types from F10 to F14 inclusive. The mechanical construction of the dual-reed Self-Rectifying Elkonode is the same in all types with the exception of size and number of turns of wire on Elkonode coil.

P. R. MALLORY & CO.

**MODEL 1933-34 Type
Dual Reed Elkonodes
Dismantling-Repair**

Following is a table of characteristics indicating output obtainable from each standard Elkonode at storage battery terminal voltage of 6.6, for the 6-volt, 13.2 for 12-volt type.

ELKONODE RATING TABLE

Elkonode Type	Volts Output	For Receivers Requiring the Following Current in Milliamperes in the B Minus Lead at 200 V. on Signal		Elkonode Rated Output Watts	Storage Battery Drain in Amps.
		Without Voltage Dividers in Elim.	With 2 M. A. (100,000 Ohm) Voltage Divider in Elim.		
10	200	40-45	38-43	8.4	2.1
11	200	35-40	33-38	7.4	1.9
12	200	30-35	28-33	6.4	1.6
13	200	25-30	23-28	5.4	1.4
14	200	20-25	18-23	4.4	1.2

Routine for Dismantling Dual-Reed or Self-Rectifying Elkonodes for the Purpose of Replacing Contact and Reed Springs

- (a) Remove screws which fasten outer housing or can to base.
- (b) Hold can in upright position and tamp gently against hand, permitting base and rubber housing inside of can to drop out gently. (CAUTION: Do not attempt to remove Elkonode assemblies from cans by pulling on base.)
- (c) Remove rubber cushion from Elkonode assembly in the same manner as entire assembly was removed from can.
- (d) With internal assembly in view, displace condensers by turning each outward from center carefully.

Current at which Phantom Load Relay should be adjusted

Elkonode Type	No. 10	No. 11	No. 12	No. 13	No. 14
Current	20 M.A.	17.5M.A.	15 M.A.	12.5M.A.	10 M.A.

TO REMOVE SPRINGS AND REEDS:

- (e) Remove contact spring assembly by extracting screws at point marked "A" on above diagram, No. III.
- (f) Remove reed assembly by extracting screws at point marked "B" on above diagram No. III.
- (g) Install reed assembly, using care to insure that metal brackets in which these reeds are mounted are squarely aligned with reeds. (NB—Use only Kester Rosin Core Solder.)
- (h) Install contact spring assembly using care to properly align metal brackets and blocks with which this assembly is mounted.

Special Types Should be Adjusted to SET MFRS. Specifications (See Paragraph "N")

The following reproductions picture the Mallory dual-reed or self-rectifying Elkonode in two positions: (3) is a side view showing the Elkonode with cover and rubber cushion removed, and (4) is a front view with cover and cushion removed. Numbered arrows clearly indicate position of Elkonode parts involved in installing new contact spring and new reed assemblies.

- No. III
 - 1. Air-gap
 - 2. Reed counter weights
 - 3. Stop-post Locking-screw
 - 4. Stop-post
 - 5. Reed Spring Assm.
 - 6. Contact Spring Assm.
- No. IV
 - 7. Coil mounting nut
 - 8. Coil
 - 9. Stop-post mounting block
 - 10. Position contact spring behind stop-post head
 - 11. Contact points

- (i) Inspect alignment of contact points to insure that contacts on reed and contacts on springs are in proper alignment. Their surfaces must engage squarely and evenly. Alignment of points is controlled by the position of the springs. Screws mounting these springs should not be tightened firmly until points are in alignment.
- (j) With points in proper alignment, air-gap or clearance between pole-piece of coil and counter-weights on ends of reed assemblies should be adjusted to approximately 1/32 inch, when reeds are pulled in to center position. This adjustment is provided for by removing or inserting shims between the Elkonode frame and coil, at top of coil.
- (k) Loosen locking screw of stop posts (identified at point 3, diagram III, above) so that tips of contact spring assembly engage screw-side of stop post head, allowing contacts to meet with contacts on reed assemblies at light pressure. Stop post is adjusted by turning to left until head of contact post pulls contact springs away from contact on reed assembly. Then turn stop post screw to right (about 1/8 to 1/4 turn) until contact points on both contact spring and reeds meet with light pressure. At this point, stop post locking screw should be firmly tightened to hold stop post in this position.

P. R. MALLORY & CO.

Routine for Dismantling Elkonodes for the Purpose of Replacing Contact and Reed Springs

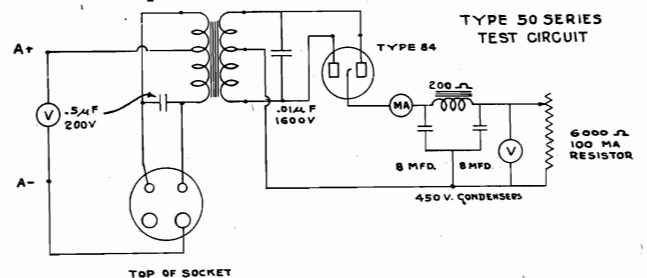

- (a) Remove screws holding cover on can.
- (b) Loosen cover from can and hold in upright position, prongs down; gently shake the rubber sock and Elkonode from the can.
- (c) Closely observe the manner in which the leads from the prong base to the Elkonode are placed in the outer slots of the rubber sock. This is important for correct placement of wires when replacing assembly in can.
- (d) Observe the location of the various parts, especially the position of the reed Armature (2) with respect to the coil pole shoe of the Elkonode. (1).
- (e) Unsolder the three leads at the Elkonode terminals, noting that the top lead (with Elkonode held as in diagram) crosses over the ground lead to the center connection at the plug. Unsolder the coil wire at the spring terminal.
- (f) Loosen lock nuts A, and A2 and turn the adjusting screws B, and B2 counter clockwise until the insulating bushings (5) are against the frame, then remove screws and slide out bushings.
- (g) Loosen stack screws (3) and remove. Press on the under side of the bakelite stack and reed so as to move the assembly out from between the frame. Save the insulating bushings (5), stack screws (3), connector plate (4), adjusting screws, and the lock nuts. Remove the bakelite stack spacers and insulating tubes from the assembly.

ROUTINE FOR REBUILDING THE ELKONODE:

- (h) Rebuild the stack assembly, making sure to use the thicker of the four bakelite spacers on either side of the reed.
- (i) Since the Elkonode is largely magnetic in operation, extreme care must be taken to prevent particles or filings of iron from attaching themselves to the iron parts of the Elkonode. Clean the pole shoe, frame, and reed thoroughly.
- (j) Hold the assembly with the reed in the position shown in the illustration, place the frame under the assembly, as shown also, and insert the assembly from the top. It may be necessary to spread the frame slightly in order to make the insertion. Inspect the stack screws for signs of weakening, and if satisfactory, replace with the connector plate and tighten slightly.
- (k) The reed should stand approximately in the center of the frame at rest. The end of the reed should be parallel to the face of the pole shoe and from .003" to .005" distant from it when the reed is pulled down opposite its center. This distance should be accurately set by feeler gauges. The reed may be adjusted because of play in the mounting holes.
- (l) Insert the insulating bushings in the slots in the ends of the springs, thread the adjusting screws into place, together with the lock nuts. Adjust the screws to place the contacts close to the reed contacts. The springs should be moved so as to allow the contacts to strike the reed contacts without overlapping. The contacts should be fairly flat in making contact, and still not bind on the insulated adjusting bushing.

- (m) Tighten the stack firmly without disturbing the adjustments. Hold the reed over a piece of white paper in the vertical position shown in the illustration. The end edge of the reed, on the opposite side from the armature should rest from flush with the edge of the pole piece to .003" above same. Any bending of the reed should be done at the extreme armature end, and only slight alterations should ever be necessary. Should the pole shoe not be parallel with the armature in a vertical direction, turn the pole shoe with a pair of long-nosed pliers; *do not attempt to twist the reed*. Check the air-gap spacing and tightness of coil mounting screws, if such adjustments are made, then recheck alignment.
- (n) Solder the leads back as before, with the ungrounded heater terminal lead to the reed tail. The connector plate is soldered to the reed tail also, at the same time, and the coil wire to the near spring lug.
- (o) Some method of exerting high pressure upon the stack end of the Elkonode while the final tightening of the clamping screws is taking place is essential. It is suggested that an arbor press, capable of exerting a total pressure of about 2000 pounds, be used. Pressure should be exerted directly over the stack, between the screws, while a large screw driver draws the screws down firmly. This prevents loosening of the stack in service and consequent failure.
- (p) Turn the adjusting screw B-1 clockwise until the space between the contacts G and H is between .003" and .004", as measured carefully with a feeler gauge, with the lock nut A-1 tightened firmly. Proceed likewise with B-2 and A-2 until clearance between contacts E and F is between .004" to .006". Check lock nuts for tightness. The unit should then be ready for operation.

Following is a test circuit which may be set up for electrically testing and adjusting Elkonodes of the "50" Series. "Sound" tests may be obtained only with receiver in operation.

(Transformer should be the same as used in set from which the Elkonode was taken. The set itself may be used for test if an extension lead is made up. Do not expect quiet operation while set is open and unit is uncanned.)

- (q) If test equipment is available, operate the Elkonode on this equipment before placing it in the Elkonode can. The unit should start operation at 4.4 volts (2 cells of 6-volt battery on charge), should provide correct output at 6.6 volts and should operate satisfactorily at 8.8 volts (4 cells on charge). Should any adjustment be necessary, adjust screw B-2 only. A very slight movement of the screw should permit final adjustment.

CAUTION

- Do not attempt to bend contact springs.
Use only Kester Rosin Core Solder.
Keep moisture from all parts of the Elkonode.
Keep metallic particles out of Elkonode.
Keep dust, moisture, grease and liquid from the contact surfaces. Clean contact surfaces with a dry, clean piece of linen paper.

P. R. MALLORY & CO.

MODEL 50 Series
Elkonodes-Repair

The 50 Series Mallory Elkonode is a single-reed full-wave inverter for use in supplying alternating-current voltage which in turn is rectified by a tube rectifier for supplying the high direct-current voltage needed for radio receiver plate supply.

This Elkonode is used in three standard types, Nos. 50, 51, and 53, and in certain modified forms for special requirements. For 12-volt operation, the type number is prefixed with the letter "G" to designate the change in construction. Likewise, for 32-volt operation, the letter "F" is used. The mechanical construction for all types is the same except for a change in the driver-coil windings for the 12-volt and again for the 32-volt types. The types 50 and 51 Elkonodes are adjusted and intended to carry output loads up to 11 watts. The type 53 Elkonode is designed for loads from 11 to 18 watts. These types have an advantage over earlier types in not being limited to a narrow range of load conditions. Ratings are given, in every case, for operating battery voltages of 6.6, 13.2, and 33 volts, for the 50, G-50, and F-50 Series, respectively.

The following reproduction pictures the Mallory Type 50 Series Elkonode in a top view, with covers removed.

1. Magnet coil pole shoe
2. Reed armature
3. Stack clamping screw
4. Connector plate
5. Insulating bushing
6. Reed foil

A—lock-nut. B—adjusting screw.
E, F, G, H—contact points

Instructions For Adjusting Contact Springs When Such Springs Do Not Require Replacement

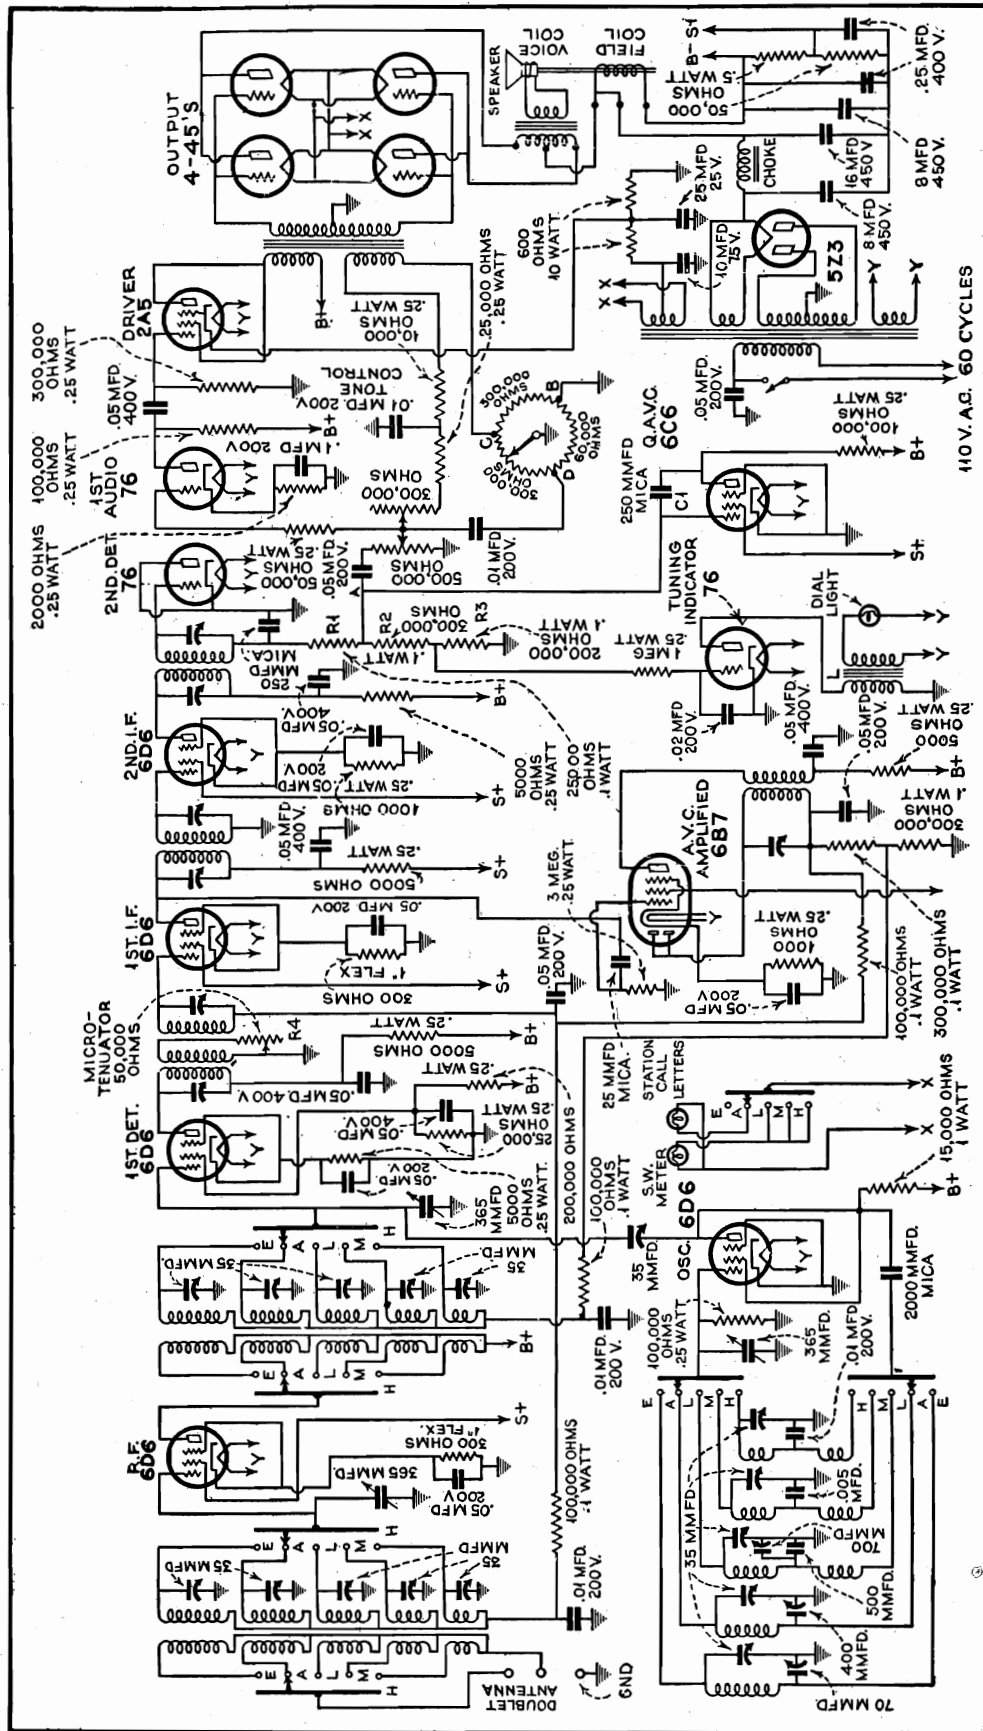

As with automobile ignition contacts, the tungsten contact points in Elkonodes will show some evidence of wear after they have been in service for a long period of time. This wear progresses gradually, and as long as the Elkonode is capable of operation, any amount of wear at the contact points will have no influence whatever on the performance of the radio set or on the voltage supplied to the tubes. However, after a long period of service the Elkonode may refuse to start, and when this point is reached it should be taken as indicative of excessively worn contact points. The Elkonode has been designed with a generous reserve of tungsten in its contact points, and this reserve may be utilized to give the Elkonode extended life, providing one simple adjustment is made. This adjustment is outlined as follows:

1. Remove the Vibrator unit from the can and rubber sock, by following closely the directions covered by paragraphs A, B, C and D in the procedure for dismantling Elkonode. Use care to avoid bending wires at the soldered connections.
2. Place the Elkonode on a piece of white paper, so that when viewed from above it appears exactly as in drawing above.

3. Loosen lock nut (A2) and turn screw (B2) clockwise until .005" of light can be seen between contacts (F) and (E). If the contact points are roughened, the light can not be seen across their entire diameter, even though they are correctly spaced (i. e., within .005" of touching each other).
4. A check on the accuracy of the spacing adjustment is obtained by pressing lightly against the center of the reed with a small pointed metal instrument in the direction and location shown by arrow (K). When the reed is thus moved, so as to just close contacts F and E, the weight (2) on the free end of the reed should move 1/64 inch from its "at rest" position. Check should be made after lock nut has been firmly tightened down.
5. DO NOT readjust spacing between contacts G and H, unless the tungsten is nearly all worn away. In this case, readjustment is obtained in exactly the same manner as for contacts F and E.
6. In reinserting the Elkonode into its rubber sock, be very careful to turn the "flats" of the sock hole so that they are in line with the lock-nuts. This provides ample space in the sock for the free movement of the reed. In reinserting the "socked" Elkonode into the can, be sure that the can seam lines up with the wider of the wire-carrying channels on the outside of the sock. This is important.

CAUTION: Inasmuch as the Elkonode mechanism is partially magnetic, extreme care should be observed while making adjustments to prevent iron filings or similar metallic matter from getting into the Elkonode.

MODEL 62-118

Alignment, Data

MONTGOMERY-WARD & CO.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and accurately calibrated signals at and around 262.5 K. C., the intermediate frequency and an output indicating meter are desirable.

Do not take the chassis out of the box. First set the signal generator at approximately 262.5 K. C. Connect the antenna lead from the generator to the control grid of the I. F. 78 tube, through a .05 mfd. condenser. The ground lead of the generator goes to the ground of the receiver. Turn the rotor plates of the tuning condenser completely out and keep the signal weak enough to prevent A. V. C. action. Note from Fig. 1 that the second I. F. transformer is self-tuned and cannot be adjusted. Adjust the frequency of the signal generator until the output meter shows maximum output. The intermediate frequency setting of the generator is then correct, although it may be a very small percentage higher or lower than 262.5 K. C.

Next connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Do not change the signal generator setting. Then adjust the 1st I. F. trimmer condenser screws for maximum output. There are 2 holes at one end of the chassis box. The 2 trimmer screws can be reached through these holes. CAUTION—use an insulated screwdriver to prevent short circuiting to ground.

Now disconnect the signal generator and adjust it to exactly 1400 K. C. The antenna lead from the generator is then connected to the antenna lead of the receiver. Connect the tuning condenser flexible drive shaft to the chassis if it has been disconnected. Turn the station selector knob until the rotor plates are completely in mesh. Then with a screwdriver turn the calibration screw on the back of the control unit, until the pointer is at the lowest frequency mark. This is the large point, 5 points below the 55 mark. Then turn the station selector knob until the pointer on the dial scale is at 1400 K. C.

Then adjust the oscillator, R. F., and antenna trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator section first. See Fig. 2.

Next, set the signal generator for a signal of 600 K. C. and adjust the oscillator 600 K. C. trimmer. This condenser is mounted on the end of the gang condenser. See Fig. 2.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K. C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

If the control unit or flexible shaft is moved after the set has been aligned, the setting of the dial pointer may change. This can be adjusted by turning the control unit calibration screw until the pointer is at the correct setting.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 K. C. with the volume control about three-fourths on. Remove the cover of the chassis box. The antenna trimmer is the trimmer condenser closest to the terminal strip—see Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Removing and Replacing Units From Chassis Box

Removing Chassis Unit From Box

Disconnect the flexible shafts, antenna cable and pilot lamp lead at the chassis box. Pull off the tone control knob and disconnect the battery cable at the fuse receptacle. Remove the cover of the box and take off the black lead on the cover screw. Disconnect the "A" and "B+" leads at the terminal strip. Pull the battery cable inside of the box.

Take out the 4 screws around the speaker grill. Then pull the chassis out by means of the "A" choke and condenser block. Do not pull the chassis out by means of the gang condenser as this might injure the cushion mounting.

Removing "B" Unit From Box

Disconnect the "A" and "B+" leads at the terminal strip. On the end of the box at which the "B" unit is located will be found 9 screws around the edge. Remove these 9 screws. The "B" unit and end plate can then be lifted out.

Replacing the Vibrator

Note that vibrator unit is of the plug-in type. This unit can be inserted and removed in the same manner as a tube.

Replacing Chassis Unit

In replacing the chassis unit be sure that the ground spring near the output transformer makes a good contact with the chassis box. Reverse the procedure as given above for removing this unit.

Replacing "B" Unit

When replacing the "B" unit be sure that the ground spring makes a good contact to the partition wall in the chassis box. Reverse the procedure as given above for removing this unit.

Removing Speaker

If service work is required on the chassis, it is advisable in some cases to remove the speaker, as this will permit ready access to all of the units and wiring.

The pot magnet is secured to the vertical walls of the chassis base by means of 3 screws, 2 on one side and 1 on the other. Remove these screws. Then carefully lift out the speaker as far as the leads will permit. The yellow field lead and the black secondary lead may then be unsoldered.

Trouble Shooting and Service

Vibrator Unit

When servicing this receiver a new vibrator unit should be tried out in the same manner as a new set of tubes would be tried out. These units are plugged in in the same manner as a tube. One or more vibrator units should be kept on hand for replacement purposes.

"B" Unit

In case of failure in the "B" unit try out a new vibrator. If this does not remedy the difficulty and the "B" unit cannot be repaired locally it is not necessary to return the entire chassis. Remove the "B" unit from the chassis box as per the instructions in this manual after which this unit may be carefully packed and returned separately.

MODEL 62-120, 62-122
62-126, 62-128

MONTGOMERY-WARD & CO.

Alignment, Voltage

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

First set the signal generator to a frequency of 175 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector thru a .05 mfd. condenser. The ground lead from the signal generator goes to the ground lead of the receiver. Adjust trimmer condenser C9 on the back panel of the chassis until maximum output is obtained. **A non-metallic screw driver should be used in making this adjustment as the I. F. trimmer is at B+ potential.**

Next set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 3 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Then set the signal generator for 1400 K. C. and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To obtain dial scale calibration tune in an 800 K. C. signal and set the dial pointer at that mark on the dial scale. When calibrated in this manner, the setting will be approximately correct at both ends of the scale.

Fig. 4—Using Voltage Regulator with 3 Volt "A" Battery

The use of the cut plate type of condenser eliminates the necessity of a 600 K. C. padder and no adjustment at this frequency, therefore, is required.

Low Volume

In a battery operated receiver the two most common causes of low volume are run down batteries and defective tubes.

Check the "B" and "C" batteries under load with a high resistance voltmeter. See if the filament voltage is low and if so, put in a new "A" unit. A high resistance voltmeter is not necessary for testing the "A" batteries.

The next most common cause of low volume is defective tubes. In any case of low volume, therefore, procure a new set of tubes that have been tested or have been operating satisfactorily in another receiver. Insert these in the chassis one at a time and note any difference in performance.

Altho a short inside antenna is sometimes satisfactory, a good outside antenna 100 to 150 ft. in length is recommended. If the antenna system is faulty or in a shielded location, the volume may be low on distant or weak stations. This is particularly true if the antenna is in or near a steel building. The antenna and lead-in should be inspected for poor connections and grounds. In a shielded location try a longer antenna in a different location.

Misaligning or mistracking of variable tuning condensers is another possible cause of low volume. Instructions for realigning are contained in this manual. Do not, however, attempt realignment unless other causes of low volume have first been investigated.

Other causes of low volume are defective speaker, and various opens, shorts and grounds in the receiver assembly.

Voltages

Check the voltages at the sockets to see if correct values are being delivered to the tubes. The antenna and ground should be disconnected and the antenna and ground leads from the set connected together. The

- (4) As read at "C" battery.

volume control should be turned to the right or maximum position.

All of the voltage readings as shown in the chart are read with a 1,000 ohm-per-volt meter. As high a range as possible should be used. In general, the higher the resistance of the meter, the more accurate the reading will be.

The voltage chart gives the voltages with all tubes in, the speaker connected and the set in operating condition. These voltages are typical of the sets but will vary slightly with variations in individual receivers, tubes, test equipment used and battery voltages.

Oscillation and Whistle

Should the set oscillate on being connected up, it may be due to tubes whose characteristics vary considerably from the standard. In case of oscillation, therefore, change the tubes around and try out some new ones.

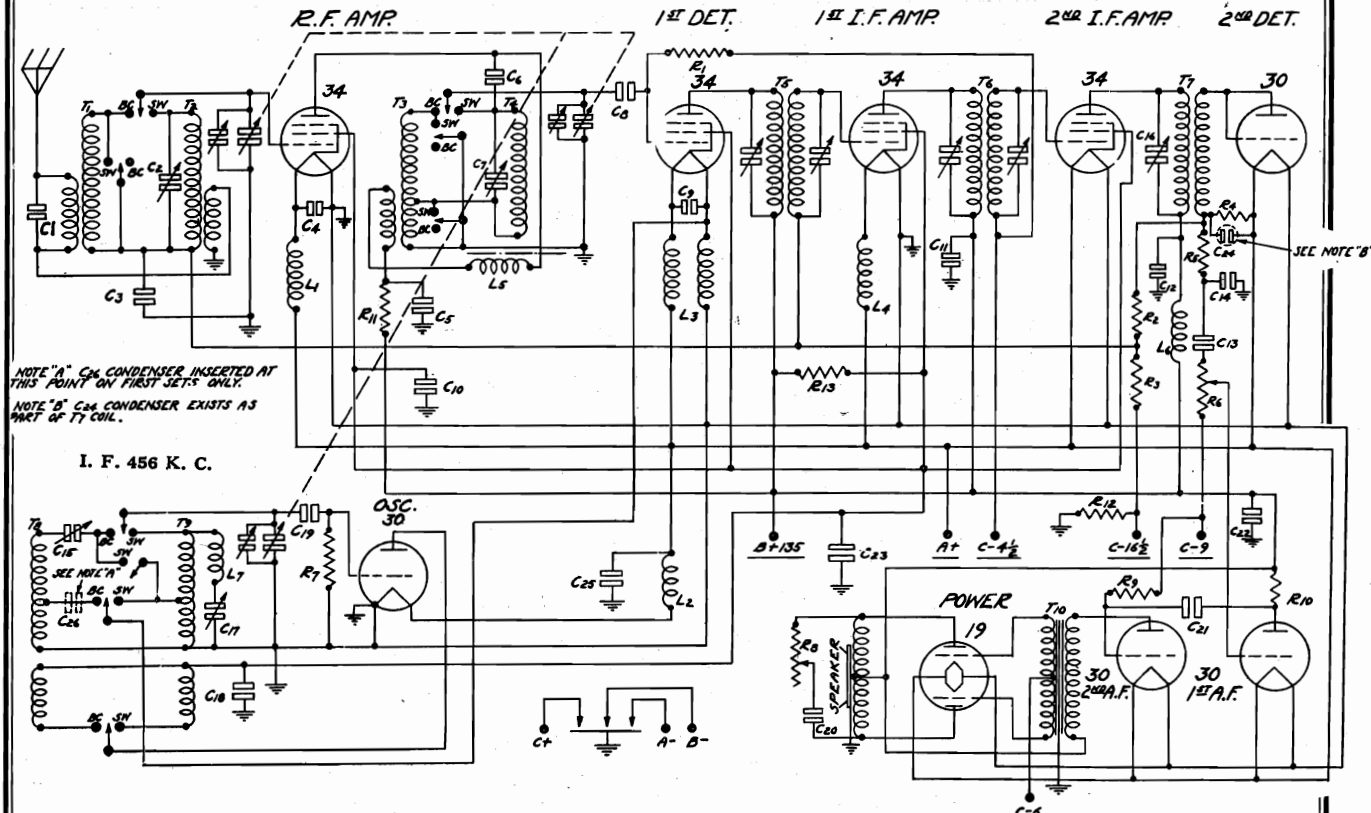

See if the receiver is properly grounded and if it is, try out a new ground. See if any of the battery voltages are excessively high.

The tube shields must all be on and the control grid leads to the top grid connection tubes firmly in place. Otherwise oscillation may result.

An open bypass condenser or open leads to the bypass condensers are a common cause of oscillation. Check the bypass condensers for capacity and the leads to them for continuity of circuit. A quick way to check bypass condensers for opens is to take a good condenser with test leads attached to the terminals and connect the new condenser across the condenser in the chassis. Oscillation may also be caused by poor chassis ground connections and by poor tuning condenser ground contacts. A shorted "A" line choke would, in some instances, result in oscillation.

MODEL 62-124, 62-129

Alignment

MONTGOMERY-WARD & CO.

Condenser Alignment

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator, that will provide an accurately calibrated signal of 456 K. C. and accurately calibrated signals over the broadcast and short wave bands, 530-1730 K. C. and 5.8-16.0 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning

Fig. 3—Trimmer Locations

condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings of these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION—Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 3 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broad-

Fig. 4—Optional "C" Battery Connections

cast position. Set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is

obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 3. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjust-

Fig. 5—Using Voltage Regulator with a 3 Volt "A" Battery

ment of any of the broadcast band trimmers. In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies, at which a signal is heard, in order that the oscillator in the receiver will be 456 K. C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 3 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

Changes in Early Models

The condenser, C26 was used only on the early models of this receiver. Another change was in the tone control circuit. In the early models R8 was a 150,000 ohm resistor paralleled by a 60,000 ohm resistor. However, in the later models this arrangement was replaced by a single 45,000 ohm resistor to provide greater sensitivity in tone control.

MONTGOMERY-WARD & CO.

MODEL 62-124, 62-129
Voltage, Socket,
Drive Cord Data

Fig. 6—Drive Cord Replacement

Replacing Drive Cord

Lift off the pilot light assembly. Detach the large pointer by removing the center screw. Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 6.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 6. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 6.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately 3/8" from the flange of the drum as shown in Fig. 6. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly.

Batteries

To prolong "B" battery life instruct the customer to keep the volume down as high volume increases the "B" drain considerably. The average "B" drain is 23.5 milliamperes. The reception of weak signals also increases the "B" drain.

This receiver is designed to operate from a 2 volt

Fig. 2—Arrangement of Tubes, Batteries and Controls

storage cell but can be operated from a 3 volt dry cell used in conjunction with the voltage regulator shown in Fig. 5. This device consists of a rheostat in series with the supply, for controlling the voltage and a voltmeter for measuring it.

The voltmeter should not indicate more than 2 volts when the above arrangement is used, an optimum setting being 1.9 to 2.0 volts.

For the grid bias a special 22 1/2 volt "C" battery with 4 1/2, 6, 9 and 16 1/2 volt taps (Fig. 2) may be used. If not available, a standard 4 1/2 volt "C" and a standard 22 1/2 volt "C" battery can be connected as shown in Fig. 4.

MONTGOMERY-WARD & CO.

MODEL 62-132, 62-137
Alignment, Voltage**Condenser Alignment**

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 456 K. C. and accurately calibrated signals over the broadcast and short wave bands, 530-1740 K. C. and 5.8-18.3 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans - See Fig. 2. The openings to these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION - Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 2 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C.

lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K. C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2. If a maximum output peak cannot be reached, it may be due to the fact that the antenna and 1st detector short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum output.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 2 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty-cycle, receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

A 115-230 Volt, 40-60 cycle Power Transformer is also available for this model.

Phono Connections

Phonograph connections can be made as shown in Fig. 5. A single pole double throw switch and double pin jack are required. These should be mounted on the back panel of the chassis close to the 2nd detector. The connections are made by opening the diode circuit at the point shown in the illustration and completing the connections to the switch and pin jacks as indicated. A high impedance pick-up should be used. If a low impedance pick-up is used a step-up transformer will be required for sufficient volume. The volume control of the set will regulate the phono volume.

Socket, Trimmers
Drive Cord Data

MONTGOMERY-WARD & CO.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 4.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 4. Insert one end of the drive cord from the outside through the hole in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 4.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

Fig. 2—Tube Arrangement & Location of Trimmers

Fig. 4—Drive Cord Replacement

turns in a clockwise direction until it is up to the hole in this drum as illustrated.

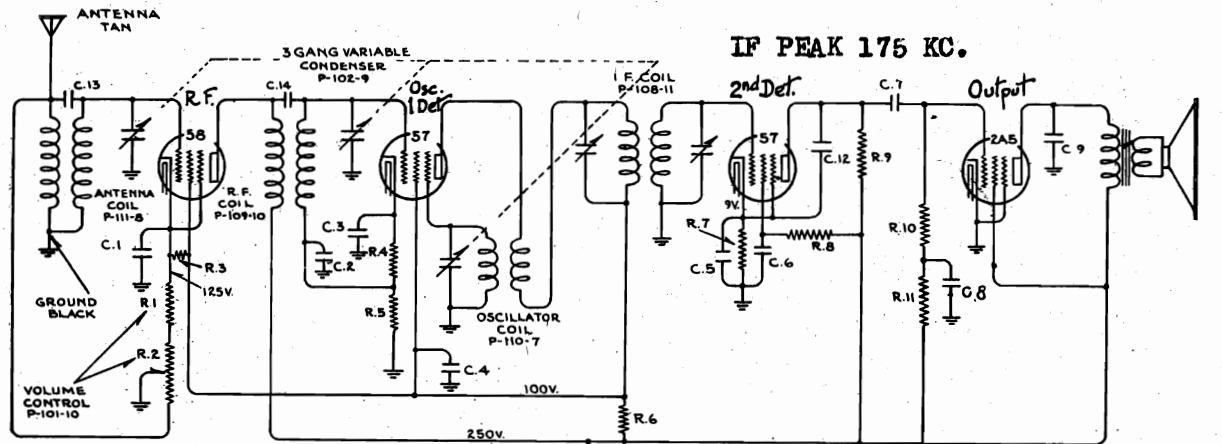

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately 3/4" from the flange of the drum as shown in Fig. 4. Cut off the surplus length of cord after it is knotted.

Change in Early Models

In the early models of this receiver the side of the trimmer condenser C27 which is shown in Fig. 1 as connected to ground was connected to the B+ side of the 3rd I. F. coil primary.

MONTGOMERY-WARD & CO.

VOLTAGES TAKEN FROM POINTS INDICATED TO CHASSIS GROUND, VOLUME CONTROL ON FULL.
CONDENSERS C.5, C.6, C.7, C.8, C.9 IN ONE UNIT P-145-2.

SERVICE SUGGESTIONS:

Make certain of the following: That all tubes are pushed firmly in their proper sockets and that the clips are securely fastened to the caps. That the aerial connection is good and not short-circuited to ground. (Pilot lights illuminate when set is turned on.)

PILOT LIGHT:

The pilot light used is 2.5 volt Mazda No. T41-G3 $\frac{1}{2}$. To replace, remove receptacle clipped to top of the variable condenser:

| Common Black to Yellow | — .05 x 200 Volts |

Service Notes

Voltages taken from different points of circuit to chassis are measured with volume control full on, using a voltmeter having a resistance of 1000 ohms per volt. These voltages are indicated on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of similar capacity which is known to be in good condition, until the defective unit is located. Part numbers 145-2 and 145-3 are by-pass condenser blocks and consist of the following condensers:

Should any section of either of these blocks fail, it is not necessary to replace the entire condenser. A small tubular condenser may be used to replace the defective section.

Excessive hum, low volume or reduction in all D. C. voltages is usually caused by open or shorted electrolytic filter condensers. Open by-pass condensers cause oscillation and distorted reproduction.

MODEL 62-140, 62-140X
62-148, 62-148X
Alignment, Parts List

MONTGOMERY-WARD & CO.

25 Cycle Chassis

The 25 cycle model 62-148X chassis may be used on a power supply of from 105 to 125 volts, 60 cycles, but the 60 cycle model 62-148 must not under any circumstances be operated on 25 cycles.

All resistors are RMA color coded—specify value and/or resistor (per schematic diagram) and model number.

When ordering condensers, specify part number, model number and/or capacitor (per schematic diagram) and model number.

When ordering parts, always specify part and model number as well as serial-number of chassis.

Alignment

The set should be thoroughly checked for all other possible causes of trouble, such as defective tubes, condensers, poor installations and low line voltages before any attempt is made at re-alignment.

Aligning I. F. Transformer

1. With volume control full on, at extreme right of its rotation, and with variable condenser at its maximum capacity position (extreme right of its rotation) make the following adjustments:

- (a) Connect an external oscillator adjusted to 175 kilocycles, in series with a .1 mfd. condenser, to the control grid cap of the type 57 tube located between the R. F. coil (part numbers 109-10) and the I. F. transformer (part number 108-11) and chassis.
- (b) Adjust trimming condensers of I. F. transformer (part number 108-11) to resonance. See top view of chassis. Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or between the plate and screen terminals of the type 2A5 tube, by means of an adapter. Maximum deflection of the meter indicates resonance. Care must be taken to use only enough signal to give a readily readable output, as excessive input will result in overload and a false resonance point.

NOTE: The two trimmer condensers which tune the primary and secondary of the I. F. transformer are adjusted by set screws accessible from the back of the chassis.

Aligning R. F. and Oscillator Circuits

1. Connect the external oscillator set at 1720 kilocycle and in series with a 200 Mfd. condenser, between the antenna (tan) and ground (black) leads.

- (a) With volume control full on and variable condenser plates in minimum capacity position, plates entirely out of mesh (extreme left of its rotation), adjust trimmer of rear oscillator section of variable condenser to resonance.
- (b) Shift external oscillator frequency from 1720 to 1400 kilocycles, pick up signal by rotating variable condenser and peak R. F. (center) and antenna (front) section trimmers of variable condenser to resonance.
- (c) Check tracking at 1500, 1200, 1000, 800, 600 and 530 kilocycles by changing external oscillator frequency and rotating variable condenser to pick up signal. Adjust slotted end plates of R. F. (center) and antenna (front) sections to increase output, if necessary. DO NOT BEND OSCILLATOR PLATES.

NOBLITT SPARKS INDUSTRIES**SPECIAL INSTALLATION BULLETIN FOR THE
MODEL 25 ARVIN CAR RADIO****1934 Models Plymouth and Dodge**

The model 25 Arvin Car Radio will install very satisfactorily on these model cars in an *inverted* position directly above the accelerator pedal, leaving the entire right hand side of the dash for mounting an Arvin Heater.

First: Disconnect the free wheeling cable at the bottom, drill another hole in the dash 5 or 6 inches to the right and relocate the cable back through this hole. Connect the freewheeling cable again, making sure that this is done correctly so that it will engage and disengage. The oil pressure gauge tube should be moved to the left by disconnecting it at both ends and relocating it through another hole 4 or 5 inches to the left of its present location. The water temperature gauge tube does not have to be moved. A groove should be cut in the dash insulation for this tube to run in and then the set can be mounted over this. Make sure, however, that the tube is not bent nor pinched by the mounting bracket when the set is pulled up tight.

Now, to mount the set upside down, the mounting bracket is inserted, with the two mounting bolts in place, in the *horizontal* tapered slots in the back of the case. This bracket will then be in a horizontal position on the bulkhead when the set is mounted.

Locate the set just to the left of the cowl vent lever and as high as it will go. The flexible shafts and Bowden wire then enter at the bottom of the set. The tubes will operate satisfactorily in an inverted position. A special socket prevents them from falling out.

1933 Models Plymouth and Dodge

The same installation as explained above may be used on the 1933 models Plymouth and Dodge cars in which case it will not be necessary to relocate the oil pressure gauge tube.

Another way to install the Arvin No. 25 on the 1933 Plymouth and Dodge is as follows:

Relocate the free wheeling cable to either side of its present location. Then attach the radio to the right hand side of the dash directly under (or just to the left of) the glove compartment. The set is mounted in normal position with remote control connections at the top.

This location of the radio leaves room for an Arvin Hot Water Heater just above and to the right of the brake pedal.

**SPECIAL INSTALLATION BULLETIN FOR THE
MODEL 15 ARVIN CAR RADIO**

NOTE: All parts of the model 15 Arvin Radio mentioned in this bulletin are fully described in the regular installation instruction sheet furnished with each set.

All Model V-8 Ford Cars

The model 15 Arvin Car Radio can be installed very satisfactorily on Ford V-8 Cars directly below the glove compartment on the right hand side of the dash.

Remove the glove compartment by taking out the six screws around its front edge and also remove the door by taking the two screws out of the hinges which hold it. Now, by means of a hammer and anvil, flatten out the turned up lip at the rear of the instrument panel flange so as to provide a wider flange on which to mount the front end of the radio. Bend up the ears on either side of the front mounting bracket to conform to the contour of the bottom of the instrument panel. Also spread this bracket apart so that it forms about a 105 degree angle instead of a 90 degree angle.

Now, hold the front mounting bracket up against the instrument panel flange with its shorter leg butting up against the flange, and the longer leg extending upward behind the dash. Locate this bracket so that the right hand edge of its longer leg is just to the left of the loop in the door spring, or in other words, so that this spring will just clear the radio when the door is shut.

Mark the location of the holes to be drilled in the flange by inserting a pencil through the tapped holes in the mounting bracket. Drill a 9/32" hole at each of these two points. Now lift the bracket into place with the shorter leg underneath and against the instrument

panel flange (the illustration in the model 15 installation instruction sheet erroneously shows this leg resting on top of the flange with the screw entering from the bottom) and insert the 1/4-20 oval head screw from the top, first through the flange and then into the tapped holes in the bracket by reaching through the glove pocket door opening. Draw these screws up tight with a short screw driver.

Next remove the main mounting plate from the radio as explained in the regular installation instruction sheet and install the rear mounting bracket onto this plate with its longer leg extending horizontally to the rear. Insert the threaded studs extending from the front end of this plate through the oval shaped holes in the bracket just mounted and fasten with the proper washers and nuts.

The rear end of the set is supported by one carriage bolt through the square hole in the center of the rear mounting bracket and clamped to the step plate in the dash. Mark the location of this hole and drill one 11/32" hole. Insert the carriage bolt and draw up tight with the proper washers and nuts.

You are now ready to replace the glove compartment. This can be pushed through the door opening in the dash from the front and bolted into place in exactly the same manner as it came out. The lower front edge, of course, will have to be bent down around the top of the radio. However, this can be done without great difficulty. Now slip the radio chassis and outer cover, with speaker attached, up into place in the main mounting plate and complete the installation exactly as explained in the regular installation instruction sheet.

This procedure might appear to be a rather complicated and involved installation, however, it really is not at all difficult and in the end makes a very neat and workmanlike job.

30-A
Alignment

NOBLITT SPARKS INDUSTRIES

ALIGNMENT PROCEDURE FOR ARVIN CAR RADIOS

Models 10-A, 20-A, 20-B and 30-A

NOTE: All adjustments in the following instructions should be made with an output meter or some indicating device connected with the output of the radio receiver to insure maximum sensitivity and selectivity.

Remove the radio chassis from the case. Connect grounding wire from the radio chassis to the power pack. Connect the output of the oscillator to the grid cap of the 77 or 6A7 tube after removing the grid clip and adjust the oscillator to 175 kilocycles. Set the output to the lowest amount giving a satisfactory deflection of the output meter. Adjust with a Bakelite screwdriver the first and second I. F. transformer for a maximum output. Replace the grid clip, connect the output of the oscillator to the antenna terminal of the radio set through a .0001 mfd mica condenser and set the oscillator to 1510 kilocycles. Rotate the variable condenser fully out of mesh, then back until the rotor plates begin to enter the stator. Adjust the oscillator padder condenser until the maximum signal is attained. Then readjust the oscillator input to 1400 kilocycles, rotate the variable condenser until the signal is again heard.

Now adjust the antenna and R. F. padders until the output is again at the peak. With the Model 10A, 20A and 30A Radios further ad-

justment is made at other frequencies by bending the split plates on the R. F. and antenna sections either in or out, depending upon whether more or less capacity is needed to bring the set into resonance.

On the 20B receiver, set the oscillator output to 600 kilocycles and rotate the variable condenser until a signal is heard and then adjust the oscillator series padder condenser located on the right hand condenser back and forth until a point is found where the setting of the padder gives maximum deflection on the output meter. Setting of the padder and variable condenser are both variable, each dependent upon the other, there being one point on the setting of the variable condenser where a maximum deflection will be obtained.

After the 600 kilocycle adjustment has been made return to the 1400 kilocycle position and recheck slightly the adjustment of the radio frequency and the antenna padders to insure no change has been made.

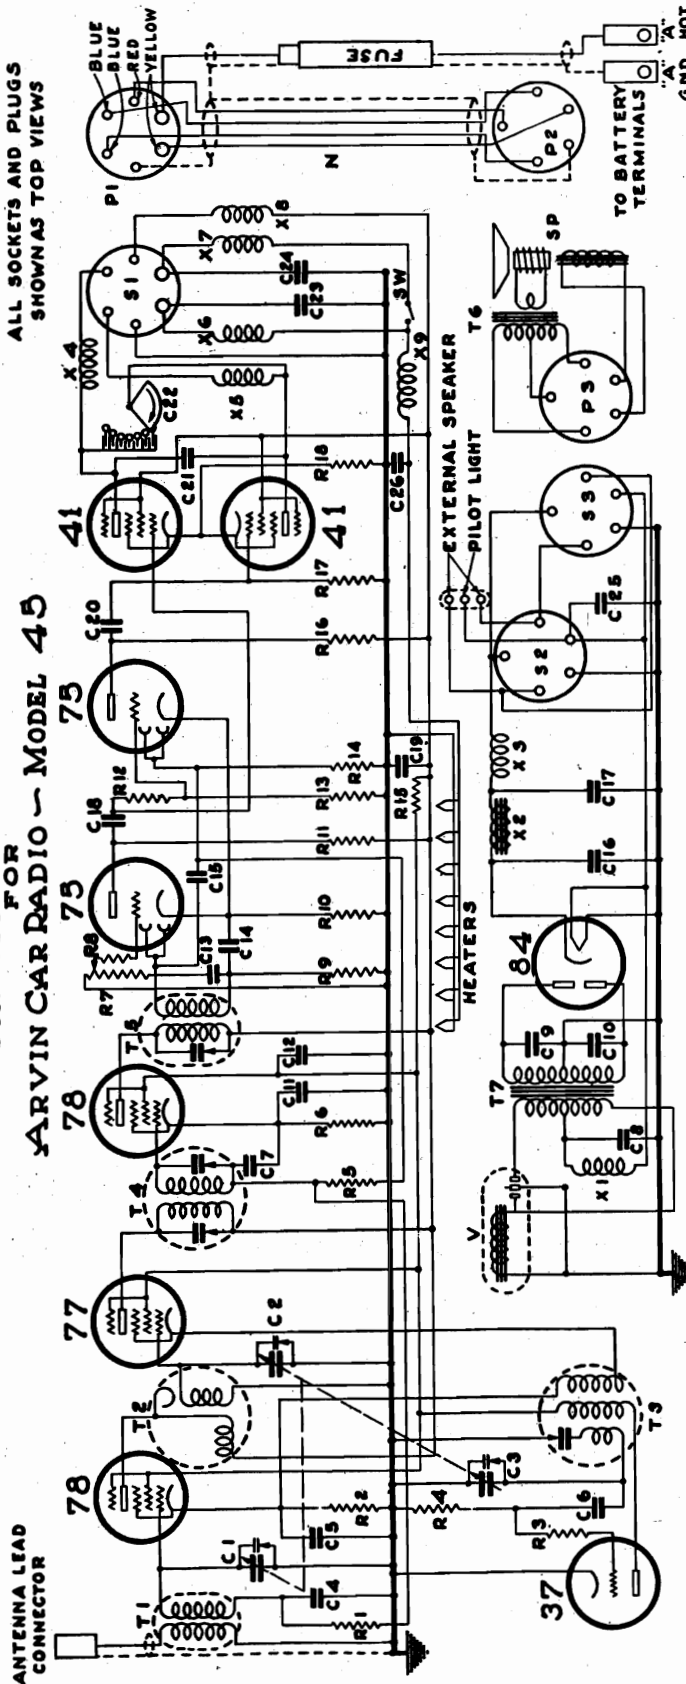

NOTE: After installation on some cars slight readjustment of the antenna padder on all Radios—except model 10A—materially improves the sensitivity of the receiver.

Notes

NOBLITT SPARKS INDUSTRIES

ALIGNMENT PROCEDURE FOR ARVIN**Models 15, 25, 35, and 45**

NOTE: All adjustments in the following instructions should be made with an output meter or some indicating device connected with the output of the radio receiver to insure maximum sensitivity and selectivity: Output meter may be connected to external speaker jack on all models.

Remove the radio chassis from the case. Connect the output of the oscillator to the grid cap of the 78 detector (2nd tube in set) or 6A7 tube after removing the grid clip and adjust the oscillator to 175 kilocycles. Set the output of the oscillator to the lowest amount giving a readable deflection of the output meter. Adjust with a Bakelite screwdriver the first and second I. F. transformer for maximum output. Replace the grid clip, connect the output of the oscillator to the antenna terminal of the radio set through a .0001 mfd mica condenser and set the oscillator to 1530 kilocycles. Rotate the variable condenser fully out of mesh, then back until the rotor plates begin to enter the stator. Adjust the oscillator padder, which is the section opposite shaft end, until the maximum signal is attained.

SPECIAL SERVICE BULLETIN**for Models 35 and 45****Motor Noise Elimination**

The Model 35 and 45 Arvin Car Radios have been especially designed for ease of elimination of motor noise.

The Chassis case is well shielded to prevent chassis pick-up and a special motor noise suppression system has been built into the set to block out "feed-back" through the "A" line. With these two sources of entry of motor noise blocked any such interference present must be picked up by the antenna and carried into the set exactly as a station signal. This type of motor noise is the easiest to eliminate and can usually be suppressed by standard suppression.

In rare cases, however, where a car is exceptionally "hot" it has been found that a slight amount of "chassis-pick-up" is present in

Then readjust the oscillator input to 1400 kilocycles, rotate the variable condenser until the signal is again tuned in.

Now adjust the antenna (shaft end) and R. F. (middle) padders until the output is again at maximum.

Then adjust the oscillator series padder condenser (located by the 6B7 tube in the Model 15; on the left-hand side in the Model 25; in the top of the oscillator coil can in the compartment with the 37 tube in the Models 35 and 45) until a maximum deflection is obtained at 550 to 600 kilocycles (condenser plates almost in full mesh). At 600 kilocycles the adjustment of the series padder condenser are both variable; each dependent on the other. However, there is only one point where the relation between their settings will give maximum sensitivity.

NOTE: After installation to car antenna slight readjustment of antenna padders, through holes provided on all models (see installation notes) will improve sensitivity and performance. Always adjust at about ten to twenty dial setting.

the Model 35 and 45 Arvin sets—and the purpose of this bulletin is to suggest a method of eliminating this.

Solder one end of a $3\frac{1}{2}$ " length of shielding to the underneath side of the condenser pulley mounting bracket directly between the two 6-32 screws which hold the Bowden wire housing clamp onto this bracket.

The other end of this piece of shielding is then hung over the edge of the chassis case on top of the copper case ground shim, and when the cover is put on the set, it automatically bonds the condenser pulley assembly to the outer case.

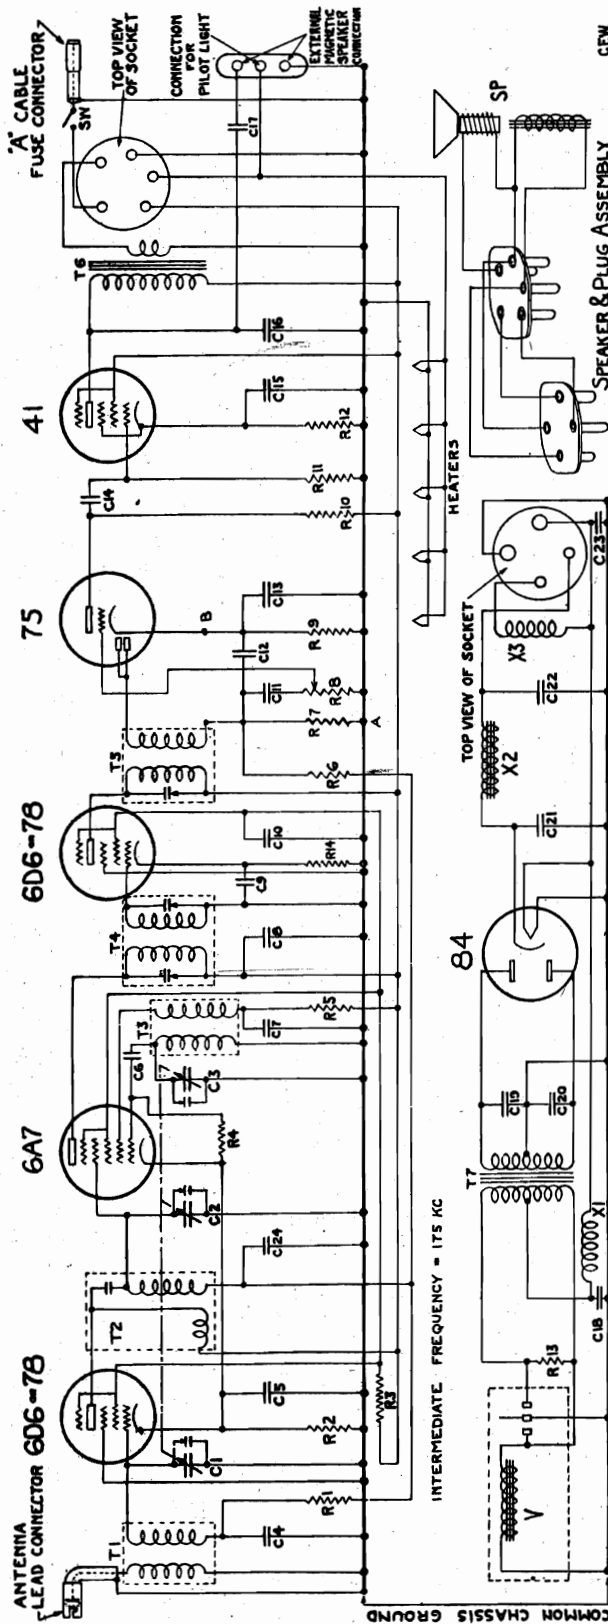

It has been found that this extra ground eliminates the last trace of "chassis-pick-up" motor noise interference from the Model 35 and 45 Arvin Car Radios.

In districts where signal strength is abnormally low, a slight increase in sensitivity may be obtained by removing the inter-channel noise suppression feature. Disconnect R7 at A and reconnect at B.

NOTE: On orders for replacement parts, state part number and quantity desired.

MISCELLANEOUS GENERAL INFORMATION RELATIVE TO REMOVING MOTOR NOISE

When primary wires to the coil run through the same conduit as the secondary or spark plug wire run—remove this wire from the conduit and shield it if necessary, grounding the shielding at both ends to some part of the motor block or the bulkhead between the passenger's compartment and the motor.

Also, be sure when shielding the secondary lead from the coil to the distributor to ground both ends of this shield, either to the motor or to the bulkhead. On some few cars the hood over the engine appears to be ungrounded or at least is a very high resistance ground and should be grounded with pigtailed of shielding cable soldered to both sides of the hood and also to the motor bulkhead or motor block.

On cars equipped with co-incidental lock on the steering post an extra generator condenser should be installed from one switch terminal to ground. The exact terminal on which to install this condenser can be determined only by experiment. The condenser body should be grounded to the dash or to the motor bulkhead. On some Ford V-8's it is necessary to install an extra generator condenser on the generator to the other terminal of the cutout relay, thus making two condensers on the same relay—one on each terminal to ground.

On some Chevrolets, generally of the older models, it is necessary to install an extra condenser from the primary of the ignition coil to ground. The exact terminal to connect this condenser to can only be determined by experiment. Be sure that the grounding of this con-

denser is solid, preferably to the motor block or to the motor bulkhead.

On all cars equipped with "Electrolock" it may be found necessary to remove the primary return wire from the switch to the coil and replace it with a new wire run through a piece of shielding loom grounded near the switch and also to the metal bulkhead on the motor side of the dash. This lead should be brought out through the dash as far as possible from the rest of the electrical wiring of the car.

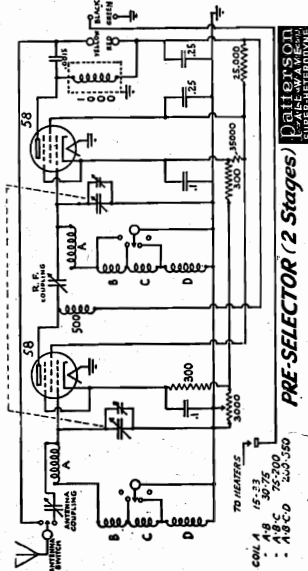

It may be pointed out that loose connections anywhere in the electrical circuit of the car will cause motor noise or what appears to be motor noise. If this condition exists it is wise to check the entire electrical circuit of the car and make sure that all connections are tight before trying any other extreme methods of motor noise elimination.

The use of a choke and condenser at the ammeter with the 10A has proven to be a great help in the elimination of motor noise. (See illustration above.)

PHONOGRAPH CONNECTION
INSTRUCTIONS FOR CONNECTING ELECTRIC PICKUP
TO ALL MODEL RECEIVERS:

The use of jacks and switches for operation of electric phonograph pickups is unsatisfactory with the modern highly perfected radio receivers. The electrical loss in the long leads used to connect the switch and jack into the circuit is enough to unbalance these highly sensitive, long distance receivers and the full capabilities of the set are lost.

For best radio and phonograph operation the rules below should be followed. With the methods graphically shown, full efficiency of the radio and phonograph are utilized and the greatest satisfaction is obtained.

METHOD No. 1

Remove shield cover "C." Remove cap "A."
Place cap "B," with attached clip, on top of 55 tube. Connect one phonograph pickup wire to clip "B." Connect other phonograph wire to clip "D." Phonograph will now play and volume control on radio will control phonograph.
Some pickups work better with a 4 1/2 volt C battery in series with lead that connects to clip "D." (+) to clip. (-) to pickup lead.

METHOD No. 2

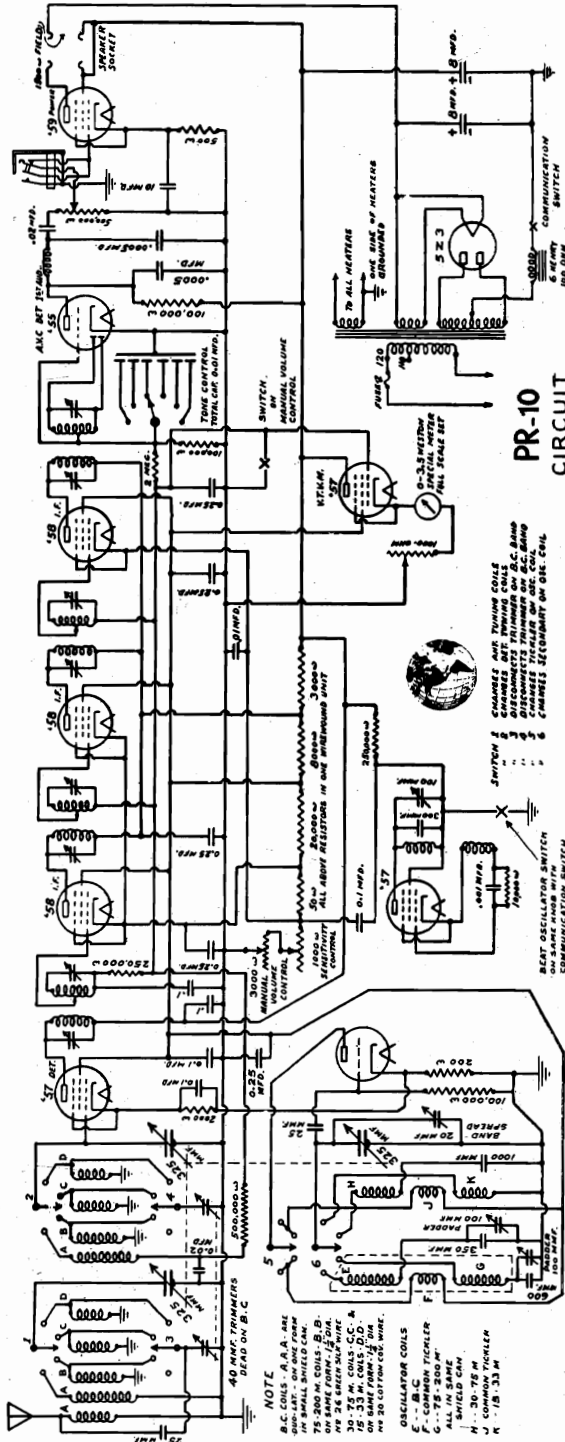

Use Method 2 where extreme volume is required. Remove shield cover "C." Remove cap "A." Place cap "B" (with attached clip), on top of 55 tube. Connect one of transformer (secondary) terminals to negative terminal (-) of 4 1/2 volt battery. Connect positive terminal of battery (+) to clip "D." Connect other (secondary) terminal of transformer to clip "B." Connect phonograph pickup terminal wires to transformer primary terminals. Any good audio transformer may be used as a step up for phonograph use. Phonograph will now operate and volume control on radio set will control phonograph volume.
Cap "A" and cover "C" are not used when phonograph is played. Remove cap "B" and replace cap "A" for radio operation.

MODEL PR-10
Schematic
Socket

PATTERSON RADIO CO.

To rebalance the receiver does not require any equipment. The meter will indicate the exact resonance point of the I.F. trimmers and also the condenser gang. Proceed as follows: Set band spread dial at "O," then tune in a station on the high frequency end of the Broadcast band (any station around 1400 K.C. is okay). Next, adjust the trimmer on the condenser section nearest the dial until the station reads exactly on its known K.C. Now, tune in a station in around 600 K.C. and be careful to be on the exact center of the carrier. All of the above operations must be made with the manual control in off position. Next, turn the sensitivity control toward minimum so that the meter reads about R-9. Now, adjust each of the eight I.F. trimmers very carefully until the meter swings the farthest to the right. You probably will not be able to increase the gain more than 1.5-R. It should not be necessary to turn any trimmer more than 1/8 of a turn.

PHILCO RADIO & TELEV. CORP.

MODEL G
Installation Data

CHRYSLER • DODGE • PLYMOUTH • CAR RADIO

The Model "CGD" is a custom built radio which is made exclusively for the Chrysler Corporation and its various car divisions and which is sold only through their dealer organizations.

The Receiver and controls are specially designed for installation in the 1934 Chrysler Six Models CA and CB, the Dodge Models DR and DS and the Plymouth Models PE and PF. Many of these cars will be equipped at the car factory with the Philco custom built radio. In many others, the installation will be made by you in your service stations.

Don't file this "Service Broadcast" in your Office. The men in your service station must know how to install and service these radios if you expect to get your share of this profitable installation and service work.

Carefully unpack the cartons and check the contents with the material packing lists. Examine the parts and compare them with illustrations given in these instructions so that you may become familiar with them and thus make the installation easily and quickly.

Receiver and Speaker Installation

Refer to Figure 1, which gives detailed dimensions for the location and drilling of the holes in the dash. Remove the paint from the dash for $\frac{3}{4}$ " from around the holes to insure good ground contact after drilling. All dimensions are shown from the engine side of the dash. After drilling the holes, bolt the two (2) mounting brackets to the inside of the dash, using both the flat and the lockwashers under the nuts. The left-hand bracket (over the steering column) is for the speaker unit; the right-hand bracket is for the Receiver.

Remove the car wiring cable outlet grommet cap on the left-hand side of the dash, so that the battery cable can be installed. Push the metal fuse housing end of the cable through the grommet from the engine side, leaving just enough slack so that the cable can be connected and fastened in place as shown in Figure 4. Route the cable through the clip that holds the car wiring harness and along under the floor boards to the battery. Replace the grommet and cap, but do not connect the cable terminal to the battery terminal at this time.

The Receiver mounting plate must be fastened to the Receiver housing, using the four (4) self-tapping screws. Four (4) holes are provided for these screws in the side of the housing. To fasten the speaker mounting plate to the speaker, first remove the four (4) hex-head machine screws from the back of the speaker. Use these same four (4) screws to fasten the mounting plate to the back of the speaker. Figures 2 and 3 show the correct positions of the brackets

and mounting plates. Hang the Receiver on its bracket and fasten it securely with the hex-head retaining screw at the bottom of the plate.

Before installing the speaker, remove the car wiring fuse on ammeter. To get the speaker in place turn it sideways with the back against the left front kick pad. Then slide it in between the kick pad and the steering column. Push the clutch pedal down to get sufficient clearance and then turn the speaker around over the steering column with its back against the dash. Hang the speaker in place on its bracket and fasten it securely with the hex-head retaining screw at the bottom of the plate. The battery cable must be placed over top of speaker.

Connect the interconnecting cable to both the Receiver and the Speaker, the six (6) hole plug connecting to the Receiver and the four (4) hole plug to the Speaker. The shield terminals at the cable ends must be grounded under their respective ground terminal screws on the Receiver and Speaker housings, shown in Figures 2 and 3. Ground the pigtail in the center of the cable to the dash, using the hole that holds the dash lining retainer and the 8-32 screw.

The antenna lead branches out of the interconnecting cable near the Receiver. Place this lead over the top of the Receiver, splice, and tape it to the antenna lead-in as close as possible to where the lead-in leaves the front right windshield pillar. Cut off excess car

Service Data**

PHILCO RADIO & TELEV. CORP.

lead-in. The shielding must be grounded to the cowl panel by drilling a $\frac{1}{8}$ " hole where the hood overlaps and as close to the A pillar as possible, using the 8-32 bolt and nut supplied for this purpose. (See Figures 4 and 5.) Remove paint from around hole.

Place the fuse and fuse insulator in the metal fuse housing of the battery cable and connect it to the small fuse connector which branches out of the interconnecting cable close to the Speaker. The two (2) shield terminals at the fuse housing must be connected under the same terminal screw that is used to ground the speaker cable shield at the speaker. Figure 4 shows the general layout of the cables and connections.

**Instrument Panel
Control**

Remove the ash receiver from the panel with an upward pull. Remove the ash receiver bezel from the panel by compressing the retaining tabs at the bottom of the bezel assembly. This can be done best by using a screw-driver and working from in back of the instrument panel. While pushing up on an end tab, pull the bezel forward and it will come out.

Loosen the two (2) screws which secure the instrument board brace to the instrument board flange. The cradle assembly can then be slid forward. Next, loosen the bolts on the brace in back of the instrument panel and remove the toggle spring. Slide the entire assembly forward and remove. Figure 6 gives the details of the ash receiver assembly, while Figure 7 gives an enlarged view of the Section A in Figure 6. Be sure to tighten all bolts and screws that were loosened for this operation. (See Note 1.)

Loosen the car lighting switch to permit more working space.

While this operation is not absolutely necessary, it makes the following operation easier.

Push the flexible shafts of the control through the opening in the panel and install the control unit in this opening.

The "U" retaining clamp must be placed over the studs on the back of the control and the hex-

FIGURE 5

nuts tightened to draw the control bezel flush with the instrument panel. (See Figure 8.) Replace and tighten the car lighting switch.

The flexible shafts must be placed around to the Receiver. The ends of the two (2) shafts are different so that they can only be installed in the proper couplings. The long shaft and housing is on the left of the control unit, while the short one is on the right.

FIGURE 4

The set screws on the coupling bushings must be loosened sufficiently to allow the shaft housings and couplings to be properly seated. After the shafts have been coupled, tighten the set screws again.

Battery Connections

Connect the battery lead to the negative terminal of the storage battery. Be sure this connection is tight. The shield terminal must be connected to positive or ground terminal of the storage battery.

The black lead from the control unit must be connected to the pilot light terminal on the Speaker. (See Figure 3.)

Adjustment

Turn on the Receiver and tune in a station whose frequency in kilocycles is known. (The numbers on the dial represent channel numbers which, with the addition of a cipher, become the frequency numbers.) Pull the knob from the right-hand control shaft and loosen the set screw found there. (See Figure 8.) Turn the shaft until the indicator points to the correct number on the dial. Then tighten the set screw and replace the knob.

Motor Interference Suppression

Cut the elbow terminals from the spark plug cables and screw on the molded bakelite elbow suppressor terminals. Cut off the end of the distributor center lead cable

and screw the straight molded resistor into the lead. Then plug this into the distributor cap. Install a one microfarad by-pass condenser on the generator. Mount it on the generator frame under the screw that holds the generator relay in place. Connect the condenser lead under the screw that connects the generator battery lead to the ray

FIGURE 6

FIGURE 7

NOTE 1.—A hole large enough for the dash control has been provided in the center of the instrument panel in all standard Plymouth Model, Code PF. This hole is covered with a special Plymouth plate which can be removed easily by forcing it out from the rear with the fingers or with a screw-driver.

PHILCO RADIO & TELEV. CORP.

MODEL G
Alignment Data
Adjustments
Socket Layout

(see Figure 4). Install a 1/2 microfarad by-pass condenser, splicing and soldering it to the dome light lead as close as possible to the point where it enters the windshield pillar. The condenser must be fastened to the cowl panel in front of the hood line by drilling a 3/8" hole where the hood overlaps and as close to the pillar as possible, using the 8-32 bolt and nut supplied for this purpose. (See Figures 4, and 5.) Remove paint from around hole. Replace the car lighting fuse—test the lights and horn.

There may be some interference caused by an excessive gap between the distributor rotor and the high tension contacts. This can be overcome by lengthening the contact end of the rotor.

The following procedure should be carefully followed: Remove the distributor cap and chalk the inside faces of the stationary contacts. Remove the rotor and place the contact end on a small anvil or steel block. Peen or hammer the end carefully with a small machinists' hammer. Replace the rotor and the cap, then turn the engine over by hand. After a couple of revolutions, examine the distributor cap to see if the rotor has scraped or touched any of the stationary contacts in the cap. If so, dress lightly with a fine file. Repeat the above operation until the rotor just clears the contacts.

In some stubborn cases, it may be necessary to solder a bond to the control wires and tubes where they enter the dash, grounding them securely under one of the dash grommet cap screws. No. 14 stranded and tinned copper wire can be used for this purpose, a length of which is provided (see Figure 9). Be sure that all the high tension wires are properly seated in their sockets in the distributor cap.

REMOVE PAINT FROM UNDER SCREW HEAD

FIGURE 9

An additional 1/2 microfarad condenser may at times be used to advantage. This condenser should be mounted on the bottom edge of the instrument board and connected to one of the terminals on the ignition switch directly behind the instrument panel.

I. F. Transformer and Padders

The new style I. F. transformer complete with padders is used in the Model G.

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figures 10 and 11.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Figure 1.

If replacements are ever necessary, replace the entire coil assembly 32-1236 for the first I. F. stage and 32-1237 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

FIGURE 10

FIGURE 8

Model G Adjustments

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The Philco Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and turned on for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the lid from the Receiver. Remove the grid cap from the 6A7 tube (for location see Figure 11).

Set up the signal generator and adjust it to exactly 260 K. C. Connect the generator lead to the grid cap of the 6A7 tube. (See Figure 11.) The output meter must be connected by means of an adapter to the small prong of the speaker plug and to the chassis.

The Receiver volume control must be turned on to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

FIGURE 11

The padders (24) and (26) are adjusted first (Figures 11 and 12). Turn the adjusting screw (24) all the way in. A metal screw-driver can be used for this. Then, with generator attenuator set so there is approximately half-scale reading, adjust the nut (26) with a fibre wrench for the maximum reading on the output meter.

Then adjust the screw (24) for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

Repeat the above procedure with the condensers (16) and (18).

After padding the first I. F. stage, remove the generator lead from the 6A7 tube and reconnect the grid lead to the 6A7 tube. Set the generator to 1500 K. C. and then connect the generator lead to the antenna lead.

There are four holes in line, one in each of the sections of the tuning condenser housing. (See Figure 11.) Place a nail of the size that fits snugly through the holes and then turn the condenser plates out of mesh until they strike against the nail.

With the tuning condenser in this position adjust the high-frequency padder (9) until the maximum reading is obtained in the output meter. This is the true setting for 1500 K. C., 150 on the dial scale.

Next turn the condenser plates in mesh to 140 on the scale, 1400 K. C., and set the signal generator for 1400 K. C. The R. F. padder (8) and the antenna padder (3) are next adjusted for the maximum reading on the output meter.

Turn the condenser plates in mesh to 60 on the scale, 600 K. C., and readjust the signal generator to this frequency. Adjust the low-frequency padder (19) for the maximum meter reading.

Recheck the adjustments and then remove all test leads. If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the Receiver is adjusted properly.

MODEL 10 (Code 122)
Alignment Data
Socket Layout

MODEL 10 (Code 122) RECEIVER

THE MODEL 10 (Code 122) represents the latest developments in single-unit automobile radio. Compact and easy to install, its performance is amazing.

A superheterodyne, using six of the latest tubes designed for automobile radio, it has a tremendous power output and is equipped with a full-size electro-dynamic speaker, the same type used in high-priced home radio Receivers.

Bass compensation gives full rounded tone at any volume. Four point tone control is provided to satisfy the individual preference. Greater sensitivity, a three-section tuning condenser giving improved selectivity and fidelity, inherently quiet circuits and all the other improvements, make this model the outstanding automobile radio.

The new interference filters and improvement in shielding, cut installation time to just a fraction of what it would be without these improvements. The ease of installation characteristic of this model (only one unit to install, one lead to the antenna and one lead to the ammeter) makes it the most desirable one to sell, install or own.

I. F. TRANSFORMER AND PADDERS

A new style I. F. transformer complete with padders is used in the Model 10. (Code 122.)

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1236 for the first I. F. stage and 32-1237 for the second I. F. Stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

FIG. 1

A new type first I. F. transformer is used, but retains the same part no. 32-1236.

This transformer can be distinguished from the old type, since the bottom fibre spacer is painted green.

MODEL 10 (Code 122) ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The Philco Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and turned on for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the speaker lid from the Receiver and disconnect the antenna lead from the Receiver. Remove the grid cap from the 6A7 tube (for location see Fig. 2).

Set up the signal generator and adjust it to exactly 260 K. C. Connect the generator lead to the grid cap of the 6A7 tube. (See Fig. 2.) The output meter must be connected by means of an adapter to the small prong of the speaker plug and to the chassis.

The Receiver volume control must be turned on to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The padders ⑩ and ③ must be adjusted first. These padders should be adjusted to peak. (Figs. 2 and 3.) First adjust the screw, then the nut.

The padders ⑫ and ⑨ must be adjusted next. (Figs. 2 and 3.) Turn the adjusting screw ⑫ all the way in. A metal screwdriver can be used for this. Then, with generator attenuator set so there is approximately half-scale reading, adjust the nut ⑨ with a fibre wrench for the maximum reading on the output meter.

Then adjust the screw ⑭ for maximum reading on the meter. This adjustment is critical. Note the maximum

reading obtainable and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

After padding the first I. F. stage, remove the generator lead from the 6A7 tube and reconnect the grid cap to the 6A7 tube. Connect the antenna lead to the Receiver. Set the generator to 1500 K. C. and then connect the generator lead to the antenna lead.

There are four holes in line, one in each of the sections of the tuning condenser housing. (See Fig. 2.) Place a nail of the size that fits snugly through the holes and then turn the condenser plates out of mesh until they strike against the nail.

With the tuning condenser in this position adjust the high-frequency padder ⑫ until the maximum reading is obtained in the output meter. This is the true setting for 1500 K. C., 150 on the dial scale.

Next turn the condenser plates in mesh to 140 on the scale, 1400 K. C., and set the signal generator for 1400 K. C. The R. F. padder ⑩ and the antenna padder ③ are next adjusted for the maximum reading on the output meter.

Turn the condenser plates in mesh to 60 on the scale, 600 K. C., and readjust the signal generator to this frequency. Adjust the low-frequency padder ⑬ for the maximum meter reading.

Recheck the adjustments and then remove all test leads. If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the Receiver is adjusted properly.

JULY, 1934

PHILCO RADIO & TELEVISION CORP.

MODEL 11
Alignment Data
Socket Layout

MODEL 11 RECEIVER

THE PHILCO auto. radio Model 11 is a new Philco development in single-unit automobile radio. It is compact, easy to install and will give exceptional performance.

A superheterodyne, using six of the latest tubes designed for automobile radio, it has a genuine Philco electrodynamic speaker, the same type that is used in many of the larger home radio Receivers. A three-section tuning condenser giving improved selectivity, remarkable sensitivity and tone, inherently quiet circuits and other improvements make this model one of the outstanding and most popular automobile radios.

Added to this, the ease of installation characteristic of this model (only one unit to install, one lead to the antenna and one lead to the ammeter) and the handy, attractive steering-column control which makes this model universal in its use are additional features which make the Model 11 a very desirable one for the dealer and for the owner.

I. F. TRANSFORMER AND PADDERS

The new style I. F. transformer complete with padders is used in the Model 11.

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1329 for the first I. F. stage and 32-1237 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

FIG. 1

MODEL 11 ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The Philco Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and turned on for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the speaker lid from the Receiver. Remove the grid cap terminal from the 77 tube (for location see Fig. 2).

Set up the signal generator and adjust it to exactly 260 K. C. Connect the generator lead to the grid cap of the 77 tube. (See Fig. 2.) The output meter must be connected.

The Receiver volume control must be turned on to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The padders ② and ③ are adjusted first (Figs. 2 and 3). Turn the adjusting screw ② all the way in. A metal screwdriver can be used for this. Then, with generator attenuator set so there is approximately half-scale reading, adjust the nut ③ with a fibre wrench for the maximum reading on the output meter.

Then adjust the screw ④ for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

FIG. 2

Repeat the above procedure with the condensers ② and ③.

After padding the first I. F. stage, remove the generator lead from the 77 tube and reconnect the grid lead to the 77 tube. Set the generator to 1500 K. C. and then connect the generator lead to the antenna lead.

There are four holes in line, one in each of the sections of the tuning condenser housing. (See Fig. 2.) Place a nail of the size that fits snugly through the holes and then turn the condenser plates out of mesh until they strike against the nail.

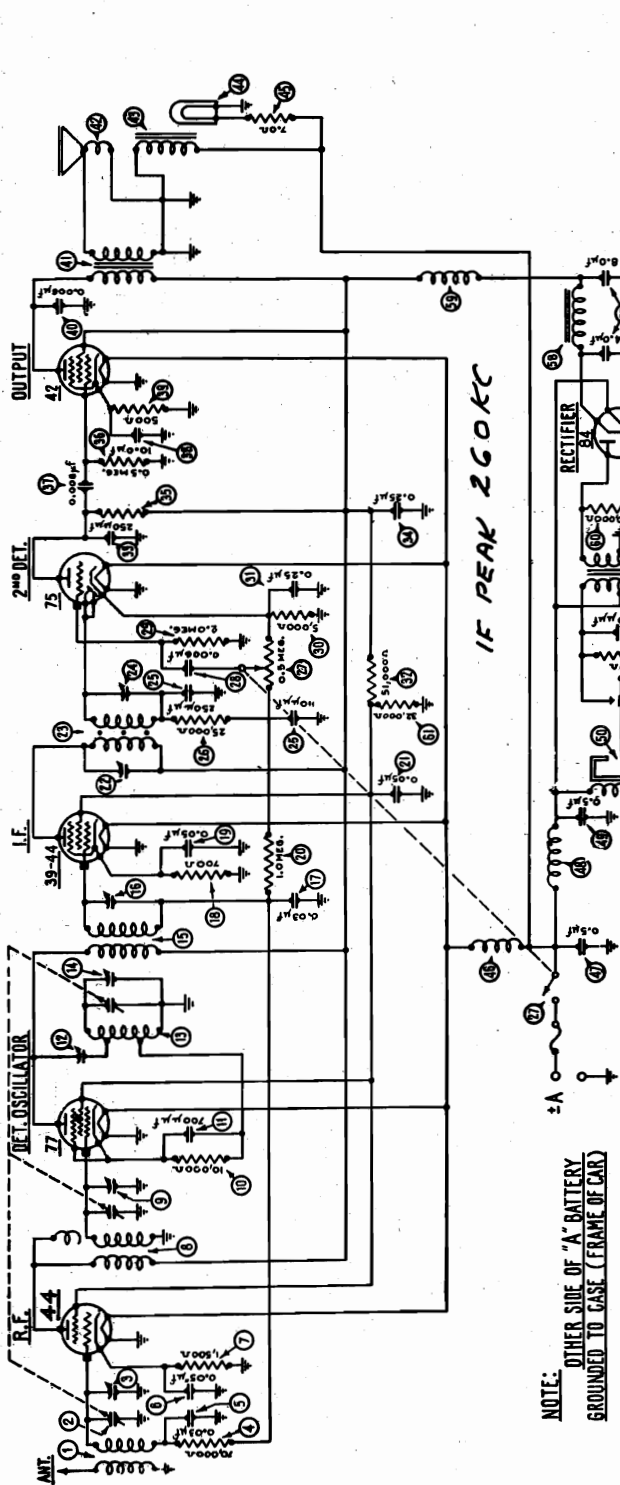

With the tuning condenser in this position adjust the high-frequency padder ④ until the maximum reading is obtained in the output meter. This is the true setting for 1500 K. C., 150 on the dial scale.

Next turn the condenser plates in mesh to 140 on the scale, 1400 K. C., and set the signal generator for 1400 K. C. The R. F. padder ⑤ and the antenna padder ③ are next adjusted for the maximum reading on the output meter.

Recheck the adjustments and then remove all test leads. If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the Receiver is adjusted properly.

MODEL 18 (Code 124)
Alignment, Voltage
Parts List

Model 18 (Code 124)

Model 18 (code 124) is an eight-tube superheterodyne receiver, for operation on alternating current (A.C.) The range of receivable frequencies is from 530 to 1720 kilocycles which includes standard broadcasts and police stations on the first (lowest) police band. The tubes used are: Type 78 R.F.; type 6A7 detector-oscillator; type 78 I.F.; type 75 2d detector, 1st A.F.; type 42 driver; two type 42 output tubes, and type 80 rectifier. The intermediate frequency is 260 kilocycles.

Adjusting Compensating Condensers

The adjustment of the compensating or padding condensers in Model 18 (124) requires an accurate signal generator, such as the Philco Model 024, an output meter, and a special insulated hex wrench. The adjustments are made as follows:

1. I. F. (Intermediate Frequency). Remove the grid clip from the cap on the 6A7 tube and attach the shielded antenna lead from the signal generator to the grid cap of the 6A7. Set the switch of the signal generator at 260 K. C. (the I. F. of Model 18) and the dial of the set at 550. Turn on the set and signal generator. Adjust each of the three I. F. compensating condensers in turn to give maximum reading in the output meter (connected to primary of output transformer). If the needle on the meter goes off scale, turn down the attenuator adjustment on the signal generator. See Fig. 4 for locations of the I. F. compensating condensers. The first and 2d I. F.

primary condensers ⑫ and ⑬ are accessible through the two holes in the chassis sub-base directly over them. The 1st I. F. secondary ⑭ is accessible from the rear.

2. ANT. H. F., DET., and OSC. H. F. CONDENSERS (⑤, ⑩, and ⑪.) These are located on top of the tuning condenser assembly and adjusted from above. ⑤ is mounted on the section nearest front of set. Replace the grid cap clip on the 6A7 and connect the antenna lead of signal generator direct to antenna post of set for these adjustments. Set signal generator at 1500 and dial of set at 1500.

3. OSC., L. F.—This adjustment ⑮ is made from rear of chassis (see Fig. 4). Set Signal Generator and dial of set at 600. The tuning condenser assembly should be "rocked" while this adjustment is being made.

Replacement Parts for Model 18 (Code 124)

Tube Socket Voltages

Circuit	R. F.	Det. Osc.	I. F.	1st A. F.	Driver	Output (Class "A")		Rectifier
Type Tube	78	6A7	78	75	42	42	42	80
Filament (F-F)	6.3	6.3	6.3	6.3	6.3	6.3	6.3	5.0
Plate (P-K)	210	210	210	120	205	280	280	350
Screen Grid (SG-K)								
6A7	80	..	80	..	200	300	300	..
G1-K	..	35
G2-K	..	130
Cathode (K-F)	2.8	1.8	5.3	0	0	0	0	..

All the above values were obtained from the underside of the chassis, using test prods and leads with an A. C. voltmeter for filament voltages and a high-resistance multi-range D. C. voltmeter for all other values. The Philco Model 048 All-Purpose Set Tester is highly recommended for this use. Volume control at maximum and station selector at 520 K. C. Readings obtained with a plug-in adaptor will NOT be satisfactory.

MODEL 28
Alignment
Parts List

Adjusting Compensating Condensers

For adjustment of compensating (padding) condensers in Model 28, an accurately calibrated signal generator, an output meter, and a special insulated padding wrench and screwdriver are needed. We suggest the Philco Model 024 Signal Generator, which is accurately calibrated and easy to handle. Philco No. 3164 fibre wrench and No. 27-1159 fibre-handled screwdriver are also recommended. For the output meter either Philco Model 025 complete tester or Philco Model 012 shadow output meter is suggested.

The chassis must be removed from cabinet in order to make all adjustments.

Adjustments are made in the following order—

ADJUSTMENT OF THE INTERMEDIATE FREQUENCY—Remove the grid clip from the type 6-A-7 tube and connect the "ANT" output terminal of the signal generator to the grid cap of the tube. Connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver chassis.

Connect the output meter adapter leads to the plate and cathode prongs of the type 43 tube. Set the signal generator at 460 K.C. (the intermediate frequency of Model 28) and with the receiver and signal generator turned on, the wave band switch at left and dial at 600 K.C., adjust each of the I. F. compensating condensers in turn, to give maximum response in the output of the receiver. The three pairs of I. F. compensating condensers are located one pair at the top of each of the three I. F. transformer shields. These are the three metal "cans" near the rear of the chassis. Each of the transformers has a dual compensating condenser mounted at its top, and accessible through a hole in the top of the coil shield. In the dual compen-

sators, the Primary circuit is adjusted by turning the screw; the Secondary circuit is adjusted by turning the hex-head nut.

ADJUSTMENT OF THE WAVE TRAP—Replace the grid clip upon the Detector-Oscillator tube (Type 6-A-7). Connect the output leads from the signal generator directly to the antenna and ground terminals of the receiver. Set the Wave-Band Switch of the receiver to the standard broadcast band (left-hand position) and the Station Selector at the low frequency (540 K.C.) end. Adjust the Wave Trap condenser to give MINIMUM response to a 460 K.C. signal from the signal generator. The Wave Trap (2) is located at rear and underneath the chassis, and is shown in Figure 1. It is reached from the rear of the chassis by inserting the fibre wrench through the hole near left-hand rear corner of chassis.

ANTENNA AND OSCILLATOR "HIGH" AND "LOW" FREQUENCY ADJUSTMENTS—The "antenna" and "oscillator H. F." compensators are located on top of the tuning condenser assembly, reached from above.

Set the signal generator at 1500 K.C., tune in this signal on the set and adjust the antenna compensator (8) (nearest tuning control) to give maximum reading in the output meter.

Next adjust the oscillator H. F. condenser (14) (located on the other section of tuning condenser) to maximum reading.

Finally, set the signal generator at 600, tune in this signal and adjust the "oscillator L. F." condenser, located underneath chassis (18) in Fig. 1) to maximum reading. This adjustment is reached through the hole in top of chassis, between the two electrolytic condensers (left-hand end of chassis when facing rear).

MODEL 29
Alignment Data
Voltage, Layouts

Philco Model 29 is a superheterodyne receiver operating on alternating current and capable of receiving either standard and police broadcasts between 540 and 1720 kilocycles, or short-wave stations between 4.2 and 13 megacycles. The left hand side of the dial is calibrated in kilocycles and the right in megacycles. A two-position switch changes reception from standard to short-waves. This model is equipped with shadow tuning, three point tone control with fixed bass compensation, and automatic volume control. The output is 5 watts.

Model 29 uses a type 6-A-7 detector-oscillator, two type 39-44 I. F. tubes, type 75 2d detector, type 42 output tube, and type 80 rectifier. The power consumption is 70 watts. The intermediate frequency is 460 K.C.

Adjusting Compensating Condensers

For adjustment of compensating (padding) condensers in Model 29, an accurately calibrated signal generator and a special insulated padding wrench and screwdriver are needed. We suggest the Philco Model 024 Signal Generator or the 048 Tester which includes a similar instrument. Philco No. 3164 wrench and 27-1159 screwdriver are recommended in addition.

Adjustments are made in the following order:—

ADJUSTMENT OF INTERMEDIATE FREQUENCY—Remove the grid clip from the type 6-A-7 tube and connect the "ANT" output terminal on the signal generator to the grid cap of the tube. Connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver chassis.

Connect the output meter to the primary terminals of the output transformer. Set the signal generator at 460 K.C. (the intermediate frequency of Model 29) turn wave-band switch of receiver to left and dial to 600 K.C. Turn receiver and Signal Generator "ON". Adjust each of the I. F. compensating condensers in turn, to give maximum response in the output of the receiver. The three pairs of I. F. compensating condensers are located, one pair at the top of each of the three I. F. transformer shields. These are the metal "Cans" near the rear of chassis. Each of these transformers has a dual compensating condenser mounted at its top, and accessible thru a hole in the top of the coil shield. In the dual compen-

sators, the Primary circuit is adjusted by turning the screw; the secondary circuit is adjusted by turning the hex-head nut.

ADJUSTMENT OF WAVE TRAP—Replace the grid clip upon the Detector-Oscillator tube (Type 6-A-7). Connect the output leads from the Signal Generator directly to the antenna and ground terminals of the receiver. Set the wave-band switch of the receiver to the standard broadcast band (left hand position) and the Station Selector at the low frequency (540 K.C.) end. Adjust the Wave Trap condenser to give MINIMUM response to a 460 K.C. Signal from signal generator. The Wave Trap ① is located at rear and underneath the chassis, and is shown in Figure 4. It is reached from the rear of the chassis, thru hole at right hand end of set base.

DETECTOR; AND OSCILLATOR — "HIGH" AND "LOW FREQUENCY" ADJUSTMENTS—The "Antenna" and "Oscillator H. F." compensators are located on top of the tuning condenser assembly, reached from above.

Set the signal generator at 1500 K.C., tune in this signal on the set, and adjust the antenna compensator ⑦ (nearest tuning control), to give maximum reading in the output meter.

Next adjust the oscillator H. F. condenser ⑧, located on the other section of tuning condenser, to maximum reading. Finally set the signal generator at 600, tune in this signal and adjust the oscillator L. F. condenser, located underneath chassis (⑤ in Fig. 4) to maximum reading. This adjustment is reached thru the hole in top of chassis, between the two electrolytic condensers (left-hand end of chassis when facing rear).

Tube Socket Voltages—(Line Voltage 115)

PHILCO RADIO & TELEV. CORP.

MODELS 16, 18-124,
29(123-TX)
29, 45

Model 16

Changes

Starting with run No. 14, all type Model 16 will use a different type tone control. This will be Part No. 30-4168 which replaces 30-4069 formerly used. Condenser 7653-C (⊗ on wiring diagram in Bulletin 165-B) is replaced by 3615-L.

The new tone control has fixed bass compensation, effective on all four positions, which helps subdue background noise and thus favorably affects short-wave reception.

Starting with Run No. 15, a No. 30-4125 tubular condenser, .006 mfd, will be added, connected between the plate of the 77 tube and the tone control. This gives a smoother variation in control and prevents too great a change in tone from one step to another.

Starting with Run No. 16, the tone control used on Model 16 will be part No. 30-4204, which replaces 30-4168. (See June 1st change notices.) At the same time, condenser 3615-L replaces 3615-J, and external tone control condenser 30-4125 is removed. This latter condenser is now built in as part of the new tone control, thus simplifying assembly of the set.

Model 18-124

Starting with Run No. 4, Resistor ⊗ on wiring diagram of Model 18-124 will be Part No. 5837 (1000 ohms) instead of No. 7775 (2500 ohms). There is a slight change in the antenna and oscillator transformers, the new ones being identified by a red paint mark on the bracket. No change in part number. Change to increase sensitivity.

Model 29 (Code 123-TX)

The differences between regular Model 29 and the TX type are that the latter has the following parts added:

- Output transformer 32-7256
- Speaker switch (toggle) 3116
- Speaker Type P-22

Model 29-TX also includes a furniture-type speaker, HR-2, which is connected to the receiver by a 25-foot cable and plug assembly, part No. 36-3327, attached to the speaker cabinet.

The A. C. cord on 29-TX is a flat cable and contains an extra wire, which is for use as an antenna lead by connecting the antenna to the binding post mounted on the side of the special flat A. C. plug used. However, the antenna *may* be connected to the regular antenna clip terminal on the receiver chassis if desired and more convenient.

The part number of this special cable and plug assembly is 41-3104.

Model 29

Effective July 1st, condenser ⊗ in wiring diagram of Model 29 is changed from 4989 AM, (.09 mfd.) to 3615 AW (.05 mfd.). This improves the fixed bass compensation used in this model.

Starting with Run No. 8, the cathode resistor (⊗ in wiring diagram of Model 29) will be changed from Part No. 6977 (500 ohms) to 33-3016 (400 ohms). This will prevent variation in performance of sets due to considerable variation in 6A7 tubes.

Starting with Run No. 9, electrolytic condenser ⊗ (on wiring diagram) will be a Part No. 30-2026 instead of 30-2020. The new type is of a higher working voltage.

Models 29 & 45

Effective July 1st, a new wave-trap will be used in this model. Part ⊙ on wiring diagram of Model 29 is changed from Part No. 38-5199 to 38-5995. The new wave trap uses an improved construction which facilitates production.

Effective July 1st, mica condenser ⊗ on wiring diagram of Model 29 was changed from Part No. 7301 to 30-1028. No change in capacity; change to facilitate wiring only.

MODELS 19,38,89

Notes

PHILCO RADIO & TELEV. CORP.

Correcting Intermittent Operation

On some of the earlier models of the 89, 19 and 38, difficulty may occasionally be experienced with intermittent operation. This condition usually occurs during periods of humid weather, and is caused by stopping of the oscillator. In some cases, the radio may be completely dead and at other times this in-operative condition may exist over a portion of the dial only.

There are a number of possible causes for the difficulty and the necessary steps have been taken in later production to correct the condition. On a few of the earlier sets, however, it may be necessary to make one or more of the changes outlined below:

1. **OSCILLATOR TUBE:** In most cases, partial or complete failure of the oscillator circuit can be corrected by replacing the oscillator tube.
2. **BATTERY VOLTAGE:** In the Model 38, low voltage of the "A" or "B" battery may cause failure in oscillation.
3. **CATHODE RESISTOR:** In the Models 89 and 19, correct performance can usually be restored by changing the cathode resistor $\text{\textcircled{R}}$ in the wiring diagrams of service bulletins 146 and 146A from 15,000 ohms to 10,000 ohms (Philco Part No. 4412). In the Model 38, the cathode resistor $\text{\textcircled{R}}$ in the wiring diagram of service bulletin 106 is changed from 6,000 ohms to 4,000 ohms (Philco Part No. 33-1040).
4. **COMPENSATING CONDENSERS:** The first I. F. compensating condensers in Models 89 and 19 $\text{\textcircled{C}}$ in service bulletin 146, $\text{\textcircled{C}}$ in service bulletin 146-A and $\text{\textcircled{C}}$ in service bulletin 166 have been changed from Part No. 04000-M to Part No. 31-6016. The new condenser has a larger insulating surface between the plates of the condenser and the mounting holes. The possibility of moisture absorption is thus eliminated. It is necessary to re-drill a hole in the chassis so that the condenser can be mounted correctly with respect to the opening in the chassis for the compensating condenser wrench.
5. **BAKELITE WASHERS:** In order to prevent moisture absorption with resulting drifting in the compensating condenser adjustment, a bakelite washer and a metal washer are now being used on top of the compensating condenser, in place of the fibre washers previously used. The part number of the bakelite washer is 27-4109 and the metal washer (placed on top of the bakelite) is W-1331. These two replace the old fibre washer Part No. 3500.
6. **MICA INSULATION:** It was found on some sets that the mica which separates the leaves of the high frequency oscillator compensating condensers was extremely thin and would crack easily. Moisture absorption in the cracks was sufficient to stop oscillation. This condition was corrected by replacing the mica.
7. **WIRE INSULATION:** The wire which connects from the oscillator tuning condenser to the oscillator coil should be rubber-covered. Possible moisture absorption in the insulation of the cotton-covered wire may be sufficient to produce leakage to ground.
8. **OSCILLATOR COIL IMPREGNATION:** In some cases, it may be desirable to re-impregnate the oscillator coils in accordance with the present methods of production. The coil is dipped in hot paraffine for twenty seconds. The entire coil, including the terminals, is submerged; the only part which is out of the paraffine is a portion of the mounting lug, thus assuring a good ground connection. The coil and the paraffine both are allowed to cool until the paraffine becomes a considerably heavier consistency, at which time the coil is again dipped, thus allowing a fairly heavy covering over the entire coil. The coil is now entirely sealed and will not be affected by any moisture changes.
9. **TUNING CONDENSER:** A few tuning condensers of the 89 and 38 Models went out of the factory with a sanded surface on the bakelite between the stator and rotor plates. Moisture absorption at this point was sufficient to stop oscillation. Changing the tuning condenser to the type with smooth bakelite insulation will correct the trouble. In present production, these bakelite pieces are dipped in insulating varnish to seal all possible openings which might absorb moisture.
10. **OSCILLATOR SOCKETS:** In extreme cases it may be necessary to change the detector-oscillator tube socket. Moisture absorption occasionally takes place around the rough edges of the socket.

PHILCO RADIO & TELEV. CORP.

ELIMINATION OF NOISE INTERFERENCE CAUSED BY THE FARM LIGHTING SYSTEM

The operation of a radio receiver directly from a 32 volt farm lighting system is sometimes interfered with by noises in reception, caused by the operation of the lighting system's charging equipment. These noises are radiated from the service lines and picked up by the antenna and lead-in. A certain amount of the noise also comes directly thru the lines. A whirring or crackling noise may be caused by sparking at the brushes of the generator; and a "clicking" by the sparks at the spark plug of the gasoline motor used to drive the generator, and by the operation of the "breaker" in the spark coil primary.

Installation of the proper type of antenna system is of considerable importance in eliminating these troublesome noises. For maximum freedom from noise the antenna should be the special Philco "Three-Purpose" aerial system, which was designed to prevent pick-up of noise by the antenna lead-in.

The antenna wire should in all cases be run in a direction from the house opposite to that of the service leads from the lighting system, as indicated in Fig. 8. Where the Three-Purpose System is used, the instructions furnished with it should be very carefully followed. Note that this system employs a special "transmission line" lead-in, at each end of which a special transformer is installed. The transformers must be installed as per instructions, and if this is done the transmission line (lead-in) will be completely noise-proof. All other necessary parts for the antenna installation such as ground clamps, lighting arrester, etc. are included with the Three-Purpose Antenna System.

Philco has designed a special interference-suppression and filter for 32 volt systems which will eliminate most if not all of the interference encountered in the majority of installations. This unit consists

Fig. 8—Best Method of Antenna Installation for Model 32

of filter chokes and condensers, and is connected directly in the output lines of the generator as per instructions supplied with this special unit. The unit may be obtained from your Philco Distributor.

It is generally advisable also to connect a 1/2 mfd. fixed condenser (Philco Part No. 30-4015) from each set of generator brushes to the frame of the generator (which should be grounded). The method of locating these condensers is indicated in Fig. 9 which shows a cut-away view of one end of a generator. These condensers help eliminate the whirring or crackling caused by the generator brushes.

To reduce the clicking noise caused by the ignition at the spark plug, a suppressor (Philco Part No. 4531) should be inserted in series between the terminal of the plug and the cable leading to it. See Fig. 10.

Fig. 9—Condensers Attached to Generator for Suppressing Interference

Fig. 10—Suppressing Ignition Interference from Spark Plug

MODEL 32

**Alignment Data
Layouts**

PHILCO RADIO & TELEV. CORP.

Model 32

Philco Model 32 is a superheterodyne radio receiver designed to operate directly from a 32 volt D. C. (direct current) electric system, such as used on many farms for lighting purposes. In this model the filaments of the tubes (except the rectifier) are connected in series, while the necessary plate and grid voltages are secured from a special vibrator-

and-rectifier unit, contained in a separate metal box mounted on a shelf of the radio cabinet. The rectifier tube is inside the vibrator-and-rectifier unit box. It obtains its filament voltage from a secondary winding of the transformer which is also located in the vibrator-and-rectifier unit box.

Model 32 uses the following tubes: R. F., type 39-44; Detector-Oscillator, type 36; I. F., type 39-44; 2d detector, type 75; Output type 42; Rectifier, type 84.

The frequency range of the model 32 is 520 to 3260 kilocycles. The intermediate frequency (I. F.) is 260 K. C. The power consumption is 50 watts when the line voltage is 32, and approximately 70 watts when the line voltage reaches 38.

With a line voltage of 35 volts to the vibrator and an effective voltage of 28 at primary of power transformer (voltage from white lead to white-black-tracer), the A. C. voltage across secondary should be about 300 volts at 65 milliamperes. Secondary voltage measured from yellow lead to yellow-green-tracer. Voltage across 84 filament approximately 7 volts at .5 amperes. (Filament leads have blue insulation.)

Fig. 1—Top View of Model 32

NOTE: In 32-volt systems where the batteries are old, the voltage is high (40 volts) when generator is running (due to the higher internal resistance of the batteries). In such cases it will help conserve life of the tubes in the set if battery charging is done at periods of the day when the radio is not in use.

Tube Socket Data Line Voltage 34 Volts

Circuit	RF	Det.-Osc.	IF	AF	Output	Rect.
Type Tube	39-44	36	39-44	75	42	84
Filament Volts.....	6.8	6.8	6.8	6.8	6.8	6.8
Plate Volts.....	205	200	235	155	220	300
Screen Grid Volts (SG to K).....	85	83	85	240
Cathode Volts (K to Gnd).....	4	8.5	4	0	0

The above voltage values were obtained with a high-resistance, multi-range D. C. voltmeter. The readings were taken from the underside of the chassis, with test prods and leads. The PHILCO MODEL 048 ALL-PURPOSE SET TESTER is an ideal instrument for taking these readings, and is highly recommended for this purpose. When the above values were obtained, the Station Selector was set at the low frequency (550 K. C.) end of the scale; the Volume Control was at maximum

Fig. 2—Terminal Arrangement of Tube Sockets Viewed from Under Side of Chassis

Fig. 3—Rear of Model 32 Chassis, showing location of I.F. Compensating Condensers. I.F. of Model 32 is 260 K. C.

Fig. 4—Top View of Chassis Showing Compensating Condensers Mounted on Tuning Condenser, also Low Frequency Compensating Condenser.

ADJUSTMENT OF MODEL 32

COMPENSATING CONDENSERS

These receivers are adjusted accurately before they are shipped from the Factory. If re-adjustment is required, it is usually necessary to re-align only the intermediate frequency compensating condensers. Fig. 3 shows the location of these compensating condensers. The intermediate frequency is 260 kilocycles.

An accurately calibrated signal generator is required for these adjustments. The PHILCO MODEL 024 is a precision signal generator supplying frequencies from 105 kilocycles to 2000 kilocycles and is recommended for this work.

To adjust the I. F. condensers, remove the grid cap clip from the type 36 tube and connect the shielded antenna lead from the signal generator to the grid cap. Connect the ground lead from signal generator to ground post of set.

Connect the primary terminals of the output transformer to an output meter. Set the signal generator frequency switch at 260 K. C., turn it and the receiver "on" and adjust the attenuator of the signal generator so as to get a half scale deflection on the meter. Now with the fibre hex wrench, adjust each of the I. F. condensers in turn so as to obtain maximum reading in the meter.

If re-adjustment of the intermediate frequency circuits is not sufficient to restore sensitivity, the high frequency and low frequency compensating condensers are re-aligned as described in the following paragraphs. Figure 4 shows the location of these compensating condensers.

When making these adjustments replace the grid clip on the 36 tube, and connect the antenna and ground leads from the signal generator direct to the antenna and ground posts of set.

The High Frequency compensating condenser is first adjusted. This adjustment is made with the signal generator set at 1400 kilocycles. Next the Detector and Antenna Condensers, located on the tuning condenser assembly, should be adjusted, with the signal generator still operating at 1400. It may be necessary to readjust the attenuator on the signal generator for these adjustments.

The last adjustment is that of the low frequency (LF) compensating condenser which is accessible from above through the hole in chassis alongside the tuning condenser assembly. This adjustment is made with the signal generator set to give a 700 K. C. signal.

VIBRATOR AND RECTIFIER UNIT

PHILCO RADIO & TELEVISION CORP.

MODEL 34, 34-A
Schematic
Layouts

Model 34 is intended for use with the Philco type 172-R 2-volt storage A battery, model 34A uses Philco type 896 dry A battery. Both sets use the Philco type P968 combination B & C battery unit.

The current drain is: A battery—750 milliamperes; B battery—16 to 19 milliamperes. The ballast tube used in the model 34A keeps the voltage delivered by the dry A battery to the filament at nearly two volts at all times.

FIG. 4—Schematic Wiring Diagram

IF PEAK 460 KC

NOTE: Output transformer is mounted on receiver (under chassis) instead of on speaker as indicated in diagram. Also speaker magnet is not grounded.

CIRCUIT	Det.-Osc.	1st I. F.	2nd I. F.	2nd Det.	1st A. F.	Driver	Output
TYPE TUBES	1C6	34	34	30	32	30	19
Filament Volts.....	1.9	1.9	1.9	1.9	1.9	1.9	1.9
Plate Volts.....	P-135 G2-120	135	135	..	40	135	135
Screen Grid Volts.....	67½	67½	67½	..	35

*The above values were obtained from the underside of the chassis, using test prods and leads, with a high-resistance multi-range D. C. voltmeter. The Philco Model 048 All Purpose Set Tester is highly recommended for all tests of this character. Receiver volume control at maximum; station selector at 520 kilocycles. Readings taken with a plug-in adapter will not be satisfactory.

ADJUSTING MODEL 34

The compensating condensers of Model 34 have been adjusted accurately before shipment. If later adjustment is required, in most cases only the intermediate frequency and low frequency compensating condensers should be done. Extreme care must be given the adjustment of the high frequency circuits, and the adjustment should NOT be undertaken unless the receiver is seriously out of alignment.

DO NOT ATTEMPT TO ADJUST the compensating condensers mounted upon sections numbered 3 and 4 of the Tuning Condenser Assembly. These have been adjusted, and sealed, at the factory.

Philco Model 048 All-Purpose Set Tester, which incorporates a signal generator covering broadcast and police band frequencies, is recommended for the adjustment of the intermediate frequency and low frequency compensating condensers.

Philco Model 091 crystal-controlled Signal Generator is recommended for the high frequency adjustments. It gives an accurate and constant 3600 kilocycle (3.6 megacycle) signal, the harmonics of which include the necessary high frequencies for adjusting the compensating condensers in the high frequency circuits.

1—ADJUSTMENT OF THE INTERMEDIATE FREQUENCY—Remove the grid clip from the type 1C6 tube and connect the "ANT" output terminal of the signal generator to the grid cap of the tube. Connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver chassis.

Connect the output meter to the primary terminals of the output transformer. Set the signal generator at 460 K.C. (the intermediate frequency of Model 34) and adjust each of the I.F. compensating condensers in turn, to give maximum response in the output of the receiver. The location of the I.F. compensating condensers is shown in Figure 2. Each of these transformers has a dual compensating condenser mounted at its top, and accessible thru a hole in the top of the coil shield. In the dual compensators, the Primary circuit is adjusted by turning the screw; the Secondary circuit is adjusted by turning the hex-head nut.

2—ADJUSTMENT OF THE WAVE TRAP—Replace the grid clip upon the Detector-Oscillator tube (Type IC6). Connect the output leads from the signal generator directly to the antenna and ground terminals of the receiver. Set the Wave-Band Switch of the receiver to the standard broadcast band (Range 1) and the Station Selector at the low frequency (520 K.C.) end. Adjust the Wave Trap ② condenser to give MINIMUM response to a 460 K.C. signal from the signal generator. The Wave Trap ② is located at rear and underneath the chassis, and is shown in Figures 2 and 5. It is reached from the rear of the chassis.

3—ADJUSTMENT OF THE DIAL FREQUENCIES—Model 34 has four separate frequency bands or ranges, each obtained by one of the four positions of the wave-band switch. There is a compensating condenser for each

range, which must now be adjusted. In the following procedure, the frequency ranges referred to, and obtained by the different positions of the switch are:

- Range 1..... 520 K.C.—1500 K.C.
- Range 2..... 1.5 M.C.—4.0 M.C.
- Range 3..... 4.0 M.C.—11.0 M.C.
- Range 4..... 11.0 M.C.—23.0 M.C.

Connect the output terminals of the Model 091 or equivalent Signal Generator, to the "ANT" and "GND" terminals of the receiver chassis. Connect an output meter to the primary terminals of the Output Transformer of the receiver. Set the Wave-Band Switch to Range 4, and the Station Selector at 21.6 M.C. The sixth harmonic of the 3.6 M.C. crystal in the Model 091 Signal Generator is picked up at this point. Adjust the compensating condenser ③ on Section 1 of Tuning Condenser for maximum response in the output of the receiver.

Turn the Wave-Band Switch to Range 3, and the Station Selector to 10.8 M.C. Here, the third harmonic of the 3.6 M.C. crystal will be heard. Adjust the compensating condenser ④ on Section 2 of Tuning Condenser for maximum response in the output of the receiver.

Turn the Wave-Band Switch to Range 2, and adjust the Station Selector to 3.6 M.C. The "Antenna" connection between the Signal Generator and the receiver chassis must be removed for this adjustment, otherwise the output of the Signal Generator will be too great. Adjust the compensating condenser ⑤ to give maximum response in the output circuit. This compensating condenser is located underneath the chassis and is not accessible from above. See Figure 5.

This concludes adjustments requiring the Model 091 (or equivalent) high frequency signal generator.

The Model 048 or its equivalent is now used again. Turn the Wave-Band Switch of the set to Range 2 and the Station Selector to 1.5 M.C. Set the Signal Generator at 1500 K.C. Make sure the "Antenna" connection between the Signal Generator and the Chassis has been restored. Adjust compensating condenser ⑥ located underneath the chassis, (Figure 5). Adjustment is made from the underside of the chassis.

Tune the Wave-Band Switch to Range 1 and the Station Selector to 1400 K.C. Set the Signal Generator at 1400 K.C. Adjust compensating condenser ⑦, which is located underneath the chassis. (See Figure 5). This adjustment is made from the underside of chassis.

Finally, with Wave-Band Switch at Range 1, and Station Selector at 520 K.C., set the Signal Generator at 520 K.C. and adjust compensating condenser ⑧ (Figure 5). This compensating condenser is also mounted underneath the chassis, and reached from below.

For proper and accurate adjustment of Model 34, the procedure must be followed exactly in the order given. The adjustment should not be undertaken without proper equipment as mentioned above.

MODELS 32, 34, 38-122

45

PHILCO RADIO & TELEV. CORP.

Changes**Model 32**

Starting with Run No. 4, the antenna and ground Fahnestock clip terminals will be replaced with insulated wire leads. This is done to better meet Underwriters' requirements.

Starting with Run No. 5, Model 32 will use a type 77 detector-oscillator tube instead of a type 36. This change gives more stable performance of the oscillator.

This change involves using a six-hole tube socket instead of the original five-hole socket used for type 36. It also requires making the following substitutions:

Part Ⓣ, No. 6208 resistor (15,000 ohms) is replaced by 33-1114 (8000 ohms)

Part Ⓣ, No. 5863 condenser (700 Mmfd) is replaced by 7007 (1400 Mmfd.)

On page 3, correct Part No. of Ⓢ Volume Control is 30-5063, instead of 30-5055.

(List price given (\$1.00) is correct.)

Model 34

Correct list price of Part Ⓢ, 36-3157 voice-coil and cone-assembly, KR-6 speaker, to read 0.75

Starting with Run No. 3, Model 34 will be equipped with a 4-point tone control instead of a 2-point. The part No. of the new control is 30-4168 which replaces 30-4152.

Model 38-122

This model will use a new output transformer, Part No. 32-7286. This replaces No. 2565 formerly used.

Referring to change notice of July 1st regarding ballast tube shunt resistor on Model 38-122, the correct part number of the 20 ohm resistor used will be 33-3043 instead of 33-3160.

A new ballast tube shunt resistor will be used in production effective this date. This will be part No. 33-3160, 20 ohms, instead of part No. 7155, 30 ohms. This gives a slight (desirable) increase in filament voltage.

Model 45

Starting with Run No. 5, the cathode resistor on 6A7 tube, Part No. Ⓢ on diagram will be changed from Part No. 6977 (500 ohms) to 33-3016 (400 ohms). This is to prevent variation in output of sets due to variation in 6A7 tubes.

Starting with Run No. 6, electrolytic condenser Ⓢ and Ⓢ (Part No. 30-2028) is replaced by No. 30-2079, same capacity but higher voltage rating.

Starting with Run No. 8, electrolytic condenser Ⓢ (see Service Bulletin 191) will be changed from part No. 30-2020 to 30-2026. Same capacity (6 mfd.), higher voltage rating.

Both Codes 121 and 122 on this model will now use bypass condenser 3615-W for part Ⓢ. This change was made to simplify assembly on this model and does not affect performance.

Models 45 & 29

Effective July 1st, mica condenser Ⓢ on wiring diagram of Model 29 was changed from Part No. 7301 to 30-1028. No change in capacity; change to facilitate wiring only.

Effective July 1st, a new wave-trap will be used in this model. Part Ⓢ on wiring diagram of Model 29 is changed from Part No. 38-5199 to 38-5995. The new wave trap uses an improved construction which facilitates production.

PHILCO RADIO & TELEV. CORP.

MODEL 45
Alignment Data
Voltage, Layouts

Model 45

Philco Model 45 is a six tube receiver operating on alternating current and capable of receiving either standard and police broadcasts between 540 and 1720 kilocycles, or short-wave stations between 4.2 and 13 megacycles. The left hand side of the dial is calibrated in kilocycles for standard reception and the right in megacycles for short-wave stations. A two-position switch changes reception from standard to short-waves.

Model 45 uses a type 6-A-7 detector-oscillator, two type 39-44 I. F. Tubes, type 75 2d detector, type 42 output tube, and type 80 rectifier. The power consumption is 65 watts. The intermediate frequency is 460 K.C.

Power Transformer Voltages

Terminals	Volts	Circuit	Color Leads
1-2	120	Primary	White
3-4	5.0	Fil. of 80	Blue
5-7	680	Plates of 80	Yellow
8-10	6.3	Filaments	Black
6	...	Center of 5-7	Yellow—Green tr.
9	...	Center of 8-10	Black—Yellow tr.

Tube Socket Voltages

CIRCUIT	Det. Osc.	1st IF	2d IF	2d Det.	Out-put	Rect.
Type Tube	6A7	39-44	39-44	75	42	80
Filament (F to F).....	6.3	6.3	6.3	6.3	6.3	5.0
Plate (P to K).....	280	255	255	175	250	335

Fig. 2—Chassis Top View

Adjusting Compensating Condensers

For adjustment of compensating (padding) condensers in model 45, an accurately calibrated signal generator and a special insulated padding wrench are needed. We suggest the Philco Model 024 Signal Generator or the 048 Tester which includes a similar instrument.

The chassis must be removed from cabinet in order to make all adjustments.

Adjustments are made in the following order—

ADJUSTMENT OF THE INTERMEDIATE FREQUENCY—Remove the grid clip from the type 6A7 tube and connect the "ANT" output terminal of the signal generator to the grid cap of the tube. Connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver chassis.

Connect the output meter to the primary terminals of the output transformer. Set the signal generator at 460 K.C. (the intermediate frequency of Model 45) and with the receiver and signal generator turned on, the wave band switch at left and dial at 600 K.C., adjust each of the I. F. compensating condensers in turn, to give maximum response in the output of the receiver. The three pairs of I. F. compensating condensers are located one pair at the top of each of the three I. F. transformer shields. These are the three metal "cans" near the rear of the chassis. Each of the transformers has a dual compensating condenser mounted at its top, and accessible thru a hole in the top of the coil shield. In the dual compensators, the Primary circuit is adjusted by turning the screw; the Secondary circuit is adjusted by turning the hex-head nut.

ADJUSTMENT OF THE WAVE TRAP—Replace the grid clip upon the Detector-Oscillator tube (Type 6A7). Connect the output leads from the signal generator directly to the antenna and ground terminals of the receiver. Set the Wave-Band Switch of the receiver to the standard broadcast band (left hand position) and the Station Selector at the low frequency (540 K.C.) end. Adjust the Wave Trap condenser to give MINIMUM response to a 460 K.C. signal from the signal generator. The Wave Trap ① is located at rear and underneath the chassis, and is shown in Figure 4. It is reached from the rear of the chassis, by inserting the fibre wrench thru the hole near right-hand rear corner of chassis.

DETECTOR, AND OSCILLATOR "HIGH" AND "LOW" FREQUENCY ADJUSTMENTS—The "antenna" and "oscillator H. F." compensators are located on top of the tuning condenser assembly, reached from above.

Set the signal generator at 1500 K.C., tune in this signal on the set and adjust the antenna compensator ⑦ (nearest tuning control) to give maximum reading in the output meter.

Next adjust the oscillator H. F. condenser ⑩ (located on the other section of tuning condenser) to maximum reading.

Finally set the signal generator at 600, tune in this signal and adjust the oscillator "L. F. condenser", located underneath chassis ⑬ in Fig. 4) to maximum reading. This adjustment is reached thru the hole in top of chassis, between the two electrolytic condensers (left hand end of chassis when facing rear).

PHILCO RADIO & TELEV. CORP.

MODEL 49
Alignment Data
Parts List

Model 49 is a superheterodyne radio receiver designed for operation on 115 volts direct current (D. C.) only. Model 49 covers two bands of frequencies—from 530 to 1720 KC and from 4.2 to 12.0 megacycles. This gives either standard or short wave reception by turning the wave-band switch on the panel. The intermediate frequency (I. F.) of the set is 260 kilocycles. The power consumption of Model 49 is 50 watts. The receiver uses the following tubes: Type 6A7 detector-oscillator; type 78, R. F.; type 78, I. F.; type 85 2nd detector—1st A. F.; type 76 driver; two (2) type 43 output tubes.

Adjusting Compensating Condensers

For adjusting compensating or padding condensers in Model 49, an accurately calibrated signal generator covering the broadcast range of frequencies is required and also a crystal controlled signal generator for the high frequency adjustments. For the former we suggest the Philco Model 024 Signal Generator and for the latter the Model 091, Crystal Controlled high frequency signal generator. The actual adjusting calls for a special insulated hex wrench and insulated screwdriver. Philco Part No. 3164 Fibre Wrench and No. 27-1159 Screwdriver are recommended. An output meter is also required, for connection to the receiver. Figs. 1 and 2 show the locations of the various compensating condensers.

I. F. ADJUSTMENT—The I. F. (intermediate frequency) of Model 49 is 260 K. C.

Remove the grid clip from the top of the 6A7 tube and connect the shielded antenna lead from the Signal Generator to the cap of this tube. Connect the ground lead of the Signal Generator to the ground post of receiver. Connect the output meter adapter leads to the plates of the output tubes (type 43) in the receiver. Set the wave-band switch at the left position (standard broadcast).

Set the wave switch of the Signal Generator at 260 K. C., and the dial of the receiver at 550. Turn on the set (volume full on), and the Signal Generator. Now adjust the 1st I. F. Primary and Secondary condensers (Nos. 21 and 22 in Fig. 2) and the 2d I. F. primary and secondary condensers (26 and 27) to give maximum reading on the output meter. The I. F. primary condenser is adjusted by turning the screw on top of the I. F. transformer and the secondary is adjusted by turning the nut. The I. F. transformers are in the smaller metal "cans". The screw and nut are reached through the hole in top. If the needle on the output meter goes off the scale, turn down the "attenuator" on the Signal Generator until a lower reading is obtained.

NOW REMOVE Antenna lead of signal generator from grid cap of 6A7 tube and reconnect it to antenna post of receiver. Replace cap on 6A7 tube.

ANTENNA, DETECTOR AND OSCILLATOR H. F. (Broadcast)—These condensers Nos. 3, 23, and 19, are located on top of the tuning condenser gang (See Fig. 2) adjustment made by means of the fibre wrench. Set the signal generator at 1500 K. C., tune in the signal at 1500 on dial and adjust these condensers in the order given, to give maximum output reading. 3 is located on the section nearest the front and 23 on the center section.

OSCILLATOR—LOW FREQUENCY—This is condenser 17 (see Fig. 1) located underneath chassis and accessible from underneath. Use the fibre wrench. Set signal generator switch at 600, tune in the signal at 600 on the dial and adjust condenser to maximum.

ANT. AND OSC. H. F.—SHORTWAVE—The crystal controlled signal generator is used for these adjustments. These are condensers 4 (Ant.) and 15 (Osc. H. F.) located underneath chassis. 4 is adjusted from underneath, and 15 from above, thru hole in sub-base directly behind tuning condenser assembly. The fundamental frequency of the Philco Model 091 crystal controlled signal generator is 3600 K. C. or 3.6 megacycles. The third harmonic of this is 10.8 M. C. Turn the wave-band switch of the set to the right and the dial to just below 11 M. C. The 10.8 harmonic should be picked up here and the two condensers should be adjusted to give maximum reading on the output meter, on this signal.

MODEL 59
Alignment Data
Voltage, Layouts

Model 59

Philco Model 59 is a four-tube superheterodyne receiver operating on alternating current, capable of receiving standard broadcasts, and police calls on the first (lowest) police range. The tubes are as follows: Type 77 detector-oscillator, type 77 second detector, type 42 output and type 80 rectifier. The intermediate frequency is 460 K.C. The power consumption of model 59 is 52 watts.

Tube Socket Data—Line 115 Volts

Power Transformer Data

Terminal	A. C. Volts	Circuit	Color
1- 2	105-125	Primary	White
3- 5	6.3	Filament	Black
6- 7	5.0	Filament of 80	Blue
8-10	580	Plates of 80	Yellow
4	...	Center Tap of 3-5	Black-Yellow Tracer
9	Center Tap of 8-10	Yellow-Green Tracer

*All of the above readings were taken from the underside of the chassis, using test-prods and leads with a suitable A. C. voltmeter for filament voltages and a high resistance multirange D. C. voltmeter for all other readings. Volume control at maximum and station selector turned to low frequency end. Readings taken with a plug-in adapter will NOT be satisfactory. The Philco Model 048 All-Purpose Set Tester is recommended for all tests of Model 59.

Fig. 1—Tube Socket Layout (Viewed from Bottom)

Fig. 2—Top View of Chassis

Adjusting Compensating Condensers

In Model 59 the I. F. primary and secondary condensers and the "regeneration" compensating condenser are located at the rear of chassis and accessible from the rear; the "ANT" and "OSC H. F." are located on the side of the tuning condenser gang.

Referring to Fig. 3, the I. F. primary and secondary condensers ⑧ and ⑨ should be adjusted first. Use an accurate signal generator such as the Philco Model 024. Remove the grid cap clip from the detector-oscillator tube and connect the antenna lead from the signal generator to the cap of this tube. Connect the ground lead from the signal generator to the ground terminal of the set. Connect the primary terminals of the output transformer to an output meter. Set the frequency switch of the signal generator at 460 K.C. (the I. F. of model 59), and turn the switches of the set and signal generator on. Turn volume control full on. Turn the dial pointer on the set to 600, and then adjust the I. F. compensating condensers ⑧ and ⑨ by means of a fibre wrench so that maximum reading is obtained in the output meter. If the needle goes off scale, adjust the attenuator on the signal generator so that a lower reading is obtained.

Next adjust the ANT. and OSC. H. F. (high frequency) con-

densers ④ and ⑤ located on the tuning condenser gang. To adjust these condensers it is necessary to remove the chassis from the cabinet, necessitating removing back plate, base screws, knobs and pointers. Replace the grid clip on the 77 tube and connect the antenna and ground leads of the signal generator direct to the antenna and ground terminals of the set. Set the signal generator switch at 1400, turn the tuning condenser shaft until the rotary plates barely start to mesh with the stationary ones. Tune in the 1400 K.C. signal here and adjust condensers ④ and ⑤ for maximum output meter reading. When replacing the dial pointer, be sure it is mounted exactly as it was removed.

Finally adjust the regeneration condenser ⑩. With the set connected to an antenna, turn the station selector to receive a station at about 130 on the dial. With a screw driver turn the small fibre hex-head screw (which operates the regeneration condenser) located at rear of chassis below antenna and ground terminals, clockwise until the set squeals or oscillates. Then turn the hex-screw 1/4 of a turn back until the squealing stops. Tune in other stations on different points on the scale to make sure that the squealing is eliminated. It will be necessary to readjust this condenser if a different type 77 tube is used for second detector.

MODEL 66
Alignment Data
Voltage
Parts List

Model 66

Model 66 is a five-tube superheterodyne radio receiver, capable of receiving either standard broadcasts (and police calls up to 1720 K.C.), or short-wave stations within a frequency range of 5.5 to 16.0 megacycles. The frequency range on standard broadcast is 540-1720 kilocycles.

The tubes used are: Type 6A7 detector-oscillator, type 78 intermediate frequency, type 75 2d detector, type 42 output and type 80 rectifier. The intermediate frequency of the Model 66 is 460 K.C. and the power consumption is 60 watts.

Adjusting Compensating Condensers

The adjustment of the compensating condensers in Model 66 Receiver requires the use of an accurate signal generator such as Philco Model 024, an efficient output meter (Philco Model 012 or Model 025 are recommended), and a suitable fibre hex wrench. Connect the output meter to the plate and cathode prongs of the 42 output tube.

Adjustments are made in the following order:

(1)—I. F. (Intermediate Frequency)—Remove grid clip from cap on 6A7 tube and connect antenna lead from signal generator to cap of tube. Connect ground lead to ground post on set. Turn on set and signal generator; set wave switch of latter to 460 K. C. (the I. F. of Model 66) and dial of set at 540, wave band switch to left. Adjust each of the four I. F. compensating condensers (17), (19), (22) and (24) in turn so that maximum reading is obtained in the output meter. If the meter reading goes off scale, adjust the attenuator on the signal generator so as to get a lower reading. These I. F. condensers (visible in Fig. 4) are adjusted by inserting the

hex wrench thru the holes in rear of chassis sub-base (except one to extreme left when facing rear of set). Two of the holes are covered by small metal buttons which can be removed temporarily by hand.

(2)—WAVE TRAP—Replace grid clip on cap of 6A7 tube and connect antenna lead from signal generator to antenna post on set. Set signal generator at 460 K. C. and adjust wave trap (1) so as to get MINIMUM reading in output meter.

(3)—ANT. and OSC. H. F.—These adjustments (7) and (11) are located on top of the tuning condenser assembly at right (facing front of set) and adjusted from above. The "ANT" (7) is nearest front of set. Set signal generator at 1700 and dial of set at 1700 and adjust these two condensers to get maximum output meter reading.

(4)—OSC. L. F.—This condenser (13) is located underneath chassis (see Fig. 4) and is reached from underneath. Set dial of set and signal generator switch at 600, and adjust for maximum reading.

PHILCO RADIO & TELEV. CORP.

Model 49

A change in the Shadowmeter Circuit on this model becomes effective with Run No. 4. This is in order to reduce the current thru the shadowmeter.

Referring to Figure 3 of Service Bulletin No. 199, the lead from the primary of Ⓣ (2nd I. F. transformer) is removed from one side of the Shadowmeter Ⓣ and connected to the other side. Resistor Ⓣ, Part No. 5309 is omitted.

In list of tubes for Model 49 (DC), correct to read 2 type 78 instead of 3.

Starting with Run No. 3, Part Ⓣ, 3615AX By-Pass Condenser will be replaced with 3615BB. This change facilitates wiring in the factory.

Model 66

Starting with Run No. 9 the following changes in compensating condensers will be made, which will make padding adjustments less critical.

Replace condenser Ⓣ, 04000M with an 04000J, and condenser Ⓣ 04000M with an 04000A.

Connect a mica condenser, Part No. 30-1029 (.00005 mfd.) across Ⓣ.

Effective July 1st, a new wave trap will be used. Part Ⓣ in diagram will be Part No. 38-5994 instead of 38-5199 previously used. The new wave trap uses an improved construction which facilitates mounting.

Starting July 10th, a 70-ohm wire wound resistor Part No. 33-1129 will be added. Connected in series with condenser Ⓣ on the oscillator coil side. This will prevent oscillation at extreme high frequency end of the short wave band.

The part number of the Tone Control on Model 66 will be 30-4212 instead of 30-4192 previously used. No change in wiring needed. The new Tone Control gives a slight desirable increase in response to high notes.

Effective August 1st, a 50 Mmfd. Mica Condenser, Part No. 30-1029 was added across the secondary of the 2nd I. F. Transformer. This makes adjustment of the 2nd I. F. Padder smoother and easier.

At the same time a 20,000 Ohm Resistor, Part No. 6650 was added, connected between the arm of the wave-band switch and the grounded junction of Ⓣ and Ⓣ. This corrects any tendency toward oscillation on the high end of the short-wave band.

A 70-Ohm flexible wire-wound resistor is also added, Part No. 33-3027, connected in series between condenser Ⓣ and the upper end (on diagram) of the oscillator transformer plate winding.

CURRENT MODELS—IMPROVEMENT IN COMPENSATING CONDENSER

To prevent any tendency to "Frequency Drifting" in current models, a bakelite washer and a metal washer are now being used on top of the Compensating Condenser, in place of the fibre washer previously used.

Part No. of bakelite washer is 27-4109, and of the metal washer (placed on top of bakelite) is W-1331. These two replace the old fibre washer Part No. 3500.

MODEL 118

Layout Change

MODEL 118 (Code 121)

MODEL 118 (Code 123-RX)

Changes

PHILCO RADIO & TELEV. CORP.

Model 118

Incorrect cut was used by printer for Fig. 2 of this Bulletin. Correct cut is reproduced herewith and is same as Fig. 1 of Instruction Book on Model 118.

Correct price of dial scale, Part No. 27-5046 is \$0.25

Effective with Run No. 8 on Code 121 and Run No. 2 on Code 123 (RX), the following parts on Model 118 will be changed. These changes are made to facilitate wiring. Note that resistors are not changed in value, but in current rating only. New resistors are 1/3 watt rating.

No. on Bulletin 194	Old Part No.	New Part No.	No. on Bulletin 194	Old Part No.	New Part No.
9	3615-BK	3615-AU	48	4517	6097

15	5872	33-1025			

In the Model 118A (25 Cycle Model) the part numbers of parts which differ from the 60 Cycle Model are

- ⑦ Power Transformer 32-7112 \$8.00 list price
- ⑦ Condenser 30-4093 (1.0 Mfd.) 0.60 list price

Also add a condenser, .1 Mfd. Tubular, Part No. 30-4122 connected across field coil of Speaker.

Model 118 (Code 123-RX)

Replacement parts on Model 118-RX which differ from other 118 models are as follows:

No. on Bulletin 194	Model 118	118-RX
③ Electrolytic condenser	30-2025	30-2014
④ Tuning condenser	31-1173	31-1242
Dial assembly	31-1205	31-1241
Dial scale	27-5046	27-5058

Model 118-RX uses a type HR-2 speaker, which is equipped with a 25' cable-and-plug assembly, part No. 36-3327.

The A. C. cord on Model 118-RX is a flat cable and contains an extra wire, which is for use as an antenna lead by connecting the antenna to the binding post mounted on the side of the special flat A. C. plug used. However, the antenna *may* be connected to the regular antenna clip terminal on the receiver chassis if desired and more convenient.

The part number of this special cable and plug assembly is 41-3104.

PHILCO RADIO & TELEV. CORP.

Model 118

Philco Model 118 is an eight tube superheterodyne radio receiver operating on alternating current (A. C.) and designed for reception on either the standard broadcast band (including police bands up to 1720 K. C.), or a major section of the short wave band. A two-position switch changes reception from broadcast to short-wave. The frequency ranges are 540 to 1720 K. C. and 4.2 to 12 megacycles.

Model 118 is equipped with shadow-tuning, four point tone control with fixed bass compensation, and automatic volume control. The power consumption is 110 watts and the undistorted output of the Super Class "A" Amplifier is 10 watts. The intermediate frequency (I. F.) is 260 K. C.

Model 118 is equipped with the following tubes:

R. F.....	Type 78
Detector-Oscillator.....	Type 6A7
L. F.....	Type 78
2d Det. Ist A. F.....	Type 75
Driver.....	Type 42

Adjusting Compensating Condensers

For adjusting compensating or padding condensers in Model 118, an accurately calibrated signal generator covering the broadcast range of frequencies is required and also a crystal controlled signal generator for the high frequency adjustments. For the former we suggest the Philco Model 024 Signal Generator and for the latter the Model 091, Crystal Controlled high frequency signal generator. The actual adjusting calls for a special insulated hex wrench and insulated screwdriver. Philco Part No. 3164 Fibre Wrench and No. 27-1159 Screwdriver are recommended. An output meter is also required, for connection to the receiver.

I. F. ADJUSTMENT—The I. F. (intermediate frequency) of Model 118 is 260 K. C.

Remove the grid clip from the top of the 6A7 tube and connect the shielded antenna lead from the Signal Generator to the cap of this tube. Connect the ground lead of the Signal Generator to the ground post of receiver. Connect the output meter to the primary terminals of the output transformer of receiver. Set the waveband switch at the left position (standard broadcast).

Set the wave-switch on the Signal Generator at 260 K. C., and the dial of the receiver at 550. Turn on the set (volume full on), and the Signal Generator. Now adjust the 1st I. F. Primary and Secondary condensers (Nos. ① and ② in Fig. 3) and the 2d I. F. primary and secondary condensers (③ and ④) to give maximum reading on the output meter. The I. F. primary condenser is adjusted by turning the screw on top of the I. F. transformer and the secondary is adjusted by turning the nut. The I. F. transformers are in the smaller metal "cans". The screw and nut are reached through the hole in top. If the needle on the output meter goes off the scale, turn down the "attenuator" on the Signal Generator until a lower reading is obtained.

Note: In early production the 1st I. F. compensating condensers only are adjusted as

described above. Part ⑤ is not used. The 2d I. F. primary ⑥ is an 04000A condenser reached and adjusted through hole in top of chassis near the 42 driver tube.

WAVE TRAP—Remove antenna lead from grid cap of 6A7 tube and attach it to antenna post on set. Replace cap on 6A7 tube. With Signal Generator still operating at 260 K. C., adjust wave-trap condenser (⑦ in Figs. 3 & 4) so as to get MINIMUM reading in output meter. This adjustment is made from underneath the chassis.

ANTENNA, DETECTOR AND OSCILLATOR H. F. (Broadcast)—These condensers Nos. ⑧, ⑨, and ⑩, are located on top of the tuning condenser gang, adjustment made by means of the fibre wrench. Set the signal generator at 1500 K. C., tune in the signal at 1500 on dial and adjust these condensers in the order given, to give maximum output reading. ⑧ is located on the section nearest the front and ⑩ on the center section.

OSCILLATOR—LOW FREQUENCY—This is condenser ⑪ (see Figs. 3 and 4) located underneath chassis and accessible from underneath. Use the fibre wrench. Set signal generator switch at 600, tune in the signal at 600 on the dial and adjust condenser to maximum.

ANT. AND OSC. H. F.—SHORTWAVE—The crystal controlled signal generator is used for these adjustments. These are condensers ⑫ (Ant. H. F.) and ⑬ (Osc. H. F.) located underneath chassis, and adjusted from underneath. The fundamental frequency of the Philco Model 091 crystal controlled signal generator is 3600 K. C. or 3.6 megacycles. The third harmonic of this is 10.8 M. C. Turn the waveband switch of the set to the right and the dial to just below 11 M. C. The 10.8 harmonic should be picked up here and the two condensers should be adjusted to give maximum reading on the output meter, on this signal.

Tube Socket Voltages—Line Voltage 115

1-2	120	Primary	White
3-5	6.3	Filaments	Black
6-7	5.0	Filament of 80	Blue
8-10	760	Plates of 80	Yellow
4	...	Center Tap of 3-5	Black—Yellow Tracer
9	Center Tap of 8-10	Yellow—Green Tracer

The above tests were made with an A. C. voltmeter for filament voltages and a high resistance D. C. voltmeter for all others. Dial at 550 K. C., wave band switch to left, volume control at maximum. Tests made with test prods applied to sockets underneath chassis. Philco Model 048 All-purpose Tester or Model 025 Circuit Tester are recommended for these tests. Use Fig. 1 in making tests given in left hand table above.

(45) BY-PASS CONDENSER CONNECTIONS

IF PEAK 260 KC.

I. F. = 260 K. C. Fig. 1—Schematic Wiring Diagram.

Note: Phonograph motor not shown in diagram. Numbers on this figure from ① to ⑦⑧, inclusive, are the same as in Fig. 3, Service Bulletin No. 194.

The electric motor of Model 507 is of the self-starting, synchronous type, depending on the power line frequency (cycles) for its correct speed. If the motor should develop trouble, do not attempt to repair it. Replace it, and communicate with your Distributor with regard to the faulty one. The motor should be lubricated at least once every six months. To do this, take off the turntable and put a few drops of a good grade of light machine oil in the oil-hole in the motor top-plate.

The pick-up is of the high impedance type. The impedance of the pick-up is approximately 2500 ohms, measured at 1000 cycles. The D. C. resistance is 600 ohms. Adjustment of the pick-up is described in Service Bulletin No. 89, "Adjusting the Electric Pick-up."

The tone arm must be free to rotate upon its axis at all times. Damage to the records will result if it is not.

The speaker unit is Type H-13.

Model 507 uses the same radio chassis as Model 118 Super-heterodyne.

NOTE: Part ⑦⑧ electrolytic condenser is a 80-2014 in Model 507 instead of the 80-2025 used in Model 118.

MODELS 60, 89, 144

Changes

PHILCO RADIO & TELEV. CORP.

Model 60

Effective August 1st, resistors ⑩ and ⑪ in wiring diagram of Model 60, Bulletin No. 164 will be changed from Part No. 4518 ($\frac{1}{2}$ watt) to Part No. 6098 ($\frac{1}{3}$ watt). These changes are made to facilitate wiring in assembly.

Starting with Run No. 7, the following changes will be made. Note that a Wave Trap is added, necessitating several changes; other changes are to improve sensitivity.

Part No. (Fig. 3)	Remove	Add	Location
		38-6078 Wave Trap	In series with antenna post
⑧	4989-Z Condenser	-----	-----
⑨	7217 Resistor	33-3010 (Bias Resistor, 300 Ohms, flex.)	Refer to Schematic Diagram
	-----	33-3016 (Bias Resistor, 400 Ohms)	From 78 Cathode to Ground
	-----	30-4020 (Condenser .05 Mfd. Tubular)	From 78 Cathode to Ground.
⑫	3656 (25,000 Ohms)	33-1027 (39,000 Ohms)	Refer to Schematic Diagram
⑬	4412	-----	-----
⑭	4518 (5,000 Ohms) $\frac{1}{2}$ Watt	6099 (99,000 Ohms) $\frac{1}{3}$ Watt	Refer to Schematic Diagram
⑮	4517	6097	Refer to Schematic Diagram
⑯	04000M	04000J	Refer to Schematic Diagram
⑰	30-4063 (.05-.09-.09-.5-.2) (.2 section not used)	30-4217 (.05-.09-.09-.5)	(Filter block)

Model 89

Effective with Run No. 13 compensating condenser ⑱ on diagram (1st I. F. primary) will be a Part No. 31-6024 instead of 04000M previously used.

The new condenser is of an improved construction which eliminates possibility of "frequency drift" or breakdown.

Starting with Run No. 14, Model 89 will use a type 77 tube as detector-oscillator instead of the type 36 tube previously used. This change results in more stable performance of the oscillator.

In addition to requiring the use of a six-hole socket for the detector oscillator tube instead of the 5-hole previously used, the following changes are required:

Part ⑲, No. 6208 resistor (15,000 ohms) is replaced by No. 33-1114 (8,000 ohms).

Part ⑳, No. 8174-B condenser (.09 and .0007 Mfd.) is replaced by No. 8322-B (.09 and .0014).

Model 144

Effective with Run No. 6, electrolytic condenser ㉑ (see Bulletin No. 193) will be changed from part No. 30-2020 to 30-2026. Same capacity (6 mfd.), higher working voltage.

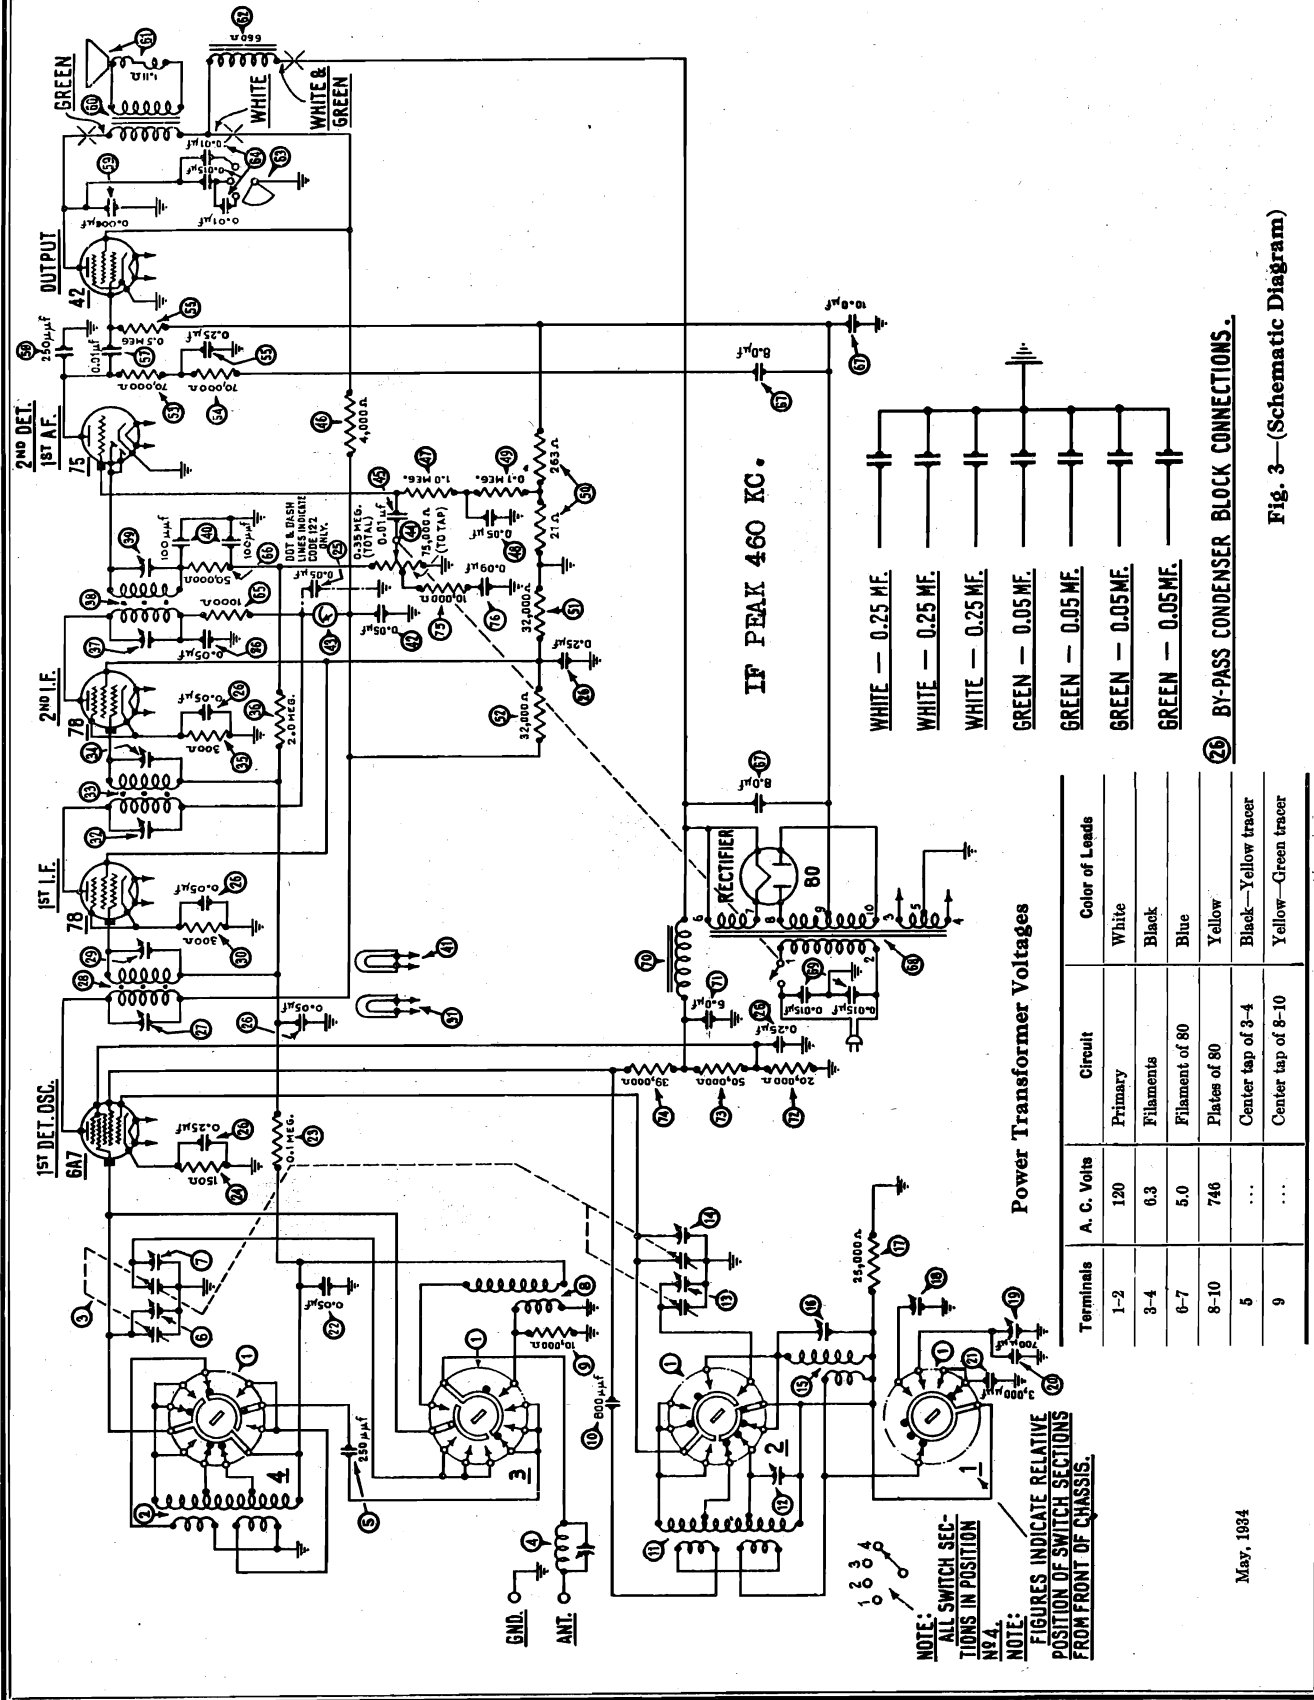

Starting with Run No. 7, Part ㉒ filter choke in Model 144 will be a 32-7018 instead of No. 5930 which has been used. This change is to adjust factory material lists and does not affect value of choke or performance of set.

The part number of the Shadowmeter to be used on the Model 144 will be 45-1106 instead of 6497 as listed on Bulletin 193. Change to identify in production.

On Fig. 3 (Schematic) fixed condenser ㉓ used in the bass compensation circuit, should be marked .02 Mfd. (Part No. 30-4113). The list of parts on Page 3 of Service Bulletin 193 gives this part number and value, which is correct.

MODEL 144

Alignment Data

PHILCO RADIO & TELEV. CORP.

Adjusting Compensating Condensers

The compensating condensers of Model 144 have been adjusted accurately before shipment. If later adjustment is required, in most cases only the intermediate frequency and low frequency compensating condensers should be done. Extreme care must be given the adjustment of the high frequency circuits, and the adjustment should NOT be undertaken unless the receiver is seriously out of alignment.

DO NOT ATTEMPT TO ADJUST the compensating condensers mounted upon sections numbered 3 and 4 of the Tuning Condenser Assembly (Fig. 5). These have been adjusted, and sealed, at the factory.

Philco Model 024, an accurately calibrated signal generator covering broadcast and police band frequencies, is recommended for the adjustment of the intermediate frequency and low frequency compensating condensers.

Philco Model 091 crystal-controlled Signal Generator is recommended for the high frequency adjustments. It gives an accurate and constant 3600 kilocycle (3.6 megacycle) signal, the harmonics of which include the necessary high frequencies for adjusting the compensating condensers in the high frequency circuits.

1—ADJUSTMENT OF THE INTERMEDIATE FREQUENCY—Remove the grid clip from the type 6A7 tube and connect the "ANT" output terminal of the signal generator to the grid cap of the tube. Connect the "GND" terminal of the signal generator to the "GND" terminal of the receiver chassis.

Connect an output meter to the primary terminals of the output transformer. Set the signal generator at 460 K.C. (the intermediate frequency of Model 144) and adjust each of the I. F. compensating condensers in turn, to give maximum response in the output of the receiver. The location of the I. F. compensating condensers is shown in Figure 5. Each of the I. F. transformers has a dual compensating condenser mounted at its top, and accessible thru a hole in the top of the coil shield. In the dual compensators, the Primary circuit is adjusted by turning the screw; the Secondary circuit is adjusted by turning the hex-head nut.

2—ADJUSTMENT OF THE WAVE TRAP—Replace the grid clip upon the Detector-Oscillator tube (Type 6A7). Connect the output leads from the signal generator directly to the antenna and ground terminals of the receiver. Set the Wave-Band Switch of the receiver to the standard broadcast band (extreme left) and the Station Selector at the low frequency (520 K.C.) end. Adjust the Wave Trap (4) condenser to give MINIMUM response to a 460 K.C. signal from the signal generator. The Wave Trap (4) is located at rear and underneath the chassis, and is shown in Figures 4 and 5. It is reached from the rear of the chassis.

3—ADJUSTMENT OF THE DIAL FREQUENCIES—Model 144 has four separate frequency bands or ranges, each obtained by one of the four positions of the wave-band switch. There is a compensating condenser for each range, which must now be adjusted. In the following procedure, the frequency ranges referred to, and obtained by the different positions of the switch are:

- Range 1..... 520 K.C.—1500 K.C.
- Range 2..... 1.5 M.C.—4.0 M.C.
- Range 3..... 4.0 M.C.—11.0 M.C.
- Range 4..... 11.0 M.C.—23.0 M.C.

Connect the output terminals of the Model 091 or equivalent Signal Generator, to the "ANT" and "GND" terminals of the receiver chassis. Connect an output meter to the primary terminals of the Output Transformer of the receiver. Set the

Wave-Band Switch to Range 4, and the Station Selector at 21.6 M.C. The sixth harmonic of the 3.6 M.C. crystal in the Model 091 Signal Generator is picked up at this point. Adjust the compensating condenser (13) on Section 1 of Tuning Condenser for maximum response in the output of the receiver. Turn the Wave-Band Switch to Range 3, and the Station Selector to 10.8 M.C. Here, the third harmonic of the 3.6 M.C. crystal will be heard. Adjust the compensating condenser (14) on Section 2 of Tuning Condenser for maximum response in the output of the receiver.

Turn the Wave-Band Switch to Range 2, and adjust the Station Selector to 3.6 M.C. The "Antenna" connection between the Signal Generator and the receiver chassis must be removed for this adjustment, otherwise the output of the Signal Generator will be too great. Adjust the compensating condenser (12) to give maximum response in the output meter. This compensating condenser is located underneath the chassis and is not accessible from above. See Figure 4.

This concludes adjustments requiring the Model 091 (or equivalent) high frequency signal generator.

The Model 024 or its equivalent is now used again. Turn the Wave-Band Switch of the set to Range 2 and the Station Selector to 1.5 M.C. Set the Signal Generator at 1500 K.C. Make sure the "Antenna" connection between the Signal Generator and the Chassis has been restored. Adjust compensating condenser (10) located underneath the chassis, (Figure 4). Adjustment is made from the underside of the chassis.

Turn the Wave-Band Switch to Range 1 and the Station Selector to 1400 K.C. Set the Signal Generator at 1400 K.C. Adjust compensating condenser (11), which is located underneath the chassis. (See Figure 4). This adjustment is made from the underside of the chassis.

Finally, with Wave-Band Switch at Range 1, and Station Selector at 520 K.C., set the Signal Generator at 520 K.C. and adjust compensating condenser (9) (Figure 4). This compensating condenser is also mounted underneath the chassis, and reached from below.

For proper and accurate adjustment of Model 144, the procedure must be followed exactly in the order given. The adjustment should not be undertaken without proper equipment as mentioned above.

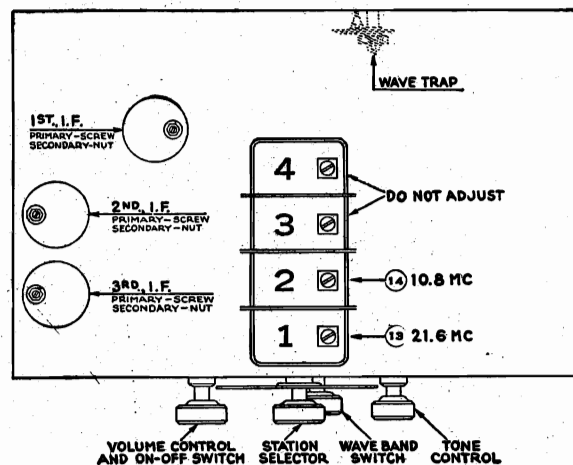

Fig. 5—Position of Compensating Condensers Reached from Above Chassis

PHILCO RADIO & TELEV. CORP.

Model 144

Philco Model 144 is a six-tube superheterodyne receiver operating on alternating current (A. C.) and designed for reception of any frequency from 520 K.C. to 23,000 K.C. (23 megacycles). It is equipped with shadow-tuning, four-point tone-control with fixed bass compensation; Model 144 has 5 watts output. The intermediate frequency (I. F.) is 460 K.C. Tubes used are the following Philco high-efficiency types:—

Detector-Oscillator	Type 6A7
1st I. F.	Type 78
2nd I. F.	Type 78
2nd Detector 1st A. F.	Type 75
Output	Type 42
Rectifier	Type 80

The power consumption of model 144 is 70 watts.

Plate Volts (P-K).....	250	230	230	185	300	350
Screen Grid Volts (SG-K)....	60	75	75	...	310	...
Cathode Volts (K-Gnd).....	1.4	2	2	0	0	...
6A7—G2 to K.....	160
6A7—G1 to K.....	20

Above values were obtained by means of an A. C. voltmeter for filament voltages and a high resistance D. C. voltmeter for all others. All values obtained from underside of chassis with test prods. Positions of controls were: Volume Control—maximum; Wave-Band Switch—extreme left (counter-clockwise); Dial at 520 K.C.

Philco Model 048 All-Purpose Tester is recommended for making the above tests. Use the illustration below (Fig. 1) as a guide to determine the points to be voltage-tested.

PHILCO RADIO & TELEV. CORP.

ADJUSTING COMPENSATING
CONDENSERS IN MODEL 200-X

The quality performance of this receiver depends to a great extent upon providing a wide channel through the R. F. and I. F. stages to permit the passage of a broadcast signal without cutting of the side bands.

In order to produce this wide tuning band, the set must be carefully and accurately adjusted. These adjustments will be more critical than in the conventional radio, and the padding procedure will be considerably more complicated.

In making the adjustments, it is necessary to use an unmodulated signal generator. The PHILCO Model 048 Set Tester or the Model 024 Signal Generator can be readily adapted for this purpose, by the installation of a single-pole double-throw switch, and an additional grid leak resistor, as shown in Figure 9. This switch will adapt the signal generator for either a modulated or an unmodulated signal.

FIGURE 9

With an unmodulated signal, it is not possible to obtain an indication of output by means of the usual form of output meter. An indirect indication can be obtained, however, through the automatic volume control system by connecting a high resistance voltmeter having a scale reading of 0-5 or 0-10 volts across the R. F. cathode resistor, shown in the wiring diagram Fig. 8. This connection can be made conveniently through the use of leads equipped with test clips. With this arrangement, maximum output at the second detector will be indicated by a minimum reading of the meter, and vice versa. In other words, the action will be just the opposite of an output meter used to measure audio frequency voltage at the power output stage. With no signal applied to the receiver, the bias voltage indicated by the voltmeter, will be approximately 8 volts. This voltage will be reduced by the application of a signal to the R. F. or I. F. input circuits.

I. F. ADJUSTMENTS

After preparing the unmodulated signal generator and connecting the voltmeter as directed, proceed as follows:

1. Set the receiver tuning dial at its extreme low frequency position. Remove the grid clip from the cap of the 6A-7 detector oscillator tube, and connect the signal generator antenna lead in its place. Connect the ground lead from the signal generator to the ground terminal of the chassis. Adjust the signal generator frequency to exactly 175 K. C. Turn the fidelity selectivity control of the receiver all the way to the left.
2. Adjust the 6 I. F. padding condensers (⊗, ⊙, ⊙, ⊙, ⊙ and ⊙ (see Fig. 10) in the tops of the 8 I. F. cans, for maximum output (minimum meter reading), starting with the padder at the front of the chassis, and continuing with the adjustments toward the rear of the set. During these adjustments, the output of the signal generator should be regulated to maintain a voltmeter reading of approximately 2 volts.
3. Connect a 250 Mmf. Condenser from the plate of the 2nd I. F. tube to ground. This will increase the voltmeter reading to approximately 2.5 volts.
4. Readjust the 3d I. F. secondary padder ⊙ for maximum output.
5. Readjust the 3d I. F. primary padder ⊙ for maximum output. Do not touch the grid padder ⊙ again.
6. Turn the fidelity selectivity control all the way to the right.
7. Adjust the 1st & 2nd I. F. tertiary padders ⊙ and ⊙ for MINIMUM output (maximum voltmeter reading).
8. Leaving the fidelity selectivity control in the right hand position, it will be found, upon varying the frequency of the signal generator, that two definite dips will appear in the voltmeter reading—one at 167 K. C. and another at 182 K. C. These dips in the voltmeter reading indicate peaks in the tuning curve. The amplitude of these peaks should be equal; that is, the same voltmeter reading should be obtained at both 167 K. C. and 182 K. C. Any variations in these two readings can be corrected by a slight readjustment of the 3rd I. F. primary padder ⊙. If the peak at 167 K. C. is higher than the one at 182 K. C., the primary padder will have to be turned out. If the reverse is true, the capacity of this padder must be increased. In any case, the voltmeter readings must be made equal by dividing the differences through readjustment.

R. F. ADJUSTMENTS.

The R. F. portion of the receiver is adjusted as follows:

9. Replace the grid clip on the detector-oscillator tube and connect the antenna terminal of the signal generator to the antenna terminal of the chassis. Turn the fidelity selectivity control all the way to the left and set the receiver dial at 1,500 K. C. The same type of output indication is employed as in the I. F. adjustments.
10. Adjust the signal generator for a frequency of 1,500 K. C. Adjust the "oscillator" padding condenser ⊙ and the "detector" padding condenser ⊙ for maximum output and in the order mentioned. Regulate the signal generator output control to maintain a voltmeter reading of 2 volts as before.
11. Turn in padder ⊙ (R. F.) until the voltmeter reads 2.5 volts and then adjust padder ⊙ (ANT.) for maximum output.
12. Readjust padder ⊙ for maximum output. Do not touch padder ⊙ again.
13. Set the receiver dial and the signal generator at 600 K. C. Adjust the "oscillator low frequency" padder ⊙ for maximum output. As the R. F. tuning is rather broad, there will be a considerable range on the dial that will give about the same output when the oscillator L. F. padder is adjusted for maximum. The padder must be adjusted at the middle of this range. This point may be determined with accuracy in the following manner: Starting with the usual voltmeter reading of 2 volts, slowly turn the receiver dial toward the low frequency end and, at the same time, readjust the padder ⊙ for maximum output until a point is reached where the maximum output is indicated by a voltmeter reading of 2.5 volts. Note carefully the exact dial reading at this point. Follow the same procedure while turning the dial in the opposite direction until the output reading decreases to the same value. Set the dial at the exact center of these two points and readjust padder ⊙, for maximum output.
14. Adjust the 3d I. F. tertiary padder ⊙ to give minimum width in the shadow tuning meter in the receiver. This padder is reached from rear of chassis.

ADJUSTMENT OF 10 K. C. FILTER

The 10 K. C. filter in the audio circuit will rarely require readjustment. As the proper adjustment of this padder (⊙ on diagram) requires an accurately calibrated audio oscillator, it should be reset only in the event that it has been tampered with or in cases where it has become necessary to replace one of the elements of this filter. An emergency adjustment of this filter can be made in the following manner:

15. Connect the signal generator to the control grid of the type 6A-7 tube, leaving the grid clip in place.
16. Disconnect the voltmeter from resistor ⊙ and connect an output meter to the plates of the power output tubes in the usual way.
17. Set the receiver dial at 550 K. C. At this point, the oscillator in the receiver will be tuned to 725 K. C. The adjustment of the signal generator (switch in unmodulated position) to approximately this same frequency will cause an audible beat note to be heard in the speaker. By means of the signal generator tuning control, reduce the frequency of this beat note until zero beat is reached, at which point the output meter reading will decrease to 0. Turning the receiver dial in either direction will gradually increase the frequency of the audible note so that at 540 or 560 K. C. a 10,000 K. C. note will be heard. At either of these points, the padder ⊙ should be adjusted for minimum reading of the output meter.

Socket Layout

MODEL 700 RECEIVER

THE latest Philco development in single-unit automobile radio is the new Model 700. This Receiver is compact, easier to install than ever before and will give exceptional performance.

It is a six-tube super-heterodyne with a genuine full-size Philco electro-dynamic speaker—the same type that is used in many of the larger home radio Receivers. It has remarkable sensitivity, a three-section tuning condenser, giving improved selectivity—wonderful tone, with a three-point tone control, and inherently quiet circuits. Interference filters in the “A” lead and in the pilot light lead greatly simplify motor interference suppression. In most installations standard suppression is sufficient.

Added to this, the ease of installation characteristic of this model (only one unit to install—one lead to the antenna, one lead to the ammeter) and the convenient, attractive airplane type steering column control, which makes this model universal in its application, are additional features of the Model 700 which appeal to both the dealer and the public.

I. F. TRANSFORMER AND PADDERS

The new style I. F. transformer complete with padders is used in the Model 700.

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1329 for the first I. F. stage and 32-1237 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

FIG. 1

MODEL 700 ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The Philco Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and turned on for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the speaker lid from the Receiver. Remove the grid cap terminal from the 77 tube (for location see Fig. 2).

Set up the signal generator and adjust it to exactly 260 K. C. Connect the generator lead to the grid cap of

the 77 tube. (See Fig. 2.) The output meter must be connected.

The Receiver volume control must be turned on to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The padders ② and ④ are adjusted first (Figs. 2 and 3). Turn the adjusting screw ② all the way in. A metal screwdriver can be used for this. Then, with generator attenuator set so there is approximately half-scale reading, adjust the nut ④ with a fibre wrench for the maximum reading on the output meter.

Then adjust the screw ④ for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

FIG. 2

Repeat the above procedure with the condensers ⑫ and ⑰.

After padding the first I. F. stage, remove the generator lead from the 77 tube and reconnect the grid lead to the 77 tube. Set the generator to 1600 K. C. and then connect the generator lead to the antenna lead.

There are four holes in line, one in each of the sections

of the tuning condenser housing. (See Fig. 2.) Place a nail of the size that fits snugly through the holes and then turn the condenser plates out of mesh until they strike against the nail.

With the tuning condenser in this position adjust the high-frequency padder 14 until the maximum reading is obtained in the output meter. This is the true setting for 1600 K. C., 160 on the dial scale.

Next turn the condenser plates in mesh to 140 on the scale, 1400 K. C., and set the signal generator for 1400 K. C. The R. F. padder 9 and the antenna padder 3 are next adjusted for the maximum reading on the output meter.

Recheck the adjustments and then remove all test leads. If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the Receiver is adjusted properly.

MODEL 800 (Code 122)

Alignment Data
Socket Layout

PHILCO RADIO & TELEV. CORP.

I. F. TRANSFORMER AND PADDERS

The new style I. F. transformer complete with padders is used in the Model 800 (Code 122).

The padders are placed in the top of the shield can one above the other.

The primary padder is adjusted by means of the screw slot, accessible through the hole in the top of the shield can. The secondary padder is adjusted by means of the small hex nut, also accessible through the hole in the top of the shield. (See Figs. 1 and 2.)

The coil windings terminate in leads instead of terminals or lugs. The color scheme of the leads is given in Fig. 1.

If replacements are ever necessary, replace the entire coil assembly 32-1471 for the first I. F. stage and 32-1449 for the second I. F. stage. Neither the coil nor the padders will be furnished separately. Order only by the above numbers.

FIG. 1

MODEL 800 ADJUSTMENTS

All adjustments have been carefully checked at the factory. If, however, it is found necessary to readjust the padding condensers, this procedure must be followed carefully. Do not attempt to make any adjustments until the procedure is clearly understood or without the use of a good oscillator or signal generator and output meter. The Philco Set Tester 048 is highly recommended for this procedure and for all service work.

The Receiver must be connected to a six-volt storage battery and turned on for operation. It is assumed that tubes have been checked and that the Receiver is in good condition except for the padding adjustments.

Remove the speaker lid from the Receiver and disconnect the antenna lead from the Receiver. Remove the grid cap from the 6A7 tube (for location see Fig. 2).

Set up the signal generator and adjust it to exactly 260 K. C. Connect the generator lead to the grid cap of the 6A7 tube, grounding the shield. (See Fig. 2.) The output meter must be connected by means of an adapter to the small prong of the speaker plug and to the chassis.

The Receiver volume control must be turned on to approximately full volume and the attenuator in the generator set for a half-scale reading of the output meter.

The padders ② and ③ are adjusted first (Figs. 2 and 3). Turn the adjusting screw ② all the way in. A metal screw driver can be used for this. Then, with generator attenuator set so there is approximately half-scale reading, adjust the nut ③ with a fibre wrench for the maximum reading on the output meter.

Then adjust the screw ④ for maximum reading on the meter. This adjustment is critical. Note the maximum reading obtainable and then turn the screw in again and readjust, just bringing the adjustment up to the maximum reading. Do not pass it and then back off.

FIG. 2

Repeat the above procedure with the first I. F. condensers, ① and ⑩.

After padding the first I. F. stage, remove the generator lead from the 6A7 tube and reconnect the grid lead to the 6A7 tube. Connect the antenna lead to the Receiver. Set the generator to 1500 K. C. and then connect the generator lead to the antenna lead.

There are four holes in line, one in each of the sections of the tuning condenser housing. (See Fig. 2.) Place a nail of the size that fits snugly through the holes and then turn the condenser plates out of mesh until they strike against the nail.

With the tuning condenser in this position adjust the high-frequency padder ⑩ until the maximum reading is obtained in the output meter. This is the true setting for 1500 K. C., 150 on the dial scale.

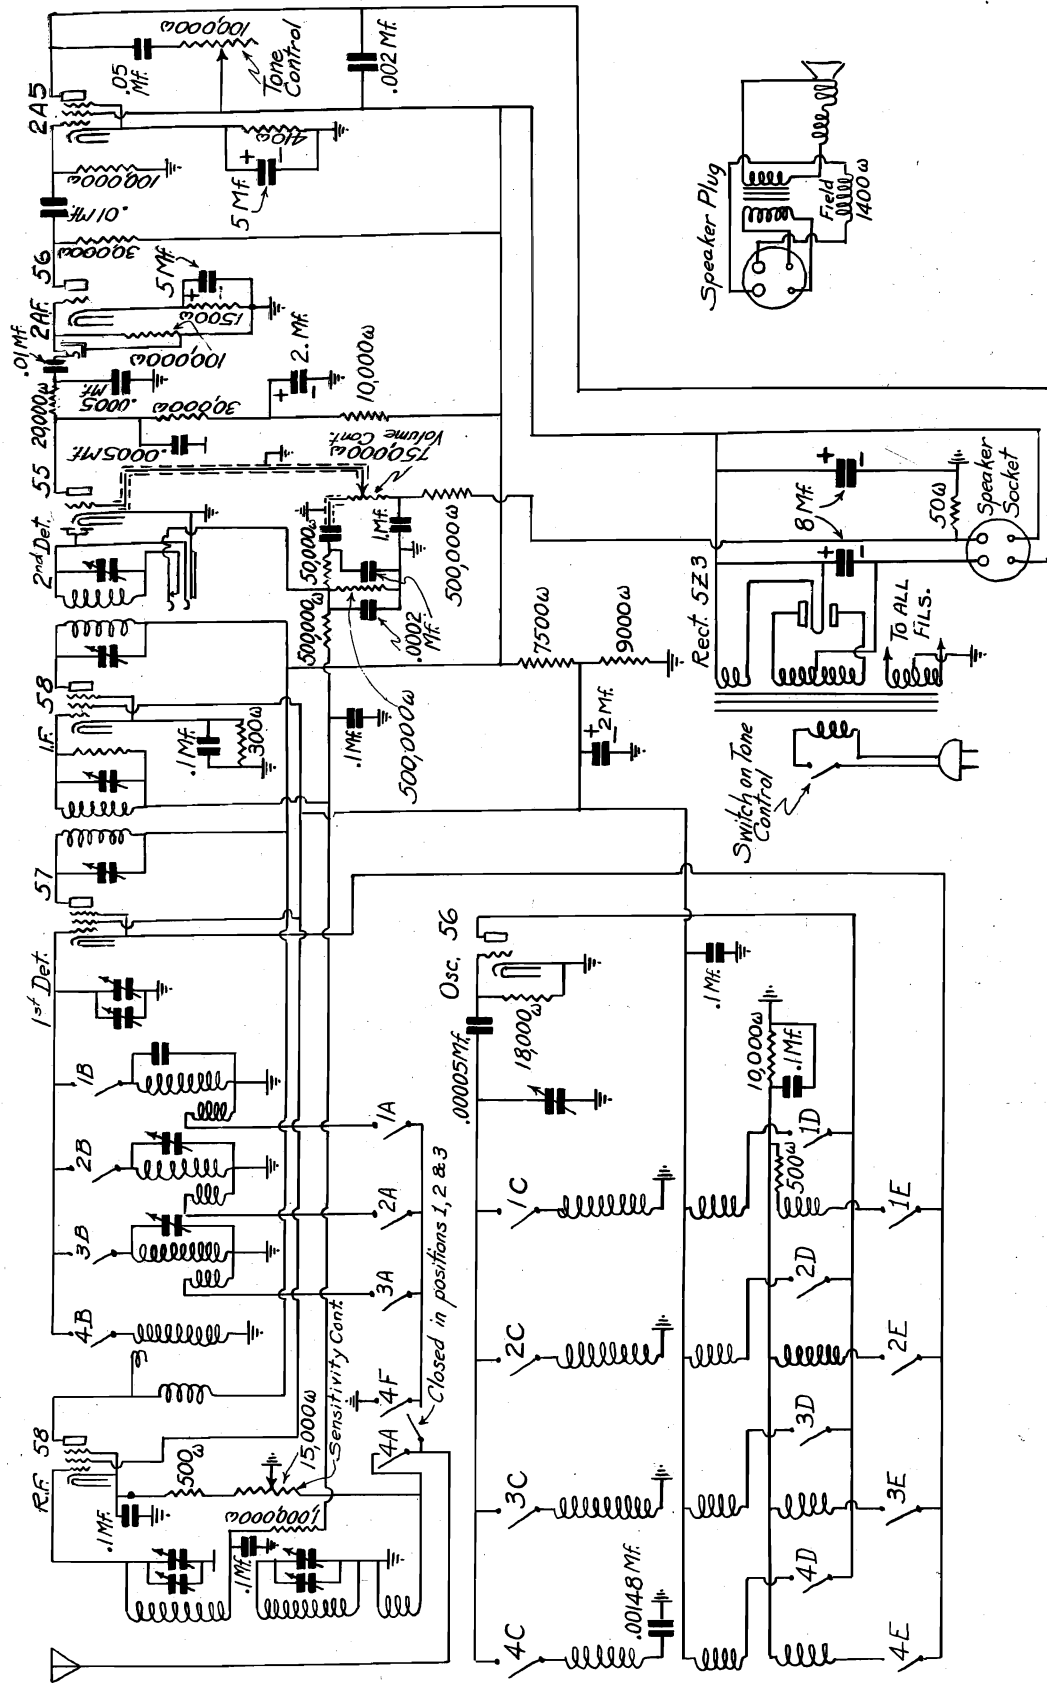

Next turn the condenser plates in mesh to 140 on the scale, 1400 K. C., and set the signal generator for 1400 K. C. The R. F. padder ⑨ and the antenna padder ③ are next adjusted for the maximum reading on the output meter.

Turn the condenser plates in mesh to 60 on the scale, 600 K. C., and readjust the signal generator to this frequency. Adjust the low-frequency padder ④ for the maximum meter reading.

Recheck the adjustments and then remove all test leads. If this procedure has been carefully followed and an accurately calibrated oscillator or signal generator used, the Receiver is adjusted properly.

 Power consumption75 watts.

Pilot "Dragon" All-Wave Superheterodyne
Models No. 8 and 84

NOTE: In Models No. 7 and No. 81 the schematic diagram is identical except for the short-wave coil circuit.

PILOT RADIO CO. (New Co.)

MODEL 8,84,7,81
(Dragon A-W. Super)
Alignment Data

REMOVAL OF CHASSIS FROM CABINET

To remove the chassis from the cabinet proceed as follows: Be certain that the line cord is not plugged in the power outlet socket. Dismount the Noise Suppression Control from the side of the cabinet. Remove the "slip-on" knobs and felt washers from the controls located at the front of the receiver.

Unfasten the four 10/32 mounting screws which support the chassis in the cabinet. They are located underneath the cabinet, one at each corner.

Remove the speaker plug from its socket at the rear of the chassis.

ADJUSTMENT OF ALIGNMENT CAPACITORS

At the factory the receiver is carefully adjusted and aligned, and precautions are taken to maintain the accuracy of the adjustment. However, should the receiver ever require realignment the following procedure should be observed. In Fig. 2 the location and description of the various alignment capacitors are clearly illustrated. An External modulated oscillator with a frequency range sufficient to cover the requirements of the receiver should be used for obtaining best results.

Before connecting the chassis to the power line, reconnect the loudspeaker cable in its socket at the rear of the chassis. When aligning the Intermediate Amplifier the external oscillator must be set at 115 kilocycles which is the I.F. frequency of the receiver. The Frequency Range Selector Switch should be in the position marked B.C. when aligning the I.F. amplifier and the Broadcast range. For the various short wave ranges its position should correspond with aligning frequency selected from the external oscillator. Connect the antenna lead from the external oscillator to the control grid of the No. 58 tube in the I.F. amplifier stage. The alignment capacitors for the I.F. are located at top of the shielded I.F. transformers. When adjusting these units it is advisable to insulate the metal blade of the screwdriver so that short circuiting the B plus to the chassis will be avoided. Slowly rotate the adjusting screws of each of the capacitors until maximum output is noted in the loudspeaker output circuit. Use an output meter if one is available as a visual indication is likely to be more accurate than the audible method. With the completion of this operation, remove the external oscillator leads from the No. 58 I.F. amplifier tube and connect them in the same manner to the control grid of the No. 57 1st Detector tube. In a similar manner rotate each adjuster screw for maximum audio response in the speaker circuit.

CAUTION: Do not readjust the I.F. stage employing the No. 58 tube, when the external oscillator leads are connected to the No. 57 1st Detector control grid.

After the I.F. Amplifier has been completely realigned remove the external oscillator leads from control grid of the No. 57 tube and connect them to the Antenna and the Ground leads of the receiver. The BLACK wire at the rear of the chassis is the antenna connection; the YELLOW lead is for the ground. Set the frequency of the external oscillator at 1400 kilocycles.

Rotate the "FREQUENCY SELECTOR DIAL" to a position where the "shadow line indicator" of the dial light is in a position coincident with the 1400 kilocycle calibration of the dial scale. Adjust the oscillator trimmer of the broadcast range (See Fig. 2) until resonance is indicated by maximum audio response in the speaker output circuit. Proceed next to the 1st Detector alignment capacitor which is located on the top of the gang condenser section of that circuit. The same procedure is followed in aligning the R.F. amplifier and the Pre-selector stages, the alignment capacitors of which are located also on top of their respective sections of the gang condenser. The correct positions are clearly illustrated in Fig. 2.

ALIGNMENT OF THE SHORT WAVE RANGES

Each of the Short Wave ranges has a separate aligning capacitor in its heterodyne circuit. The alignment frequencies for the various short wave ranges are:

Range No. 3..... 3700 kilocycles
Range No. 2..... 8600 kilocycles
Range No. 1.....15,000 kilocycles

The antenna and ground leads of the external oscillator should be connected to the black and yellow wires respectively of the receiver. Adjust the external oscillator to the required frequency for the short wave range being aligned. Rotate the "frequency selector dial" until the signal is noted in the audio output. Turn the tuning condenser slowly from the left to right in the vicinity of the signal, at the same time adjusting the alignment capacitor until the maximum signal response is noted in the loudspeaker output circuit. The signal voltage of the external oscillator should always be held constant while making alignment adjustments. The same alignment procedure should be followed on all of the short wave ranges.

REMOVAL OF FREQUENCY RANGE SELECTOR SWITCH ASSEMBLY

When removing this assembly great care must be exercised by the operator to avoid scratching or marking the coils. Remove the bottom plate and the side plate from the chassis. It is advisable to first unsolder the leads connecting the assembly to the main chassis. Remove the four 8/32 nuts which support the assembly in the chassis. The switch assembly is then ready for removal.

In replacing the switch assembly the same precautions must be observed to avoid damage to the coils. Refasten the assembly firmly in the mounting provided for it. Resolder all connections well. Use only ROSIN CORE SOLDER. DO NOT USE SOLDERING PASTE OR ACID FLUXES OF ANY TYPE. Replace the bottom plate and the side plate. It is advisable to realign the receiver after the replacement of the assembly is completed.

Voltage, Trimmers

POWER SUPPLY

The operating voltage of the receiver is indicated on the label at the rear of the chassis. In the PILOT "DRAGON" receiver a special type of "universal" power transformer is used. Its design permits the receiver to be used on line voltages of 115, 125, 150, 220, or 240 volts ALTERNATING CURRENT from forty-five to sixty cycles. At the factory the transformer is connected for operation on voltages existing in the location where the receiver is to be used. If doubt exists regarding the voltage of the electric power in your locality consult the power company for advice. When certain that the receiver is connected for the proper operating voltage then plug in the line cord to the nearest outlet.

Frequency coverage of Range Selector Switch positions.

Position	BC	540—1500 kilocycles	555—200 metres
3	1500—3900 kilocycles	200—77. metres	
2	3900—9000 kilocycles	77.—33.4 metres	
1	9000—21,400 kilocycles	33.4—14. metres	

Intermediate Frequency 115 kc. The use of this frequency provides a very favorable degree of sensitivity and selectivity.

Voltages measured at the tube socket

	R.F.	Osc.	Det.	Int. Amp.	Det.	Pwr Pentode	Rectifier	N.S.C.
Plate	235	85	230	230	*88	205	335	235

 (Broadcast - S.W. Foreign)

PILOT RADIO & TUBE CORP.

ALIGNMENT OF INTERMEDIATE-FREQUENCY AMPLIFIER:

The I-F. peak frequency is 115 kc. Remove the chassis from the cabinet. To do this remove the slip-on knobs from the controls at the front of the receiver. Next remove the four screws which hold the chassis to the base of the cabinet. Set the signal generator at 115 kc. Connect the ground lead of the signal generator to the chassis of the receiver. Place the fixed condenser in series with the antenna lead from the signal generator (approximately .002 mf.) and connect the antenna lead to the control grid of the 6A7 tube. Adjust the intermediate-frequency capacitors of the I-F. unit No.1 and No.2 for maximum sensitivity. It is advisable to make these adjustments at least twice. Use a low input from the signal generator when aligning the receiver in order that greater accuracy may be obtained.

BROADCAST BAND ALIGNMENT:

Connect the antenna and ground leads of the signal generator to the antenna and ground leads of the chassis. Use a dummy antenna in place of the .002 mf. condenser, if one be available. Set the frequency range switch of the receiver in the broadcast position. Set the signal generator at 1400 kc. Rotate the tuning condenser of the receiver until the compass dial pointer coincides with the 1400 kc. calibration mark on the dial scale. Adjust the oscillator trimmer on the gang condenser until resonance is indicated in the loudspeaker circuit. Next adjust the heterodyne stage and preselector stage for maximum sensitivity. Next set the signal generator at a frequency of 1630 kc. Adjust the image suppression circuit condenser for minimum signal response, as noted in the loudspeaker circuit. When adjusting the image suppression condenser, a strong R-F. signal should be applied to the receiver. Again set the signal generator to 1400 kc. and adjust the oscillator, heterodyne stage and preselector trimmer condensers for maximum sensitivity. Next, set the signal generator at 600 kc. and rotate the tuning condenser on the chassis until resonance is noted in the loudspeaker output circuit. Adjust the 600 kc. alignment capacitor (padder) at the same time, slowly rocking the gang condenser to the right or left for maximum sensitivity. Again, set the signal generator at 1400 kc. Rotate the tuning condenser on the chassis until the compass dial pointer coincides with the 1400 kc. calibration mark on the dial scale. Readjust the oscillator, the heterodyne stage and the preselector circuit trimmer on the gang condenser for maximum sensitivity. Check the sensitivity of the receiver at 1000 kc. and 600 kc.

SHORT-WAVE BAND No.2 ALIGNMENT:

Set the frequency range switch of the receiver on position Band No.2. Set the signal generator at 6100 kc. (49 meters.) Adjust the Band No.2 alignment capacitor for maximum sensitivity. Set the signal generator at 2400 kc. Check the sensitivity of the receiver at this point also.

SHORT-WAVE BAND No.1 ALIGNMENT:

Set the signal generator at 17,800 kc. (16.85 meters). Rotate the tuning condenser until the signal is noted in the loudspeaker circuit. The compass dial pointer should then be approximately on the 17.8 megacycle mark on the dial scale. Adjust the Band No.1 trimmer for maximum sensitivity. Set the signal generator at 7500 kc. and check the sensitivity of the set at this point.

When making all adjustments, it is advisable to have the volume control and tone control turned on full in a clockwise direction.

HIGH BAND SECTION ALIGNMENT:

Rotate the frequency range switch to the position marked "High Band". Set the signal generator at 300 kc. Rotate the tuning condenser until the 300 kc. signal is noted in the loudspeaker circuit. The signal should be observed when the dial pointer is on the 1000 meter calibration. Adjust the First Detector and the Preselector circuit alignment capacitors for maximum sensitivity. There is no oscillator capacitor adjustment at 1000 meters.

Set the signal generator at 155 kc. Rotate the tuning condenser until the signal is noted in the loudspeaker circuit at 1930 meters on the dial. Adjust the "High Band" padder condenser for maximum sensitivity. Realign the set at 1000 meters and check the sensitivity at 1500 meters (200 kc.).

This receiver is a five-tube Super-Heterodyne incorporating a Dynamic Loudspeaker as a part of the chassis; two-point tone control; single heater type Pentode Output and the inherent sensitivity, selectivity and tone quality of the Super-Heterodyne.

The circuit consists of an R. F. stage, a combined oscillator and first detector in the RCA-2A7 tube, an intermediate stage consisting of a transformer only using two tuned circuits, a second detector, an output tube and a rectifier.

Service work in conjunction with this receiver will be similar to that of other Super-Heterodyne receivers of the small compact type construction. The line-up adjustments are made in conjunction with an external oscillator and an output meter. The line-up capacitors on the gang capacitor are adjusted for maximum output when the oscillator is coupled to the antenna and the set and oscillator are both set at 1400 K. C. The I. F. frequency is 175 K. C. and the two circuits that comprise it are adjusted for maximum output at 175 K. C.

MODEL R-73
Alignment Data
Voltage

RCA-VICTOR CO., INC.

SERVICE DATA

Electrical Specifications

Voltage Rating 105-125 Volts
 Power Consumption 100 Watts
 Type and Number of Radiotrons 3 RCA-58, 1 RCA-56,
 1 RCA-55, 2 RCA-247, 1 UX-280—Total, 8
 Type of Circuit Super-Heterodyne
 with A. V. C., tone control and push-pull Pentode Output
 Undistorted Output 3 Watts
 R. F. and Oscillator Alignment Frequency
 600 K. C. and 1400 K. C.
 Intermediate Frequency 175 K. C.

This receiver is an eight tube Super-Heterodyne incorporating Automatic volume control, tone control and Push-Pull Pentode Output. Service Data will be found to be similar to that of other Super-Heterodyne receivers incorporating similar features.

Figure 5—I. F. Alignment Location

Line-up Adjustments

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 175 K. C. and the adjustment screws are accessible from the rear of the chassis. See Figure 5 for location of the adjustment screws and proceed as follows:

- Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.
- Remove the oscillator tube and connect a ground to the chassis.
- Connect the oscillator output between the 1st detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- Adjust the secondary and then the primary of the second and then the first I. F. transformers until a

maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time as there is a slight interlocking of adjustments. This completes the I. F. Adjustments.

R. F. and Oscillator Adjustments—The three gang capacitor screws are accessible through the bottom cover and the 600 K. C. oscillator trimmer through the top of the chassis adjacent to the R. F. coil. Proceed as follows:

- Procure a modulated oscillator giving a signal at 1400 K. C. and 600 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.

Figure 6—Loudspeaker Wiring

- Connect the output of the oscillator to the antenna and ground lead of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be at the short line on the dial. Then set the dial at 1400 K. C., the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.
- Adjust the three line-up capacitors accessible at the bottom of the receiver until maximum deflection is obtained in the output meter.
- Shift the oscillator frequency to 600 K. C. and tune the signal. Then adjust the 600 K. C. capacitor, accessible through the top, until maximum deflection is obtained. The main tuning capacitor must be rocked back and forth while making this adjustment.
- Then realign at 1400 K. C. This completes the adjustments.

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position and the minimum input signal necessary from the oscillator must be used.

SERVICE DATA

Electrical Specifications

Voltage Rating 105-125 Volts
Power Consumption 100 Watts
Type and Number of Radiotrons 3 RCA-58, 1 RCA-56,
1 RCA-55, 2 RCA-247, 1 UX-280—Total, 8
Type of Circuit Super-Heterodyne
with A. V. C., tone control and push-pull Pentode Output
Undistorted Output 3 Watts
R. F. and Oscillator Alignment Frequency
600 K. C. and 1400 K. C.
Intermediate Frequency 175 K. C.

This receiver is an eight tube Super-Heterodyne incorporating Automatic volume control, tone control and Push-Pull Pentode Output. Service Data will be found to be similar to that of other Super-Heterodyne receivers incorporating similar features.

Figure 5—I. F. Alignment Location

Line-up Adjustments

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 175 K. C. and the adjustment screws are accessible from the rear of the chassis. See Figure 5 for location of the adjustment screws and proceed as follows:

- Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.
- Remove the oscillator tube and connect a ground to the chassis.
- Connect the oscillator output between the 1st detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- Adjust the secondary and then the primary of the second and then the first I. F. transformers until a

maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time as there is a slight interlocking of adjustments. This completes the I. F. Adjustments.

R. F. and Oscillator Adjustments—The three gang capacitor screws are accessible through the bottom cover and the 600 K. C. oscillator trimmer through the top of the chassis adjacent to the R. F. coil. Proceed as follows:

- Procure a modulated oscillator giving a signal at 1400 K. C. and 600 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.

Figure 6—Loudspeaker Wiring

- Connect the output of the oscillator to the antenna and ground lead of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be at the short line on the dial. Then set the dial at 1400 K. C., the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.
- Adjust the three line-up capacitors accessible at the bottom of the receiver until maximum deflection is obtained in the output meter.
- Shift the oscillator frequency to 600 K. C. and tune the signal. Then adjust the 600 K. C. capacitor, accessible through the top, until maximum deflection is obtained. The main tuning capacitor must be rocked back and forth while making this adjustment.
- Then realign at 1400 K. C. This completes the adjustments.

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position and the minimum input signal necessary from the oscillator must be used.

This battery type tuned R. F. receiver incorporates excellent performance in conjunction with minimum cost and up-keep requirements. Service work consists principally of replacements and line-up adjustments. The proper method of aligning the receiver follows.

R. F. Line-up Capacitor Adjustments

Two adjustable capacitors are provided for adjusting the R. F. circuits to maximum electrical alignment. In order

to properly adjust the capacitors, a Stock No. 9050 Test Oscillator and 7065 adjustment screwdriver are required. Also an output meter should be connected across or in place of the loudspeaker winding. Proceed as follows:

- (A) Place the oscillator in operation at 1400 K. C. and connect its output to the antenna and ground of the receiver. Connect the output meter and place the receiver in operation.
- (B) Tune in the signal from the oscillator and adjust the volume control and oscillator output until a deflection is obtained in the output meter. Adjust each trimmer until maximum output is obtained. The proper adjustment is when a minimum value of trimmer capacity is used. Readjusting the dial may be necessary to arrive at such a condition. Then slightly reduce the setting of the detector trimmer by turning it clockwise. This compensates for a slight increase in the capacity of this circuit that occurs when the chassis is returned to its case. A little experimenting will disclose the proper amount of this reduction.

SERVICE DATA

Except for the replacement of defective Radiotrons, very little service work will be required in conjunction with this instrument. Figure 1 shows the schematic circuit diagram, Figure 2 the wiring diagram, and Figure 3 the various socket voltages. Figure 4 shows the assembly wiring diagram.

Service Data on Magnetic Pickup

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure 6), it is necessary to proceed as follows:

- Remove the pickup cover by removing the center holding screw and needle screw.
- Remove the pickup magnet and the magnet clamp by pulling them forward.
- Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

MODEL R-93 Phonograph Service Notes

RCA VICTOR DUO JUNIOR MODEL R-93 SERVICE NOTES

PHONOGRAPH MOTOR SERVICE DATA

The synchronous motor used in this instrument is of simple design and fool-proof construction. Among its many features are low power consumption, single moving part, ease of starting, oilless main bearing, resilient bumper, and long life with freedom from service repairs.

Figure 6 shows the main parts of the motor and the points that may require attention.

Operation:

The two stator coils are connected as shown in Figure 2 and the motor is started by giving it a clockwise spin with the hand. If it is found to be difficult of starting, or if it runs at a sub-synchronous speed such as at 70 R.P.M., such action may result from one of the following causes:

Difficult to Start—This may be due to the stator falling to rotate on the outer bearing. This can be caused by the lug being bent and rubbing in the slot, or sticking to the resilient bumper. The outer bearing not being properly lubricated may also cause this condition. It is important that the ball bearing be at the bottom of the main bearing assembly.

Slow Speed—If the turntable is jarred or slowed down, the motor may run at a sub-synchronous speed, such as 70 R.P.M. This is remedied by merely lifting the tone arm from the turntable, thereby removing the load. The turntable speed will then immediately increase to normal.

Excessive Vibration and Hum:

A small amount of hum when starting, decreasing to a negligible amount while running, is normal. If excessive vibration occurs either at starting or running, it may be due to one of the following:

- (1) Insufficient lubricant in outer bearing or any other failure that will cause the stator to bind.
- (2) Metal washer not above the leather washer at the bottom of the main bearing.
- (3) Motor not properly supported from motor board. Unless the motor is properly supported from the motor board, normal vibration will be excessive.

Removing Rotor from Stator:

The rotor which includes the turntable may be removed by loosening the screw shown in Figure 7 until it clears the rotor and then lifting the turntable. Be careful not to lose the ball end-bearing when this is removed. After replacing the rotor, tighten the retaining screw securely to eliminate the possibility of rattle in operation.

Power Consumption:

The motor consumes 4 watts. It should never be turned on when the rotor is removed, as in this condition excessive current will be drawn with consequent increase in temperature.

Note—The above values of power consumption are average for a 60-cycle motor at 125 volts. At lower voltages the power consumption will be less.

Figure 7—Details of Motor

Turntable Speed.....	78 R.P.M.
Pickup Impedance at 1000 Cycles.....	2450 Ohms
Pickup Output Voltage.....	0.4 Volt at 400 Cycles
Volume Control Resistance.....	20,000 Ohms

Physical Specifications

Turntable Diameter.....	7 Inches
Height.....	5 Inches

This phonograph turntable and pickup assembly is designed to provide record reproduction to the owner of a modern radio receiver. Use of the audio amplifying system and loudspeaker of the radio receiver provides a quality of reproduction equal to or better than that obtained from radio stations. A switch is provided for changing from radio to record reproduction, or vice-versa. Simplicity, compact size and ease of connections are outstanding features of this instrument.

Electrically, the instrument consists of a magnetic pickup—for transforming the mechanical variations

Connecting Phonograph to the Radio Receiver

When connecting a phonograph unit to a radio receiver, there are a few fundamental facts to be considered. First, the output of the pickup must be connected to the receiver at a point where sufficient audio gain between it and the speaker is available to give normal sound output. Second, when doing this some attention should be given to the possibilities of introducing hum and other undesired noise, both in the audio and in the radio circuits.

In general, it will be found that the grid or cathode circuits of the second detector of a super-heterodyne circuit are suitable for phonograph input. On used R. F. receivers, either the detector cathode or the first audio transformer primary circuit may be employed, depending upon the amount of audio gain and the type of detector used.

It is fairly common to find radio receivers employing a volume control located in the audio circuit. In these cases, it is advisable to run the phonograph volume control at maximum and use the radio receiver volume control for adjusting the phonograph output. In circuits using aurally compensated volume controls, advantage of this feature is not taken unless the radio receiver volume control is used.

Investigation of a large number of receivers has shown that four general types of connections all of which may be made without removing the chassis from the cabinet, cover practically every type of receiver. These connections are as follows:

- (1) Receivers having phonograph input jacks and the cable and switch supplied with the R-93 is not used. The phonograph output is connected direct to the phonograph input jack

to the Radio Receiver

and the Radio-Record Switch on the Receiver is used for changing from Record to Radio reproduction. The 1929 Victor Receiver and numerous Stromberg-Carlson Receivers are typical examples of this type of connection.

(2) Receivers having phonograph terminal board connections. Such connections are made in accordance with the instructions pertaining to that particular instrument.

(3) Receivers using the 2B7 or 6B7 Second Detectors. With receivers of this type, the yellow and green leads are connected in series with the grid cap connection of this tube.

(4) Receivers not having any of the foregoing features. On receivers of this type, an adaptor having a split cathode connection is necessary. Stock No. 4611, five-prong adaptor, or Stock No. 4612, six-prong adaptor, may be used. In such cases, the yellow and green leads are connected in series with the cathode, which is placed under the tube used in the second detector socket of the receiver.

It will be noted that red and blue leads are brought out from the switch for 'killing' the radio during record reproduction. With most receivers these may be connected in series with the antenna lead. However, in event this does not work satisfactorily then one of the split cathode adaptors must be used in the oscillator socket and the leads connected in series with the cathode. This will effectively 'kill' the radio on any super-heterodyne receiver. On the following page, a list of numerous receivers and their proper connections are given.

**MODEL R-93 Phonograph
Pickup Data
Parts List**

RCA-VICTOR CO., INC.

on each side, and must be removed before any bubbling occurs. The pickup should then be reassembled.

It is important to remember that in all operations after reassembling but before placing in the tone arm, the damping block should be centered.

Figure 9—Replacing Damping Block
The pickup should be magnetized and the armature centered after magnetizing. Magnetizing should be done by placing the pickup magnet on the magnetizer and sliding it onto the pole pieces after magnetizing being careful not to break the magnetic circuit.

(b) Remove the damping block from the armature and clean the armature shaft with emery paper.

(c) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the shaft diameter. This is done so that a snug fit will be obtained.

(d) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure 9, will prove desirable for fusing the block in place. The iron should be applied only long enough to melt the block sufficiently to cause a small bulge

PICKUP UNIT SERVICE DATA

(f) If the coil or pivot rubbers are to be replaced, the pickup must be further disassembled. This is done by removing the magnet and then removing screws C and D. The pole piece may now be removed and the old coil and sleeve disassembled. Acetone will be found helpful for dissolving the old cement that holds the coil in place. The new coil, with its sleeve, may now be replaced and cemented in a similar position to that occupied by the old coil. Duco household or Ambroid cement may be used to hold the coil in place. Be careful to center the coil with its paper sleeve before cementing. Only rosin core solder should be used for soldering the coil leads in the pickup.

(g) The pivot rubbers are replaced by loosening the armature adjusting screw F and removing screw G, clamp H and washer I and removing the armature from its bracket. Damping block J must be removed from the armature. After putting the new pivot rubbers in place, a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block. The rubbers can then be removed by slipping them from each end of the pivot shaft.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

(a) Disassemble the pickup as described under the preceding section.

The magnetic pickup and tone arm assembly of this instrument is of new design and unique construction. Service work will consist of centering the armature and replacing the rubber pivots, damping block and replacing the magnet coil.

Disassembling the Pickup:

The pickup may be disassembled in the following manner:

- (a) Unsolder the two cable connections to the terminal strip.
- (b) Remove the needle screw and screws "A" and "B."
- (c) Remove the pickup assembly from the arm and housing.
- (d) Resolder the two magnet coil leads attached to the terminals and then remove screw E. This will allow the removal of the terminal board.

(e) If centering the pickup armature is the only adjustment required, such centering can be done without removing the terminal board indicated in (d). The armature is centered by loosening screw F accessible through the hole shown, and holding the armature with the finger in proper position while screw F is tightened. Feeling the armature while deflecting it between its two extremes is the best manner of ascertaining proper centering. When magnet removed, it is important that the magnet be remagnetized while in place.

SERVICE DATA

Electrical Specifications

Voltage Rating . . . 105-120 Volts, 25-133 Cycles A. C. or D. C.
 Power Consumption 40 Watts
 Frequency Range 540 K. C.-1712 K. C.
 Type and Number of Radiotrons—
 1 RCA-77, 1 RCA-37, 1 RCA-38, 1 RCA-78—Total 4
 Undistorted Output 0.18 Watts

This receiver is an A. C.-D. C. table model tuned R. F. broadcast receiver. Features such as universal operation on both A. C. and D. C., wide tuning range, excellent performance and compact construction characterize this instrument. Figures A and B show the schematic and wiring diagrams

respectively. The voltage readings and replacement parts are given below.

The receiver is aligned at 1400 K. C. by means of the two trimmer capacitors located on the main tuning capacitor. The proper alignment is made by adjusting the trimmers for maximum output after tuning in a 1400 K. C. signal. This adjustment should be made when they are near their extreme minimum position. After alignment a check to make sure that a 1712 K. C. signal can be heard when the main tuning capacitor is near its extreme minimum position should be made. Stock No. 9050 Test Oscillator and Stock No. 7065 non-metallic screwdriver are desirable for making this adjustment.

RADIOTRON SOCKET VOLTAGES

Measured at Maximum Volume—115 Volt A. C. Line
 All Voltages on D. C. will be slightly lower

Loudspeaker Field Current..... 1.35 Amperes
Filtered D. C. Voltage from Rectifier..... 227 Volts
Total Plate Current..... 47.5 M. A.

This four tube Superheterodyne Automobile Receiver is of compact construction and gives excellent performance. Features such as unit construction (one unit contains the receiver, vibrator eliminator and tuning eye), use of milliammeters, frequency adjustment and a "B" battery eliminator, sensitivity and tone quality characterize this instrument.

"B" Battery Eliminator

This receiver uses a vibrator-type Inverter-Rectifier that provides source of direct current voltage for use as plate and grid supply for all Radiotrons. This unit is *occasionally adjusted and sealed at the factory and service adjustments should not be attempted.*

Line-up Capacitor Adjustments

The three R. F. line-up capacitors and two I. F. tuning capacitors are accessible and may require adjustments. The R. F. adjustments are made at 1400 K. C. and the I. F. adjustments at 175 K. C. The R. F. adjustments can be made with the receiver in its case, access to the adjusting screws being obtained through a slot in the bottom of the case. The I. F. adjustment is made by access to the oscillator tuning eye cover in order to couple the oscillator to the first detector. The following procedure should be used for these adjustments:

R. F. Adjustment

A satisfactory accurate and rapid adjustment of the three R. F. line-up capacitors can be made by ear, although, for optimum results, the use of an output meter connected across the loudspeaker voice coil is recommended. The latter method is more accurate and is used for the final adjustment. The meter, thus in turn eliminating the shielding effect of the case, the chassis and for the transformer therefore must be provided to prevent vibrator interference.

- (a) Procure a modulated oscillator giving a signal at 1400 K. C. and a non-metallic screw driver.
- (b) Couple the output of the oscillator from antenna to ground, set the dial at 140, and the oscillator at 1400 K. C.
- (c) Place the oscillator and receiver in operation and adjust the oscillator output so that a weak signal is obtained in the loudspeaker when the volume control is at its maximum position.

- (d) Then adjust the three line-up capacitors until maximum sound in the speaker or maximum deflection of the output meter is obtained. Readjust these capacitors a second time as there is a slight interlocking of adjustments.

I. F. Adjustments

In order to make the I. F. adjustments, it is necessary to remove the rear cover, due to the fact that the external oscillator must be connected between the control grid of the first detector and ground. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screw driver and an output meter.
- (b) Remove the receiver from its case, shield the transformer and Radiotrons as described under R. F. adjustments, place the receiver in operation and connect the oscillator output between the first detector grid and ground. Connect the antenna lead to ground and adjust the tuning capacitor so that no signal except the I. F. oscillator is heard at maximum volume. With the volume control at maximum, reduce the external oscillator output until a small deflection is obtained. Unless this is done, the action of the A. V. C. will make it impossible to obtain correct adjustments.
- (c) Each transformer has but one winding that is tuned by means of an adjustable capacitor, the other windings being by means of fixed capacitors. The capacitors should be adjusted for maximum output.

At this time I. F. adjustments are made it is good practice to follow this adjustment with the R. F. adjustments, due to the interlocking that always occurs. The reverse of this, however, is not always true.

Practical Hints on Installation

The following suggestions may prove useful when making installation on a particular car.

Chrysler 1933—Mount chassis on left side, and against car bulkhead and use flexible shaft. Use both capacitors, one on the ammeter and one on the generator. Use all suppressors. Place a copper screen under the top board on right side, 10" x 10" to prevent the body from radiating ignition interference which may be picked up by the antenna. This screen must be grounded.

Plymouth 1933—Mount chassis on left side, back against car bulkhead and use 3 3/4" flexible shaft. Use both capacitors, one on the ammeter and one on the generator. Use all suppressors.

Ford V-8 1932 or 1932—Mount chassis on left side, and against car frame and use short flexible shaft. Use one capacitor, connected to the generator. Install eight spark plug type suppressor only, no distributor suppressor being necessary.

The majority of cars will be found to be entirely free from ignition noise when the standard equipment is used. Usually mounting the chassis on the right side of the bulkhead will be found most desirable, although if a heater is used, the left side will be preferable.

RADIOTRON SOCKET VOLTAGES

Equipment

A. Equipment Furnished:

1. Receiver Package—Includes the receiver and remote control units joined by the wiring cable:
 - (a) The receiver contains one each of the following Radiotrons installed in sockets: RCA-78, RCA-6A7, RCA-6B7, RCA-41.
 - (b) The remote control unit contains one dial lamp (6-8 volts).
 - (c) The wiring cable includes one fuse (20 amperes) installed in attached fuse receptacle.

2. Oufit Package—Containing:

- (a) Flexible shaft (33 3/4 inches long).
- (b) Receiver unit mounting bolt (1/2 inch diameter), dash support plate, and nuts (2).
- (c) Self-tapping screws, washers and rubber bumpers (4 each).
- (d) Steering column bracket for remote control unit with strap, screws (2), plain washer (1) and lockwasher (1).
- (e) Shield clamp for antenna lead-in wire with screw (1), lockwasher (1) and nut (1).
- (f) Key (1) and knob (1) for remote control unit and eyeslets (2) for antenna connector packed in small envelope.
- (g) Ignition Interference Suppression Equipment:
 - 6 Spark plug type suppressors (additional obtainable from your dealer).
 - 1 Distributor type suppressor.
 - 2 Capacitors.
- (h) Instruction Book.

B. Additional Equipment Required:

1. Antenna—One of the following types:
 - (a) Roof (built-in) type—recommended.
 - (b) Roof (interior) type for attachment to head-lining inside car—also recommended. A special antenna of this type complete with pin-books and lead-in wire may be purchased from your dealer.
 - (c) Plate (sub-mounted) type for attachment to chassis members of car chassis—alternative. An efficient antenna completely equipped for mounting and a specially-designed shielded lead-in wire also are obtainable from the dealer.

Location of Units

Receiver and Remote Control Units—The arrangement of units shown in Figure 1 is recommended and will be found applicable to the majority of automobiles. Consideration should be given to the possibility of interference of the receiver with other equipment beneath the instrument panel or of the mounting bolt with apparatus on the engine side of the dash. By placing the receiver unit toward the right-hand side of the dash, the flexible shaft will be of correct length as furnished in practically all cases. This position, however, may be considered impractical because of its universal preference for heating devices, necessitating installation of the receiver

unit either near the center or at the extreme left-hand side of the dash and the use of a shorter flexible shaft. In such cases, the shaft may be either shortened (as described under "Mounting of Units") or exchanged for one of proper length by the dealer.

NOTE—Two support brackets are attached to the receiver case, one on the rear surface and the other on the right-hand side viewing the loud speaker opening. The side bracket must be used when the unit is mounted at the extreme left-hand end of the dash in order to avoid sharp bends in the flexible shaft and resultant unsatisfactory operation.

As furnished, the remote control unit is equipped for attachment to the steering column of the car. Its clamp bracket is so designed that the driver may select from a wide variety of possible mounting positions for maximum accessibility. The associated bracket strap will be found to accommodate practically any diameter steering column. If considered desirable, however, the remote control unit may be supported upon the instrument panel by means of an accessory bracket procurable from the dealer.

Antenna:

(a) Roof (Built-in) Type—Best results will be obtained by use of a built-in roof antenna. The majority of modern automobiles (closed body types only) are already equipped with such an antenna installed at the factory, the lead-in wire from which will usually be found coiled-up beneath the instrument panel. Many other earlier cars employ a piece of metallic screen—for top material support—which, if unrounded (not in electrical contact with the metallic frame), may be readily utilized as an antenna.

NOTE—The presence of a top support screen and of grounds in that screen may be determined without removing any portion of the inside fabric (head-lining). First procure any sharp-pointed metallic tool, push the point through the fabric (at several points if necessary) and feel around in an attempt to scrape the screen surface—being careful not to puncture the weather-proof top. If a screen is found, connect an ordinary dash or mobile ammeter and the tool, re-insert the tool through the head-lining and make contact with the screen. If the lamp lights, however dimly, it shall be assumed that the screen is grounded.

In order to use an ungrounded support screen, first release the head-lining at the front corner nearest the receiver. Then connect a flexible rubber-insulated lead to the corner of the screen and solder the joint. Feed the free end of the lead down the adjacent pillar-post of the car into the driving compartment and replace the head-lining.

If the top support screen is grounded, or if no screen is present, it will be necessary to drop the entire head-lining (see Figure 2). In the former case, the screen may be insulated by removal of a strip several inches from all edges and from the dome

MODEL M-105 Installation Data

RCA-VICTOR CO., INC.

lead-in wire and the shield braid over the loom.

(b) **Roof Antenna (Interior Type)**—If an interior type antenna is used, the lead-in wire should be brought down the outside of that front pillar post nearest the receiver.

(c) **Plate Type Antenna**—With the plate type antenna, the full-shielded end of the special cable should be brought into the automobile driving compartment through a 1/2 inch hole drilled in the toe-board (if no other opening is available). This end is to be connected to the receiver unit antenna lead (as explained in following paragraphs) and the opposite (unshielded) end then cut off as required to eliminate excessive slack upon connection to the plate. The pigtail extension from the end of the shield must be soldered or bonded to the frame of the car.

Refer to the detailed view of the antenna connector shown in Figure 1 and proceed to attach the lead-in wire (if shielded) as follows: First, cut the end of the lead-in so that the internal insulated wire and loom (if present) are flush with the end of the shield covering and push back the shield approximately 1 1/2 inches. Cut the loom to the end of the shield and then remove sufficient insulation to expose one inch of clean bare-conductor. Now disconnect the female portion of the connector attached to the receiver antenna lead and remove the small internal bushing and spring.

To assemble, slip the bare conductor through the female portion of the connector and then through the spring and bushing, making certain that the insulation enters the end of the connector. Bend over and spread the strands of the conductor against the forward end of the bushing and then force one of the eyelets (packed in small envelope in outfit package) into the bushing to hold the conductor in position. Cut off the end of the conductor strands approximately 1/4 inch beyond the edge of the eyelet and bend the strands over toward the center of the eyelet. The assembly may be now attached to the receiver portion of the connector and the shield covering on the lead-in wire pushed forward to cover the adjacent end of the female portion. Finally, bond the shield to the connector by means of the small clamp furnished. No soldering operations are required.

NOTE—An unshielded lead-in wire (as in the case of the interior-type antenna) may be attached to the antenna connector as described above except that all references to the shield braid and loom may be neglected.

the shaft held in this position, insert the opposite end of the shaft through the bushing at the rear of the remote control unit and push forward until the flatted portion of the shaft protrudes through the front cover. Then proceed to tighten the external set-screw (located at the bottom of the case—see Figure 3) adjusting the shaft position as necessary until the screw is felt to engage in the groove. Tighten the screw fully to the bottom of the slot and then loosen it approximately one-quarter of a turn. Finally, secure the flexible casing in place by tightening the set-screws at each end firmly, so as to provide good electrical contact as well as solid mechanical support.

NOTE—In many installations it will be found necessary or desirable to use a flexible shaft of shorter length than 33 1/2 inches. While it is simplest to procure a shaft of proper length from the dealer as mentioned heretofore, very little difficulty should be experienced in shortening the original part if deemed expedient. To shorten the shaft, refer to Figure 3 and proceed as follows:

1. Determine the minimum shaft length permissible for the installation.
2. Remove the slotted coupling (using a soldering iron) and withdraw the shaft from its casing.
3. Cut the shaft only at the center of a swaged joint, selecting that joint which allows at least the required length.
4. Cut from the shaft casing a length equal to the amount of shaft removed. (This operation may be simplified by plugging the casing between wooden blocks in a vise so that the block ends will serve to guide the hack saw blade.)
5. Replace the shaft in its casing and solder the slotted coupling to the end of the shaft.

Connections

Refer to Figure 1 and make connections as follows:

Antenna to Receiver—For least ignition interference, any portion of the antenna lead-in wire which extends behind the instrument panel or into the engine compartment of the car should be fully shielded and cut to eliminate excessive slack when attached to the receiver antenna connector. Before connecting the antenna to the receiver, the following comments applying to the particular type of antenna adopted should be observed:

(a) **Roof Antenna (Built-in Type)**—The lead-in wire from a factory-installed built-in roof antenna usually is unshielded and often is of insufficient length to reach the receiver. If necessary, an extra length of insulated wire may be spliced to the existing lead-in, in which case the joint must be soldered and wrapped with tape. In general, it will be advisable to shield the exposed length of lead-in wire, procuring for this purpose from your dealer a length of shield braid and an equivalent length of insulating loom (or rubber tubing) sufficient to extend between the end of the lead-in wire and its point of entrance from the body pillar post. Slip the loom over the

examination of the battery connections and ascertain which terminal is grounded (that is, connected to the frame of the car). The positive terminal is usually marked (+) and tends to form corrosion far more rapidly than the negative (-). If the positive terminal is grounded, no change in the electrical connections of the receiver unit will be required. However, if the opposite is true, the cover of the receiver case must be removed and the red and green leads (attached by spade-type connectors to the two terminals nearest the bottom of the chassis terminal board) shown in Figure 1 must be reversed.

Now replace the case cover and support the assembled unit against the dash in the chosen position. Allow a clearance of at least two inches above the top surface, where possible, to permit subsequent removal of the case from the mounting bolt head, mark with a pencil or crayon on the dash four points corresponding to the corners of the adjacent case surface. Then determine the exact center of the area bounded by these four points (by drawing diagonal lines between opposite corners) and mark that position with a center-punch. Next drill a 1/2 inch hole at the center-punch mark and insert the mounting bolt. The support plate and the two nuts then should be assembled upon the bolt from the engine side of the dash as shown but should not be tightened. Attach the four rubber bumpers, by means of the washers and self-tapping screws, at the four small holes on the selected mounting surface of the case. Finally hang the receiver over the bolt head, align sides vertically and tighten the nuts in place.

Remote Control Unit—In attaching the remote control unit to the steering column of the car, it will be advisable first to examine the detailed view (in Figure 1) showing the assembly of its mounting bracket. Four small holes are contained in the associated flexible strap at distances proper for use with steering columns of the most common diameters (1 1/4, 1 3/8, 1 1/2, 1 3/4 inches) but the strap length will be found sufficient to permit the insertion of an additional hole if necessary to accommodate a 2 inch column. The proper hole may be determined by wrapping the clamp strap tightly around the column, inserting the machine screw furnished through that hole found to be nearest in alignment with the tapped hole in the clamp bracket. Three tapped holes are provided in the back of the remote control unit, permitting support of that unit either at the right- or left-hand side or above the steering column.

Flexible Shaft—Insert that end of the flexible shaft to which is attached the slotted coupling through the bushed opening in the left side of the receiver unit. Then rotate the shaft from the free end until the coupling slot is felt to engage over the pin contained in the tuning mechanism and slide the shaft forward to the full depth of the slot. With

light fixture. The possibility of subsequent shifting may be eliminated by tacking the screen to one or more of the ribs and by lacing the sides with cord. Where no support screen is used, a copper screen having a total area of at least ten square feet should be inserted. It should be located as far to the rear as possible and insulated from all metallic parts grounded to the frame of the car. The antenna finally should be tested for grounds (see the foregoing "NOTE" for test procedure). If satisfactory, attach the lead-in wire and replace the head-lining of the car.

NOTE—Since a degree of skill—only acquired by experience—is necessary in removing and replacing the top fabric material, such work should be allotted to a competent "trim" man.

(b) **Roof (Interior) Type**—The accessory interior-type roof antenna also will provide very satisfactory performance and, in addition, is extremely simple to install. It may be quickly attached to the head-lining inside the car (preferably as far to the rear as possible) by means of pin-hooks, thereby precluding removal of the fabric. An antenna of this type, however, should not be used in any automobile having a grounded top material support screen since the proximity of that screen would seriously reduce its efficiency. Before purchase, therefore, it will be advisable to check this possibility, following the test procedure described under "Roof (Built-in) Type."

As furnished, the interior-type antenna is equipped with a sufficient length of lead-in wire ready attached. The effective antenna wire is enclosed by long-wearing paper procurable either in "gray" or "tan" finish as desired to harmonize with the car upholstery.

(c) **Plate Type**—For those cases where the installation of a built-in roof antenna is considered too costly and the interior roof antenna impractical, good reception from local or semi-distant powerful stations may be procured with the special plate-type antenna also obtainable as an accessory. This unit should be clamped to the frame of the chassis as far to the rear as possible. It is adjustable in length and may be mounted either lengthwise or crosswise of the chassis, which position should be selected with due regard to the prevention of overcrowding. The plate must be placed as close to the ground as possible, but not below the lowest portion of the chassis at the desired location, as sufficient road clearance must be retained. It is also important to avoid any position in which the plate will impede free motion of chassis parts such as springs, drive shaft, or axles in order to prevent damage to the antenna.

Mounting of Units

Details of mounting the various units are shown in Figure 1. The following procedures are recommended:

Receiver Unit—It is necessary first to determine the electrical polarity of the storage battery supply. This may be done most conveniently by making an

Alignment Data

SERVICE DATA

(1) Removing Units from Chassis:

The three major units, the power unit, the loudspeaker and the receiver chassis, are easily removed independently without disturbing the other units not removed. To do this, the use of a screwdriver and soldering iron are the only tools required. Figure 2 shows the details of the screws and terminals to be removed in each individual case.

(2) Line-Up Capacitor Adjustments:

Adjustable capacitors are provided in the R. F. oscillator and intermediate frequency amplifier to provide a means of properly aligning the receiver. A modulated R. F. oscillator such as Full-Range Test Oscillator, type TMV-97-B (Stock No. 9050), a non-metallic screwdriver such as alignment wrench Stock No. 4160 and an output meter are required for properly aligning this receiver. Refer to Figure 3 for the location of the line-up capacitors.

I. F. Tuning Adjustments:

Two transformers comprising three tuned circuits (the secondary of the second transformer is untuned) are used in the intermediate amplifier. These are tuned to 175 K. C. and the adjustment screws are accessible from beneath the chassis as shown in Figure 3. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screwdriver such as Stock No. 4160 and an output meter.
- (b) Short-circuit the antenna and ground leads and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- (c) Connect the oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- (d) Adjust the primary of the second, and the primary and secondary of the first I. F. transformers, until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments:

The three-gang capacitor trimmer screws are located

on the main tuning capacitor, accessible at the top of the chassis. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 1400 K. C. and 600 K. C., a non-metallic screwdriver such as Stock No. 4160 and an output meter.
- (b) Connect the output of the oscillator to the antenna and ground lead of the receiver. Place the receiver in operation and attach the control box as in normal operation. Turn the tuning control until the tuning capacitors are fully meshed. Then set the indicator on the dial at the 530 K. C. reading. Turn the tuning control until the dial reads 1400. Then set the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the three-gang capacitor trimmer screws until maximum output is obtained. Be careful not to disturb the relation of the control box to the receiver after setting the dial.
- (c) After making the 1400 K. C. adjustment, shift the oscillator to 600 K. C. and tune in the signal. Adjust the 600 K. C. trimmer, accessible from the side of the chassis for maximum output while rocking the gang-capacitor back and forth. Then again check the adjustment described in (b).

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position and the minimum input signal necessary from the oscillator must be used.

(4) R. F. Interference from Vibrator with Shielded Lead-In Disconnected from Antenna:

In event R. F. interference originating with the vibrator inverter-rectifier unit is encountered, check the following points:

- (a) Vibrator not properly seated. The vibrator must be pushed tight against its socket at all times.
- (b) The various by-pass capacitors, such as C-28, C-29 and C-30 and chokes L-13, L-14 and L-16, must be properly connected, and in operating condition. It is well to remember that some of the interference produced by the vibrator is of a frequency as high as one meter and any replacement of capacitors must always be made with one of similar mechanical as well as electrical construction.

(5) Voltage Readings:

The following voltages are those at the tube socket while the receiver is in operating condition. No allowance has been made for currents drawn by the meter and if low resistance meters are used, such allowances must be made.

means of special equipment at the factory and then sealed to prevent tampering. The unit is provided with a special plug-in base so that in event of suspected failure it may be easily interchanged with one of known condition.

(6) Vibrator Inverter:

The Vibrator Inverter unit used in this receiver is of advanced design and construction. It is adjusted by

With the seals unbroken, the Vibrator carries the standard ninety-day guarantee, which also applies to all parts of the receiver. Vibrator defects should be remedied by replacement, not by attempted adjustment.

Power Requirements 105-125 volt,
50-60 Cycle A. C. or 6-volt Storage Battery
Power Consumption . . 115 Volts, 60 Cycles A. C.—40 Watts,
Battery—5.7 Amperes at 6.3 Volts
Number and Types of Radiotrons 1 RCA-78,
1 RCA-6A7, 1 RCA-6B7, 1 RCA-41, 1 RCA-1-V—Total 5
Maximum Undistorted Power Output 1.8 Watts
Maximum Output 3.6 Watts
Type of Rectifier A. C.—Radiotron RCA-1-V
Battery—Vibrator Inverter-Rectifier
Tuning Frequency Range 540 K. C.—1500 K. C.

This automobile receiver is of unique design and construction. Among its many features is its adaptability to either battery or 110-volt alternating current operation. This is accomplished by having a separate power transformer and a

Figure C—Location of Line-up Capacitors

tube rectifier for alternating current, while the conventional vibrator inverter-rectifier with its associated transformer is used for battery operation.

Other important features include its compact portable size, full vision "airplane" type dial, tone control, sensitivity switch, electro-dynamic loudspeaker and the inherent sensitivity, selectivity and tone quality characteristic of the super-heterodyne.

Figure A shows the schematic diagram, Figure B the wiring diagram, Figure C the location of the line-up capacitors and Figure D the wiring of the battery cable. A brief description of the circuit follows:

Radio Circuit—The radio circuit consists of four Radiotrons; namely, an RCA-78 R. F. stage, an RCA-6A7 first detector-oscillator, an RCA-6B7 intermediate frequency amplifier, second detector and A. V. C. and an RCA-41 output amplifier.

Power Circuit—The power circuit for battery operation consists of a vibrator inverter-rectifier with its associated transformer and filter circuits. The heaters of the various Radiotrons are powered direct from the car storage battery. The operating switch is so arranged that at one position battery operation is obtained, while at the other position, proper connections are made for A. C. operation.

When the switch is at the A. C. position, the A. C. input current is connected to the primary of the A. C. transformer. Two secondaries are provided, one for furnishing power to the Radiotron heaters and the dial lamp, the other for plate supply to Rectifier RCA-1-V. The output of the rectifier is then filtered by the same filtering system as that used for battery operation. The loudspeaker field is used as a filter reactor.

Inverter-Rectifier Adjustments

This receiver uses a vibrator inverter-rectifier for supplying all plate and grid voltages when operated from a battery source. This unit is accurately adjusted and sealed at the factory and service adjustment should not be attempted.

Line-up Capacitor Adjustments

The three R. F. line-up capacitors and two I. F. tuning capacitors are accessible and may require adjustments. The R. F. adjustments are made at 1400 K. C. and the I. F. adjustments at 175 K. C. In order to make these adjustments, it is first necessary to remove the cover of the instrument. The following procedure should be used:

R. F. Adjustment :

- (a) Check the position of the dial pointer. It should be aligned with the low-frequency end graduation, as indicated by the small arrow marked "Max. Cap." when the tuning capacitor rotor is fully meshed with the stator.
- (b) Procure a modulated oscillator giving a signal at 1400 K. C. (Stock No. 9050), a non-metallic screw driver (Stock No. 7065) and an output meter. Connect the output meter across the cone coil of the loudspeaker.
- (c) Couple the output of the oscillator from antenna to ground, set the dial at 140, and the oscillator at 1400 K. C.
- (d) Place the oscillator and receiver in operation and adjust the oscillator output so that a small deflection is obtained in the output meter when the volume control is at its maximum position.
- (e) Then adjust the three line-up capacitors until a maximum deflection in the output meter is obtained. Readjust these capacitors a second time, as there is a slight interlocking of adjustments.

I. F. Adjustments :

- (a) Procure a modulated oscillator giving a signal at 175 K. C. (Stock No. 9050), a non-metallic screw driver (Stock No. 7065) and an output meter.
- (b) Connect the oscillator between the control grid of the first detector and ground.
- (c) Connect the output meter across the voice coil of the loudspeaker. Then connect the antenna lead to ground and adjust the tuning capacitor so that no signal except the I. F. oscillator is heard at maximum volume. With the volume control at maximum, reduce the external oscillator output until a small deflection is obtained. Unless this is done, the action of the A. V. C. will make it impossible to obtain correct adjustments.
- (d) Each transformer has but one winding that is tuned by means of an adjustable capacitor, the other windings being untuned. The capacitors should be adjusted for maximum output. At the time I. F. adjustments are made it is good practice to follow this adjustment with the R. F. adjustments, due to the interlocking that always occurs. The reverse of this, however, is not always true.

SERVICE DATA

(1) Line-Up Capacitor Adjustments:

To properly align this receiver, it is essential that a modulated R. F. oscillator, such as Stock No. 9050, an output indicator and an alignment tool (Stock No. 4160) be available. Figure 5 shows the location of the various line-up capacitors.

I. F. Tuning Adjustments:

Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 460 K. C. and the adjustment screws are accessible as shown in Figure 6. Proceed as follows:

(a) Short-circuit the antenna and ground terminals and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the ground terminal.

(b) Connect the test oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.

(c) Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments:

The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the top of the chassis. Proceed as follows:

(a) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully meshed. It should be coincident with the radial line adjacent to the dial reading of 540. Then set the Test Oscillator at 1720 K. C., the dial indicator at 1720 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.

(b) With the Range Switch at the "in" position, adjust the two trimmers under the two R. F. coils, designated as BC in Figure 6, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor, accessible from the top of the chassis, should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1720 K. C. adjustment.

(c) Now place the Range Switch at the "out" position, shift the Test Oscillator to 18,000 K. C. and set the dial at 48M. Adjust the two trimmer capacitors designated as SW in Figure 5 for maximum output, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two positions at which the signal will give maximum output. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator, while the position that uses a higher capacitance is correct for the detector. The detector trimmer must be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Both of these adjustments must be made as indicated irrespective of output.

The important points to remember are the need for using the minimum oscillator output to obtain a deflection in the output meter with the volume control at its maximum position and the manner of obtaining the proper high frequency oscillator and detector adjustments.

(9) Radiotron Socket Voltages:

The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if lower resistance meters are used, such allowances must be made:

(3) Power Transformer Connections:

Models supplied for 220-volt power supply, use a power transformer having a tapped primary. The tapped primary permits it to be used either on lines of 100-130 volts or 195-250 volts. Figure 5 shows the internal connections of the transformer and the voltages to be used with the various taps. The taps are located on a terminal strip at the top of the transformer so that necessary changes may be made without removing the receiver from the cabinet.

- Tuning Frequency Range.....540 K. C.—1600 K. C.
Maximum Undistorted Output.....4.2 Watts
Maximum Output.....6.8 Watts
Line-up Frequencies.....175 K. C., 600 K. C., 1400 K. C.

(1) Removing Units from Chassis:

The three major units, the power unit, the loudspeaker and the receiver chassis, are easily removed independently without disturbing the other units not removed. To do this, the use of a screwdriver is the only tool required. Figure 2 shows the details of the screws and terminals to be removed in each individual case.

(2) Loose or Tight Tuning Action:

An adjustment screw is provided at the worm drive unit, so that proper tension may be provided for the particular worm being used. The instruction

book accompanying the instrument describes the proper manner of turning the drive assembly when using either right or left hand drives. However, whenever this change is made, the adjusting screw located on the front of the drive unit should be loosened or tightened until a satisfactory amount of tension and elimination of backlash is obtained.

(3) Line-up Capacitor Adjustments:

Adjustable capacitors are provided in the R. F. oscillator and intermediate frequency amplifier to provide a means of properly aligning the receiver. A modulated R. F. oscillator such as Full Range Test Oscillator, Type TMV-97-B (Stock No. 9050), a non-metallic screwdriver such as alignment wrench Stock No. 4160 and an output meter are required for properly aligning this receiver. Refer to Figure 3 for the location of the line-up capacitors.

I. F. Tuning Adjustments:

Two transformers comprising three tuned circuits (the secondary of the second transformer is untuned) are used in the intermediate amplifier. These are tuned to 175 K. C. and the adjustment screws are accessible from beneath the chassis as shown in Figure 3. Proceed as follows:

- Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screwdriver such as Stock No. 4160 and an output meter.
- Short-circuit the antenna and ground leads and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- Connect the oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- Adjust the primary of the second, and the secondary and primary of the first I. F. transformers, until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments:

The three-gang capacitor screws are located on the main tuning capacitor, accessible at the top of the chassis. Proceed as follows:

- Procure a modulated oscillator giving a signal at 1400 K. C. and 600 K. C., a non-metallic screwdriver such as Stock No. 4160 and an output meter.
- Connect the output of the oscillator to the antenna and ground lead of the receiver. Place the receiver in operation and attach the control box as in normal operation. Turn the tuning control until the tuning capacitors are fully meshed. Then set the indicator on the dial at the 530 K. C. reading. Turn the tuning control until the dial reads 1400. Then set the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the three-gang capacitor trimmer screws until maximum output is obtained. Be careful not to disturb the relation of the control box to the receiver after setting the dial.
- After making the 1400 K. C. adjustment, shift the oscillator to 600 K. C. and tune in the signal. Adjust the 600 K. C. trimmer, accessible from the side of the chassis for maximum output while rocking the gang capacitor back and forth. Then again check the adjustment described in (b).

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position and the minimum input signal necessary from the oscillator must be used.

(4) R. F. Interference from Vibrator:

In event R. F. interference originating with the vibrator inverter-rectifier unit is encountered, check the following points:

- Vibrator not properly sealed. The vibrator must be pushed tight against its socket at all times.
- The clip from the top of the R. F. tube shield to the gang-capacitor must be in place.

- The various by-pass capacitors, such as C-29, C-30, C-31, C-34, C-37, and chokes L-16 and L-14, L-13, must be properly connected, and in operating condition. It is well to remember that some of the interference produced by the vibrator is of a frequency as high as one meter and any replacement of capacitors must always be made with ones of similar mechanical as well as electrical construction.

(5) Voltage Readings:

The following voltages are those at the tube socket while the receiver is in operating condition. No allowance has been made for currents drawn by the meter and if low resistance meters are used, such allowances must be made.

(6) Vibrator Inverter-Rectifier:

The Vibrator Inverter-Rectifier unit used in this receiver is of advanced design and construction. It is adjusted by means of special equipment at the factory and then sealed to prevent tampering. The unit is provided with a special plug-in base so that in event of suspected failure it may be easily interchanged with one of known condition.

With the seals unbroken, the Vibrator carries the standard ninety-day guarantee, which also applies to all parts of the receiver. Vibrator defects should be remedied by replacement, not by attempted adjustment.

(7) Stiff Tuning Mechanism:

In event the station selector turns hard or stiff, it is probably due to excessive pressure between the worm and drive gear. Proper tension between these units exists when the gear is pushed $\frac{1}{8}$ " beyond the point of contact with the worm, before being tightened.

(8) Antenna Lead Clamp

A clamp has been provided for holding the antenna lead securely to the side of case. This clamp is held by one of the chassis mounting screws and prevents the antenna lead from interfering with the operation of the brake pedal or starter button. When making an installation, it is important to see that this lead is securely clamped.

Voltage Rating.....105-125 Volts
Frequency Rating.....25-60 and 50-60 Cycles
Power Consumption...60 Cycle 75 Watts, 25 Cycle 80 Watts
Number and Types of Radiotrons.....2 RCA-58,
1 RCA-2A7, 1 RCA-2B7, 1 RCA-2A5, 1 RCA-80—Total 6
Undistorted Output.....1.75 Watts
Frequency Range.....540 K. C. to 1500 K. C.
and 1400 to 2800 K. C.

This receiver is a six tube Superheterodyne incorporating features such as Dynamic Loudspeaker, automatic volume control, single heater type Pentode output tube, continuously variable type tone control and the inherent sensitivity, selectivity and tone quality of the Superheterodyne.

A special feature is a Range Switch that allows reception of signals either of the broadcast band or higher frequencies. Figure A shows the schematic circuit, Figure B the wiring diagram and Figure C the loudspeaker wiring. With the switch in the broadcast band position, the frequency range is from 540 to 1500 K. C. At the higher frequency position, the receiver covers the 1400 to 2800 K. C. band.

Figure C—Loudspeaker Wiring

The circuit consists of an R. F. stage using Radiotron RCA-58, a combined oscillator and first detector in the RCA-2A7 tube, an intermediate stage using Radiotron RCA-58, an RCA-2B7 functioning a combined second detector and automatic volume control, an output stage using the new heater Pentode RCA-2A5 and the RCA-80 functioning as a rectifier.

Service work in conjunction with this receiver will be similar to that of other Superheterodyne receivers incorporating a similar type automatic volume control.

LINE-UP ADJUSTMENTS

I. F. Tuning Adjustments—Two transformers comprising three tuned circuits (the secondary of the second transformer is untuned) are used in the intermediate amplifier.

These are tuned to 175 K. C. and the adjustment screws are accessible as shown in Figure D. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.
- (b) Short-circuit the antenna and ground terminals and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- (c) Connect the oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- (d) Adjust the primary of the second, and the secondary and primary of the first I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

Figure D—Location of I. F. Line-up Adjustment Screws

R. F. and Oscillator Adjustments—The three gang capacitor screws are accessible at the bottom of the chassis. The high frequency capacitor screws are located on the Range Switch. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 1400 and 2440 K. C., a non-metallic screw driver such as Stock No. 7065 and an output meter.
- (b) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be opposite the last division of the low frequency end of scale with the indicator at its center position. Then set the dial at 140, the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.
- (c) With the Range Switch at the counter-clockwise position, adjust the three tuning condenser line-up capacitors until maximum deflection is obtained in the output meter. Then shift the oscillator to 2440 K. C., the Range Switch to the clockwise position and the dial to 120. The three line-up capacitors located on the Range Switch should then be adjusted for maximum output.

When making both the I. F. and R. F. adjustments, the important points to remember are that the receiver volume control must be at its maximum position and that the input signal from the external oscillator must be no greater than necessary.

SERVICE DATA

(1) Important

Always disconnect the batteries before attempting to remove the chassis from the cabinet. Always turn the operating switch "off" before changing tubes, batteries or fuses.

Figure 3—Loudspeaker Wiring

(2) Line-up Capacitor Adjustments

Line-up capacitors are provided in the first detector, oscillator and intermediate amplifier to provide a means of properly aligning the receiver. A modulated R. F. oscillator, such as Full Range Test Oscillator, type TMV-97-B (Stock No. 9050), a non-metallic screw driver, such as alignment wrench (Stock No. 4160), and an output indicator are required for properly aligning this receiver. Refer to Figure 4 for the location of the line-up capacitors.

I. F. Adjustments

Two transformers comprising four circuits, two of which have trimmer capacitors, are used in the I. F. amplifier. Proceed as follows:

(a) Short-circuit the antenna and ground terminals and connect the output of the oscillator between the control grid cap of the first detector (RCA-1A6) and ground. Connect an output indicator across the voice coil leads of the loudspeaker. Place the oscillator in operation at 460 K. C. and adjust its output and

the receiver volume control until a deflection is obtained in the output indicator.

(b) Adjust the secondary and then the primary of the first I. F. transformer (see Figure 4) until a maximum deflection is obtained in the output indicator.

This completes the I. F. adjustments. It is good practice to always follow the I. F. adjustments with the detector and oscillator adjustment, as there is an interlocking of adjustments that always occurs.

Detector-Oscillator Adjustments

The two-gang capacitor trimmer screws are accessible at the top of chassis. The series (600 K. C.) trimmer is accessible from the rear. Proceed as follows:

(a) Connect the oscillator between the antenna and ground terminals of the receiver. Connect the output meter across the voice coil leads of the loudspeaker.

(b) Place the oscillator in operation at 1400 K. C., set the dial at 140 and adjust the oscillator output and receiver volume control until a deflection is obtained in the output indicator.

(c) Adjust each trimmer on the gang capacitor until a maximum deflection is obtained.

(d) Set the oscillator at 600 K. C. and tune in the signal on the receiver. Then adjust the series trimmer, located on the rear of the chassis, until maximum output is obtained. While making this adjustment, rock the tuning capacitor back and forth through the signal. Then again check the adjustments in (b).

(3) Voltage Readings

The following voltages are those at the tube sockets while the receiver is in operating condition. No allowance has been made for current drawn by the meter and if low resistance meters are used, such allowances must be made.

RADIOTRON SOCKET VOLTAGES

135-Volt "B" Supply—No Signal—Maximum Volume Control

RADIOTRON No.		CONTROL GRID TO GROUND VOLTS, D. C.	SCREEN GRID TO GROUND VOLTS, D. C.	PLATE TO GROUND VOLTS, D. C.	PLATE, M. A.	FILAMENT VOLTS, D. C.
RCA-1A6	1st Det.	*3.0	67.5	135	1.7	2.0
	Osc.	—	—	135	1.8	
RCA-34—I. F.		*3.0	67.5	135	3.0	2.0
RCA-32—2nd Det.		*6.5	67.5	*95	0.4	2.0
RCA-30—Driver		*9.0	—	130	3.5	2.0
RCA-30—Output		12.0	—	135	1.0	2.0
RCA-30—Output		12.0	—	135	1.0	2.0

*These voltages cannot be measured with ordinary voltmeter, as they are obtained by means of high resistance bleeders across a 22½-volt "C" battery.

† Full discount not allowed.

Proceed as follows:
(a) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully meshed. It should be coincident with the radial line adjacent to the dial reading of 54. Then set the Test Oscillator at 1400 K. C., the dial indicator at 140 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.

(b) With the Range Switch at the "in" position, adjust the three trimmers under the three R. F. coils, designated as L in Figure 4, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor accessible from the rear of the chassis, should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1400 K. C. adjustment.

(c) Now place the Range Switch at the "out" position, shift the Test Oscillator to 15,000 K. C. and set the dial at 150. Adjust the three trimmer capacitors designated as S in Figure 4 for maximum output, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two positions at which the signal will give maximum output. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator, while the position that uses a higher capacitance is correct for the detector. Both of these adjustments must be made as indicated irrespective of output. The R. F. is merely peaked. In conjunction with the detector adjustment, it is necessary to rock the main tuning capacitor back and forth while making the adjustment. This completes the line-up adjustments.

The important points to remember are the need for using the minimum oscillator output to obtain a deflection in the output meter with the volume control at its maximum position and the manner of obtaining the proper high frequency oscillator and detector adjustments.

CAUTION—This receiver operates on 220-volt direct current without a transformer between the line and the various parts of the receiver, such as A. C. receivers use. It is therefore extremely important to use the utmost caution when operating the receiver outside of the cabinet. Also a knob must always be placed on the shaft of the main tuning capacitor, as under certain conditions the full line voltage is obtained between this point and ground.

(1) Line-up Capacitor Adjustments

To properly align this receiver, it is essential that a modulated R. F. oscillator, such as Stock No. 9050, an output indicator and an alignment tool (Stock No. 4160) be available. Figure 4 shows the location of the various line-up capacitors.

I. F. Tuning Adjustments

Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 370 K. C. and the adjustment screws are accessible as shown in Figure 4. Proceed as follows:

(a) Short-circuit the antenna and ground leads and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the ground terminal.

(b) Connect the test oscillator output between the first detector control grid and chassis ground, preferably through a series condenser. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.

(c) Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments

The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the rear of the chassis.

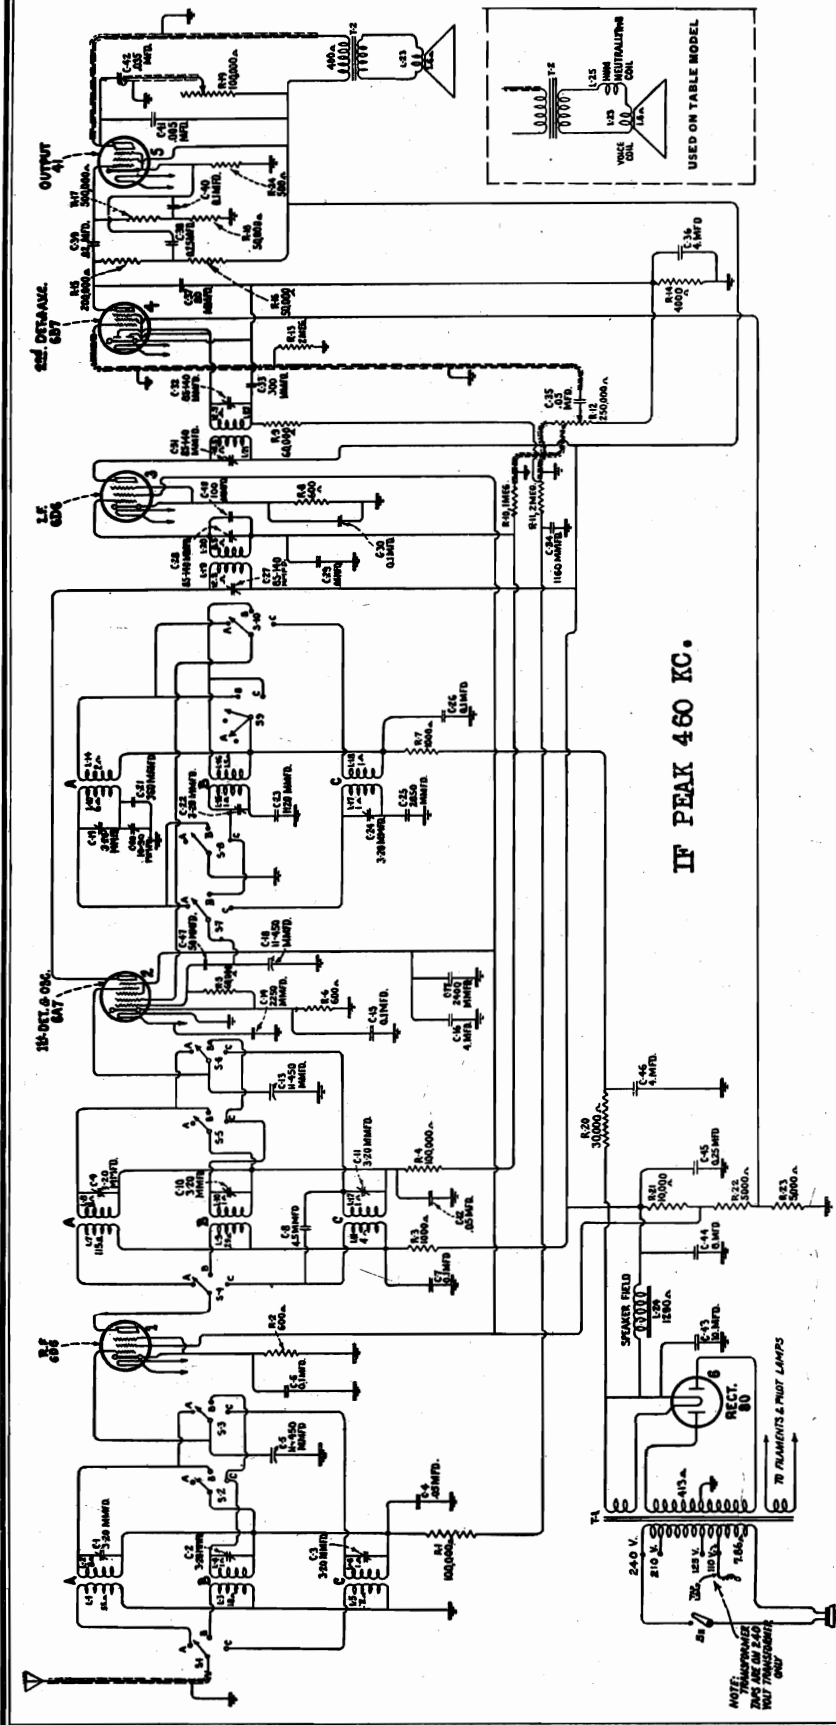

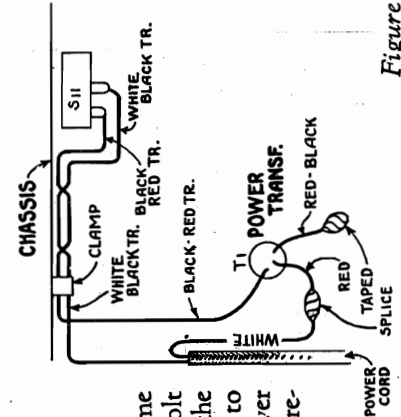

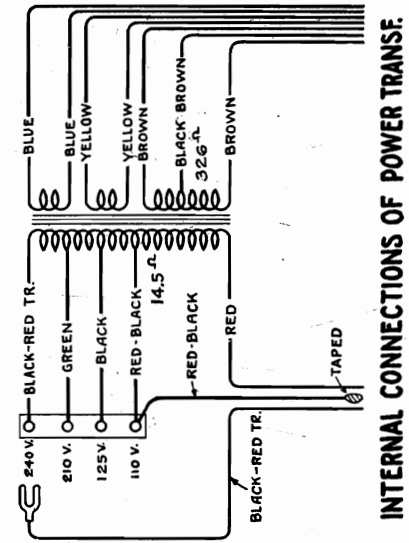

Figure 1—Schematic Circuit Diagram

POWER TRANSFORMER CONNECTIONS

The 220-volt power transformer furnished with some instruments includes taps for operating on 110-volt lines. Figure 5 shows the schematic circuit of the transformer and the proper voltage to be applied to the various taps. The taps are located on the power transformer assembly and are accessible without removing the chassis from the cabinet.

 Circuit Data

DESCRIPTION OF ELECTRICAL CIRCUIT

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector, an I. F. stage, a combined second detector and automatic volume control and a single Pentode output stage. An RCA-80 rectifier, together with a suitable filtering system, provides plate and grid voltages for all tubes and field excitation for the loudspeaker. Figure 1 shows the schematic circuit diagram, Figure 2 the chassis wiring, and Figures 3 and 4 the loudspeaker wiring.

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang-capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang-capacitor.

Combined with the signal in the first detector is the local oscillator, which is always at a 460 K. C. frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang-capacitor are used in this circuit.

In conjunction with these three tuned circuits, it is well to point out that three different groups of tuned circuits are used, one for each tuning band. A three-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to the absorption effects caused by the coils, the natural period of which, with tuning capacitor disconnected, fall in the next higher frequency band.

The output of the first detector, which is the I. F. signal (460 K. C.), is fed directly through two tuned circuits to the grid of the I. F. amplifier stage. The I. F. stage, which utilizes Radiotron RCA-6D6, uses two transformers, which consist of four tuned circuits, all of which are tuned to 460 K. C.

The output of the I. F. amplifier is then applied to the diode electrodes of the RCA-6B7, which is a combined second detector, automatic volume control and A. F. amplifier. The direct current component of the rectified signal produces a voltage drop across resistor

Figure 7—Tube Socket Voltages

ALL VOLTAGES ARE TO GROUND

RCA-VICTOR CO., INC.

(3) R. F. OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS

Four R. F., oscillator and first detector adjustments are required in band "A." Three are required in bands "B" and "C."

To properly align the various bands, each band must be aligned individually in the order given. This is "A," "B" and "C." The preliminary set-up requires the external oscillator to be connected between the antenna and ground terminals of the receiver and the output indicator must be connected across the voice coil of the loudspeaker. The volume control must be at its maximum position and the input from the oscillator must be at the minimum value possible to get an output indication under these conditions. In the high frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.

The dial pointer must be properly set before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end of the pointer should point exactly at the horizontal line at the lowest frequency end of band "A," while the other end should point to within $\frac{1}{4}$ -inch of the horizontal line at the highest frequency end of band "A."

Figure 8—Location of Coils in Shields

Figure 6 shows the location of the trimmers for each band. Care must be exercised to merely adjust the trimmers in the band under test.

Band "A"

- (a) Set the Band Switch at "A."
- (b) The oscillator series capacitor, located on the rear apron of the chassis, should be set at about the center of its range.
- (c) Tune the external oscillator to 1,720 K. C., set the pointer at 1,720 K. C. and adjust the oscillator, detector and R.-F. trimmers for maximum output.

(d) Shift the external oscillator frequency to 600 K. C. Tune in the 600 K. C. signal, irrespective of scale calibration, and adjust the series trimmers, located on rear apron of chassis, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 1,720 K. C. as described in (c).

Band "B"

- (a) Set the Band Switch at "B."
- (b) The detector and antenna trimmers should first be tightened to approximately $\frac{3}{4}$ maximum capacity (turned $\frac{3}{4}$ inch).
- (c) Tune the external oscillator to 5,160 K. C., set the pointer at 5,160 K. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
- (d) Check for the image signal which should be received at approximately 4,240 K. C. on the dial. It may be necessary to increase the external oscillator output for this check.
- (e) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then aligned with the oscillator circuit and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

(f) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Band "C"

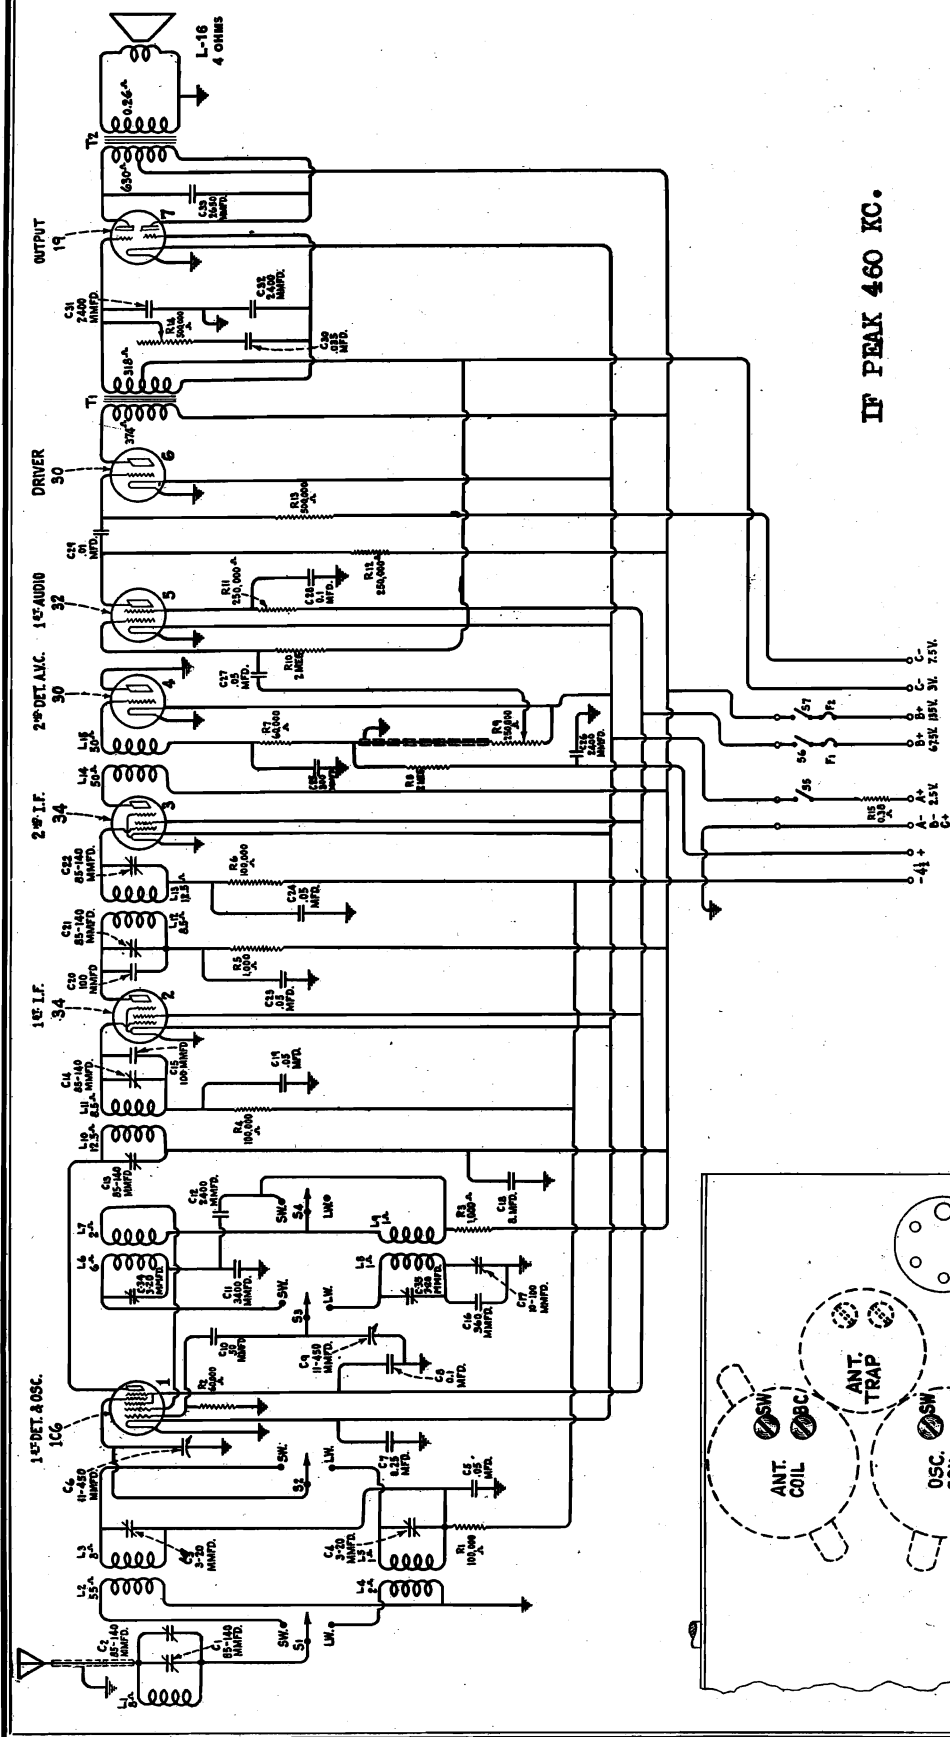

- (a) Set the Band Switch at "C."
- (b) The detector and antenna trimmers should first be tightened to approximately $\frac{3}{4}$ maximum capacity (turned $\frac{3}{4}$ in.)
- (c) Tune the external oscillator to 18,000 K. C., set the pointer at 18 M. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
- (d) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.

(e) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then aligned with the oscillator circuit and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

(f) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Circuit Data
Alignment Data

SERVICE DATA

Electrical Specifications

Voltage Rating.....	100-125 Volts and 200-250 Volts
Frequency Rating.....	25-60 (100-125 Volts Only) and 50-60 Cycles
Power Consumption.....	110 Watts
Type and Number of Radiotrons.....	3 RCA-58, 1 RCA-2A7, 1 RCA-2B7, 1 RCA-56, 1 RCA-53, 1 RCA-80—Total, 8
Type of Circuit.....	Straight Super-Heterodyne for all frequencies with Class "B" Output Stage.
Undistorted Output.....	6 Watts

This all-wave super-heterodyne receiver is of the continuous tuning type, utilizing a straight super-heterodyne circuit in all bands. The bands are as follows:

Selector Switch Position	Frequency Range (Kilocycles)	Wave-Length Range (Meters)
X	150-410	2000-732
A	540-1500	555-200
B	1500-3900	200-77.0
C	3900-10000	77.0-300
D	8000-18000	37.5-16.7

This receiver will be supplied in two models, one including all bands and one with band X omitted. These instructions, however, will cover both types of the receiver. The variations in the wiring for the two models are plainly shown in the illustrations. Figures A, B and C show the schematic circuit and wiring diagrams.

The circuit consists of an R. F. stage using Radiotron RCA-58, a combined oscillator and first detector using Radiotron RCA-2A7, an I. F. stage using RCA-58, a second detector and A. V. C. using RCA-2B7, an A. F. driver using RCA-56, and a Class "B" output stage using an RCA-53. The RCA-80 functions as the rectifier in the power supply circuits.

The foregoing tubes and circuit functions apply to bands X, A, B and C only. In the case of band D, an additional R. F. stage utilizing an additional Radiotron RCA-58 is used. This is to increase the sensitivity and image frequency selectivity and to reduce the interference caused by tube hiss and signals corresponding to the intermediate frequency.

The intermediate frequency is 445 K. C. The use of this frequency gives an especially good image frequency ratio and facilitates alignment of the oscillator at the higher frequency bands.

Mechanical Construction

The chassis consists of two major assemblies, which must be disassembled for certain repair work. These assemblies consist of the chassis proper, including the main frame, power transformer, etc., and the coil assembly. The coil assembly consists of fifteen transformers supported upon individual tubular bakelite forms, each fastened to a separate porcelain strip upon which the coil terminals are mounted with their associate trimmer capacitor. This entire assembly, with the selector switch, is grouped in a shielded compartment which is mounted in the base of the main chassis assembly.

In order to remove this assembly it is necessary to remove the four nuts shown in Figure D and unsolder the connections of the fifteen leads shown in Figure C at the points where they connect to the main chassis. The leads should be allowed to remain on the coil assembly. After this is done,

the coil assembly may be removed and repairs to it or to the main chassis may be easily made. If a coil or its associated trimmer is to be replaced, then only the bottom shield of the coil assembly must be removed. This is done by removing the four nuts that hold it to the chassis studs. This is shown in Figure D.

Line-Up Capacitor Adjustments

This receiver is aligned in a similar manner to that of a standard broadcast band receiver. That is, the three main tuning capacitors are aligned by means of three trimmers in each band and, on the three lowest frequency bands, a series trimmer is adjusted for aligning the oscillator circuit. The other two bands do not require this low-frequency trimmer, it being fixed in value. In the case of band D, it is necessary to adjust four trimmers, due to the additional F. R. stage used.

The intermediate frequency amplifier is aligned in a similar manner to that of standard broadcast receivers except that it is aligned at 445 K. C. In order to properly align the receiver, it is essential that the Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 90 K. C. to 25,000 K. C., continuously, has good stability and includes an attenuator. In addition to the oscillator, a 300-ohm resistor, for use as a "dummy" antenna, a non-metallic screw-driver such as Stock No. 4160, and an output meter are required. The output meter should be preferably a thermocouple galvanometer connected either across or in place of the cone coil of the loudspeaker.

To align the intermediate frequency circuits, connect the output of the external oscillator to the grid of the first detector. For the R. F. and oscillator adjustments, the oscillator output should be connected to the antenna and ground terminals of the receiver with a 300-ohm resistor inserted in series with the antenna lead. In many cases, however, the signal strength obtained with this direct connection will be too great to permit proper alignment, even at the minimum setting of the oscillator attenuator. When this is true, the external oscillator must be loose-coupled to the receiver. This is done by connecting the 300-ohm resistor between the antenna and ground terminals of the receiver and attaching a short length of wire to the antenna post. Lay the free end of this wire across the oscillator case, adjusting its position as necessary to obtain the degree of pickup required.

The output of the external oscillator should be at the minimum value necessary to obtain a deflection in the output meter when the volume control is at its maximum position. All adjustments are made for a maximum deflection in the output meter.

The accuracy of line-up of each band may be checked without touching the trimmer condensers, by the use of the tuning wand, Stock No. 6679.

One end of the wand consists of a brass cylinder. When this is inserted in a coil the effective inductance of the coil is lowered.

The other end of the wand contains a special finely divided iron suitable for use at radio frequencies. When this is inserted in a coil the inductance is raised.

To use the tuning wand a signal is first tuned in at the frequency at which a check is desired on alignment. The wand is then inserted slowly in the Antenna and R. F. transformers, using first one end and then the other end of the wand. Unless the alignment is perfect, it will be found that the power output indicated by the meter will be increased to a peak for a critical position of the wand in the coils.

The end of the wand required indicates whether the coil is high or low.

Voltage
Wave Band Data

Power Supply—The instruments in this series are supplied in either of two alternating current power supply ratings: (1) 100-125/200-250 volts, 50-60 cycles and (2) 100-125 volts, 25-60 cycles (see rating label inside cabinet). To insure correct Radiotron operating voltages, both types are equipped to permit rearrangement of the internal connections to conform with the actual voltage available. Thus, the 50-60 cycle models may be adapted for 100-115, 115-125, 200-230 or 230-250 volts; and the 25-60 cycle models for either 100-115 or 115-125 volts.

Of course, alignment correction at the high-frequency end of a tuning range should be accomplished by the use of the trimmer condenser. If alignment correction should be required at the low-frequency end of a tuning range, it may be accomplished by sliding the end coil of the transformer. The winding farthest from the trimmer panel is pushed toward the trimmer panel to increase the inductance, and farther away to decrease the inductance. On band D coils, the last two or three turns may be pushed in a similar manner to obtain the proper inductance.

This adjustment should not be attempted unless a quite appreciable improvement will result (as shown by the tuning wand).

The following chart gives the details of all line-up adjustments. The receiver should be lined up in the order of the adjustments given on the chart. Refer to Figure E for the location of the line-up capacitors.

Pickup Connections

A terminal board is provided at the rear of the chassis for attaching a magnetic pickup to this instrument. Such connections are shown in Figures F, G and H.

Transformer Connections

The power transformer of the 50-60 cycle receiver uses two tapped primary windings. By connecting them in parallel or in series, the receiver may be used either on 110 or 220 volt lines. Figure J shows the proper manner of making the various connections possible for this transformer.

The 25-60 cycle transformer uses only one 100-125-volt winding, a tap being provided for the lower voltages. Normally the transformer is connected for 115-125-volt lines, but the connection shown in Figure I may be used for 100-115-volt lines.

TUBE SOCKET VOLTAGES

* Voltages and current apply to detector portion of tube.

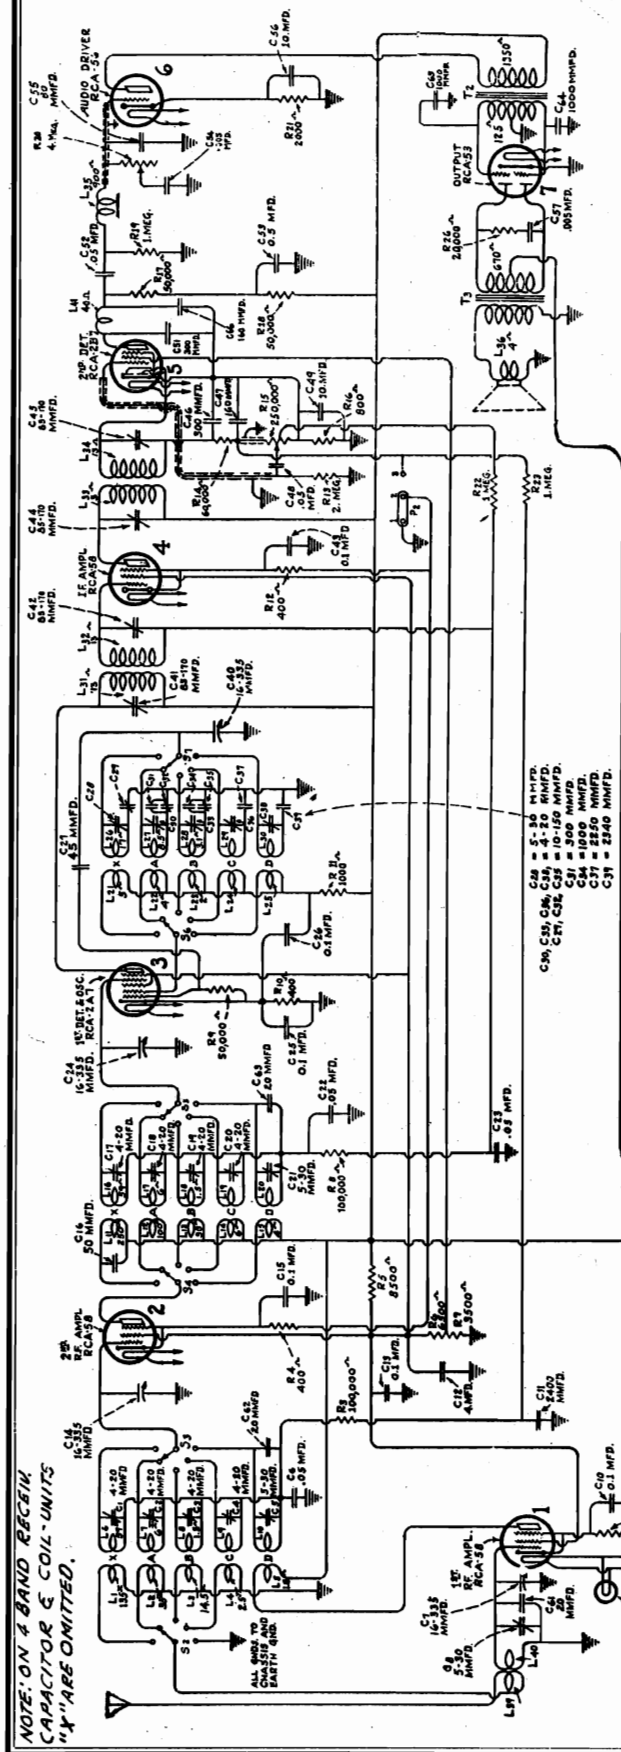

** These voltages cannot be measured because of the high resistance of the circuits.

External Oscillator Frequency	Dial Setting	Location of Line-Up Capacitors	Position of Selector Switch	Adjust for	Number of Adjustments To be Made
445 K. C.	Any setting that does not bring in station.	At rear of chassis.	Any position that does not bring in station.	Maximum output.	4
370 K. C.	370 K. C.	Bottom of chassis.	X	Maximum output.	3
175 K. C.	Set for signal.	Top of chassis.	X	Maximum output while rocking dial back and forth.	1
1400 K. C.	1400 K. C.	Bottom of chassis.	A	Maximum output.	3
600 K. C.	Set for signal.	Top of chassis.	A	Maximum output while rocking dial back and forth.	1
3900 K. C.	3900 K. C.	Bottom of chassis.	B	Maximum output.	3
1710 K. C.	Set for signal.	Top of chassis.	B	Maximum output while rocking dial back and forth.	1
10 M. C.	10 M. C.	Bottom of chassis.	C	Maximum output. (See Note.)	3
15 or 18 M. C.	15 or 18 M. C.	Bottom and top.	D	Maximum output. (See Note.)	4

NOTE—It is important to note, when aligning bands C and D, that two peaks will be observed on the trimmers for the oscillator and for the first detector. The correct oscillator peak is the one obtained using the lower trimmer capacitance, whereas the correct detector peak is the one obtained with the greater capacitance. It is essential that the proper peak be chosen, as otherwise tracking and sensitivity will be very poor at other frequencies. When adjusting the detector trimmer, the tuning capacitor should be rocked, since there is a reaction on the oscillator tuning.

This eight-tube, four-band Superheterodyne receiver is of the "all-wave" type, having a continuous tuning range extending from 140 K. C. to 18,000 K. C., except for one break between 410 K. C. and 540 K. C. Such a tuning range permits the listener to receive all of the important broadcasting, police, aircraft and amateur call bands used throughout the world.

Excellent sensitivity, selectivity and tone quality,

together with a high output (4 watts undistorted), Class A amplifier gives the receiver outstanding performance. Operating features include an "airplane" type dial, a double-ratio vernier drive, a visual band indicator, and a special "second hand" on the dial for logging short-wave stations. Other important features include automatic volume control, sensitivity control, large loudspeaker unit and a terminal board for easily attaching a magnetic pickup.

DESCRIPTION OF ELECTRICAL CIRCUIT

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector, an I. F. stage, a combined second detector and automatic volume control, a first audio stage and a push-pull Pentode output stage. An RCA-80 rectifier, together with a suitable filtering system, provides plate and grid voltages for all tubes and field excitation for the loudspeaker. Figures 1 and 2 show the schematic diagrams, Figures 5 and 7 the chassis wiring, and Figures 3 and 4 the loudspeaker wiring.

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang capacitor.

Combined with the signal in the first detector is the local oscillator, which is always at a 460 K. C. frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang capacitor are used in this circuit.

In conjunction with these three tuned circuits, it is well to point out that four different groups of tuned circuits are used, one for each tuning band. A four-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to the absorption effects caused by the coils, the natural period of which, with the tuning capacitor disconnected, falls in the next higher frequency band.

MODEL 143,242
Loud Speaker Data
Circuit Data

RCA-VICTOR CO., INC.

The output of the first detector, which is the I. F. signal (460 K. C.), is fed directly through two tuned circuits to the grid of the I. F. amplifier stage. The I. F. stage, which utilizes Radiotron RCA-6D6, uses two transformers, which consist of four tuned circuits, all of which are tuned to 460 K. C.

Figure 3—Console Loudspeaker Wiring

The output of the I. F. amplifier is then applied to the diode electrodes of the RCA-75, which is a combined second detector, automatic volume control and A. F. amplifier. The direct current component of the rectified signal produces a voltage drop across resistor R-32. The full voltage drop constitutes the automatic bias voltage for the R. F. while a tap is provided for the first detector and I. F. voltage. These automatic bias voltages for the R. F., first detector and I. F. give the automatic volume control action of the receiver. The volume control selects the amount of audio voltage that is applied to the grid of the RCA-75 and thereby regulates the audio output of the entire receiver.

The output of the detector is resistance coupled to the grid of the RCA-76, first audio stage, which is transformer coupled to the push-pull output stage. On some models the grid coupling resistor between

the detector and audio stage is 1 megohm (R-21, Figure 1). Other models have two resistors, R-59, 400,000 ohms, and R-21, 2 megohms (Figure 2), with the band selector switch shorting out R-21 in bands B and C. The purpose of this latter type of connection is to reduce the low frequency output in bands B and C, thereby improving the performance of the receiver in these bands.

The output stage uses two RCA-42's, which give a low distortion, high audio output to the loudspeaker. A high frequency tone control, which consists of a variable resistor and capacitor, is connected across the grids of the output stage. At the minimum resistance position of the variable resistor, maximum attenuation of the high audio frequencies is obtained.

Figure 4—Table Loudspeaker Wiring

The plate circuit of the output stage is matched to the cone coil of the reproducer by means of a step-down transformer.

Plate and grid voltages for all tubes are supplied from the output of the rectifier-filter system. An RCA-5Z3 is used as a rectifier and a suitable network of capacitors and resistors gives the necessary filtering and voltages. The loudspeaker field is used as a filter reactor.

SERVICE DATA

(1) LINE-UP PROCEDURE

The line-up procedure of this receiver is somewhat involved and it is important that these instructions be carefully followed when making adjustments. Properly aligned, this receiver has outstanding performance; improperly aligned, it may be impossible to receive signals on all bands.

Equipment

To properly align this receiver, proper test equipment must be used. This consists of a modulated R. F. oscillator having proper frequency range, an output indicator, an alignment tool and a tuning wand.

These parts, which are shown on page 15, have been developed by the manufacturer of this receiver for use by service men to duplicate the original factory adjustments.

Checking With Tuning Wand

Before making any R. F., oscillator or first detector adjustments, the accuracy of the present adjustments may be checked by means of the tuning wand (Stock No. 6679). The tuning wand consists of a bakelite rod having a brass cylinder at one end and a special finely divided iron insert at the other end. Inserting the cylinder into the center of a coil lowers its inductance,

RCA-VICTOR CO., INC.

MODEL 143,242
Alignment Data
Voltage

- (c) Check for the image signal, which should be received at approximately 4,740 K.C. on the dial. It will be necessary to increase the external oscillator output for this check.
- (d) The antenna and detector trimmers should now be peaked for maximum output.

Band "C"

- (a) Set the band switch at "C."
- (b) Tune the external oscillator to 18,000 K.C. and set the pointer at 18 M. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
- (c) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.
- (d) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then at the oscillator frequency and the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.
- (e) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

To properly align the various bands, each band must be aligned individually. The preliminary set-up requires the external oscillator to be connected between the antenna and ground terminals of the receiver and the output indicator across the voice coil of the loudspeaker. The volume and sensitivity controls must be at the maximum position and the input from the oscillator must be at the minimum value possible to get an output indication under these conditions. In the high frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.

The dial pointer must be properly set before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end of the pointer should point exactly at the horizontal line at the lowest frequency end of Band "A," while the other end should point to within 1/64 inch of the horizontal line at the highest frequency end of Band "A."

Figure 8 shows the location of the trimmers for each band. Care must be exercised to only adjust the trimmers in the band under test.

Band "X"

- (a) Set the band switch at "X."
- (b) Tune the external oscillator to 410 K.C., set the dial pointer at 410 K.C. and adjust the oscillator, detector and R.F. trimmers for maximum output.
- (c) Shift the external oscillator frequency to 175 K.C. Tune in the 175 K.C. signal irrespective of scale calibration and adjust the series trimmer, marked 175 K.C. on Figure 8, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 410 K.C. as described in (b).
- Band "A"
- (a) Set the band switch at "A."
- (b) Tune the external oscillator to 1,720 K.C., set the pointer at 1,720 K.C. and adjust the oscillator, detector and R.F. trimmers for maximum output.
- (c) Shift the external oscillator frequency to 600 K.C. Tune in the 600 K.C. signal, irrespective of scale calibration, and adjust the series trimmers, marked 600 K.C., Figure 8, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 1,720 K.C. as described in (b).

Band "B"

- (a) Set the band switch at "B."
- (b) Tune the external oscillator to 5,160 K.C. and set the pointer at 5,160 K.C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.

while inserting the iron end increases its inductance. From this, it is seen that unless the trimmer adjustment for a particular coil is perfect at alignment frequencies, inserting one end of the wand may increase the output of a particular signal. A perfect adjustment is evidenced by a lowering of output when either end of the wand is inserted into a coil.

The shields over the R. F. coil assembly have a hole at their top for entrance of the tuning wand. The location of the various coils inside of the shield is shown in Figure 6. An example of the proper manner of using the tuning wand would be to assume the external oscillator were set at 1720 K. C. and the signal tuned in, and the output indicator connected across the voice coil of the loudspeaker. Then the tuning wand should be inserted, first one end and then the other end, into the top of the three transformers at the left of the R. F. assembly, facing the front of the chassis. A perfect adjustment of the trimmer would be evidenced by a reduction in output when each end of the wand is inserted in each of the three transformers. If one end—for example, the iron end—when inserted in one coil caused an increase in output, then that circuit is low. An increase in the trimmer capacitance would be the proper remedy.

(8) I. F. TUNING CAPACITOR ADJUSTMENTS

This receiver has one I. F. stage with two transformers having four adjustable capacitors that may require adjustment. The transformers are all peaked at 460 K. C.

A detailed procedure for making this adjustment follows:

- (a) Connect the output of an external oscillator tuned to 460 K. C. between the first detector grid and ground. Connect the output indicator across the voice coil of the loudspeaker.
- (b) Place the oscillator in operation and adjust the station selector until a point is reached (Band A) where no signals are heard and turn the volume control to its maximum position. Reduce the oscillator input until a slight indication is obtained in the output indicator.
- (c) Refer to Figure 8. Adjust each trimmer of the I. F. transformers until maximum output is obtained. Go over the adjustments a second time.

This completes the I. F. adjustments. However, it is good practice to follow the I. F. adjustments with the R. F. and oscillator adjustments due to interlocking which always occurs.

(3) R. F., OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS

Four R. F., oscillator and first detector adjustments are required in Bands "A," and "X." Three are required in Bands "B" and "C."

Figure 6—Location of Coils in Shields

Group 3—R-28 and C-52 are removed from the resistor board inside of chassis and mounted externally on phonograph terminal board. No. 3 terminal has been added to terminal board. Electrically, this group is identical with Group 2, the schematic and wiring diagrams being shown in Figures 1 and 5.

Group 4—Resistor R-10 has been removed. Resistor R-59 has been added and Resistor R-21 has been changed to 2 megohms. Capacitors C-52 and C-43 have been changed to 1120 mmfd. Figures 2 and 7 show the schematic and wiring diagrams of the models having these changes.

(7) FIDELITY LINK

It will be noted that a small link is mounted on the rear apron of the chassis which is closed on table models and open on console models. The purpose of the link is to increase the low frequency output of the receiver when open.

(8) VOLTAGE READINGS

The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if low-resistance meters are used, such allowances must be made.

Electrical Specifications

Voltage Rating.....100-125 Volts
 Frequency Rating.....25-60 and 50-60 Cycle
 Power Consumption.....60 Cycle, 75 Watts; 25 Cycle, 80 Watts
 Number and Type of Tubes.....2 RCA-58,
 1 RCA-2A7, 1 RCA-2B7, 1 RCA-2A5, 1 RCA-80—Total 6
 Tuning Ranges.....540 K. C.—1500 K. C.—5400 K. C.—15,350 K. C.
 Undistorted Output.....1.75 Watts

Figure C—Loudspeaker Wiring

This receiver is a six-tube two-band A. C. operated Superheterodyne Receiver combining the standard and short-wave broadcasting bands. The frequency ranges are selected by means of a two-position switch. Other features include a double reduction vernier drive using two concentric knobs giving a 10-1 and a 55-1 ratio of speed reduction, a continuously variable tone control, ten-inch electrodynamic loudspeaker, automatic volume control, single Pentode output tube and the inherent sensitivity, selectivity and tone quality of the Superheterodyne.

The chassis is of compact construction, affording unusual accessibility to all parts and adjustments. An "Airplane" type dial calibrated in frequency and showing the location of the short-wave bands is a special feature of this instrument. Figure A shows the schematic circuit, Figure B the wiring diagram and Figure C the loudspeaker wiring.

Line-Up Capacitor Adjustments

In order to properly align this receiver, it is essential that Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 150 K. C. to 20,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a non-metallic screwdriver such as Stock No. 7065 and an output meter are required. The output meter should be preferably a thermo-couple galvanometer connected across or in place of the cone coil of the loudspeaker.

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 370 K. C. and the adjustment screws are accessible as shown in Figure D. Proceed as follows:

- (a) Short-circuit the antenna and ground terminals and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- (b) Connect the test oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- (c) Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments—The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual

position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the rear of the chassis. Proceed as follows:

- (a) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully meshed. It should be coincident with the radial line adjacent to the dial reading of 540. Then set the Test Oscillator at 1400 K. C., the dial indicator at 1400 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.
- (b) With the Range Switch at the "in" position, adjust the three trimmers under the three R. F. coils, designated as L. W. in Figure D, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor, accessible from the rear of the chassis, should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1400 K. C. adjustment.
- (c) Now place the Range Switch at the "out" position, shift the Test Oscillator to 15,000 K. C. and set the dial at 15 on the megacycle scale. Adjust the three trimmer capacitors designated as S. W. in Figure D for maximum output, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two positions at which the signal will give maximum output. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator, while the position that uses a higher capacitance is correct for the detector. Both of these adjustments must be made as indicated irrespective of output. The R. F. is merely peaked. In conjunction with the detector adjustment, it is necessary to rock the main tuning capacitor back and forth while making the adjustment. This completes the line-up adjustments.

The important points to remember are the need for using the minimum oscillator output to obtain a deflection in the output meter with the volume control at its maximum position and the manner of obtaining the proper high frequency oscillator and detector adjustments.

Power Transformer Connections

The power transformer used in this model has a tapped primary winding. The transformer is normally connected for lines ranging in voltage from 110 to 125 volts. If for any reason the line is normally below 110 volts,

Figure D—Location of Line-Up Capacitors

the connections should be changed so the tap will be used. This is done by unsoldering the black with red tracer transformer lead connected to the power switch (on tone control) and substituting the red and black lead normally taped up. The black with red tracer lead should then be carefully taped to prevent short-circuit.

115 Volts, A. C. Line—No Signal

RCA VICTOR MODEL 223
SERVICE NOTES

Electrical Specifications

Voltage Rating.....26-40 Volts D. C.
Power Consumption.....60 Watts at 32 Volts
Number and Types of Radiotrons.....2 RCA-6D6,
1 RCA-6A7, 1 RCA-6B7, 1 RCA-38, 1 RCA-84
—Total, 6
Type of Ballast Lamp.....Amperize 5-16
Undisordered Output.....1.1 Watts (Max. 1.6 Watts)
Tuning Frequency Range.....540 K. C.—1500 K. C.
and 1400 K. C.—2800 K. C.

This receiver is a six-tube, 32-volt D. C. super-heterodyne designed primarily for operation from 32-volt farm lighting circuits. Excellent sensitivity and selectivity, large undisordered output and excellent tone quality are inherent features of this receiver. Other outstanding features include 10-inch electro-dynamic loudspeaker, wide tuning range (police, aviation and broadcast), ballast lamp for voltage fluctuations, and a separate power supply with a newly designed filter units.

Figure 1 shows the schematic circuit diagram, Figures 2 and 3 the chassis and power unit wiring, and Figure 5 the assembly wiring diagram. The replacement parts are given on page 9.

Description of Circuit

The circuit of this receiver is similar in many ways to the usual six-tube superheterodyne, although the power supply differs in several respects. Chiefly among the differences is the use of a vibrator interrupter for obtaining alternating current and a tube rectifier for rectifying it at a higher voltage.

The R. F. stage uses Radiotron RCA-6D6, which is a six-volt heater type super-control R. F. amplifying tube. The function of this stage is to select and amplify the desired incoming signal and apply it to the first detector.

The next tube is a combined oscillator-detector which is known as the RCA-6A7 and which provides a local signal and a detector for obtaining an I. F. frequency. The local oscillator, due to the bridge circuits used, provides a signal that has a constant frequency difference from the incoming R. F. signal (175 K. C. higher) at all points throughout the tuning range. The detector portion of the tube serves to extract the beat frequency from the combined signals (oscillator and signal) and apply it to the grid of the I. F. stage.

The plate circuit of the first detector and the grid and plate circuits of the I. F. tube are all tuned by

taps and capacitors is to change the tuning range as follows:

1. At the broadcast position all of the additional circuits are open as shown in Figure 1.
2. At the police band position, all of the additional switches are closed. Shorting of turns in the grid coils reduces their inductance so that the tuning capacitors cover the high frequency range. Connecting the two coupling capacitors increases the coupling and thereby the sensitivity at the higher frequency position. The trimmer capacitor on the oscillator circuit provides proper tracking with the R. F. circuits.

Line-up Adjustments

Inoperation, poor tone quality, or lack of proper sensitivity and selectivity are direct results of lack of alignment. In event the receiver is to be aligned, carefully use the following procedure:

1. TUNING ADJUSTMENTS—Two transformers comprising three tuned circuits (the secondary of the second transformer is untuned) are used in the intermediate amplifier. These are tuned to 175 K. C. and the adjustment screws are accessible as shown in Figure 4. Proceed as follows:
 - (a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screwdriver such as Stock No. 4160 and an output meter. Test Oscillator, Stock No. 9050, is suitable and recommended for making these adjustments.
 - (b) Short-circuit the antenna and ground terminals. Set the volume control at maximum and connect a ground to the chassis.
 - (c) Connect the oscillator output between the first detector control grid and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that with the receiver volume control at maximum, a slight deflection is obtained in the output meter.

Field excitation for the loudspeaker is obtained by connecting it directly across the 32-volt direct current supply. Heater excitation for the tubes described is obtained by connecting them in series and placing the entire circuit across the 32-volt line.

Plate and grid voltages for all tubes are obtained from a special plate supply unit which consists of a vibrator, a tube rectifier, a thermal voltage regulator and a special filter network for reducing hum or vibrator interference to a negligible degree. The purpose of the vibrator is to interrupt the direct current and apply it first in one direction and then in the opposite direction across individual sections of the primary of the power transformer. The transformer steps the voltage up several times and applies it to the plates of the full-wave rectifier, Radiotron RCA-84. The filament of this tube is connected in series with the Amperize 5-16 voltage regulating tube. This regulating tube maintains a constant current through the rectifier filament over a wide variation of line voltages.

TUBE SOCKET VOLTAGES

32-Volt D.C. Input — No Signal — Volume Control at Minimum

RADIOTRON No.	CATHODE TO GROUND, VOLTS	CATHODE TO SCREEN GRID, VOLTS	CATHODE TO PLATE, VOLTS	PLATE CURRENT, M. A.	HEATER VOLTS
RCA-6D6 R. F.	8.4	77	246	4.2	6.2
RCA-6A7—Osc. Det.	9.7	76	245	6.5	6.2
RCA-6D6 I. F.	8.4	77	246	4.2	6.2
RCA-6B7—2nd Det.	5.7	80	52	1.9	6.2
RCA-38 Pwr.	19.5	205	197	24.5	6.2
RCA-84 Rect.	244			50	6.5-7.0*

*Varies with ballast tubes and with time.

- (a) Procure a modulated oscillator giving a signal at 1400 and 2440 K. C. (Stock No. 9050), a non-metallic screwdriver such as Stock No. 4160, and an output meter.
- (b) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be at the last division. Then set the dial at 140, the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.
- (c) With the Range Switch at the counter-clockwise position, adjust the three tuning condenser line-up capacitors until maximum deflection is obtained in the output meter. Then shift the oscillator to 2440 K. C., the Range Switch to the clockwise position and the dial to 120. The three line-up capacitors located on the Range Switch should then be adjusted for maximum output.

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position. Also the minimum input signal necessary from the oscillator will permit a more accurate adjustment.

R. F. AND OSCILLATOR ADJUSTMENTS—The three-gang capacitor screws are accessible at the bottom of the chassis. The high frequency capacitor screws are located on the Range Switch. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 1400 and 2440 K. C. (Stock No. 9050), a non-metallic screwdriver such as Stock No. 4160, and an output meter.
- (b) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the dial at the extreme maximum position of the tuning capacitor. The indicator should be at the last division. Then set the dial at 140, the oscillator at 1400 K. C. and connect the output meter across the cone coil. Adjust the oscillator output so that a slight deflection is obtained when the receiver volume control is at maximum.
- (c) With the Range Switch at the counter-clockwise position, adjust the three tuning condenser line-up capacitors until maximum deflection is obtained in the output meter. Then shift the oscillator to 2440 K. C., the Range Switch to the clockwise position and the dial to 120. The three line-up capacitors located on the Range Switch should then be adjusted for maximum output.

When making both the I. F. and R. F. adjustments, the important point to remember is that the receiver volume control must be at its maximum position. Also the minimum input signal necessary from the oscillator will permit a more accurate adjustment.

Noise Suppression
Assembly Wiring**

RCA-VICTOR CO., INC.

Figure 5—Assembly Wiring Diagram

SUPPRESSION OF GENERATOR AND IGNITION INTERFERENCE

GENERATOR CAPACITOR.—A capacitor is connected from each brush of the generator to the generator frame, which must be grounded. This reduces the interference caused by sparking at the commutator of the generator. If excessive sparking occurs, it is very unlikely that the capacitors will reduce the noise sufficiently. In this case, the commutator must be thoroughly cleaned and sanded and the brushes reseated. In bad cases it is usually best to clean the foreign matter from between the commutator segments by means of a three-cornered file, and then sand the commutator by placing the sand-paper around a small block and holding it squarely against the commutator while it is running. *Never use emery cloth.*

COIL CAPACITOR.—Some installations will require a capacitor connected from the battery side of the ignition coil to ground. This reduces the interference caused by the primary breaker.

CAVOUNS.—It is important that the frame of the generator be thoroughly grounded. A steel ground-rod, driven at least six feet in moist earth, provides a good ground. In event one side of the line is grounded, it is important that the ground be a good one. The ground should be applied at the generator, at the point where the line enters the building, where the radio receiver is located and at the extreme far end of the line.

Operating this receiver while the 32-volt generator is running may present difficulties caused by the radiation of radio-frequency interference from the generator and gasoline engine. This interference usually travels over the lightning lines and is picked up by the antenna system of the receiver. There are two methods of reducing this interference, both of which may be required in bad cases.

1. Suppression of the interference at its source by means of the accessories furnished with the receiver.
2. Placing the antenna in such a position that the interference will not be picked up, and using a Stock No. 7718 Shield Kit for transmitting the signal from the antenna to the receiver without picking up noise on the lead-in.

Figure 4 shows a typical installation of the suppression equipment. This equipment is connected as follows:
Suppressor.—In single-cylinder installations, the suppressor is connected to the spark-plug for the suppression of the high-tension interference generated at this point. In twin-cylinder installations, the single-distributor type suppressor should be installed and should eliminate this interference. However, in some cases it may be necessary to install both distributor and plug suppressors.

RCA-VICTOR CO., INC.

DESCRIPTION OF ELECTRICAL CIRCUIT

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector, and I. F. stage, a combined second detector and automatic volume control, an audio stage, a push-pull driver stage and a push-pull Pentode output stage. Plate and grid voltages are supplied by the RCA-5Z3 heavy duty rectifier combined with a suitable filtering stage, of which the loudspeaker field is a part. Figures 1 and 2 show the schematic circuit diagrams.

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang-capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang-capacitor.

Combined with the signal in the first detector is the local oscillator signal, which is always at a 460 KC frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang-capacitor are used in the oscillator circuit.

In conjunction with these three tuned circuits it is well to point out that five different groups of tuned circuits are used, one group for each tuning band. A five-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to absorption effects caused by the coils, the natural period of which without the gang-capacitor connected falls in the next higher frequency band. This gang-switch also has additional contacts for changing the sensitivity in the various bands.

The sensitivity control in bands X and A controls the R. F. and first detector while in bands B, C and D it controls the R. F., first detector and I. F. stage. This is caused by the action of the selector switch. It should also be noted that the sensitivity control is paralleled with a 500-ohm resistor (R-12, Figure 1) in bands B, C and D.

The output of the first detector, which is the I. F. signal (460 KC), is fed directly through two tuned circuits to the grid of the I. F. amplifier stage. The I. F. stage, which utilizes Radiotron RCA-6D6, uses two transformers, which consist of four tuned circuits, all of which are tuned to 460 KC.

The output of the I. F. amplifier is then applied to the grid of the RCA-76 second detector. The plate of this tube is connected to its cathode and the tube operated as a diode detector and automatic volume control. The direct current component of the rectified signal produces a voltage drop across resistors R-32 and R-17. The voltage drop across both resistors constitutes the automatic bias voltage for the R. F. stage, while the drop across R-17 alone constitutes

the bias voltage for the first detector and I. F. stage. These automatic bias voltages for the R. F., first detector and I. F. stages give the automatic volume control action of the receiver. It should be noted that resistor R-33 is connected in parallel across resistors R-32 and R-17. This reduces the total amount of resistance in the circuit to a proper value. Resistor R-34 and capacitor C-43, which are connected in series and from a tap on the volume control to ground, provide low frequency, low volume compensation.

The volume control selects the amount of audio voltage that is applied to the grid of the RCA-76 A. F. stage and thereby regulates the volume of the entire receiver. The first audio stage is coupled through a high and low frequency tone control system and transformer to the grid circuit of the push-pull drive stage. It should be noted that a link has been provided in series with the cathode of this stage, so that phonograph connections may be easily made if required.

The driver stage is transformer coupled to the output stage, which consists of two Radiotrons, RCA-42, connected in push-pull. A feature of the output stage is the use of fixed bias, which reduces distortion and increases the available output. This is accomplished by the use of the drop across R-29, which carries the entire DC output from the rectifier. Naturally the output stage uses but a portion of the total rectified current and current variations in it have but little effect on the drop across the resistor.

The output of the power stage is coupled through a step-down transformer to the voice coil of the loudspeaker. A separate winding, which is shunted by a capacitor, has been provided in this transformer which gives a very sharp, high-frequency cut-off for the entire audio system. This greatly reduces the reproduction of any high-frequency interchannel interference or other disturbance of a high-frequency character which is outside of the useful musical range.

VARIATIONS IN MODELS

The preceding description of the electrical circuit applies to numerous models of this receiver. However, there are other models in which a change from the foregoing has been made. This change consists of using the section of the band selector switch that formerly changed the sensitivity control, for changing the fidelity in various bands, the sensitivity remaining the same in all bands. This permits the receiver to maintain the utmost fidelity in bands X and A while reducing the low frequency output in bands B, C and D. Such a change results in improved performance.

The sensitivity control in these models operates as formerly in bands X and A. That is, the sensitivity control adjusts the residual bias for the R. F. and first detector stages.

Maximum Output.....	14 Watts

SERVICE DATA

A detailed procedure for making this adjustment follows:

- (a) Connect the output of an external oscillator tuned to 460 KC between the first detector grid and ground. Connect the output indicator across the voice coil of the loudspeaker.
- (b) Place the receiver in operation at 460 KC. Station selector in operation and adjust the volume control until a point is reached (Band A) where no signals are heard and turn the volume control to its maximum position. Reduce the oscillator input until a slight indication is obtained in the output indicator.

{ Band A—	540 KC—	1720 KC
{ Band B—	1720 KC—	5400 KC
{ Band C—	5400 KC—	18,000 KC
{ Band D—	18,000 KC—	36,000 KC

(1) LINE-UP PROCEDURE

The line-up procedure of this receiver is somewhat involved and it is important that these instructions be carefully followed when making adjustments. Properly aligned, this receiver has outstanding performance; improperly aligned, it may be impossible to receive signals on all bands.

Equipment

To align this receiver, proper test equipment must be used. This consists of a modulated R. F. oscillator having proper frequency range, an output indicator, an alignment tool and a tuning wand. These parts, which are shown on page 15, have been developed by the manufacturer of this receiver for use by service men to duplicate the original factory adjustments.

Checking with Tuning Wand

Before making any R. F. oscillator or first detector adjustments, the accuracy of the present adjustments may be checked by means of the tuning wand (Stock No. 6679). The tuning wand consists of a bakelite rod having a brass cylinder at one end and a special finely divided iron insert at the other end. Inserting the cylinder into the center of a coil lowers its inductance, while inserting the iron end increases its inductance. From this, it is seen that unless the trimmer adjustment for a particular coil is perfect at alignment frequencies, inserting one end of the wand may increase the output of a particular signal. A perfect adjustment is evidenced by a lowering of output when either end of the wand is inserted into a coil.

The shields over the R. F. coil assembly have a hole at their top for entrance of the tuning wand. The location of the various coils inside of the shield is shown in Figure 5. An example of the proper manner of using the tuning wand would be to assume the external oscillator were set at 1720 KC and the signal tuned in. The output indicator should be connected across the voice coil of the loudspeaker. Then insert the tuning wand, first one end and then the other end, into the top of the three transformers at the left of the R. F. assembly, facing the front of the chassis. A perfect adjustment of the trimmer would be evidenced by a reduction in output when each end of the wand is inserted in each of the three transformers. If one end—for example, the iron end—when inserted in one coil caused an increase in output, then that circuit is low. An increase in the trimmer capacitance would be the proper remedy.

(2) I. F. TUNING CAPACITOR ADJUSTMENTS

This receiver has one I. F. stage, and two transformers having four adjustable capacitors which may require adjustment. The transformers are all peaked at 460 KC.

requires the external oscillator to be connected between the antenna and ground terminals of the receiver and the output indicator must be connected across the voice coil of the loudspeakers. The volume control must be at its maximum position and the input from the oscillator must be at the minimum value possible to get an output indication under these conditions. In the high-frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.

The dial pointer must be properly set, before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end of the pointer should point exactly at the horizontal line at the lowest frequency end of band "A," while the other end should point to within 1/64 inch of the horizontal line at the highest frequency end of band "A."

Figure 7 shows the location of the trimmers for each band. Care must be exercised to only adjust the trimmers in the band under test.

Band "X"

- (a) Tune the external oscillator to 410 KC, set the pointer at 410 KC and adjust the oscillator, detector and R. F. trimmers for maximum output.
- (b) Shift the external oscillator to 175 KC. Tune in the 175 KC signal irrespective of scale calibration and adjust the series trimmer marked 175 KC on Figure 7 for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 410 KC as described in (a).

Band "A"

- (a) Tune the external oscillator to 1720 KC, set the pointer at 1720 KC and adjust the oscillator, detector and R. F. trimmers for maximum output.
- (b) Shift the external oscillator to 600 KC. Tune in the 600 KC signal irrespective of scale calibration and adjust the series trimmer, marked 600 KC, on Figure 7, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 1720 KC as described in (a).

Band "B"

- (a) Tune the external oscillator to 5160 KC, and set the pointer at 5160 KC. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
- (b) Check for the image signal, which should be received at approximately 4240, which should be it will be necessary to increase the external oscillator output for this check.

Figure 5—Location of Coils in Shields

- (c) Refer to Figure 7. Adjust each trimmer of the I. F. transformers until a maximum output is obtained. Go over the adjustments a second time.

This completes the I. F. adjustments. However, it is good practice to follow the I. F. adjustments with the R. F. and oscillator adjustments due to interlocking which always occurs.

(3) R. F. OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS

Four R. F. oscillator and first detector adjustments are required in bands "A," "X," "B," and "C." These are required in bands "B" and "C." None are required in band "D."

To properly align the various bands, each band must be aligned individually. The preliminary set-up

- (c) The antenna and detector trimmers should now be peaked for maximum output.

Band "C"

- (a) Tune the external oscillator to 18,000 KC, and set the pointer at 18 M. C. Adjust the oscillator trimmer for maximum output. The

Figure 9—Junior "Duo" Connections

trimmer should be set at the first peak obtained when increasing the trimmer capacity from minimum to maximum.

- (b) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.
- (c) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then aligned with the oscillator circuit, and the RCA-047 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

- (d) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Band "D"

No adjustments are required for band "D."

(4) MAGNETIC PICKUP CONNECTIONS

A terminal board (link in series with first audio stage cathode) is provided at the rear of the chassis for adding phonograph facilities to this instrument. Figure 9 shows the connections that will be required for the Junior "Duo" turntable assembly.

(5) VOLTAGE READINGS

The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if low-resistance meters are used, such allowances must be made. Figure 11 shows a chart in which the various voltages of the tube contacts are shown.

* R12 Resistor—500 ohms—Some Models

RCA-VICTOR CO., INC.

DESCRIPTION OF ELECTRICAL CIRCUIT

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector stage, two I. F. stages, a combined second detector and automatic volume control, a push-pull audio driver stage and a push-pull Class A output stage. Plate and grid voltages are supplied by the RCA-5Z3 heavy duty rectifier combined with a suitable filtering system. In addition, a double channel A. V. C. stage is provided

frequency band. This gang switch also has additional contacts for performing other functions which will be discussed.

The output of the first detector which is the I. F. signal (460 K. C.) is fed directly through two tuned circuits to the grid of the automatic volume control I. F. amplifier stage. A coupling coil adjacent to the secondary of this transformer is connected directly to the signal I. F. stage, which is in effect parallel to the A. V. C., I. F. stage. Examining the signal amplifier further we find that the output of the first signal I. F. stage is applied through a transformer to the second I. F. stage and thence through a second transformer to the second detector. Both circuits of each transformer are accurately tuned to the I. F. signal, which is 460 K. C.

Further examining the A. V. C., I. F. stage it will be seen that the output of this stage is applied to the A. V. C. tube through an untuned I. F. transformer. The A. V. C. stage, which is an RCA-76, is operated as a straight rectifier, its plate being grounded and only the grid being used. This tube is shielded in the usual manner. A small grid voltage, approximately 5.0 volts, is maintained so that rectification does not occur until the signal level exceeds this grid voltage. When this occurs, a portion of the rectified signal produces a voltage drop across resistors R-18 and R-19. The drop across both of these resistors constitutes the automatic bias voltage for the R. F. stage. The drop across R-19 alone gives the automatic bias voltage for the first detector and first I. F. stage on bands X and A.

Examining the second detector, the diode electrodes provide the detector action while the grid and plate give audio amplification. A portion of the rectified signal also gives a voltage drop across R-23 which is a second automatic volume control system for the receiver. The voltage drop is applied to the second I. F. stage in all bands and to the first detector and first I. F. stage in bands B and C. The change in

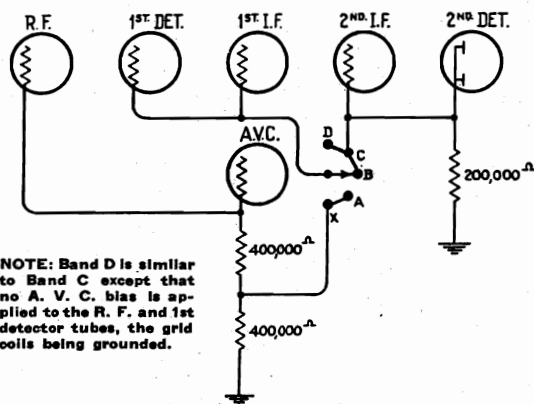

Figure 3—Switching Arrangement of Automatic Volume Control Systems

which uses two additional tubes. Figure 1 shows the over-all schematic circuit diagram while Figure 2 shows the R. F. assembly wiring.

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang-capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang-capacitor.

Combined with the signal in the first detector is the local oscillator signal, which is always at a 460 K. C. frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang-capacitor are used in the oscillator circuit.

In conjunction with these three tuned circuits it is well to point out that five different groups of tuned circuits are used, one group for each tuning band. A five-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to absorption effects caused by the coils, the natural period of which without the gang capacitor connected falls in the next higher

Figure 4—Sensitivity Control Switching Arrangement

automatic volume control systems is made by an additional group of contacts on the band selector switch. Figure 3 shows the switching arrangements for changing the A. V. C. system in the various bands.

MODEL 281
Alignment Data

RCA-VICTOR CO., INC.

Figure 7—Location of Various Coils in Shields

A detailed procedure for making this adjustment follows:

- (a) Connect the output of an external oscillator tuned to 460 K. C. between the first detector grid and ground. Connect the output indicator across the voice coil of the loudspeaker. Replace the A. V. C. tube in the receiver with the "dummy" RCA-76.
- (b) Place the oscillator in operation at 460 K. C.; place the receiver in operation and adjust the station selector until a point is reached (Band A) where no signals are heard and turn both the volume and sensitivity controls to their maximum position. Reduce the oscillator input until a slight indication is obtained in the output indicator.
- (c) Refer to Figure 9. Adjust each trimmer of the I. F. tuning capacitors until a maximum output is obtained. Go over the adjustments a second time.

No. 6679). The tuning wand consists of a bakelite rod having a brass cylinder at one end and a special finely divided iron insert at the other end. Inserting the cylinder into the center of a coil lowers its inductance, while inserting the iron end increases its inductance. From this it is seen that unless the trimmer adjustment for a particular coil is perfect at alignment frequencies, inserting one end of the wand may increase the output of a particular signal. A perfect adjustment is evidenced by a lowering of output when either end of the wand is inserted into a coil.

The shields over the R. F. coil assembly have a hole at their top for entrance of the tuning wand. The location of the various coils inside of the shield is shown in Figure 7. An example of the proper manner of using the tuning wand would be to assume the external oscillator were set at 1720 and the signal tuned in. The A. V. C. tube would be replaced by the "dummy" RCA-76 and the output indicator could be connected across the voice coil of the loudspeaker. Then the tuning wand would be inserted, first one end and then the other end, into the top of the three transformers at the left of the R. F. assembly, facing the front of the chassis. A perfect adjustment of the trimmer would be evidenced by a reduction in output when each end of the wand is inserted in each of the three transformers. If one end—for example, the iron end—when inserted in one coil caused an increase in output, then that circuit is low. An increase in the trimmer capacitance would be the proper remedy.

(2) I. F. TUNING CAPACITOR ADJUSTMENTS

Although this receiver has three I. F. stages, two for the signal and one for the A. V. C., only three transformers having six adjustable capacitors require adjustment. The fourth transformer is in the A. V. C. circuit and is broadly tuned, not requiring adjustments. The transformers are all peaked, being tuned to 460 K. C.

frequencies at low sound levels. A low and a high frequency tone control enables the listener to alter the fidelity of the receiver to his individual taste.

The driver stage, which is a pair of RCA-76 Radiotrons connected in push-pull, is transformer coupled to a pair of RCA-42's which are the output stage. A feature of the output stage is the use of fixed bias, which reduces distortion and increases the available output. This is accomplished by the use of the drop across R-38 and R-39, which carries the entire D. C. output from the rectifier. Naturally the output stage uses but a portion of the total rectified current and current variations in it will have but little effect on the drop across the resistor.

The output of the power stage is coupled through a step-down transformer to the voice coil of the loudspeaker. A separate winding, which is shunted by a capacitor, has been provided in this transformer which gives a very sharp, high-frequency cut-off for the entire audio system. This greatly reduces the reproduction of any high-frequency interchannel interference or other disturbance of a high-frequency character, which is outside of the useful musical range.

The loudspeaker used is of the large field ten-inch type. It is fully capable of handling the high-power, high-quality output of the receiver and converting it into faithful sound reproduction.

Figure 5 shows the chassis wiring while Figure 6 shows the loudspeaker wiring.

(1) LINE-UP PROCEDURE

The line-up procedure of this receiver is somewhat involved and it is important that these instructions be carefully followed when making adjustments. Properly aligned, this receiver has outstanding performance; improperly aligned, it may be impossible to receive signals on all bands.

Equipment

To properly align this receiver, the following equipment must be used. This is a modulated R. F. oscillator having proper frequency range, an output indicator, an alignment tool, a tuning wand, and a "dummy" Radiotron RCA-76. These parts, which are shown in Figure 8, have been developed by the manufacturer of this receiver for use by service men to duplicate the original factory adjustments. The "dummy" Radiotron, RCA-76, is obtained by removing one heater prong from an otherwise perfect tube.

Checking with Tuning Wand

Before making any R. F. oscillator or first detector adjustments, the accuracy of the present adjustments may be checked by means of the tuning wand (Stock

At this point, an explanation as to why two automatic volume control systems are used and why the sensitivity control is changed in different bands may be in order.

Two automatic volume control systems are used because of the different receiving conditions in different bands. For example, in the broadcast and long-wave band (X and A) signal levels are very high. Also due to the use of an aurally compensated volume control, a constant input to the second detector must be maintained. From this, it is evident that the double channel I. F. automatic volume control is ideal. It maintains a constant input to the second detector and yet does not function on an extremely weak signal. In the short-wave bands, however, conditions are different. Signal strengths are always very low and fluctuate widely. For this reason it is important to have some automatic volume control action below the level at which the double channel system works. This is provided by the diode A. V. C. of the second detector, which functions on the first detector and two I. F. stages on the short-wave bands. It should be noted that this action is present on the second I. F. stage on all bands. This further flattens the action of the double-channel system in bands X and A.

At this point it is well to examine the sensitivity control which also changes on different bands. The sensitivity control adjusts the residual bias on the R. F. and first detector stages in bands X and A while it controls the R. F., 1st detector and both I. F. stages on bands B, C, and D. Figure 4 shows the switching arrangement used.

The sensitivity control is changed so that in bands X and A it controls the R. F. and 1st detector while in bands B, C, and D it controls the R. F., 1st detector, 1st I. F. and 2nd I. F. stages. The reason for this is that for a given degree of sensitivity in bands X and A the residual bias will be considerably higher in the R. F. and 1st detector stages than in the bands B, C, and D used. This is to prevent possible overloading of these stages due to the high-signal strengths encountered in bands X and A. Also, in bands B, C, and D, for a given degree of sensitivity the R. F. stage operates at a higher gain, which gives an improved signal to noise ratio. This is caused by the paralleling of the sensitivity control with an 850-ohm resistor in these bands.

Returning to the second detector, we find its output circuit is coupled to the grid circuit of the driver stage through a compensated volume control system, tone control system and transformer. The volume control uses two stages of compensation, which serves to increase the high and low frequencies as the volume is reduced. This compensates for the natural loss in sensitivity of the human ear to the high and low

Figure 8—Equipment Required for Aligning Receiver

Voltage**

RCA-VICTOR CO., INC.

(4) MAGNETIC PICKUP CONNECTIONS
A Terminal Board is provided at the rear of the chassis for adding phonograph facilities to this instrument. In general, it is best to operate the phonograph with its volume control at its maximum output position and use the radio receiver volume control for adjusting volume. The radio volume control is compensated and will result in much better tone quality at low volume than will be obtained if it is operated open and the volume adjusted from the pickup volume control. Figure 11 shows the various types of connections that will be required for the different turntable assemblies.

(5) VOLTAGE READINGS
The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if low-resistance meters are used, such allowances must be made.

Power Transformer connected to 120-volt Tap.

for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacity from minimum to maximum.

(c) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.

(d) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then aligned with the oscillator circuit and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

(e) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Band "D"

No adjustments are required for Band D.

Band "A"

(a) The oscillator series capacitor, marked 600 K. C., Figure 9, should be set at about the center of its range.

(b) Tune the external oscillator to 1720 K. C., set the pointer at 1720 K. C. and adjust the oscillator, detector and R. F. trimmers for maximum output.

(c) Shift the external oscillator to 600 K. C. Tune in the 600 K. C. signal irrespective of scale calibration and adjust the series trimmer, marked 600 K. C. on Figure 9, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust it 1720 K. C. as described in (b).

Band "B"

(a) The detector and antenna trimmers should first be tightened to approximately $\frac{3}{4}$ maximum capacity (turned $\frac{3}{4}$ in).

(b) Tune the external oscillator to 5160 K. C., and set the pointer at 5160 K. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.

(c) Check for the image signal, which should be received at approximately 4240 on the dial. It may be necessary to increase the external oscillator output for this check.

(d) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then aligned with the oscillator circuit and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

(e) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Band "C"

(a) The detector and antenna trimmers should first be tightened to approximately $\frac{3}{4}$ maximum capacity (turned $\frac{3}{4}$ in).

(b) Tune the external oscillator to 18,000 K. C., and set the pointer at 18 M. Adjust the oscillator trimmer

This completes the I. F. adjustments. However, it is good practice to follow the I. F. adjustments with the R. F. and Oscillator adjustments due to interlocking which always occurs.

(3) R. F. OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS

Four R. F. oscillator and first detector adjustments are required in bands "X" and "A." Three are required in bands "B" and "C," while none are required in band "D." Band "D" uses the second harmonic of the oscillator while the detector and R. F. coils do not have trimmers.

To properly align the various bands, each band must be aligned individually in the order given. This is "X," "A," "B," "C," and "D." The preliminary setup requires the external oscillator to be connected between the antenna and ground terminals of the receiver. The output indicator must be connected across the voice coil of the loudspeaker while the "dummy" RCA-76 must be placed in the A. V. C. socket. The sensitivity and volume controls must be at their maximum position and the input from the oscillator must be at the minimum value possible to get an output indication under these conditions. In the high-frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.

The Dial Pointer must be properly set before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end should point exactly at the horizontal line at the lowest frequency end of band "A," while the other end should point to within $\frac{1}{8}$ " of the horizontal line at the highest frequency end of band "A."

Figure 9 shows the location of the trimmers for each band. Care must be exercised to only adjust the trimmers in the band under test.

Band "X"

(a) The oscillator series capacitor, marked 175 K. C., Figure 9, is first tightened to near its maximum capacity position (screwed "in").

(b) Tune the external oscillator to 410 K. C., set the pointer at 410 K. C. and adjust the oscillator, detector and R. F. trimmers for maximum output.

(c) Shift the external oscillator to 175 K. C. Tune in the 175 K. C. signal irrespective of scale calibration and adjust the series trimmer marked 175 K. C. on Figure 9, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 410 K. C. as described in (b).

SERVICE DATA

Voltage Rating.....105-125 Volts
Frequency Rating.....25, 50 and 60 Cycles
Power Consumption.....45 Watts
Number and Types of Radiotrons—
1 RCA-6A7, 1 RCA-6F7, 1 RCA-41, 1 RCA-1-V

Undistorted Output.....1.9 Watts
Frequency Range.....540-1500 K. C. and 1600-3500 K. C.

This table type combination instrument consists of a four tube super-heterodyne chassis and a new compactly constructed motor board assembly. The receiver incorporates features such as wide tuning range, electro-dynamic loudspeaker, two-point tone control, illuminated dial and the inherent sensitivity, selectivity and tone quality of the super-heterodyne.

The following description of the circuit describes several new design features which are incorporated in this receiver.

The first tube is a combined first detector and oscillator using Radiotron RCA-6A7. Separate tuned circuits are provided for each function. The detector coil is tapped so that the tuning range may be extended merely by shorting out a portion of the coil. The oscillator circuit is not tapped, the high frequency range being obtained by use of its second harmonic instead of the fundamental for obtaining the I. F. frequency.

The next tube is a combined I. F. stage and second detector using Radiotron RCA-6F7. It has two sets of elements, one being used as a screen grid I. F. amplifier and one as a triode detector. The I. F. frequency in this receiver is 460 K. C. The output stage is a single Pentode RCA-41.

The rectifier is an RCA-1-V used in a half-wave rectifying circuit. A feature of this circuit is that only one transformer secondary is used. This is accomplished by having a cathode type rectifier, a series arrangement of filaments and a tapped secondary winding.

Figure A shows the pickup details, Figure B the assembly wiring, Figure C the schematic circuit and Figure D the wiring diagram and Figure E the loudspeaker wiring.

RADIOTRON SOCKET VOLTAGES
120 Volt, 60 Cycle Line—Maximum Volume Control
Setting—No Signal

Radiotron No.	Cathode to Control Grid, Volts D. C.	Cathode to Screen Grid, Volts D. C.	Cathode to Plate, Volts D. C.	Plate Current, M.A.	Heater or Filament, Volts

Oscillator	—	—	180	3.5	
RCA-6F7 I. F.	1.25	70	235	5.5	6.3
Second Det.	19	—	145*	0.4	
RCA-41 Output	17	240	230	26.5	6.3
RCA-1-V Rectifier	—	—	335 RMS	50	6.3

* Actual voltage cannot be measured with ordinary voltmeter.

Line-Up Adjustments

The detector and oscillator line-up trimmer capacitors are adjusted by setting both the dial and an external oscillator first at 1400 K. C. and

adjusting the tuning capacitor trimmer capacitors for maximum output, then changing the oscillator frequency and dial setting to 600 K. C. and adjusting the submounted trimmer capacitor for maximum output. The I. F. adjustments are made by adjusting the two trimmer capacitors located on the first I. F. transformer for maximum output when a 460 K. C. signal is connected between the control grid of the first detector and ground. Be sure and set the station selector at a point where no signal is being received when making I. F. adjustments.

Pickup Service Data

The magnetic pickup and tone-arm assembly of this instrument is of new design and unique construction. Service work will consist of centering the armature, replacing the rubber pivots and replacing the magnet coil.

Disassembling the Pickup

The pickup may be disassembled in the following manner:

- (a) Unsolder the two cable connections to the terminal strip.
- (b) Remove the needle screw and screws "A" and "B."
- (c) Remove the pickup assembly from the arm and housing.
- (d) Unsolder the two magnet coil leads attached to the terminals and then remove screw E. This will allow the removal of the fibre terminal board.
- (e) If centering the pickup armature is the only adjustment required, such centering can be done without removing the fibre terminal board indicated in (d). The armature is centered by loosening screw F, accessible through the hole shown, and holding the armature with the finger in proper position while screw F is tightened. "Feeling" the armature while deflecting it between its two extremes is the best manner of ascertaining proper centering. When centering, after work has been done or the magnet removed, it is important that the magnet be remagnetized while in place.
- (f) If the coil or pivot rubbers are to be replaced, the pickup must be further disassembled. This is done by removing the magnet and then removing screws C and D. The pole piece may now be removed and the old coil and sleeve disassembled. Acetone will be found helpful for dissolving the old cement that holds the coil in place. The new coil, with its sleeve, may now be replaced and cemented in a similar position to that occupied by the old coil. Duco household or Ambroid cement may be used to hold the coil in place. Be careful to center the coil with its paper sleeve before cementing.
- (g) The pivot rubbers are replaced by loosening the armature adjusting screw F and removing the armature from its bracket. The rubbers can then be removed by slipping them from each end of the pivot shaft.

It is important to remember that in all operations after reassembling but before placing in the tone arm, the pickup should be magnetized and the armature centered after remagnetizing. Magnetizing should be done by placing the pickup magnet on the magnetizer and sliding it onto the pole pieces, after magnetizing being careful not to break the magnetic circuit.

MODEL 301
Assembly Wiring
Phonograph Data

PHONOGRAPH MOTOR SERVICE DATA

The synchronous motor used in this instrument is of simple design and foolproof construction. Among its many features are low power consumption, single moving part, ease of starting, oilless main bearing, resilient bumper, and long life with freedom from service repairs.

Figure E shows the main parts of the motor and the points that may require attention.

Operation—The two stator coils are connected in series and the motor is started by giving it a clockwise spin with the hand. If it is found to be difficult of starting, or if it runs at a sub-synchronous speed such as at 70 R. P. M., such action may result from one of the following causes:

Difficult to Start—This may be due to the stator failing to rotate on the outer bearing. This can be caused by the spaghetti sleeve being jammed in the slot, or sticking to the resilient bumper. The outer bearing not being properly lubricated may also cause this condition. It is important that the ball bearing be at the bottom of the main bearing assembly.

Slow Speed—If the turntable is jarred or slowed down, the motor may run at a sub-synchronous speed, such as 70 R. P. M. This is remedied by merely lifting the tone arm from the turntable, thereby removing the load. The turntable speed will then immediately increase to normal.

Excessive Vibration and Hum—A small amount of hum when starting decreasing to a

negligible amount while running is normal. If excessive vibration occurs either at starting or running, it may be due to one of the following:

- (1) Insufficient lubricant in outer bearing or any other failure that will cause the stator to bind.
- (2) The metal washer should be above the leather washer at the bottom of the main bearing.
- (3) Motor not properly supported from motor board. Unless the motor is properly supported from the motor board, normal vibration will be excessive.

Removing Rotor from Stator—The rotor which includes the turntable may be removed by loosening the screw shown in Figure E until it clears the rotor and then lifting the turntable. Be careful not to lose the ball end-bearing when this is removed. After replacing the rotor, tighten the restraining screw securely to eliminate the possibility of rattle in operation.

Power Consumption—The motor consumes 4 watts. It should never be turned on when the rotor is removed, as in this condition excessive current will be drawn with consequent increase in temperature.

NOTE: The above values of power consumption are average for a 60 cycle motor at 125 volts. At lower voltages the power consumption will be less.

Figure D—Loudspeaker Wiring

This "Selective Short-Wave" combination instrument utilizes the new six tube double band superheterodyne together with the standard two-speed motor board assembly. Excellent quality of record reproduction together with unusual radio performance characterize this instrument.

The receiver is a six-tube two-band A. C. operated Superheterodyne receiver combining the standard and short-wave broadcasting bands. The frequency ranges are selected by means of a two position switch. Other features include a double reduction vernier tuning drive using two concentric knobs giving a 10-1 and a 55-1 ratio of speed reduction, a continuously variable tone control, six-inch electrodynamic loudspeaker, automatic volume control, single Pentode output tube and the inherent sensitivity, selectivity and tone quality of the Superheterodyne.

The chassis is of compact construction, affording unusual accessibility to all parts and adjustments. An "Airplane" type dial calibrated in frequency and showing the location of the short-wave bands is a special feature of this instrument. Figure A shows the schematic circuit, Figure B the wiring diagram, Figure C the assembly wiring and Figure D the loudspeaker wiring. Service data on the magnetic pickup is given on one of the following pages.

Line-Up Capacitor Adjustments

In order to properly align this receiver it is essential that Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 150 K. C. to 25,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a non-metallic screwdriver such as Stock No. 7065 and an output meter are required. The output meter should be preferably a thermo-couple galvanometer connected across or in place of the cone coil of the loudspeaker.

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 370 K. C. and the adjustment screws are accessible as shown in Figure D. Proceed as follows:

- Short-circuit the antenna and ground terminals and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- Connect the test oscillator output between the first detector control grid, and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments—The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual

position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the rear of the chassis. Proceed as follows:

- Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully meshed. It should be coincident with the radial line adjacent to the dial reading of 54. Then set the Test Oscillator at 1400 K. C., the dial indicator at 140 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.
- With the Range Switch at the "in" position, adjust the three trimmers under the three R. F. coils designated as L. W. in Figure D, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor accessible from the rear of the chassis should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1400 K. C. adjustment.
- Now place the Range Switch at the "out" position, shift the Test Oscillator to 15,000 K. C. and set the dial at 150. Adjust the three trimmer capacitors designated as SW in Figure D for a peak, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two peaks. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator while the position that uses a higher capacitance is correct for the detector. Both of these adjustments must be made as indicated irrespective of output. The R. F. is merely peaked. In conjunction with the detector adjustment, it is necessary to rock the main tuning capacitor back and forth while making the adjustment. This completes the line-up adjustments.

The important points to remember are the need for using the minimum oscillator output to obtain a deflection in the output meter with the volume control at its maximum position and the manner of obtaining the proper high frequency oscillator and detector adjustments.

Power Transformer Connections

The power transformer used in this model has a tapped primary winding. The transformer is normally connected for lines ranging in voltage from 110 to 125 volts. If for any reason the line is normally below 110 volts,

Figure E—Location of Line-Up Capacitors

the connections should be changed so the tap will be used. This is done by unsoldering the black with red tracer transformer lead connected to the power switch (on tone control) and substituting the red and black lead normally taped up. The black with red tracer lead should then be carefully taped to prevent short-circuit.

SERVICE DATA FOR MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure G), it is necessary to proceed as follows:

- (a) Remove the pickup cover by removing the center holding screw and needle screw.
- (b) Remove the pickup magnet and the magnet clamp by pulling them forward.
- (c) Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure F

- (d) Remove screws A and B, Figure G, and then remove the mechanism assembly from the pole pieces.
- (e) The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber; then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- (f) The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- (g) After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure G), and sliding the mechanism slightly in relation to the pole pieces.
- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- (a) Disassemble the pickup as described under the preceding section.

Figure G

- (b) Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- (c) Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- (d) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure H, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure H

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (h).

Electrical Specifications

Voltage Rating..... 105-125 Volts
 Frequency Rating..... 25, 30, 50 and 60 Cycles
 Power Consumption... 30, 50 and 60 Cycle, 105 Watts; 25 Cycle, 110 Watts
 Number and Type of Radiotrons..... 2 RCA-58
 1 RCA-2A7, 1 RCA-2B7, 1 RCA-2A5, 1 RCA-80—Total 6
 Tuning Ranges..... 540 K. C.—1500 K. C. and 5400 K. C.—15,350 K. C.
 Undistorted Output..... 1.75 Watts

This "Selective Short-Wave" combination instrument utilizes the new six tube double band superheterodyne together with the standard two-speed motor board assembly. Excellent quality of record reproduction together with unusual radio performance characterize this instrument.

The receiver is a six-tube two-band A. C. operated Superheterodyne receiver combining the standard and short-wave broadcasting bands. The frequency ranges are selected by means of a two position switch. Other features include a double reduction vernier tuning drive using two concentric knobs giving a 10-1 and a 55-1 ratio of speed reduction, a continuously variable tone control, eight-inch electrodynamic loudspeaker, automatic volume control, single Pentode output tube and the inherent sensitivity, selectivity and tone quality of the Superheterodyne.

The chassis is of compact construction, affording unusual accessibility to all parts and adjustments. An "Airplane" type dial calibrated in frequency and showing the location of the short-wave bands is a special feature of this instrument. Figure A shows the schematic circuit, Figure B the wiring diagram, Figure C the assembly wiring and Figure D the location of the line-up capacitors. Service data on the magnetic pickup is given on one of the following pages.

Line-Up Capacitor Adjustments

In order to properly align this receiver it is essential that Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 150 K. C. to 25,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a non-metallic screwdriver such as Stock No. 7065 and an output meter are required. The output meter should be preferably a thermo-couple galvanometer connected across or in place of the cone coil of the loudspeaker.

I. F. Tuning Adjustments—Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 370 K. C. and the adjustment screws are accessible as shown in Figure D. Proceed as follows:

- (a) Short-circuit the antenna and ground terminals and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the chassis.
- (b) Connect the test oscillator output between the first detector control grid, and chassis ground. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- (c) Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments—The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the rear of the chassis. Proceed as follows:

- (a) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully meshed. It should be coincident with the radial line adjacent to the dial reading of 540. Then set the Test Oscillator at 1400 K. C., the dial indicator at 1400 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.

- (b) With the Range Switch at the "in" position, adjust the three trimmers under the three R. F. coils designated as L. W. in Figure D, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor accessible from the rear of the chassis should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1400 K. C. adjustment.
- (c) Now place the Range Switch at the "out" position, shift the Test Oscillator to 15,000 K. C. and set the dial at 15 on megacycle scale. Adjust the three trimmer capacitors designated as S.W. in Figure D for a peak, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two peaks. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator while the position that uses a higher capacitance is correct for the detector. Both of these adjustments must be made as indicated irrespective of output. The R. F. is merely peaked. In conjunction with the detector adjustment, it is necessary to rock the main tuning capacitor back and forth while making the adjustment. This completes the line-up adjustments.

The important points to remember are the need for using the minimum oscillator output to obtain a deflection in the output meter with the volume control at its maximum position and the manner of obtaining the proper high frequency oscillator and detector adjustments.

Power Transformer Connections

The power transformer used in this model has a tapped primary winding. The transformer is normally connected for lines ranging in voltage from 110 to 125 volts. If for any reason the line is normally below 110 volts,

Figure D—Location of Line-Up Capacitors

the connections should be changed so the tap will be used. This is done by unsoldering the black with red tracer transformer lead connected to the power switch (on tone control) and substituting the red and black lead normally taped up. The black with red tracer lead should then be carefully taped to prevent short-circuit.

SERVICE DATA ON MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance, it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers,
Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure F), it is necessary to proceed as follows:

- (a) Remove the pickup cover by removing the center holding screw and needle screw.
- (b) Remove the pickup magnet and the magnet clamp by pulling them forward.
- (c) Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure E

- (d) Remove screws A and B, Figure F, and then remove the mechanism assembly from the pole pieces.
- (e) The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- (f) The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- (g) After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure F), and sliding the mechanism slightly in relation to the pole pieces.
- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- (a) Disassemble the pickup as described under the preceding section.

Figure F

- (b) Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- (c) Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- (d) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure G, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure G

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the air gap as explained under (h).

SERVICE DATA

CAUTION—This receiver operates on 220-volt direct current without a transformer between the line and the various parts of the receiver, such as A. C. receivers use. It is therefore extremely important to use the utmost caution when operating the receiver outside of the cabinet. Also a knob must always be placed on the shaft of the main tuning capacitor, as under certain conditions the full line voltage is obtained between this point and ground.

(1) Line-Up Capacitor Adjustments

To properly align this receiver, it is essential that a modulated R. F. oscillator, such as Stock No. 9050, an output indicator (Stock No. 4317) and an alignment tool (Stock No. 4160) be available. Figure 4 shows the location of the various line-up capacitors.

I. F. Tuning Adjustments

Two transformers comprising four tuned circuits are used in the intermediate amplifier. These are tuned to 370 K. C. and the adjustment screws are accessible as shown in Figure 4. Proceed as follows:

- (a) Short-circuit the antenna and ground leads and tune the receiver so that no signal is heard. Set the volume control at maximum and connect a ground to the ground terminal.
- (b) Connect the test oscillator output between the first detector control grid and chassis ground, preferably through a series condenser. Connect the output meter across the voice coil of the loudspeaker and adjust the oscillator output so that, with the receiver volume control at maximum, a slight deflection is obtained in the output meter.
- (c) Adjust the secondary and primary of the first and then the second I. F. transformers until a maximum deflection is obtained. Keep the oscillator output at a low value so that only a slight deflection is obtained on the output meter at all times. Go over these adjustments a second time, as there is a slight interlocking of adjustments. This completes the I. F. adjustments.

R. F. and Oscillator Adjustments

The R. F. line-up capacitors are located at the bottom of the coil assemblies instead of their usual position on the gang capacitor. They are all accessible from the bottom of the chassis except the 600 K. C. series capacitor, which is accessible from the rear of the chassis. Proceed as follows:

- (a) Connect the output of the oscillator to the antenna and ground terminals of the receiver. Check the position of the indicator pointer when the tuning capacitor plates are fully

meshed. It should be coincident with the radial line adjacent to the dial reading of 54. Then set the Test Oscillator at 1400 K. C., the dial indicator at 140 and the oscillator output so that a slight deflection will be obtained in the output meter when the volume control is at its maximum position.

- (b) With the Range Switch at the "in" position, adjust the three trimmers under the three R. F. coils, designated as L in Figure 4, until a maximum deflection is obtained in the output meter. Then shift the Test Oscillator frequency to 600 K. C. The trimmer capacitor, accessible from the rear of the chassis, should now be adjusted for maximum output while rocking the main tuning capacitor back and forth through the signal. Then repeat the 1400 K. C. adjustment.
- (c) Now place the Range Switch at the "out" position, shift the Test Oscillator to 15,000 K. C. and set the dial at 150. Adjust the three trimmer capacitors designated as S in Figure 4 for maximum output, beginning with the oscillator trimmer. It will be noted that the oscillator and first detector trimmers will have two positions at which the signal will give maximum output. The position which uses the lower trimmer capacitance, obtained by turning the screw counter-clockwise, is the proper adjustment for the oscillator, while the position that uses a higher capacitance is correct for the detector. Both of these adjustments must be made as indicated irrespective of output. The R. F. is merely peaked. In conjunction with the detector adjustments, it is necessary to rock the main tuning capacitor back and forth while making the adjustment. This completes the line-up adjustments.

(3) Service Data on Magnetic Pickup

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

MODEL 327
Pickup Data

inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure 8), and sliding the mechanism slightly in relation to the pole pieces.

Figure 7

- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be .009" on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

(5) Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.
- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip,

constructed as shown in Figure 9, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the

Figure 8

end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious

Figure 9

subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the air gap as explained under (h).

SERVICE DATA

Electrical Specifications
 Voltage Rating..... 105-125 Volts
 Frequency Rating..... 25, 30, 50 and 60 Cycles
 Power Consumption..... 140 Watts
 Type and Number of Radiotrons..... 3 RCA-58, 1 RCA-2A7, 1 RCA-3B7, 1 RCA-56, 1 RCA-53, 1 RCA-80—Total 8
 Type of Circuit..... Straight Superheterodyne
 for all frequencies with Class "B" output
 Undistorted Output..... 6 Watts
 This all-wave combination instrument utilizes the new perfected continuous tuning superheterodyne chassis and the standard two speed motor-board assembly. Excellent quality performance, characterized by unusual radio performance, characterizes this instrument.
 Service data for the magnetic pickup used on the tone arm of the motor-board assembly is given on the following pages. Service data for the radio receiver follows.

The tuning bands for the receiver chassis are as follows:

Selector Switch Position	Frequency Range (Kilocycles)	Wave Length Range (Meters)
X	150-410	2000-732
A	540-1500	555-200
B	1500-3900	200-77.0
C	3900-10000	77.0-30.0
D	8000-18000	37.5-16.7

REMOVE THE NUTS & LOCKWASHERS FROM REMOVING BOTTOM SHIELD OF CON. ASSEMBLY.

Figure D—Assembly Wiring

in the wiring for the two models are plainly shown in the illustrations. Figures A, B and C show the schematic circuit and wiring diagrams.

The circuit consists of an R. F. stage using Radiotron RCA-58, a combined oscillator and first detector using Radiotron RCA-2A7, an I. F. stage using RCA-56, a second detector and A. V. C. using RCA-3B7, an A. F. driver using RCA-53 and a Class "B" output stage using an RCA-80. The RCA-80 functions as the rectifier in the power supply circuit.

The foregoing tubes and circuit functions apply to bands X, A, B and C only. In the case of band D, an additional R. F. stage utilizing an additional Radiotron RCA-58 is used. This is to increase the sensitivity and image frequency selectivity and to reduce the interference caused by tube hiss, static and signals corresponding to the intermediate frequency.

The intermediate frequency is 445 K. C. The use of this frequency gives an especially good image frequency ratio and facilitates alignment of the oscillator at the higher frequency band.

Mechanical Construction

The chassis consists of two major assemblies, which must be disassembled for certain repair work. These assemblies consist of the chassis proper and the motor-board assembly. The motor-board assembly consists of the coil assembly, four tubular bakelite forms, each fastened to a separate porcelain strip upon which the coil terminals are mounted with their associate trimmer capacitor. This motor-board assembly with the associated trimmer capacitors is mounted in a bracket which is mounted in the base of the main chassis assembly.

In order to remove this assembly it is necessary to remove the four nuts shown in Figure E and unsolder the connections of the fifteen leads shown in Figure C at the points where they connect to the main chassis. The leads should be allowed to remain on the coil assembly. After this is done, the coil assembly may be removed. If the trimmer capacitor trimmer is to be replaced, then only the bottom shield of the coil assembly must be removed. This is done by removing the four nuts that hold it to the chassis studs. This is shown in Figure E.

Line-Up Capacitor Adjustments

This receiver is aligned in a similar manner to that of a standard broadcast band receiver. That is, the three main tuning capacitors are aligned by means of three trimmers in each band and on the three lowest frequency bands a series of four trimmers are used. Adjusting the low frequency trimmer capacitors does not require this low frequency trimmer, it being fixed in value. In the case of band D, it is necessary to adjust four trimmers due to the additional R. F. stage used.

TUBE SOCKET VOLTAGES (RADIO OPERATION)
 120 Volt A. C. Line

*Voltage and current apply to detector portions of tube.
 **These voltage cannot be measured because of the high resistance of the circuit.

RCA-VICTOR CO., INC.

MODEL "All Wave Duo"
340, 340-E
Alignment Data

The intermediate frequency amplifier is aligned in a similar manner to that of standard broadcast receivers except that it is aligned at 445 K. C. In order to properly align the receiver, it is essential that the Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 90 K. C. to 25,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a 300-ohm resistor for use as a "dummy" antenna, a non-metallic screwdriver (such as Stock No. 4160), and an output meter are required. The output meter should be preferably a thermocouple galvanometer connected either across or in place of the cone coil of the loudspeaker.

Figure F—Location of line-up capacitors

To align the intermediate frequency circuits, connect the output of the external oscillator to the grid of the first detector. For the R. F. and oscillator adjustments, the oscillator output should be connected to the antenna and ground terminals of the receiver with a 300-ohm resistor inserted in series with the antenna lead. In many cases, however, the signal strength obtained with this direct connection will be too great to permit proper alignment, even at the minimum setting of the oscillator attenuator. When this is true, the external oscillator must be loose-coupled to the receiver. This is done by connecting the 300-ohm resistor between the antenna and ground terminals of the receiver and attaching a short length of wire to the antenna post. Lay the free end of this wire across the oscillator case, adjusting its position as necessary to obtain the degree of pickup required.

The output of the external oscillator should be at the minimum value necessary to obtain a deflection in the output meter when the volume control is at its maximum position. All adjustments are made for a maximum deflection in the output meter.

The accuracy of line-up of each band may be checked without touching the trimmer condensers, by the use of the tuning wand, Stock No. 6679.

One end of the wand consists of a brass cylinder. When this is inserted in a coil the effective inductance of the coil is lowered.

The other end of the wand contains a special finely divided iron suitable for use at radio frequencies. When this is inserted in a coil the inductance is raised.

To use the tuning wand a signal is first tuned in at the frequency at which a check is desired on alignment. The wand is then inserted slowly in the Antenna and R. F. transformers, using first one end and then the other end of the wand. Unless the alignment is perfect, it will be found that the power output indicated by the meter will be increased to a peak for a critical position of the wand in the coils.

The end of the wand required indicates whether the coil is high or low.

Of course, alignment correction at the high-frequency end of a tuning range should be accomplished by the use of the trimmer condenser. If alignment correction should be required at the low-frequency end of a tuning range it may be accomplished by sliding the end coil of the transformer. The winding farthest from the trimmer panel is pushed toward the trimmer panel to increase the inductance, and farther away to decrease the inductance. On band D coils, the last two or three turns may be pushed in a similar manner to obtain the proper inductance.

This adjustment should not be attempted unless a quite appreciable improvement will result (as shown by the tuning wand).

The following chart gives the details of all line-up adjustments. The receiver should be lined up in the order of the adjustments given on the chart. Refer to Figure F for the location of the line-up capacitors.

Transformer Connections

The power transformer of the 50-60 cycle receiver uses two tapped primary windings. By connecting them in parallel or in series, the receiver may be used either on 110 or 220 volt lines. Figure H shows the proper manner of making the various connections possible for this transformer. Note: The transformer is normally connected for 115-125-volt lines, and a 100-volt motor supplied. The 220-volt connections must not be used unless the motor is also changed. However, 220-volt operation of the standard equipment may be obtained by using the Stock No. 9034 step-down line transformer.

The 25-60 cycle transformer uses only one 105-125-volt winding, a tap being provided for the lower voltages. Normally the transformer is connected for 115-125-volt lines, but the connection shown in Figure G may be used for 100-115-volt lines.

External Oscillator Frequency	Dial Setting	Location of Line-Up Capacitors	Position of Selector Switch	Adjust for	Number of Adjustments to be Made
445 K. C.	Any setting that does not bring in station.	At rear of chassis.	Any position that does not bring in station.	Maximum output.	4
370 K. C.	370 K. C.	Bottom of chassis.	X	Maximum output.	3
175 K. C.	Set for signal.	Top of chassis.	X	Maximum output while rocking dial back and forth.	1
1400 K. C.	1400 K. C.	Bottom of chassis.	A	Maximum output.	3
600 K. C.	Set for signal.	Top of chassis.	A	Maximum output while rocking dial back and forth.	1
3900 K. C.	3900 K. C.	Bottom of chassis.	B	Maximum output.	3
1710 K. C.	Set for signal.	Top of chassis.	B	Maximum output while rocking dial back and forth.	1
10 M. C.	10 M. C.	Bottom of chassis.	C	Maximum output. (See Note.)	3
15 or 18 M. C.	15 or 18 M. C.	Bottom and top.	D	Maximum output. (See Note.)	4

NOTE—It is important to note, when aligning bands C and D, that two peaks will be observed on the trimmers for the oscillator and for the first detector. The correct oscillator peak is the one obtained using the lower trimmer capacitance, whereas the correct detector peak is the one obtained with the greater capacitance. It is essential that the proper peak be chosen, as otherwise tracking and sensitivity will be very poor at other frequencies. When adjusting the detector trimmer, the tuning capacitor should be rocked, since there is a reaction on the oscillator tuning.

Pickup Data

SERVICE DATA ON MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance, it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure K), it is necessary to proceed as follows:

- Remove the pickup cover by removing the center holding screw and needle screw.
- Remove the pickup magnet and the magnet clamp by pulling them forward.
- Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure I

- Remove screws A and B, Figure J, and then remove the mechanism assembly from the pole pieces.
- The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure J), and sliding the mechanism slightly in relation to the pole pieces.
- The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.

Figure J

- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure K, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both side, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure K

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (h).

Assembly Wiring
Voltage, Circuit Data

RCA-VICTOR CO., INC.

SERVICE DATA

In the wiring for the two models are plainly shown in the illustrations. Figures A, B and C show the schematic circuit and wiring diagrams.

The circuit consists of an R. F. stage using Radiotron RCA-58, a detector and amplifier using Radiotron RCA-2A7, an I. F. amplifier using Radiotron RCA-56, and an A. V. C. using Radiotron RCA-2B7, an A. F. driver using Radiotron RCA-56, and a Class "B" output stage using an RCA-53. The RCA-50 functions as the rectifier in the power supply circuit.

The foregoing tubes and circuit functions apply to hands X, A, B and C only. In the case of hand D, an additional R. F. stage utilizing an additional Radiotron RCA-58 is used. This is to increase the sensitivity and image frequency rejection of the receiver. The intermediate frequency tube bias, static and signals corresponding to the intermediate frequency.

The intermediate frequency is 445 K. C. The use of this frequency gives an especially good image frequency ratio and facilitates alignment of the oscillator at the higher frequency bands.

Mechanical Construction

The chassis consists of two major assemblies, which must be disassembled for certain repair work. These assemblies consist of the chassis proper, including the main frame, power transformer, etc., and the coil assembly. The coil assembly consists of the transformers supported upon individual tubular brackets from which the coil terminals are mounted with their strip upon which the coil terminals are mounted with their associate trimmer capacitor. This entire assembly with the selector switch is grouped in a shielded compartment which is mounted in the base of the main chassis assembly.

In order to remove this assembly it is necessary to remove the four nuts shown in Figure E and unsolder the connections of the fifteen leads shown in Figure C at the points where they connect to the main chassis. The leads should be cut to a length of one inch and the nuts should be removed. After this is done, the coil assembly may be lifted out of the chassis. The main chassis may be easily made. If a coil or its associated trimmer is to be replaced, then only the bottom shield of the coil assembly must be removed. This is done by removing the four nuts that hold it to the chassis studs. This is shown in Figure E.

Line-Up Capacitor Adjustments

This receiver is shipped in standard form with three standard broadcast band receivers. That is, the three main tuning capacitors are aligned by means of three trimmers in each band and on the three lowest frequency bands a series trimmer is adjusted for aligning the oscillator circuit. The user will find it necessary to adjust the low frequency trimmer, if he has a low frequency station to receive. This is done by adjusting four trimmers due to the additional R. F. stage used.

Electrical Specifications

- Voltage Rating.....105-125 Volts
- Frequency Rating.....25, 30, 50 and 60 Cycles
- Power Consumption.....140 Watts
- Type and Number of Radiotrons.....3 RCA-58, 1 RCA-2A7, 1 RCA-2B7, 1 RCA-56, 1 RCA-53, 1 RCA-50—Total 8
- Type of Circuit.....Straight Superheterodyne
- Undistorted Output.....for all frequencies with Class "B" output.....6 Watts

This all-wave combination instrument utilizes the new perfected continuous tuning superheterodyne chassis and the high efficiency of record reproduction, together with unusual radio performance, characterizes this instrument.

Service data for the magnetic pickup used on the tone arm of the motor-based assembly is given on the following pages. Service data for the radio receiver follows.

The tuning bands for the receiver chassis are as follows:

Selector Switch Position	Frequency Range (Kilocycles)	Wave Length (Meters)
X	150-410	2000-732
A	540-1500	555-200
B	1500-3900	200-77.0
C	3900-10000	77.0-30.0
D	8000-18000	37.5-16.7

REMOVE FOUR NUTS & UNSOLDER TO REMOVE COIL ASSEMBLY FROM RECEIVER CHASSIS AS SHOWN IN FIGURE E.

Figure E—Location of nuts and lockwashers holding coil assembly

This receiver will be supplied in two models, one including all the features of the Model 340-E. The other model, however, will cover both types of the receiver. The variations

* Voltages and current apply to detector portion of tube.
 ** These voltages cannot be measured because of the high resistance of the diodes.

Figure D—Assembly Wiring Diagram

RCA-VICTOR CO., INC.

The intermediate frequency amplifier is aligned in a similar manner to that of standard broadcast receivers except that it is aligned at 445 K. C. In order to properly align the receiver, it is essential that the Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 150 K. C. to 20,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a 300 ohm resistor for use as a "dummy" antenna, a non-metallic screwdriver (such as Stock No. 7065), and an output meter are required. The output meter should be preferably a thermocouple galvanometer connected either across or in place of the cone coil of the loudspeaker.

Figure F—Location of line-up capacitors.

To align the intermediate frequency circuits, connect the output of the external oscillator to the grid of the first detector. For the R. F. and oscillator adjustments, the oscillator output should be connected to the antenna and ground terminals of the receiver with the 300 ohm resistor inserted in series with the antenna lead. In many cases, however, the signal strength obtained with this direct connection will be too great to permit proper alignment, even at the minimum setting of the oscillator attenuator. When this is true, the external oscillator must be loose-coupled to the receiver in the following manner: Connect the 300 ohm resistor between the antenna and ground terminals of the receiver and attach a short length of wire to the antenna post. Lay the free end of this wire across the oscillator case, adjusting its position as necessary to obtain the degree of pickup required.

The output of the external oscillator should be at the minimum value necessary to obtain a deflection in the output meter when the volume control is at its maximum position. All adjustments are made for a maximum deflection in the output meter.

The accuracy of line-up of each band may be checked without touching the trimmer condensers, by the use of the tuning wand, Stock No. 6679.

One end of the wand consists of a brass cylinder. When this is inserted in a coil the effective inductance of the coil is lowered.

The other end of the wand contains a special finely divided iron suitable for use at radio frequencies. When this is inserted in a coil the inductance is raised.

To use the tuning wand a signal is first tuned in at the frequency at which a check is desired on alignment. The wand is then inserted slowly in the Antenna and R. F. transformers, using first one end and then the other end of the wand. Unless the alignment is perfect, it will be found that the power output indicated by the meter will be increased to a peak for a critical position of the wand in the coils.

The end of the wand required indicates whether the coil is high or low.

Of course, alignment correction at the high frequency end of a tuning range should be accomplished by the use of the trimmer condenser. If alignment correction should be required at the low frequency end of a tuning range it may be accomplished by sliding the end coil of the transformer. The winding farthest from the trimmer panel is pushed toward the trimmer to increase the inductance, and farther away to decrease the inductance. On band D coils, the last two or three turns may be pushed in a similar manner to obtain the proper inductance.

This adjustment should not be attempted unless a quite appreciable improvement will result (as shown by the tuning wand).

The following chart gives the details of all line-up adjustments. The receiver should be lined up in the order of the adjustments given on the chart. Refer to Figure F for the location of the line-up capacitors.

External Oscillator Frequency	Dial Setting	Location of Line-Up Capacitors	Position of Selector Switch	Adjust for	Number of Adjustments To Be Made
445 K. C.	Any setting that does not bring in station.	At rear of chassis.	Any position that does not bring in station.	Maximum output.	4
370 K. C.	370 K. C.	Bottom of chassis.	X	Maximum output.	3
175 K. C.	Set for signal.	Top of chassis.	X	Maximum output while rocking dial back and forth.	1
1400 K. C.	1400 K. C.	Bottom of chassis.	A	Maximum output.	3
600 K. C.	Set for signal.	Top of chassis.	A	Maximum output while rocking dial back and forth.	1
3900 K. C.	3900 K. C.	Bottom of chassis.	B	Maximum output.	3
1710 K. C.	Set for signal.	Top of chassis.	B	Maximum output while rocking dial back and forth.	1
10 M. C.	10 M. C.	Bottom of chassis.	C	Maximum output. (See Note)	3
15 or 18 M. C.	15 or 18 M. C.	Bottom and top.	D	Maximum output. (See Note)	4

NOTE—It is important to note, when aligning bands C and D, that two peaks will be observed on the trimmers for the oscillator and for the first detector. The correct oscillator peak is the one obtained using the lower trimmer capacitance, whereas the correct detector peak is the one obtained with the greater capacitance. It is essential that the proper peak be chosen, as otherwise tracking and sensitivity will be very poor at other frequencies. When adjusting the detector trimmer, the tuning capacitor should be rocked, since there is a reaction on the oscillator tuning.

Transformer Connections

The power transformer of the 50-60 cycle receiver uses two tapped primary windings. By connecting them in parallel or in series, the receiver may be used either on 110 or 220 volt lines. Figure H shows the proper manner of making the various connections possible for this transformer. Note: The transformer is normally connected for 115-125-volt lines and a 110-volt motor supplied. The 220-volt connections must not be used unless the motor is also changed. However, 220-volt operation of the standard equipment may be obtained by using the Stock No. 9034 step-down line transformer.

The 25-60 cycle transformer uses only one 105-125-volt winding, a tap being provided for the lower voltages. Normally the transformer is connected for 115-125-volt lines, but the connection shown in Figure G may be used for 100-115-volt lines.

Figure H—Power Transformer Connections (50-60 cycles)

RCA-VICTOR CO., INC.

MODEL 340, 340-E
Pickup Data

SERVICE DATA ON MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance, it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers,
Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure K), it is necessary to proceed as follows:

- (a) Remove the pickup cover by removing the center holding screw and needle screw.
- (b) Remove the pickup magnet and the magnet clamp by pulling them forward.
- (c) Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure I

- (d) Remove screws A and B, Figure J, and then remove the mechanism assembly from the pole pieces.
- (e) The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- (f) The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- (g) After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure J), and sliding the mechanism slightly in relation to the pole pieces.
- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- (a) Disassemble the pickup as described under the preceding section.

Figure J

- (b) Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- (c) Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- (d) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure K, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both side, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure K

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (h).

FIGURE 2 - CHASSIS WIRING

MODEL 341
Assembly Wiring
Circuit Data

RCA-VICTOR CO., INC.

DESCRIPTION OF ELECTRICAL CIRCUIT

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector, an I. F. stage, a combined second detector, A. F. amplifier and automatic volume control, a driver audio stage and a push-pull Pentode output stage. An RCA-5Z3 rectifier, together with a suitable filtering system, provides plate and grid voltages for all tubes and field excitation for the loudspeaker. Figure 1 shows the schematic diagram, Figure 2 the chassis wiring, Figure 3 the loudspeaker wiring and Figure 4 the assembly wiring.

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang capacitor.

Combined with the signal in the first detector is the local oscillator, which is always at a 460 K. C. frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang capacitor are used in this circuit.

In conjunction with these three tuned circuits, it is well to point out that four different groups of tuned circuits are used, one for each tuning band. A four-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to the absorption effects caused by the coils, the natural period of which, with the tuning capacitor disconnected, falls in the next higher frequency band.

The output of the first detector, which is the I. F. signal (460 K. C.), is fed directly through two tuned circuits to the grid of the I. F. amplifier stage. The I. F. stage, which utilizes Radiotron RCA-6D6, uses two transformers, which consist of four tuned circuits, all of which are tuned to 460 K. C.

The output of the I. F. amplifier is then applied to the input electrodes of the RCA-75, which is a combined second detector, A. F. amplifier and automatic volume control. The direct current component of the rectified signal produces a voltage drop across resistor R-32. The full voltage drop constitutes the automatic bias voltage for the R. F. while a tap is provided for the first detector and I. F. voltage. These automatic bias voltages for the R. F., first detector and I. F. give the automatic volume-control action of the receiver. The volume control selects the amount of audio voltage that is applied to the grid of the RCA-75 and thereby regulates the audio output of the entire receiver.

The output of the A. F. section of the RCA-75 is resistance coupled to the grid of the RCA-76, first audio stage, which is transformer coupled to the push-pull output stage.

The output stage uses two RCA-42's, which give a low distortion, high audio output to the loudspeaker. A high-frequency tone control, which consists of a variable resistor and capacitor, is connected across the grids of the output stage. At the minimum resistance position of the variable resistor, maximum attenuation of the high audio frequencies is obtained.

The plate circuit of the output stage is matched to the cone coil of the reproducer by means of a step-down transformer.

Plate and grid voltages for all tubes are supplied from the output of the rectifier-filter system. An RCA-5Z3 is used as a rectifier and a suitable network of capacitors and resistors gives the necessary filtering and voltages. The loudspeaker field is used as a filter reactor.

RCA-VICTOR CO., INC.

MODEL 341
Alignment Data**SERVICE DATA****(1) LINE-UP PROCEDURE**

The line-up procedure of this receiver is somewhat involved and it is important that these instructions be carefully followed when making adjustments. Properly aligned, this receiver has outstanding performance; improperly aligned, it may be impossible to receive signals on all bands.

Equipment

To properly align this receiver, proper test equipment must be used. This consists of a modulated R. F. oscillator having proper frequency range, an output indicator, an alignment tool and a tuning wand. These parts, which are shown

have been developed by the manufacturer of this receiver for use by service men to duplicate the original factory adjustments.

Checking with Tuning Wand

Before making any R. F., oscillator or first detector adjustments, the accuracy of the present adjustments may be checked by means of the tuning wand (Stock No. 6679). The tuning wand consists of a bakelite rod having a brass cylinder at one end and a special finely divided iron insert at the other end. Inserting the cylinder into the center of a coil lowers its inductance, while inserting the iron end increases its inductance. From this, it is seen that unless the trimmer adjustment for a particular coil is perfect at alignment frequencies, inserting one end of the wand may increase the output of a particular signal. A perfect adjustment is evidenced by a lowering of output when either end of the wand is inserted into a coil.

The shields over the R. F. coil assembly have a hole at their top for entrance of the tuning wand. The location of the various coils inside of the shield is shown in Figure 5. An example of the proper manner of using the tuning wand would be to assume the external oscillator were set at 1720 K. C. and the signal tuned in, and the output indicator connected across the voice coil of the loudspeaker. Then the tuning wand should be inserted, first one end and then the other end, into the top of the three transformers at the left of the R. F. assembly, facing the front of the chassis. A perfect adjustment of the trimmer would be evidenced by a reduction in output when each end of the wand is inserted in each of the three transformers. If one end—for example, the iron end—when inserted in one coil caused an increase in output, then that circuit is low. An increase in the trimmer capacitance would be the proper remedy.

(2) I. F. TUNING CAPACITOR ADJUSTMENTS

This receiver has one I. F. stage with two transformers having four adjustable capacitors that may require adjustment. The transformers are all peaked at 460 K. C.

A detailed procedure for making this adjustment follows:

- (a) Connect the output of an external oscillator tuned to 460 K. C. between the first detector grid and ground. Connect the output indicator across the voice coil of the loudspeaker.
- (b) Place the oscillator in operation at 460 K. C. Place the receiver in operation and adjust the station selector until a point is reached (Band A) where no signals are heard and turn the volume control to its maximum position. Reduce the oscillator input until a slight indication is obtained in the output indicator.
- (c) Refer to Figure 6. Adjust each trimmer of the I. F. transformers until maximum output is obtained. Go over the adjustments a second time.

This completes the I. F. adjustments. However, it is good practice to follow the I. F. adjustments with the R. F. and oscillator adjustments due to interlocking which always occurs.

MODEL 341

Alignment Data
Pickup Data

RCA-VICTOR CO., INC.

- (3) **R. F. OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS**
- Four R. F. oscillator and first detector adjustments are required in Bands "A", "B", and "C". Three are required in Bands "D", "E", and "F".
- To properly align the various bands, each band must be aligned individually. The preliminary set-up requires the external oscillator to be connected between the antenna and ground terminals of the receiver and the output indicator across the voice coil of the loudspeaker. The volume and sensitivity controls must be at the maximum position and the input from the oscillator at the minimum value possible to get an output indication under these conditions. In the high frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.
- The dial pointer must be properly set before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end of the pointer should point exactly at the horizontal line at the lowest frequency end of Band "A", while the other end should point to within 1/64 inch of the horizontal line at the highest frequency end of Band "A".
- Figure 6 shows the location of the trimmers for each band. Care must be exercised to only adjust the trimmers in the band under test.
- Band "A"**
- Set the band switch at "A."
 - Tune the external oscillator to 1,720 K. C., set the pointer at 1,720 K. C., and adjust the oscillator, detector and R. F. trimmers for maximum output.
 - Shift the external oscillator frequency to 600 K. C. Tune in the 600 K. C. signal, irrespective of scale calibration, and adjust the series trimmers, marked 600 K. C., Figure 6, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 1,720 K. C. as described in (b).
- Band "B"**
- Set the band switch at "B."
 - Tune the external oscillator to 5,160 K. C. and set the pointer at 5,160 K. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
 - Check for the image signal, which should be received at approximately 4,240 K. C. on the dial. It will be necessary to increase the external oscillator output for this check.
 - The antenna and detector trimmers should now be peaked for maximum output.
- Band "C"**
- Set the band switch at "C."
- (b) Tune the external oscillator to 19,000 K. C. and set the pointer at 18 M. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.
- (c) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.
- (d) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then at the oscillator frequency and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.
- (e) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.
- Band "X"**
- Set the band switch at "X."
 - Tune the external oscillator to 410 K. C., set the dial pointer at 410 K. C., and adjust the oscillator, detector and R. F. trimmers for maximum output.
 - Shift the external oscillator frequency to 175 K. C. Tune in the 175 K. C. signal, irrespective of scale calibration, and adjust the series trimmers, marked 175 K. C. on Figure 6, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 410 K. C. as described in (b).
- (4) **POWER TRANSFORMER CONNECTIONS**
- The 220-volt power transformer furnished with some instruments includes taps for operating on 110-volt lines. Figure 7 shows the schematic circuit of the transformer and the proper voltage to be applied to the various taps. The taps are located on the power transformer assembly and are accessible without removing the chassis from the cabinet.
- (5) **FIDELITY LINK**
- It will be noted that a small link is mounted on the rear apron of the chassis which is open. Closing the link reduces the low frequency output of the receiver.
- (6) **VOLTAGE READINGS**
- The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if low-resistance meters are used, such allowances must be made. Figure 8 shows the voltages at each individual socket contact.
- (7) **SERVICE DATA ON MAGNETIC PICKUP**
- The Magnetic Pickup used in this combination instrument is of a new design, with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.
- The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.
- (8) **REPLACING MAGNET COIL, PIVOT RUBBERS, ARMATURE OR DAMPING BLOCK**
- In order to replace a defective coil or the hardened pivot rubbers (see Figure 10), it is necessary to proceed as follows:
- Remove the pickup cover by removing the center holding screw and needle screw.
 - Remove the pickup magnet and the magnet clamp by pulling them forward.
 - Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.
 - Remove screws A and B, Figure 10, and then remove the mechanism assembly from the pole pieces.
 - The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
 - The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—when the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization. The magnetizer shown on page 18 is useful for magnetizing pickups.
- (9) **REPLACING THE DAMPING BLOCK**
- If it is desired to replace the damping block, it may be done in the following manner:
- Disassemble the pickup as described under the preceding section.
 - Remove the armature entirely by unsoldering it at its joint with the mechanism support.
 - Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- (g) After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure 10), and sliding the mechanism slightly in relation to the pole pieces.
- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.
- In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be .009" on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.
- Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered under (e) above, the armature by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the air gap as explained under (h), section (8).

RCA-VICTOR CO., INC.

MODEL 341
Pickup Data
Record Changer Data

Figure 12—Automatic Record Changer Adjustments

The above covers the proper manner of making adjustments, assuming all parts are in normal condition. Of course, if any part is defective, it must be replaced. The spring gear may be checked by turning it until the spring is tight and unwinding it slowly. It should unwind $4\frac{1}{4}$ turns.

(10) AUTOMATIC RECORD CHANGER

The automatic record changer used in this instrument is of simple design and fool-proof construction. Under normal operating conditions service difficulties should be negligible. However, in event adjustments are required, a reference to Figure 12 will disclose the proper method of making all adjustments.

(11) ADJUSTMENT OF DIAL VERNIER MECHANISM

A small vernier indicator is provided for giving a simple means of band spread. Under normal conditions, adjustment of this mechanism will not be required. However, in event the initial adjustment is not satisfactory or adjustment is required because of replacement, the following procedure should be used:

- (a) Remove the chassis from the cabinet to a place convenient for work.
- (b) Check the tension on the vernier hand by pushing it in a clockwise direction. There should be considerable tension against such a push. If this tension does not exist, the action of the hand may be erratic and possibly fail to return to the same position for a particular station.
- (c) Pull off the long hand with a pair of long-nose pliers.
- (d) Straighten the lugs that hold the dial in place. Then remove the dial "vernier" hand and stem gear together.
- (e) Then remove the "vernier" hand from the stem gear.

PHONOGRAPH

The record reproducing facilities consist of a low impedance magnetic pickup with its associated inertia type tone arm, a compensated volume control, the audio amplifier of the receiver and the loudspeaker of the receiver. The radio receiver is made inoperative by the switch used for changing from radio to record reproduction. The turntable assembly consists of the perfected automatic record changer, which is simple and fool-proof in operation.

- (d) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure 11, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Figure 11—Special Soldering-Iron Tip

- (f) Turn the dial to each extreme and to its center position and check the backlash of the back gear (closest to reflector). There should be definite backlash in each direction at each of these three positions.
- (g) If this backlash is not obtained, loosen the nut on the back of the reflector which holds the shaft of these gears and slide the shaft toward the outer edge of the reflector. The hole is elongated to permit this adjustment.
- (h) After making sure there is backlash at the three check points mentioned, turn the outside gear in a clockwise direction $1\frac{1}{2}$ turns. Hold it at this position and replace the stem gear.
- (i) Turn the dial throughout its range. If the gears become noisy, move the gear further toward the reflector edges described in (g).
- (j) Replace the dial scale, making sure the hole clears the spindle.
- (k) Replace the vernier hand. It should point at zero when the tuning capacitor is fully meshed.
- (l) Replace the large hand. One end of one pointer should point exactly at the horizontal line at the lowest frequency end of Band "A" when the tuning capacitor is fully meshed.

This eight-tube, four-band all-wave combination radio-phonograph instrument provides entertainment either from the perfected all-wave radio receiver or from records of all types. Record or radio reproduction is characterized by unusual tone quality. The perfected phonograph enables one to play a number of selections without any attention whatever, due to its automatic record-changing feature.

The eight-tube, four-band Superheterodyne receiver is of the "all-wave" type, having a continuous tuning range extending from 140 K. C. to 18,000 K. C., except for one break between 410 K. C. and 540 K. C. Such a tuning range permits the listener to receive all of the important broadcasting, police, aircraft and amateur call bands throughout the world.

Excellent sensitivity, selectivity and tone quality, together with a high output (4 watts undistorted), Class A amplifier gives the receiver outstanding performance. Operating features include an "airplane" type dial, a double-ratio vernier drive, a visual band indicator, and a special "second hand" on the dial for logging short-wave stations. Other important features include automatic volume control, sensitivity control and a large loudspeaker unit.

MODEL 9-Tube General

Purpose A-W.

RCA-VICTOR CO., INC.

Alignment Data

SERVICE DATA

The circuit consists of an R. F. stage using Radiotron RCA-58, a combined oscillator and first detector using Radiotron RCA-2A7, an I. F. stage using RCA-58, a second detector and A. V. C. using RCA-2B7, an A. F. driver using RCA-56, and a Class "B" output stage using an RCA-53. The RCA-80 functions as the rectifier in the power supply circuits.

The foregoing Radiotrons and circuit functions apply to bands X, A, B and C only. In the case of band D, an additional R. F. stage utilizing an additional Radiotron RCA-58 is used. This is to increase the sensitivity and image frequency selectivity and to reduce the interference caused by tube hiss and 445 K. C. signals or static.

The intermediate frequency is 445 K. C. The use of this frequency gives an especially good image frequency ratio and makes easier alignment of the oscillator at the higher frequency bands.

In order to receive pure C W signals, an I. F. heterodyne oscillator has been provided. This oscillator is an RCA-56 that operates at a 1000-cycle higher frequency than the I. F. An adjustable capacitor is provided so that the pitch of the heterodyne frequency may be varied throughout the audible range.

The intermediate frequency amplifier is aligned in a similar manner to that of standard broadcast receivers except that it is aligned at 445 K. C. In order to properly align the receiver, it is essential that the Stock No. 9050 Test Oscillator be used. This oscillator covers the frequencies of 90 K. C. to 25,000 K. C. continuously, has good stability and includes an attenuator. In addition to the oscillator, a 300 ohm resistor for use as a "dummy" antenna, a non-metallic screwdriver (such as Stock No. 4160), and an output meter are required. The output meter should be preferably a thermocouple galvanometer connected either across or in place of the cone coil of the loudspeaker.

To align the intermediate frequency circuits, connect the output of the external oscillator to the grid of the first detector. For the R. F. and oscillator adjustments, the oscillator output should be connected to the antenna and ground terminals of the receiver with a 300 ohm resistor inserted in series with the antenna lead. In many cases, however, the signal strength obtained with this direct connection will be too great to permit proper alignment, even at the minimum setting of the oscillator attenuator. When this is true, the external oscillator must be loose-coupled to the receiver. This is done by connecting the 300 ohm resistor between the antenna and ground terminals of the receiver and attaching a short length of wire to the antenna post. Lay the free end of this wire across the oscillator case, adjusting its position as necessary to obtain the degree of pickup required.

The output of the external oscillator should be at the minimum value necessary to obtain a deflection in the output

meter when the volume control is at its maximum position. All adjustments are made for a maximum deflection in the output meter.

The accuracy of line-up of each band may be checked without touching the trimmer condensers, by the use of the tuning wand, Stock No. 6679.

One end of the wand consists of a brass cylinder. When this is inserted in a coil the effective inductance of the coil is lowered.

The other end of the wand contains a special finely divided iron suitable for use at radio frequencies. When this is inserted in a coil the inductance is raised.

To use the tuning wand a signal is first tuned in at the frequency at which a check is desired on alignment. The wand is then inserted slowly in the Antenna and R. F. transformers, using first one end and then the other end of the wand. Unless the alignment is perfect, it will be found that the power output indicated by the meter will be increased to a peak for a critical position of the wand in the coils.

The end of the wand required indicates whether the coil is high or low.

Of course, alignment correction at the high frequency end of a tuning range should be accomplished by the use of the trimmer condenser. If alignment correction should be required at the low frequency end of a tuning range it may be accomplished by sliding the end coil of the transformer. The winding farthest from the trimmer panel is pushed toward the trimmer panel to increase the inductance, and farther away to decrease the inductance. On band D coils, the last two or three turns may be pushed in a similar manner to obtain the proper inductance.

This adjustment should not be attempted unless a quite appreciable improvement will result (as shown by the tuning wand).

The following chart gives the details of all line-up adjustments. The receiver should be lined up in the order of the adjustments given on the chart. Refer to Figure E for the location of the line-up capacitors.

The CW oscillator beat frequency may be adjusted by means of the trimmer capacitor shown in Figure E. (It may be necessary to slightly loosen the shielding cover to gain access to this screw.) A weak modulated or telephone signal should be accurately tuned-in with the oscillator "off" The oscillator should then be turned "On" and the trimmer screw adjusted until a 1000 cycle note is obtained.

Line-up Capacitor Adjustments

This receiver is aligned in a similar manner to that of a standard broadcast band receiver. That is, the three main tuning capacitors are aligned by means of three trimmers in each band and on the three lowest frequency bands a series trimmer is adjusted for aligning the oscillator circuit. The other two bands do not require this low frequency trimmer, it being fixed in value. In the case of band D, it is necessary to adjust four trimmers due to the additional R. F. stage used.

External Oscillator Frequency	Dial Setting	Location of Line-Up Capacitors	Position of Selector Switch	Adjust for	Number of Adjustments To Be Made
445 K. C.	Any setting that does not bring in station.	Top of chassis.	Any position that does not bring in station.	Maximum output.	4
370 K. C.	370 K. C.	Bottom of chassis.	X	Maximum output.	3
175 K. C.	Set for signal.	Top of chassis.	X	Maximum output while rocking dial back and forth.	1
1400 K. C.	1400 K. C.	Bottom of chassis.	A	Maximum output.	3
600 K. C.	Set for signal.	Top of chassis.	A	Maximum output while rocking dial back and forth.	1
3900 K. C.	3900 K. C.	Bottom of chassis.	B	Maximum output.	3
1710 K. C.	Set for signal.	Top of chassis.	B	Maximum output while rocking dial back and forth.	1
10 M. C.	10 M. C.	Bottom of chassis.	C	Maximum output. (See Note)	3
15 or 18 M. C.	15 or 18 M. C.	Bottom and top.	D	Maximum output. (See Note)	4

NOTE—It is important to note, when aligning bands C and D, that two peaks will be observed on the trimmers for the oscillator and for the first detector. The correct oscillator peak is the one obtained using the lower trimmer capacitance, whereas the correct detector peak is the one obtained with the greater capacitance. It is essential that the proper peak be chosen, as otherwise tracking and sensitivity will be very poor at other frequencies. When adjusting the detector trimmer, the tuning capacitor should be rocked, since there is reaction on the oscillator tuning.

RCA-VICTOR CO., INC.

MODEL 9-Tube General Purpose A-W. Transformer Data Trimmer Locations

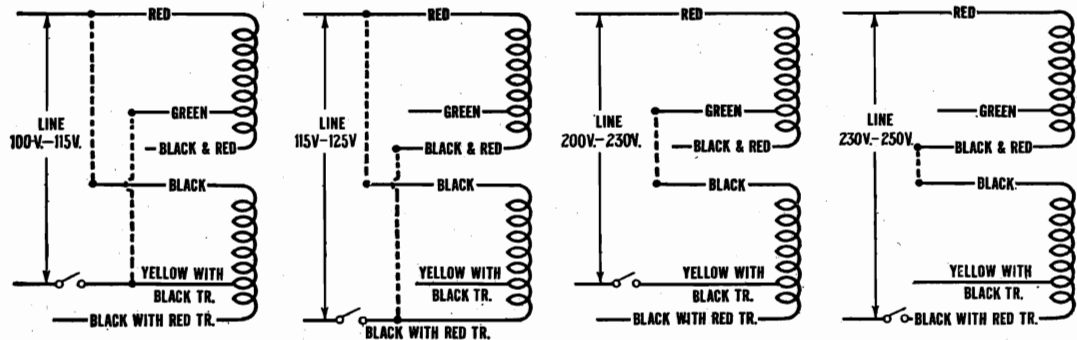

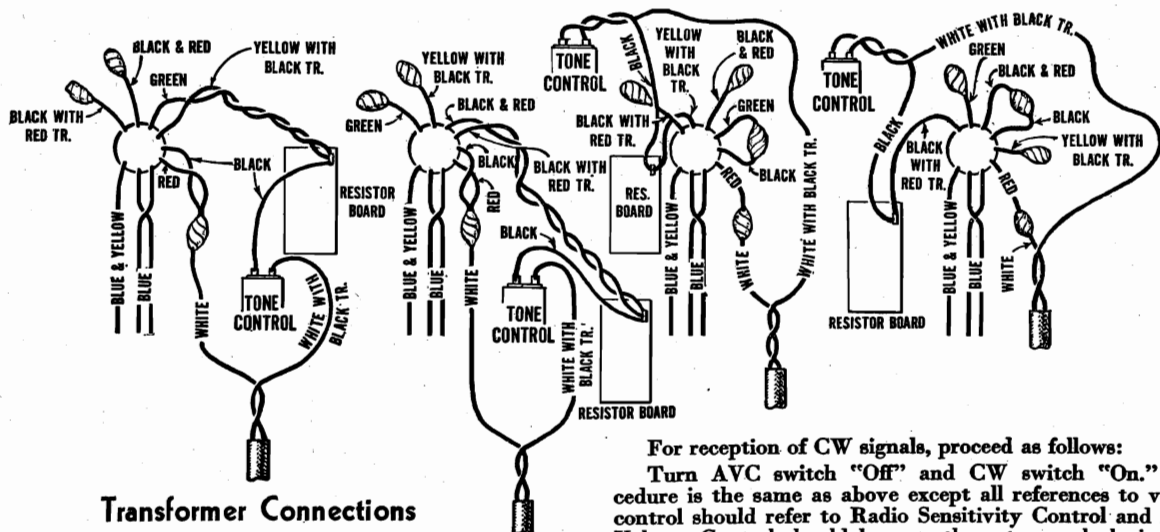

Figure F—Power Transformer Connections (50-60 cycles)

Transformer Connections

The power transformer of the 50-60 cycle receiver uses two tapped primary windings. By connecting them in parallel or in series, the receiver may be used either on 110 or 220 volt lines. Figure F shows the proper manner of making the various connections possible for this transformer.

- (1) **Range Switch (Upper Left-hand Knob)**—This switch converts the receiver for operation within any of the tuning ranges provided. As indicated on the selector dial, the letters on the switch escutcheon signify:
 - X—*Long-Wave Range*—150 to 410 kilocycles (2000 to 732 meters). Airport band.
 - A—*Standard Broadcast Band*—540 to 1500 kilocycles (555 to 200 meters).
 - B—*Police Band*—1500 to 3900 kilocycles (200 to 77 meters). Services available within this band include police calls at 1574, 1712 and 2450 kilocycles, amateur radio "phone" communications between 1800 and 2000 kilocycles, and aviation communications (phone) between 2500 and 3500 kilocycles.
 - C—*Short-Wave Range*—3900 to 10,000 kilocycles (77 to 30 meters). Within the limits of this range are included two of the internationally-assigned short-wave broadcast bands. These are known as the 49 and 31 meter bands. (The portion of this range from 8000 to 10,000 kilocycles, which includes the 31 meter band, is preferably received on range D.)
 - D—*Short-Wave Range*—8,000 to 18,000 kilocycles (37.5 to 16.7 meters). This range embraces four of the standardized short-wave broadcast bands located at 31, 25, 19 and 16 meters, respectively.

For reception of CW signals, proceed as follows:

Turn AVC switch "Off" and CW switch "On." Procedure is the same as above except all references to volume control should refer to Radio Sensitivity Control and Audio Volume Control should be near the extreme clockwise position. Each station tuned in will be indicated by a whistle caused by the beating of the CW oscillator frequency with the signal frequency. This feature provides unmistakable signal indication and may also be used when tuning signals other than CW, noting the presence of the signal with the oscillator "On" and tuning the station in finally with the oscillator turned "Off."

Electrical Specifications

Voltage Rating..... 105-125 Volts
Power Consumption (60 Cycle)..... 175 Watts
Type and Number of Radiotrons..... 4 RCA-56, 4 RCA-58,
1 RCA-55, 2 RCA-59, 1 RCA-5Z3—Total 12
Frequency Range.540 K.C.-1500 K.C.—1400 K.C.-2800 K.C.
Undistorted Output..... 10.0 Watts

This combination instrument utilizes the new perfected automatic record changing mechanism and the twelve-tube Deluxe Super-Heterodyne receiver. Excellent fidelity on both radio and record reproduction is an inherent feature of this instrument. Other features include double tuning range (540 K. C.—1500 K. C. and 1400 K. C.—2800 K. C.), high and low frequency tone control, compensated volume control and the inherent sensitivity, selectivity and tone quality of the Super-Heterodyne.

Figure B—Location of Line-up Capacitors

Figure A shows the schematic circuit, Figure B the location of the adjustable capacitors, Figure C the chassis wiring, and Figure D the assembly wiring diagram. The Radiotron socket voltages, the line-up procedure and the replacement parts are given on the following pages.

R. F. and Oscillator Line-up Capacitor Adjustments

Four adjustable capacitors are provided for aligning the R. F. circuits and adjusting the oscillator frequency so that the oscillator will maintain a constant frequency—175 K. C.—difference from that of the incoming signal. Poor quality, insensitivity, poor A. V. C. action and possible inoperation of the receiver may be caused by these capacitors being out of adjustment.

If the other adjustments have not been tampered with—the intermediate transformer tuning capacitors—the following procedure may be used for aligning these capacitors.

- Procure an R. F. Oscillator, such as Stock No. 9050, giving a modulated signal at 600 K. C., 1400 K. C., and 2440 K. C. Also procure a non-metallic screw driver such as Stock No. 7065.
- An output meter is necessary. This should be a 0-10 milliammeter connected in series with the plate supply to the second detector.
- A dummy Radiotron RCA-56 is necessary to substitute for the one normally used in the A. V. C. socket. This should be a tube that is otherwise normal in all respects, but having one heater prong removed. Insert this tube in the A. V. C. socket.
- First check the chassis and carefully ascertain that the dial pointer reads exactly at the first line on the scale when the tuning capacitor rotor plates are fully meshed with the stator plates.
- Place the oscillator in operation at exactly 1400 K. C. and couple its output to the antenna. Set the Range Switch counter-clockwise and the dial scale at exactly 1400. Connect the output meter to the set and place the volume control and suppressor control, if

- noise level will permit, at its maximum position. Adjust the oscillator input so that only a slight reduction in current is obtained in the output meter.
- With a suitable socket wrench—the nuts are at ground potential—adjust the oscillator, first detector and R. F. line-up capacitors, until a minimum deflection is obtained in the output meter.
- The high frequency band is adjusted at 2440 K. C. This is done in a similar manner to the R. F. adjustments except that the oscillator is set at 2440 K. C., the dial at 1200 and the Range Switch in the clockwise position. The line-up capacitors on the Range Switch are adjusted for minimum output at this frequency.
- Set the oscillator at 600 K. C. Tune in the signal with the receiver until a slight deflection is obtained in the output meter. Now adjust the 600 K. C. series capacitor, Figure B, until a minimum deflection is obtained in the output meter. Rock the tuning capacitor back and forth while making this adjustment, as the tuning capacitor and oscillator series capacitor adjustments interlock.
- Change the frequency of the oscillator to 1400 K. C. and set the dial at 1400. Again make the adjustments given under (f), (g), and then (h).

So adjusted, the R. F. circuits are properly aligned and the oscillator will maintain a constant frequency difference from the incoming R. F. signal.

I. F. Tuning Capacitor Adjustments

Although this receiver has two I. F. stages, one for the second detector and one for the A. V. C., only two of the three I. F. transformers are tuned by adjustable capacitors and require adjustment. The stage used for the A. V. C. is broadly tuned and does not require any adjustment.

The transformers are all tuned to 175 K. C. and the circuits broadly peaked.

A detailed procedure for making this adjustment follows:

- Procure a modulated R. F. Oscillator, such as Stock No. 9050, that gives a modulated 175 K. C. signal. Also procure a non-metallic screw driver such as Stock No. 7065.
- An output meter is necessary. This should be a 0-10 milliammeter connected in series with the plate supply to the second detector.
- A dummy Radiotron RCA-56 is necessary to substitute for the one normally used in the A. V. C. socket.
- Remove the oscillator tube and make a good ground connection to the chassis. Place the oscillator in operation and couple its output from the control grid of the first detector to ground. Adjust the oscillator output, with the receiver volume control at maximum, until a slightly reduced deflection is obtained in the output meter.
- Refer to Figure B. Adjust the secondary and primary of the second and then the first I. F. transformer until a minimum deflection is obtained in the output meter. Go through these adjustments a second time, as a slight readjustment may be necessary.

When the adjustments are made the set should perform at its maximum efficiency. However, due to the interlocking of adjustments, it is good practice to follow the I. F. adjustments with the R. F. and oscillator line-up capacitor adjustments. The correct method of doing this is given in the preceding section.

Antenna Connections—It will be noted that three antenna terminals are provided at the rear of the receiver chassis. Two of these will normally be used for the usual antenna and ground connections, while the third one is for use in connection with a shielded antenna system. The tap eliminates the need of the transformer usually used for coupling the shielded line to the radio receiver.

Stock No. 7717 shield kit, which comprises a lightning arrester, transformer assembly, a 200 mmfd. capacitor, and 100 feet of shielded wire, is recommended. When such an antenna system is used, it is necessary to connect the 200 mmfd. capacitor between terminals 1 and 2. This prevents the first R. F. circuit from being detuned and results in maximum gain from the antenna. This capacitor is included with the Stock No. 7717 Kit.

Automatic Record Changer—The automatic record changer used in this instrument is of simple design and excellent construction. The various adjustments that may be required are shown in Figure E. A point to remember with this instrument is that it must always be level, otherwise proper operation will not be obtained.

MODEL Duo 380
Phonograph Data

RCA-VICTOR CO., INC.

OPERATION—PHONOGRAPH

Automatic Operation

Important Precautions—The following precautions must be observed during operation:

1. In loading the turntable, make certain that the first record inserted (last to be played) is flat—that is, essentially free from warpage.

2. Before starting the turntable, make certain that the reject pocket (at the left of the phonograph compartment) is either empty or sufficiently clear to permit proper disposal of records by the automatic mechanism.

3. Never restrain by force the normal motion of any part of the automatic mechanism while it is changing records.

Procedure—The phonograph operating controls are located on the front panel and in the playing compartment as shown in Figures 1 and 2. Proceed as follows:

1. Set the Transfer Switch counter-clockwise for record reproduction.

2. Apply power by turning the Radio Volume Control clockwise from the "off" position. Set the two Tone Controls for full-range reproduction (see paragraph 7 under "Operation—Radio").

3. With the Motor Switch in the "off" position (Record Volume Control fully counter-clockwise), load the turntable with records, as follows:

- (a) Set the Index Lever at "Manual." Always do this before loading or unloading records.
- (b) Place the electric pickup on the rubber rest.
- (c) Raise the Record Ejector arm (very slowly, at first, until the internal weight has rolled to the rear of the arm, then as rapidly as desired) to its upper position of rest. Always raise the ejector arm in this manner.
- (d) Select the records to be played. All records for one loading must be of the same diameter (either ten or twelve inches), close to standard thickness and operable at the same speed (either 78 or 33 $\frac{1}{3}$ R. P. M.).

CAUTION—Do not use thin flexible-type records for automatic operation.

- (e) Place the records, one at a time, on the turntable (see paragraph 1 under "Important Precautions"). The spindle should resume its normal height after each record is added. The turntable is fully loaded when the top surface of the uppermost record is nearly flush with the top of the spindle. (It should not be possible to slide off the top record without lifting its edge or depressing the spindle.)
- (f) Lower the Record Ejector arm gently onto the spindle.

4. Insert a new needle in the pickup as far as it will go and tighten the needle screw. For long-playing (33 $\frac{1}{3}$ R. P. M.) records, use *only* the orange Chromium needle. For standard (78 R. P. M.) records, use the latter needle or, if preferred, either the green Chromium or the full volume (full tone) Tungstone needle. Transparent-faced (illustrated) records, however, should not be reproduced with Tungstone needles.

NOTE—With care, the orange Chromium needle should play 75, the green Chromium 100, and the Tungstone 100 to 150 records. Never re-insert in the pickup a Chromium needle which has been used (however slightly) as damage to the record grooves would result.

5. Place the pickup needle on the smooth outer rim of the record, near the first groove. Then move the Index Lever to the position (12 or 10) corresponding to the diameter (inches) of the records on the turntable. Be careful not to move the lever beyond the proper index hole. Push the index pin firmly into the hole.

CAUTION—Never attempt to move the Index Lever from the Manual position when the pickup is on the rubber rest.

6. Start the turntable by turning the Motor Switch clockwise; then set the Speed Shifter for the

Figure 2

speed (78 or 33 $\frac{1}{3}$ R. P. M.) corresponding to the records on the turntable.

NOTE—The speed shifter should not be moved inward (from the 78 to the 33 $\frac{1}{3}$ R. P. M. position) while the turntable is at rest.

7. Adjust the Record Volume Control to obtain the desired volume.

8. Close the cabinet doors to extinguish the compartment lamp and to render less prominent the mechanical noises incident to record playing and changing. If needle scratch reproduction (particularly noticeable with old records) is considered excessive, turn the treble Tone Control slightly counter-clockwise. For most faithful reproduction, however, both Tone Controls should be left in the positions which provide full illumination of the tone color indicator.

NOTE 1—When a record has been played, the ejector arm slides it off into the record pocket and the pickup moves to the outside of the next record. The records on the turntable are thus played consecutively until only one

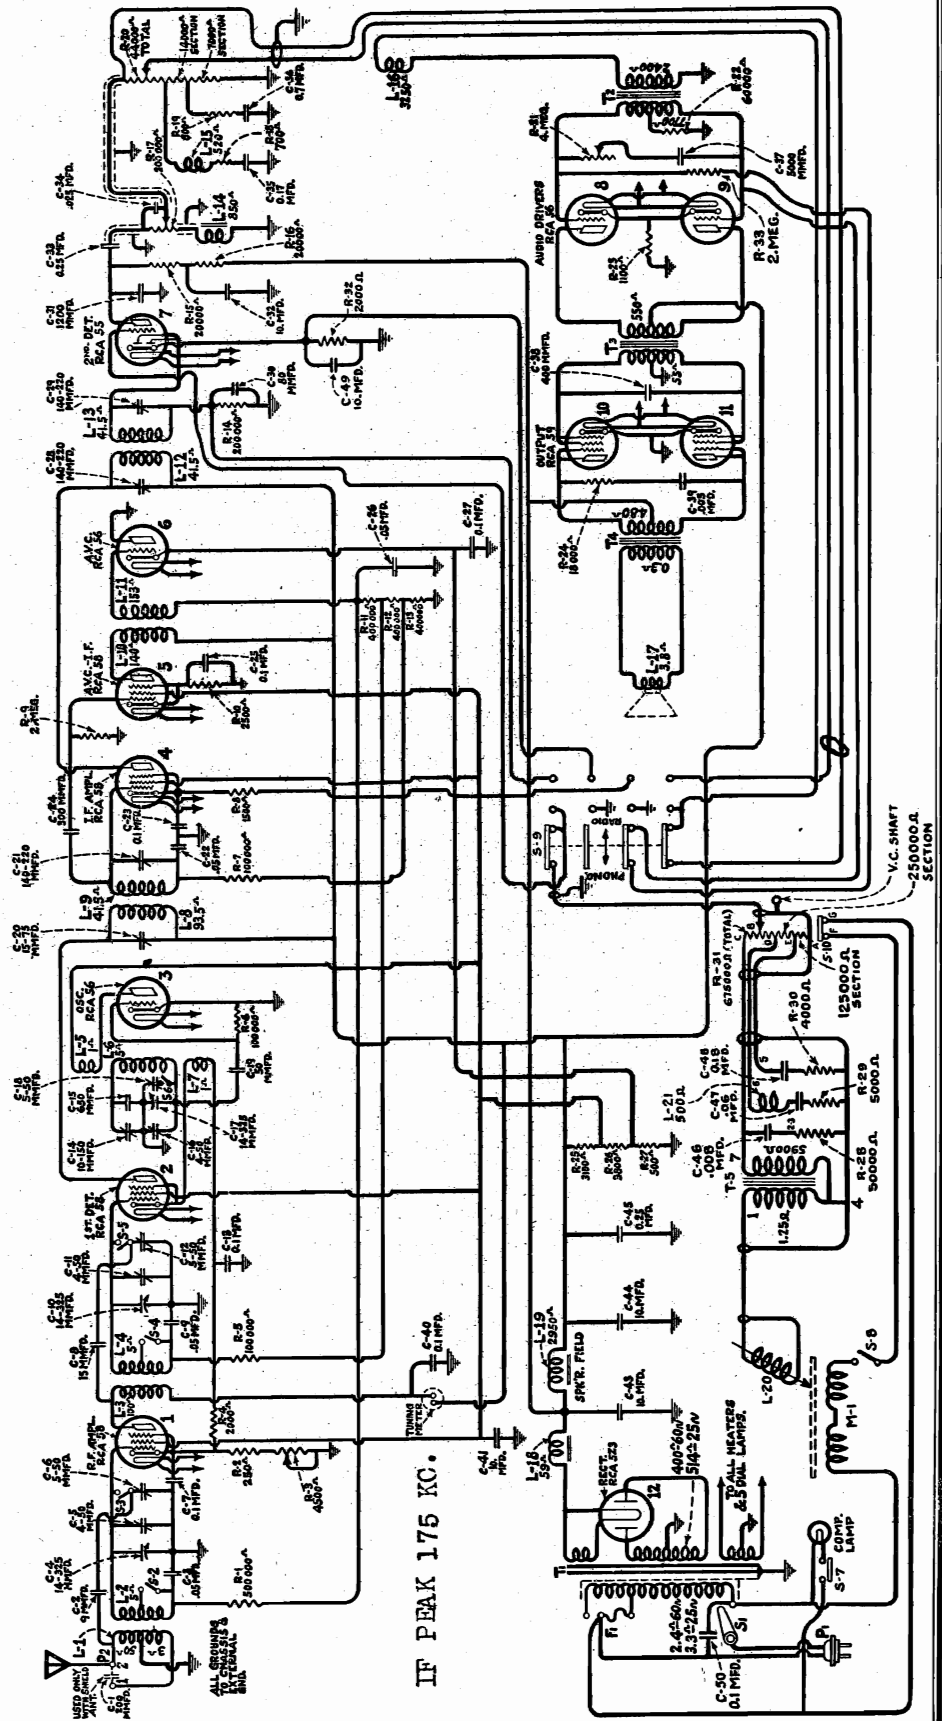

RCA-VICTOR CO., INC.

9. To reject a record while playing, lift the pickup arm and move it to the extreme left. Hold the pickup lightly until it is moved by the mechanism.

10. Before reloading or when through operating, turn the Motor Switch to the "off" position, set the index lever at "Manual" and place the pickup on the rubber rest. Never leave the pickup resting on a record (or on the turntable) when not in use. Turn the power switch "off" and close the cabinet doors when discontinuing operation of the instrument.

record remains on the turntable. This record will be played repeatedly until the motor is stopped by means of the Motor Switch.

NOTE 2—After a record has been played and changed, the needle is lowered automatically onto the smooth rim of the next record and is fed by gravity into the starting groove. After the instrument has been leveled with reference to the top of the cabinet, further slight compensation may be necessary, thus: (1) If the needle fails to enter the playing groove, the right-hand side of the instrument must be raised by inserting thin blocks under the front and rear legs on that side; or (2) If the needle slides over several grooves, thus failing to reproduce the beginning of the selection, the left-hand side of the instrument must be similarly raised.

MODEL Duo 380
Pickup Data

RCA-VICTOR CO., INC.

SERVICE DATA FOR MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure G), it is necessary to proceed as follows:

- Remove the pickup cover by removing the center holding screw and needle screw.
- Remove the pickup magnet and the magnet clamp by pulling them forward.
- Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure F

- Remove screws A and B, Figure G, and then remove the mechanism assembly from the pole pieces.
- The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure G), and sliding the mechanism slightly in relation to the pole pieces.
- The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.

Figure G

- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure H, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure H

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (h).

RCA-VICTOR CO., INC.

SERVICE DATA

Electrical Specifications

Voltage Rating	105-125 Volts
Power Consumption (60 Cycle)	175 Watts
Type and Number of Radiotrons	4 RCA-56, 4 RCA-58, 1 RCA-55, 2 RCA-59, 1 RCA-5Z3—Total 12
Frequency Range	540 K.C.-1500 K.C.—1400 K.C.-2800 K.C.
Undistorted Output	10.0 Watts

This combination home recording instrument utilizes the new perfected automatic record changing mechanism and the twelve-tube Deluxe Super-Heterodyne receiver. Excellent fidelity on both radio and record reproduction, together with facilities for recording either programs or voice are inherent features of this instrument. Other features include double tuning range (540 K. C.-1500 K. C. and 1400 K. C.-2800 K. C.), high and low frequency tone control, compensated volume control and the inherent sensitivity, selectivity and tone quality of the Super-Heterodyne.

Figure D—Location of Line-Up Capacitors

Figure A shows the schematic circuit, Figure B the chassis wiring, and Figure C the assembly wiring diagram. The Radiotron socket voltages, the line-up procedure, special service hints and the replacement parts are given on the following pages.

R. F. and Oscillator Line-up Capacitor Adjustments

Four adjustable capacitors are provided for aligning the R. F. circuits and adjusting the oscillator frequency so that the oscillator will maintain a constant frequency—175 K. C.—difference from that of the incoming signal. Poor quality, insensitivity, poor A. V. C. action and possible inoperation of the receiver may be caused by these capacitors being out of adjustment.

If the other adjustments have not been tampered with—the intermediate transformer tuning capacitors—the following procedure may be used for aligning these capacitors:

- Procure an R. F. Oscillator, such as Stock No. 9050, giving a modulated signal at 600 K. C., 1400 K. C., and 2440 K. C. Also procure a non-metallic screw driver such as Stock No. 7065.
- An output meter is necessary. This should be a 0-10 milliammeter connected in series with the plate supply to the second detector.
- A dummy Radiotron RCA-56 is necessary to substitute for the one normally used in the A. V. C. socket. This should be a tube that is otherwise normal in all respects, but having one heater prong removed. Insert this tube in the A. V. C. socket.
- First check the chassis and carefully ascertain that the dial pointer reads exactly at the first line on the scale when the tuning capacitor rotor plates are fully meshed with the stator plates.
- Place the oscillator in operation at exactly 1400 K. C. and couple its output to the antenna. Set the Range Switch counter-clockwise and the dial scale at exactly 1400. Connect the output meter to the set and place the volume control and suppressor control, if

noise level will permit, at its maximum position. Adjust the oscillator input so that only a slight reduction in current is obtained in the output meter.

- With a suitable socket wrench—the nuts are at ground potential—adjust the oscillator, first detector and R. F. line-up capacitors, until a minimum deflection is obtained in the output meter.
- The high frequency band is adjusted at 2440 K. C. This is done in a similar manner to the R. F. adjustments except that the oscillator is set at 2440 K. C., the dial at 1250 and the Range Switch in the clockwise position. The line-up capacitors on the Range Switch are adjusted for minimum output at this frequency.
- Set the oscillator at 600 K. C. Tune in the signal with the receiver until a slight deflection is obtained in the output meter. Now adjust the 600 K. C. series capacitor, Figure D, until a minimum deflection is obtained in the output meter. Rock the tuning capacitor back and forth while making this adjustment, as the tuning capacitor and oscillator series capacitor adjustments interlock.
- Change the frequency of the oscillator to 1400 K. C. and set the dial at 1400. Again make the adjustments given under (f), (g), and then (h).

So adjusted, the R. F. circuits are properly aligned and the oscillator will maintain a constant frequency difference from the incoming R. F. signal.

I. F. Tuning Capacitor Adjustments

Although this receiver has two I. F. stages, one for the second detector and one for the A. V. C., only two of the three I. F. transformers are tuned by adjustable capacitors and require adjustment. The stage used for the A. V. C. is broadly tuned and does not require any adjustment.

The transformers are all tuned to 175 K. C. and the circuits broadly peaked.

A detailed procedure for making this adjustment follows:

- Procure a modulated R. F. Oscillator, such as Stock No. 9050, that gives a modulated 175 K. C. signal. Also procure a non-metallic screw driver such as Stock No. 7065.
- An output meter is necessary. This should be a 0-10 milliammeter connected in series with the plate supply to the second detector.
- A dummy Radiotron RCA-56 is necessary to substitute for the one normally used in the A. V. C. socket.
- Remove the oscillator tube and make a good ground connection to the chassis. Place the oscillator in operation and couple its output from the control grid of the first detector to ground. Adjust the oscillator output, with the receiver volume control at maximum, until a slightly reduced deflection is obtained in the output meter.
- Refer to Figure D. Adjust the secondary and primary of the second and then the first I. F. transformer until a minimum deflection is obtained in the output meter. Go through these adjustments a second time, as a slight readjustment may be necessary.

When these adjustments are made, the set should perform at its maximum efficiency. However, due to the interlocking of adjustments, it is good practice to repeat the R. F. and oscillator line-up capacitor adjustments after completing alignment of the I. F. system. The correct method of doing this is given in the preceding section.

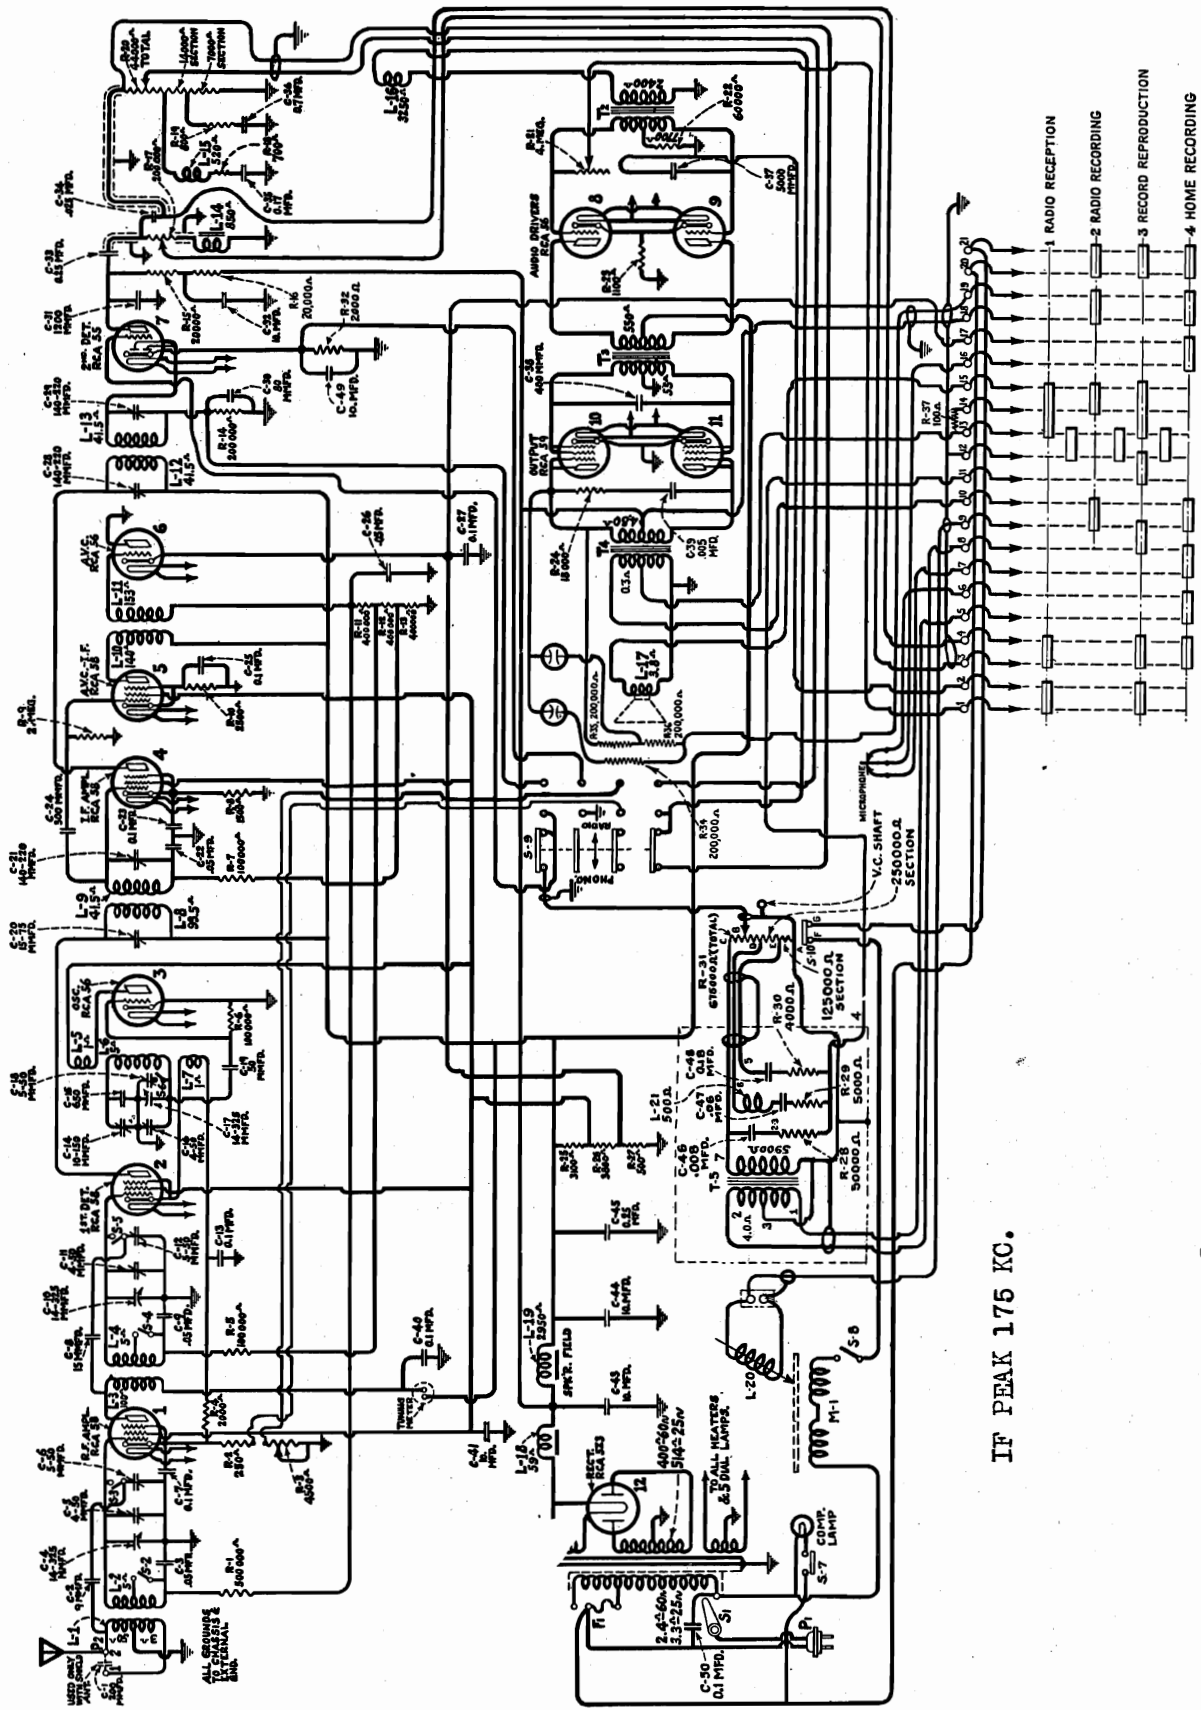

Antenna Connections—It will be noted that three antenna terminals are provided at the rear of the receiver chassis. Two of these are used for the normal antenna and ground connections, while the third one is for use in connection with a shielded antenna system. The tap eliminates the need for the transformer usually used for coupling the shielded line to the radio receiver.

Stock No. 7717 shield kit, which comprises a lightning arrester, transformer assembly, a 200 mmfd. capacitor, and 100 feet of shielded wire, is recommended. When such an antenna system is used, it is necessary to connect the 200 mmfd. capacitor between terminals 1 and 2. This prevents the first R. F. circuit from being detuned and results in maximum gain from the antenna. This capacitor is included with the Stock No. 7717 Kit.

Automatic Record Changer—The automatic record changer used in this instrument is of simple design and excellent construction. The various adjustments that may be required are shown in Figure G. A point to remember with this instrument is that it must always be level, otherwise proper operation will not be obtained.

Pickup Data

RCA-VICTOR CO., INC.

SERVICE DATA ON MAGNETIC PICKUP

The Magnetic Pickup used in this combination instrument is of a new design with an improved frequency range. While in physical appearance it is similar to that of the older type, details of construction are considerably different. It consists essentially of a chromium steel magnet, two thin pole pieces, a mechanism support and bracket, a coil, and an armature that is damped by means of an anchored damping block.

The use of the anchored damping block eliminates any bad peaks in the frequency range. The frequency-response characteristic is substantially flat from 50 to 5,000 cycles.

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or the hardened pivot rubbers (see Figure J), it is necessary to proceed as follows:

- (a) Remove the pickup cover by removing the center holding screw and needle screw.
- (b) Remove the pickup magnet and the magnet clamp by pulling them forward.
- (c) Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.

Figure I

- (d) Remove screws A and B, Figure J, and then remove the mechanism assembly from the pole pieces.
- (e) The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- (f) The mechanism should now be reassembled, except for the magnet, which must be magnetized. After being magnetized, the mechanism—with the pole pieces upward—should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- (g) After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.
- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B (Figure J), and sliding the mechanism slightly in relation to the pole pieces.
- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- (a) Disassemble the pickup as described under the preceding section.

Figure J

- (b) Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- (c) Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- (d) Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.
- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure K, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called

Figure K

acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the air gap as explained under (h).

RCA-VICTOR CO., INC.

MODEL 380-HR
Phonograph Data

OPERATION—PHONOGRAPH

Automatic Operation

Important Precautions—The following precautions must be observed during operation:

1. In loading the turntable, make certain that the first record inserted (last to be played) is flat—that is, essentially free from warpage.
2. Before starting the turntable, make certain that the reject pocket (at the left of the phonograph compartment) is either empty or sufficiently clear to permit proper disposal of records by the automatic mechanism.
3. Never restrain by force the normal motion of any part of the automatic mechanism while it is changing records.

Procedure—The phonograph controls are located on the front panel and in the playing compartment as shown in Figures 1 and 2. Proceed as follows:

1. Set the Transfer Switch for "Record Reproduction."
2. Apply power by turning the Radio Volume Control clockwise from the "off" position. Set the two Tone Controls for full-range reproduction (see paragraph 7 under "Operation—Radio").

3. With the Motor Switch in the "off" position (Record Volume Control fully counter-clockwise), load the turntable with records, as follows:

- (a) Set the Index Lever at "Manual." Always do this before loading or unloading records.
- (b) Place the electric pickup on the rubber rest.
- (c) Raise the Record Ejector arm (very slowly, at first, until the internal weight has rolled to the rear of the arm, then as rapidly as desired) to its upper position of rest. Always raise the ejector arm in this manner.
- (d) Select the records to be played. All records for one loading must be of the same diameter (either ten or twelve inches), close to standard thickness and operable at the same speed (either 78 or 33 1/3 R. P. M.).

CAUTION—Do not use thin flexible-type records for automatic operation.

- (e) Place the records, one at a time, on the turntable (see paragraph 1 under "Important Precautions"). The spindle should remain its normal height after each record is added. The turntable is fully loaded when the top surface of the uppermost record is nearly flush with the top of the spindle. (It should not be possible to slide off the top record without lifting its edge or depressing the spindle.)
- (f) Lower the Record Ejector arm gently onto the spindle.

4. Insert a new needle in the pickup arm as far as it will go and tighten the needle screw. For long-playing (33 1/3 R. P. M.) records, use only the orange Chromium needle. For standard (78 R. P. M.) records, use the latter needle or, if preferred, either the green Chromium or the full volume (full tone) Tungstone needle. Transparent-faced (illustrated) records, however, should not be reproduced with Tungstone needles.

NOTE—With care, the orange Chromium needle should play 75, the green Chromium 100, and the Tungstone 100 to 130 records. Never re-insert in the pickup a Chromium needle which has been used (however slightly) as damage to the record grooves would result.

5. Place the pickup needle on the smooth outer rim of the record, near the first groove. Then move the Index Lever to the position (12 or 10) corresponding to the diameter (inches)

Manual Operation

Records may be played individually as follows:

1. Set the Transfer Switch for "Record Reproduction" and apply the power with the Radio Volume Control as directed for automatic operation. Adjust the two Tone Controls for full-range reproduction.
2. Make sure that the Index Lever is at "Manual," that the electric pickup is on its rubber rest, and that the Motor Switch is in the "off" position.
3. Raise the Record Ejector arm to the upper rest position (see paragraph 3 (c) under "Automatic Operation").
4. Place the record on the turntable and insert a needle in the pickup. For more information, see paragraph 4 under "Automatic Operation."

NOTE—Ordinary steel needles (full volume or full tone) can be used with standard (78 R. P. M.) records,

when using the home-recording facilities of this instrument, the following precautions must be observed:

1. Always place a flat (unwarped) 10- or 12-inch record of the commercial variety beneath the home-recording record when recording.
2. To prevent surface slippage, always record with the felt recording pad inserted between the home-recording and rubber records. This pad is removed for "play-back" purposes but must never be left on the turntable when automatic operation is intended.
3. Use only the special home-recording needle (identified by its yellow shaft and blunt-point) for both recording and reproducing. Such needles, however, must not be used for playing other than home-recorded records.
4. For recording, the needle pressure on the record must be increased by placing the recording weight on the electric pickup. This weight must be removed for reproducing either the home-recorded or any other record.

NOTE—When a record has been played, the ejector arm slides it off into the record pocket and the pickup moves to the outside of the next record. The records on the turntable are thus played consecutively until only one record remains on the turntable. This record will be played repeatedly until the motor is stopped by means of the Motor Switch.

NOTE 2—After a record has been played and changed, the needle is lowered automatically onto the smooth rim of the next record and is fed by gravity into the starting groove. After the instrument has been leveled with reference to the top of the cabinet, further slight compensation may be necessary, thus: (1) If the needle fails to enter the playing groove, the right-hand side of the instrument front and rear legs on that side; or (2) If the needle slides over several grooves, thus failing to reproduce the beginning of the selection, the left-hand side of the instrument must be similarly raised.

9. To reject a record while playing, lift the pickup arm and move it to the extreme left. Hold the pickup lightly until it is moved by the mechanism.

10. Before reloading or when through operating, turn the Motor Switch to the "off" position, set the Index Lever at "Manual" and place the pickup on the rubber rest. Never leave the pickup resting on a record (or on the turntable) when not in use. Turn the power switch "off" and close the cabinet doors when discontinuing operation of the instrument.

Figure 2

OPERATION—RECORDING

7. Start the turntable by turning the Motor Switch "on," then set the Speed Shifter for the desired turntable speed.

NOTE—For best results, always record at 78 R. P. M. If a record of longer duration is desired, recording may be done at 33 1/3 R. P. M. Such records should be so marked, and must of course be reproduced at the same speed.

8. Place the needle in the outer groove of the blank record and recording will proceed automatically. During this process, however, watch the volume indicators and adjust the Radio Volume Control (if necessary) to compensate for changes in the program level.

9. Recording may be interrupted at any time by simply lifting the pickup from the record. It may be resumed on the same record if desired, provided care is taken to enter the needle in a new groove—that is, one slightly nearer the center than the last recorded groove.

10. Upon completing a recording, lift the electric pickup from the record, turn the Motor Switch "off" and place the pickup on the rubber rest.

Microphone Recording

To record voice or musical entertainment originating in the home, the procedure is essentially the same as for the recording of radio programs except that the microphone is employed. Remove this unit from the cabinet (leaving the cord connected) and place it in an upright position on a table or any other horizontal surface conveniently near the sound source.

For best results, special attention must be given to the location and arrangement of the person or persons presenting the program. All sounds to be recorded must be directed toward the front of the microphone, never toward the rear which is designated by the word "BACK" cast on the pedestal. Further, the microphone should be located at a height approximately the same distance from the floor as the sound source. Such conditions may be fulfilled easily in the case of the average adult (speaker or singer) by placing the microphone on the top of the cabinet.

When recording speech, the microphone should be spaced from three to six inches from the speaker's mouth; the speaker should talk in a normal even tone and enunciate clearly. The microphone should be at a somewhat greater distance (one to two feet) when recording musical vocal selections, the proper spacing naturally being dependent upon the number of singers present. For instrumental music, the most desirable distance between the artists and the microphone will depend upon the type (wind or string), as well as the number of instruments and may be from three to ten feet. In the case of a small

room, the procedure is essentially the same as for the recording of radio programs except that the microphone is employed. Remove this unit from the cabinet (leaving the cord connected) and place it in an upright position on a table or any other horizontal surface conveniently near the sound source.

For best results, special attention must be given to the location and arrangement of the person or persons presenting the program. All sounds to be recorded must be directed toward the front of the microphone, never toward the rear which is designated by the word "BACK" cast on the pedestal. orchestra, it would be preferable to group the members in a semi-circle with the stringed instruments nearest the microphone and the horns at the rear.

Adjustment of Recording Volume—Before the actual recording is undertaken, it will be advisable to test for the proper volume as follows:

1. Set the Transfer Switch for "Home Recording."
2. Turn the power "on" (Radio Volume Control rotated slightly clockwise). As for radio recording, make certain that the Index Lever is at "Manual," that the electric pickup is on its rubber rest and that the Motor Switch is "off."
3. Raise the Record Ejector arm and load the turntable with a blank home-recording record, first inserting a standard record and the felt recording pad, then lower the Record Ejector arm.
4. Set the Record Volume Control fully clockwise (turntable now should be rotating) and commence the program which is to be recorded.
5. Regulate the distance between the sound source and the microphone, while observing the flashing action of the neon-lamp indicators at the front of the playing compartment, until both lamps are illuminated continuously or at approximately the same intervals.
6. Turn the Record Volume Control counter-clockwise until the right-hand lamp is either "off" or flashing infrequently; however, do not reduce the setting sufficiently to

change the action of the left-hand lamp. The instrument is now properly adjusted and the test program may be discontinued while making final preparations for recording.

Procedure—After the recording volume is adjusted, leave the Record Volume Control setting intact permitting the turntable to remain in rotation, and proceed as follows:

1. Insert a *home-recording* needle in the electric pickup and place the recording weight on the pickup head.
2. Set the Speed-Shifter for the desired turntable speed (see note in paragraph 7 under "Radio Recording").
3. Place the needle in the outer groove of the blank record and commence without delay the program to be recorded.
4. When the recording is complete (see paragraph 9 under "Radio Recording"), lift the electric pickup from the record, turn the Motor Switch "off" and place the pickup on its rubber rest.

Reproduction of Home Recordings

Home-recorded records (either radio or microphone recordings) may be reproduced in the manner described for manual operation of standard records under "Operation—Phonograph." Such records, however, must not be employed with the automatic record changer and always must be reproduced with the special *home-recording* needle. Always make certain to remove the recording weight from the electric pickup when "playing-back" recordings.

GENERAL

Fuse—This instrument is protected by a fuse located at the rear of the chassis, under the metal cover marked "Caution: Remove Power Supply Before Removing Cover." If the fuse burns out, check the power supply connections and rating, and have all tubes tested by your dealer before installing a new fuse. This is a special fuse—obtain replacement fuses from your dealer—*do not use any substitute for this fuse.*

In districts where the line voltage is always below 115 (225 for 200-250 volt models), the fuse should be

set in the "110" position ("213" position for 200-250 volt models). Always disconnect the power cord from the a-c outlet before removing the fuse cover.

Maintenance—With normal use and handling, trouble-free service is to be expected. The automatic phonograph mechanism and associated parts, however, should be kept clean and well-lubricated. To insure continued efficient operation, it is recommended that the entire instrument be thoroughly inspected and adjusted by an experienced service man once each year.

Neon Lamp and
Switching Data
Record Changer Data

Figure H—Automatic Record Changer Adjustments

- (d) Set the "v" link, at rear of large switch, so that the lower corner is approximately flush with the lower side of the switch. Tighten one set screw.
 - (e) Note the position of the pin as it approaches the "v" link when turning transfer switch clockwise toward position 2 and also when the pin approaches the "v" link when turning the transfer switch counter clockwise toward position 3 from position 4. In these positions the pin must contact the "v" at approximately the same points.
 - (f) Tighten all remaining set screws at each end of the shaft.
- It will now be found that the transfer switch turns with maximum smoothness and the two-position chassis switch operates midway between positions 2 and 3 in either direction.

Audio Circuits

Figure G shows the schematic diagrams of the audio circuits that occur at each position of the transfer switch. A reference to these diagrams will enable the serviceman to quickly diagnose trouble in these circuits.

Testing Neon Level Indicating Lamps
Two Neon Level Indicating Lamps are provided so that a visual indication of the recording level may be obtained at all times. These lamps normally give long service without attention. However, if failure occurs, and all circuits have been checked and eliminated as possible source of failure, the

Figure E—Testing Circuit

lamps may be easily checked as indicated in the circuit shown in Figure E. The method for checking involves testing for lighting between certain voltages. The lamps must not light before 52 volts have been applied and must not require a voltage greater than 64 volts to cause them to light. Lamps requiring different voltages from these are defective and must not be used.

Transfer Switch Mechanism

The transfer switch used in this model is a special four-position rotary switch located on the front panel and operated in conjunction with a two-position switch located in the chassis. The switches are coupled mechanically by means of a flexible shaft and operate as a single unit. In event that any part of the switching system is removed, in order to replace or re-connect the assembly, the following procedure should be observed. Refer to Figure F.

- (a) Set the two-position switch located in the chassis to its extreme clockwise position, and attach the transfer switch to front panel of the cabinet in proper position as shown. Set the transfer switch at position 1.
- (b) Assemble the transfer switch end of the flexible shaft into the switch bracket. Place the "v" link loosely on end of shaft and tighten the pilot screw into its groove.
- (c) Assemble the other end of the flexible shaft to the two-position switch (on chassis) so that one set screw points directly back, when facing the chassis from the rear, and the other to the left. Then tighten one set screw.

DESCRIPTION OF ELECTRICAL CIRCUIT

RADIO

The general circuit arrangement consists of an R. F. stage, a combined oscillator and first detector stage, two I. F. stages, a combined second detector, automatic volume control and 1st A. F. amplifier, a push-pull audio driver stage and a push-pull Class A output stage. Plate and grid voltages are supplied by the RCA-5Z3 heavy duty rectifier combined with a suitable filtering system. In addition, a double channel A. V. C. stage is provided which uses two additional tubes. Figure 1 shows the over-all schematic circuit diagram while Figure 2 shows the R. F. assembly wiring.

Figure 3—Switching Arrangement of Automatic Volume Control Systems

The signal enters the receiver through a shielded antenna lead and is applied to the grid of the R. F. tube through the antenna coupling transformer. The secondary of this transformer is tuned to the signal frequency by means of one unit of the gang-capacitor. The output of this stage is transformer coupled to the grid circuit of the first detector, which is also tuned to the signal frequency by a unit of the gang-capacitor.

Combined with the signal in the first detector is the local oscillator signal, which is always at a 460 K. C. frequency difference (higher) from the signal frequency. A separate coil system and the third unit of the gang-capacitor are used in the oscillator circuit.

In conjunction with these three tuned circuits it is well to point out that five different groups of tuned circuits are used, one group for each tuning band. A five-position selector switch is provided for selecting the band in which the desired signal is located. In addition to selecting the desired coil system, additional groups of contacts are provided for short-circuiting the preceding lower frequency R. F. and detector coils and the two preceding oscillator coils. This is to prevent "dead" spots due to absorption effects caused by the coils, the natural period of which without the gang-capacitor connected falls in the next higher frequency band. This gang switch also has additional contacts for performing other functions which will be discussed.

The output of the first detector, which is the I. F. signal (460 K. C.), is fed directly through two tuned circuits to the grid of the automatic volume control I. F. amplifier stage. A coupling coil adjacent to the secondary of this transformer is connected directly to the signal I. F. stage, which is in effect parallel to the A. V. C. I. F. stage. Examining the signal amplifier further we find that the output of the first signal I. F. stage is applied through a transformer to the second I. F. stage and thence through a second transformer to the second detector. Both circuits of each transformer are accurately tuned to the I. F. signal, which is 460 K. C.

Further examining the A. V. C. I. F. stage it will be seen that the output of this stage is applied to the A. V. C. tube through an untuned I. F. transformer. The A. V. C. stage, which is an RCA-76, is operated as a straight rectifier, its plate being grounded and only the grid being used. This tube is shielded in the usual manner. A small grid voltage, approximately 5.0 volts, is maintained so that rectification does not occur until the signal level exceeds this grid voltage. When this occurs, a portion of the rectified signal produces a voltage drop across resistors R-18 and R-19. The drop across both of these resistors constitutes the automatic bias voltage for the R. F. stage. The drop across R-19 alone gives the automatic bias voltage for the first detector and first I. F. stage on bands X and A.

Figure 4—Sensitivity Control Switching Arrangement

Examining the second detector, the diode electrodes provide the detector action while the grid and plate give audio amplification. A portion of the rectified signal also gives a voltage drop across R-23, which is a second automatic volume control system for the receiver. The voltage drop is applied to the second I. F. stage in all bands and to the first detector and first I. F. stage in bands B and C. The change in automatic volume control systems is made by an additional group of contacts on the band selector switch. Figure 3 shows the switching arrangements for changing the A. V. C. system in the various bands.

At this point, an explanation as to why two automatic volume control systems are used and why the sensitivity control is changed in different bands may be in order.

RCA-VICTOR CO., INC.

MODEL Duo 381
Circuit Data

Two automatic volume control systems are used because of the different receiving conditions in the various bands. For example, in the broadcast and long-wave band (X and A) signal levels are very high. Also due to the use of an aurally compensated volume control, a constant input to the second detector must be maintained. From this it is evident that the double channel I. F. automatic volume control is ideal. It maintains a constant input to the second detector and yet does not function on an extremely weak signal. In the short-wave bands, however, conditions are different. Signal strengths are always very low and fluctuate widely. For this reason it is important to have some automatic volume control action below the level at which the double channel system works. This is provided by the tube marked 2nd detector and 1st A. F. which functions on the first detector and two I. F. stages on the short-wave bands. It should be noted that this action is present on the second I. F. stage on all bands. This further flattens the action of the double-channel system in bands X and A.

At this point it is well to examine the sensitivity control, which also changes on different bands. The sensitivity control adjusts the residual bias on the R. F. and first detector stages in bands X and A while it controls the R. F., 1st detector and both I. F. stages on bands B, C, and D. Figure 4 shows the switching arrangement used.

The sensitivity control is changed so that in bands X and A it controls the R. F. and 1st detector while in bands B, C, and D it controls the R. F., 1st detector, 1st I. F. and 2nd I. F. stages. The reason for this is that for a given degree of sensitivity in bands X and A the residual bias will be considerably higher in the R. F. and 1st detector stages than in the bands B, C, and D used. This is to prevent possible overloading of these stages due to the high-signal strengths encountered in bands X and A. Also, in bands B, C, and D, for a given degree of sensitivity the R. F. stage operates at a higher gain, which gives an improved signal to noise ratio. This is caused by the paralleling of the sensitivity control with an 850-ohm resistor in these bands.

Returning to the second detector, we find its output circuit is coupled to the grid circuit of the driver stage through a compensated volume control system, tone control system and transformer. The volume control uses two stages of compensation, which serves to increase the high and low frequencies as the volume is reduced. This compensates for the natural loss in sensitivity of the human ear to the high and low frequencies at low sound levels. A low and a high frequency tone control enables the listener to alter the fidelity of the receiver to his individual taste.

The driver stage, which is a pair of RCA-76 Radiotrons connected in push-pull, is transformer coupled to a pair of RCA-42's which are the output stage. A feature of the output stage is the use of fixed bias, which reduces distortion and increases the available output. This is accomplished by the use of the drop

across R-38 and R-39, which carries the entire D. C. output from the rectifier. Naturally the output stage uses but a portion of the total rectified current and current variations in it will have but little effect on the drop across the resistor.

The output of the power stage is coupled through a step-down transformer to the voice coil of the loudspeaker. A separate winding, which is shunted by a capacitor, has been provided in this transformer which gives a very sharp, high-frequency cut-off for the entire

Figure 6—Loudspeaker Wiring

audio system. This greatly reduces the reproduction of any high-frequency interchannel interference or other disturbance of a high-frequency character which is outside of the useful musical range.

The loudspeaker used is of the large-field ten-inch type. It is fully capable of handling the high-power, high-quality output of the receiver and converting it into faithful sound reproduction.

Figure 6 shows the loudspeaker wiring while Figure 7 shows the chassis wiring diagram. Figure 9 shows the assembly wiring diagram.

PHONOGRAPH AND RECORDING

The record reproducing facilities consist of a low impedance magnetic pickup with its associated inertia type tone arm, a compensated volume control, the audio amplifier of the receiver and the loudspeaker of the receiver. The radio receiver is made inoperative by the switch used for changing to record reproduction.

The recording facilities use the audio amplifier of the radio receiver, the output of which is connected to the magnetic pickup instead of the voice coil of the loudspeaker. The input to the amplifier may be either from the microphone or from the radio receiver, depending on whether radio recording or home recording is desired. It should be noted that when radio recording is being used, the loudspeaker is connected across the output through a resistor so that the program being recorded may be monitored at the same time.

Figure 7 shows schematic circuit diagram of the audio circuits at each of the four selection switch positions.

MODEL Duo 381
Alignment Data

RCA-VICTOR CO., INC.

SERVICE DATA

(1) LINE-UP PROCEDURE

The line-up procedure of this receiver is somewhat involved and it is important that these instructions be carefully followed when making adjustments. Properly aligned, this receiver has outstanding performance; improperly aligned, it may be impossible to receive signals on all bands.

Equipment

To properly align this receiver, the following equipment must be used. This is a modulated R. F. oscillator having proper frequency range, an output indicator, an alignment tool, a tuning wand, and a "dummy" Radiotron RCA-76. These parts, which are shown on page 20, have been developed by the

Figure 8—Location of Various Coils in Shields

manufacturer of this receiver for use by service men to duplicate the original factory adjustments. The "dummy" Radiotron, RCA-76, is obtained by removing one heater prong from an otherwise perfect tube.

Checking with Tuning Wand

Before making any R. F., oscillator or first detector adjustments, the accuracy of the present adjustments may be checked by means of the tuning wand (Stock No. 6679). The tuning wand consists of a bakelite rod having a brass cylinder at one end and a special finely divided iron insert at the other end. Inserting the cylinder into the center of a coil lowers its inductance, while inserting the iron end increases its inductance. From this it is seen that unless the trimmer adjustment for a particular coil is perfect at alignment frequencies, inserting one end of the wand may increase the output of a particular signal. A perfect adjustment is evidenced by a lowering of output when either end of the wand is inserted into a coil.

The shields over the R. F. coil assembly have a hole at their top for entrance of the tuning wand. The location of the various coils inside of the shield is shown in Figure 8. An example of the proper manner of using the tuning wand would be to assume the external oscillator were set at 1720 and the signal tuned in. The A. V. C. tube would be replaced by the "dummy" RCA-76 and the output indicator connected across the voice coil of the loudspeaker. Then the tuning wand should be inserted, first one end and then the other end, into the top of the three transformers at the left of the R. F. assembly, facing the front of the chassis. A perfect adjustment of the trimmer would be evidenced by a reduction in output when each end of the wand is inserted in each of the three transformers. If one end—for example, the iron end—when inserted in one coil caused an increase in output, then that circuit is low. An increase in the trimmer capacitance would be the proper remedy.

(2) I. F. TUNING CAPACITOR ADJUSTMENTS

Although this receiver has three I. F. stages, two for the signal and one for the A. V. C. only three transformers having six adjustable capacitors require adjustment. The fourth transformer is in the A. V. C. circuit and is broadly tuned, not requiring adjustments. The transformers are all peaked, being tuned to 460 K. C.

A detailed procedure for making this adjustment follows:

(a) Connect the output of an external oscillator tuned to 460 K. C. between the first detector grid and ground. Connect the output indicator across the voice coil of the loudspeaker. Replace the A. V. C. tube in the receiver with the "dummy" RCA-76.

(b) Place the oscillator in operation at 460 K. C.; place the receiver in operation and adjust the station selector until a point is reached (Band A) where no signals are heard and turn both the volume and sensitivity controls to their maximum position. Reduce the oscillator input until a slight indication is obtained in the output indicator.

(c) Refer to Figure 10. Adjust each trimmer of the I. F. transformers until a maximum output is obtained. Go over the adjustments a second time.

This completes the I. F. adjustments. However, it is good practice to follow the I. F. adjustments with the R. F. and Oscillator adjustments due to interlocking which always occurs.

(3) R. F. OSCILLATOR AND FIRST DETECTOR ADJUSTMENTS

Four R. F., oscillator and first detector adjustments are required in bands "X" and "A." Three are required in bands "B" and "C" while none are required in band "D." Band "D" uses the second harmonic of the oscillator while the detector and R. F. coils do not have trimmers.

RCA-VICTOR CO., INC.

To properly align the various bands, each band must be aligned individually. The preliminary set-up requires the external oscillator to be connected between the antenna and ground terminals of the receiver. The output indicator must be connected across the voice coil of the loudspeaker while the "dummy" RCA-76 must be placed in the A. V. C. socket. The sensitivity and volume controls must be at their maximum position and the input from the oscillator must be at the minimum value possible to get an output indication under these conditions. In the high-frequency bands, it may be necessary to disconnect the oscillator from the receiver and place it at a distance in order to get a sufficiently low input to the receiver.

The Dial Pointer must be properly set before starting any actual adjustments. This is done by turning the variable capacitor until it is at its maximum capacity position. One end should point exactly at the horizontal line at the lowest frequency end of band "A," while the other end should point to within $\frac{1}{4}$ " of the horizontal line at the highest frequency end of band "A."

Figure 10 shows the location of the trimmers for each band. Care must be exercised to only adjust the trimmers in the band under test.

Band "X"

(a) Tune the external oscillator to 410 K. C., set the pointer at 410 K. C. and adjust the oscillator, detector and R. F. trimmers for maximum output.

(b) Shift the external oscillator to 175 K. C. Tune in the 175 K. C. signal irrespective of scale calibration and adjust the series trimmer marked 175 K. C. on Figure 10, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 410 K. C. as described in (a).

Band "A"

(a) Tune the external oscillator to 1720 K. C., set the pointer at 1720 K. C. and adjust the oscillator, detector and R. F. trimmers for maximum output.

(b) Shift the external oscillator to 600 K. C. Tune in the 600 K. C. signal irrespective of scale calibration and adjust the series trimmer, marked 600 K. C. on Figure 10, for maximum output, at the same time rocking the variable tuning capacitor. Then readjust at 1720 K. C. as described in (a).

Band "B"

(a) Tune the external oscillator to 5160 K. C., and set the pointer at 5160 K. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacitor from minimum to maximum.

(b) Check for the image signal, which should be received at approximately 4240 on the dial. It will be necessary to increase the external oscillator output for this check.

(c) The antenna and detector trimmers should now be peaked for maximum output.

Band "C"

(a) Tune the external oscillator to 18,000 K. C., and set the pointer at 18 M. C. Adjust the oscillator trimmer for maximum output. The trimmer should be set at the first peak obtained when increasing the trimmer capacity from minimum to maximum.

(b) Check for the image signal, which should be received at approximately 17,080 on the dial. It may be necessary to increase the external oscillator output for this check.

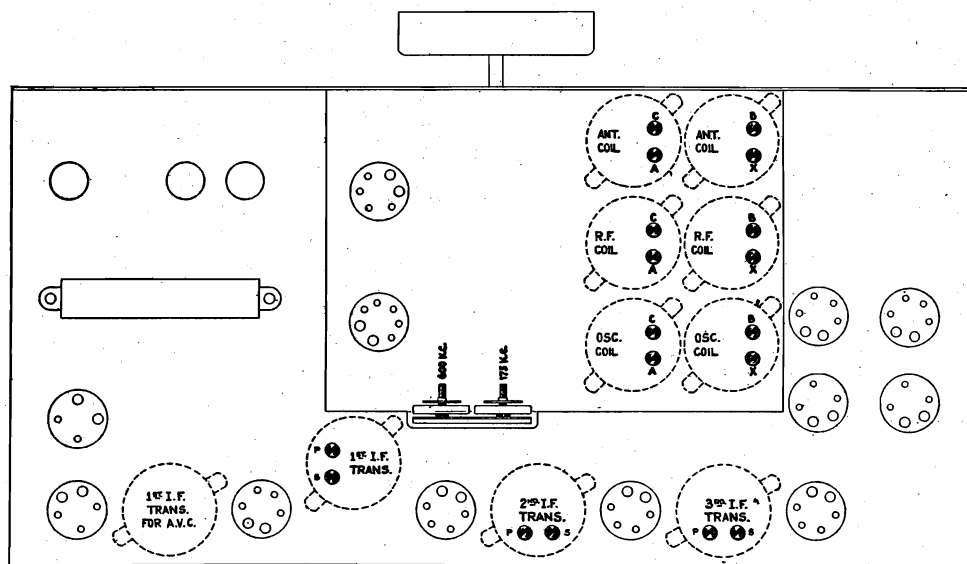

Figure 10—Location of Various Trimmer Capacitors

**MODEL Duo 381
Neon Lamp Test
Voltage**

RCA-VICTOR CO., INC.

(c) Reduce the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal disappears. The first detector circuit is then at the oscillator frequency and the RCA-6A7 tube is blocked. Then increase the capacity of the detector trimmer, while rocking the tuning capacitor, until the signal is peaked for maximum output.

(d) The antenna trimmer should now be peaked for maximum output. It is not necessary to rock the main tuning capacitor while making this adjustment.

Band "D"

No adjustments are required for Band D.

(5) VOLTAGE READINGS

The following voltages are those at the various tube sockets while the receiver is in operating condition. No allowance has been made for currents drawn by the meter, and if low-resistance meters are used, such allowances must be made. Figure 13 shows the location and voltage at each socket contact.

(6) TESTING NEON LEVEL INDICATING LAMPS

Two Neon Level Indicating Lamps are provided so that a visual indication of the recording level may be obtained at all times. These lamps normally give long service without attention. However, if failure occurs, and all circuits have been checked and eliminated as possible source of failure, the lamps may be

Figure 11—Testing Circuit

easily checked as indicated in the circuit shown in Figure 11. The method for checking involves testing for lighting between certain voltages. The lamps must not light before 52 volts have been applied and must not require a voltage greater than 64 volts to cause them to light. Lamps requiring different voltages from these are defective and must not be used.

MODEL Duo 381
Pickup Data

RCA-VICTOR CO., INC.

the same time, the metal dust cover must be placed in position.

- (h) After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have

Figure 15—Pickup Nomenclature

the armature centered properly. The adjustment is made by loosening screws A and B (Figure 15), and sliding the mechanism slightly in relation to the pole pieces.

- (i) The cover may be now replaced over the entire assembly, and the pickup returned to the tone arm.

In assembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be .009" on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

(9) REPLACING THE DAMPING BLOCK

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.
- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is

somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.

- (e) After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure 16, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be reassembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place,

Figure 16—Special Soldering-Iron Tip

as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the air gap as explained under (h), section (8).

(10) AUTOMATIC RECORD CHANGING MECHANISM

The automatic record changer used in this instrument is of simple design and fool-proof construction. Under normal operating conditions service difficulties should be negligible. However, in event adjustments are required, a reference to Figure 14 will disclose the proper method of making all adjustments.

RCA-VICTOR CO., INC.

PART IV—SERVICE DATA

Type and Number of Tubes Used 1 RCA-41,
1 RCA-78, 1 RCA-6A7, 1 RCA-6B7—Total, 4
Total Battery Current (With 6.3 volts between chassis
and A (hot) terminal) 5.35 Amperes
Undistorted Output 1.35 Watts
Loudspeaker Field Current 1.35 Amperes
Filtered D. C. Voltage from Rectifier 227 Volts
Total Plate Current 47.5 M. A.

This four tube Superheterodyne Police Receiver is of compact construction and gives excellent performance. Features such as unit construction (one unit contains the receiver, "B" battery eliminator and loudspeaker), ease of installation, freedom from ignition noise and excellent sensitivity, selectivity and tone quality characterize this instrument.

"B" Battery Eliminator

This receiver uses a vibrator-type Inverter-Rectifier that provides a source of direct current voltage for use as plate and grid supply for all tubes. This unit is accurately adjusted and sealed at the factory and service adjustments should not be attempted.

Line-up Capacitor Adjustments

The three R. F. line-up capacitors and two I. F. tuning capacitors are accessible and may require adjustments. The R. F. adjustments are made at 2508 K. C. and the I. F. adjustments at 175 K. C. The R. F. adjustments can be made with the receiver in its case, access to the adjusting screws being obtained through a slot in the bottom of the case. For the I. F. adjustments, however, it is necessary to remove the rear cover in order to couple the oscillator to the first detector. The following procedure should be used for these adjustments:

R. F. Adjustment

A satisfactorily accurate and rapid adjustment of the three R. F. line-up capacitors can be made by ear, although, for optimum results, the use of an output meter connected across the loudspeaker voice coil is recommended. The latter method however, involves removal of the rear cover to connect the meter, thus in turn eliminating the shielding effect of the case. Temporary shielding for the bottom and tube sides of the chassis and for the transformer therefore must be provided to prevent vibrator interference.

- (a) Procure a modulated oscillator giving a signal at 2508 K. C. and a non-metallic screw driver. Stock No. 9050 oscillator and 7065 screw driver are suitable.
- (b) Couple the output of the oscillator from antenna to ground, set the dial at 97, and the oscillator at 2508 K. C.
- (c) Place the oscillator and receiver in operation and adjust the oscillator output so that a weak signal is obtained in the loudspeaker when the volume control is at its maximum position.

- (d) Then adjust the three line-up capacitors until maximum sound in the speaker or maximum deflection of the output meter is obtained. Readjust these capacitors a second time as there is a slight interlocking of adjustments.

I. F. Adjustments

In order to make the I. F. adjustments, it is necessary to remove the rear cover, due to the fact that the external oscillator must be connected between the control grid of the first detector and ground. Proceed as follows:

- (a) Procure a modulated oscillator giving a signal at 175 K. C., a non-metallic screw driver and an output meter.
 - (b) Remove the receiver from its case, shield the transformer and tubes as described under R. F. adjustments, place the receiver in operation and connect the oscillator output between the first detector and ground. Connect the output meter across the voice coil of the loudspeaker. Then connect the antenna lead to ground and adjust the tuning capacitor so that no signal except the I. F. oscillator is heard at maximum volume. With the volume control at maximum, reduce the external oscillator output until a small deflection is obtained. Unless this is done, the action of the A. V. C. will make it impossible to obtain correct adjustments.
 - (c) Each transformer has but one winding that is tuned by means of an adjustable capacitor, the other windings being untuned. The capacitors should be adjusted for maximum output.
- At the time I. F. adjustments are made it is good practice to follow this adjustment with the R. F. adjustments, due to the interlocking that always occurs. The reverse of this, however, is not always true.

Practical Hints on Installation

The following suggestions may prove useful when making installations on the particular cars mentioned.

Chevrolet 1933—Mount chassis on left side, end against car bulkhead and use short flexible shaft. Use both capacitors, one on the ammeter and one on the generator. Use all suppressors. Place a copper screen under the toe board on right side, 10" x 10" to prevent the body from radiating ignition interference which may be picked up by the antenna. This screen must be grounded.

Plymouth 1933—Mount chassis on left side, back against car bulkhead and use 33 3/8" flexible shaft. Use both capacitors, one on the ammeter and one on the generator. Use all suppressors.

Ford V-8 1932 or 1933—Mount chassis on left side, end against car frame and use short flexible shaft. Use one capacitor, connected to the generator. Install eight spark plug type suppressors only, no distributor suppressor being necessary.

The majority of cars will be found to be entirely free from ignition noise when the standard equipment is used. Usually mounting the chassis on the right side of the bulkhead will be found most desirable, although if a heater is used, the left side will be preferable.

TUBE SOCKET VOLTAGES

RCA-VICTOR CO., INC.

Electrical Specifications

Voltage Rating	200-230 AC or DC
Frequency Rating (AC)	50-60 Cycles
Power Consumption	AC 60 Cycles-105 Watts-DC-85 Watts
Number and Types of Radiotrons	1 RCA-78, 1 RCA-6A7, 1 RCA-77, 1 RCA-43, 1 RCA-12Z3—Total, 5
Undistorted Output	1.5 Watts
Frequency Range	540 KC-1500 KC

Figure C—Location of Line-Up Capacitors

This receiver is a five-tube Super-Heterodyne designed to operate on AC or DC over the voltage and frequency range indicated. Features such as compact construction, dynamic speaker, single Pentode Output tube and the inherent sensitivity, selectivity and tone quality of the Super-Heterodyne are included in this instrument.

The circuit consists of an R. F. stage using Radiotron RCA-78, a combined oscillator and first detector using Radiotron 6A7, an I. F. transformer using two tuned circuits, a second detector using Radiotron RCA-77 and a power stage using Radiotron RCA-43. The rectifier is Radiotron RCA-12Z3, which is used in a half-wave circuit.

Line-Up Capacitor Adjustments

The line-up capacitor adjustments for the I. F. stage and for the R. F. circuits should be made in the following manner:

- (a) Procure a modulated oscillator giving a signal at 175 KC and 1400 KC. An output meter and non-metallic screw driver are also necessary. The Stock No. 9050 test oscillator and Stock No. 7065 screw driver are suitable for this purpose. Figure C shows the location of the I. F. capacitors.
- (b) The I. F. line-up capacitors should be first adjusted. This is done by placing the oscillator in operation at 175 KC, coupling its output between the control grid of the first detector and ground, connecting the output meter across the cone coil of the loudspeaker and adjusting the two I. F. line-up capacitors until maximum output is obtained.
- (c) After the I. F. circuits are aligned, the R. F. and oscillator circuits are adjusted at 1400 KC. Prior to making the adjustment, however, the dial should be checked. This is done by making sure the dial indicator reads 530 (indicator in center position) when the tuning capacitor rotor plates are fully meshed with the stator plates. The adjustments are then made in similar manner as that of the I. F. except that the oscillator is set at 1400 KC, its output is connected from antenna to ground of the receiver, and the dial is set at 140. The adjustment is made with the trimming capacitors located on top of the gang capacitor and each capacitor is adjusted for maximum output.

Antenna Length Chart

RCA-VICTOR CO., INC.

From the chart shown, it can be seen that a wide variation in signal strength can be obtained with various length antennas. This data applies particularly to the six-tube receiver and in general to the eight-tube receivers but does not necessarily apply to competitive instruments. The various degrees of reception are approximately equal for various antenna lengths. For example, the "good" sections give about four times as much sensitivity as the "poor" sections. As this is also an equal gain over noise, proper choice of antenna length can often make the difference between satisfactory and unsatisfactory reception.

In conjunction with the question of the relative merits of a short or long antenna for the frequencies that fall in the "good" sections of each, either length will be equally good, assuming that neither is shielded by buildings of metallic construction or other such objects. If, for example, part of the antenna or lead-in is shielded by the building, then the longer antenna will give better results.

Also the longer antenna will give better results in the broadcast band. The solid black rectangular blocks indicate both the frequencies of, and the antenna lengths recommended particularly for the short-wave broadcast bands.

ANTENNA LENGTH CHART

(Lengths shown are overall, including Lead-in Wire to Receiver—Ground Wire not to exceed 15 feet.)

RCA-VICTOR CO., INC.

World Wide Antenna Installation Data

Mounting Procedure

The actual set-up of the antenna system is very simple and can be performed by practically anyone. Since the means of supporting the antenna will of necessity be different in almost every case, that portion of the installation will not be discussed herein. General recommendations in this respect, however, are contained in Figure 1. Insofar as possible, the intent of such recommendations should be observed, even for different forms of mounting.

Assembly—As shown in Figure 1, the two doublet antennas which comprise this system are formed by the two stranded wires supplied with the kit. By means of the porcelain crossover insulator, these wires are crossed to produce two horizontal sections, each 29 feet in length, and two angularly displaced sections, each 16½ feet in length. An extra length of six inches is afforded at each end of both continuous wires for connection to the porcelain strain insulators, both (as noted under "Equipment") being 46½ feet long. In assembling these wires to the crossover insulator, be careful that the actual cross occurs on opposite sides of the insulator.

The transmission line finally should be connected to the antenna wires as indicated by the detail illustration of the crossover insulator in Figure 1. A tinned spot on each wire is provided to identify the points at which the transmission line should be attached. Make certain to insert the piece of cambric tubing at the insulator and to use only rosin-core solder for the connections as recommended. The antenna now may be suspended between the masts or intended points of support.

Connection to Receiver—The opposite end of the transmission line should be led to the receiver, using the porcelain insulator knobs (if required) and the porcelain entrance-tube insulator. Then install the coupling transformer upon the antenna-ground terminal board of the receiver, as shown in Detail A of Figure 1, and attach the transmission line to this transformer. A metal cleat and wood screw are provided to secure the transmission line to the receiver cabinet.

NOTE—For models having no terminal board, it is very important that the transformer be installed as near to the chassis as possible. To insure best noise elimination, this connection should be no longer than one inch. The connection to the antenna also should be kept as short as possible, although it is more important to avoid too close proximity of this wire to grid terminals of the receiver tubes.

Connection to Ground—A ground clamp is supplied for securing a tight and permanent connection of the ground wire from the receiver to a water pipe in the basement or to an external metallic stake driven from five to eight feet into the soil. The ground wire should be No. 14 or larger (rubber-covered) and should follow as short and direct a route as possible. Since the length required will be different for each installation, this wire is not furnished with the kit, but may be obtained locally.

General Considerations

To insure the greatest possible benefits from the RCA "World-Wide" Antenna System, three important considerations should be observed during its installation:

- (a) Height above ground.
- (b) Distance from local sources of noise interference, such as power lines, street railroads and automobile highways.
- (c) Direction of span.

Height above Ground—This consideration probably is the most important since it directly affects the strength at which signals will be received. Ordinarily, the antenna will be erected either upon the roof of a building or suspended between that roof and a nearby tree or pole. For the usual dwelling having a roof and framework of non-metallic materials, the height will be measured with respect to the actual surface of the earth. However, if the opposite condition exists, as in the case of a modern apartment house or hotel, effective ground shall be assumed as at the metal roof. For good results, the horizontal wires of the antenna should be at least 30 feet above the effective ground.

Distance from Sources of Interference—Since the antenna system excludes from the receiver all interference signals "picked-up" by the transmission line, the antenna should be erected as far as possible from sources of interference in the immediate locality. The antenna proper may be located up to 500 feet distant from the receiver, adding one or more lengths of transmission line to the length furnished, as required. To maintain the correct electrical matching, any excess length of transmission line should not be removed unless two or more full lengths have been added. Where the required length of line is less than one or two full lengths, the excess line should be coiled up neatly at the end nearest the receiver.

Direction of Span—This antenna system exhibits a slight directional effect—that is, the geographical position of the span may have some effect upon the intensity of incoming signals. Wherever possible, therefore, the antenna should point in a direction at right angles to that of the transmission path from favored broadcasting stations. If the antenna must be located near a street railroad or a much-traveled highway, direct "pick-up" of interference signals on the doublets can be minimized by erecting the span to point toward the source of interference.

RCA-VICTOR CO., INC.

ALTERNATIVE ANTENNA ARRANGEMENTS

In certain installations, space limitations may prevent the use of the full antenna span—approximately 60 feet. Three alternative arrangements, listed in order of preference, are possible:

- (a) Reduced overall length through the use of loading coils.
- (b) Reduction of the horizontal angle from a straight line span (180 degrees) to any other of not less than 90 degrees.
- (c) Vertical suspension.

The first arrangement (a), in which loading coils are inserted to replace lengths removed from the horizontal sections of the antenna as illustrated by Figure 2, is recommended as the preferred alternative. In this manner, the overall span is reduced to approximately 34 feet, without impairing the original tuning characteristics of the system except in the region of 31 meters. The loss encountered within the broadcast band at this wavelength, however, will not be serious.

Using the second alternative (b), the length of

the antenna span is decreased by reducing the horizontal angle between the halves of the system (as viewed from above), rather than by shortening the lengths of the horizontal sections. While loading coils are not required, a third support for the antenna at the crossover insulator must be provided, the installation therefore being usually more difficult than for either *straight-line* arrangement. The antenna efficiency naturally will be lowered as the angle is decreased, resulting in a signal-strength loss on all bands of approximately 30 percent at an angle of 90 degrees.

If vertical suspension (c) is employed, much less ground space than for any horizontal form of antenna is necessary. Although somewhat inferior in noise ratio to the horizontal type, the vertical system enjoys an additional advantage of being practically non-directional. Such an installation, however, is usually both difficult and expensive, but can be simplified to a large extent through the use of loading coils.

MODEL 2-19
Portable Victrola
Notes

SERVICE DATA

This instrument is a small portable type mechanical phonograph built into a cabinet resembling a small suitcase. Excellent quality, high output and good mechanical construction are features of this instrument.

LUBRICATION

Premature wear, noisy operation and failure of parts are direct results of failure to clean and lubricate the motor at necessary intervals. The various bearings and gears of the motor should be cleaned and lubricated at least once every six months. In addition to the regular lubrication, all motor parts should be covered with a light film of oil to prevent rusting. Use only Stock No. 7226 Motor Oil and Stock No. 7227 Motor Grease when lubricating this instrument.

Figure A—Lubrication Diagram

Motor. Figure A shows a view of the motor with the top plate cut away. Before lubricating the parts shown in this illustration, a thorough cleaning with carbon tetrachloride (Carbona) or gasoline is necessary. If necessary disassemble the entire motor for such cleaning.

Tone Arm. The joint between the taper tube and the sound chamber must be free to swing easily without play and be sealed with grease. This bearing is accessible when the three mounting screws are removed. Failure to seal this joint will result in poor quality. Unnecessary friction will cause undue record wear.

MOTOR

The motor used is of simple design and will give excellent performance. If kept clean and properly lubricated, little service attention will be required. The following points may prove useful when it is necessary to effect repairs. *Before doing any work on the motor the machine must be allowed to run down completely.*

Removing Motor from Cabinet. To remove the motor from the cabinet proceed as follows:

- (a) Unscrew the spindle cap and remove the turntable.

(b) Remove the five screws that hold the motor board and lid-support to the cabinet and remove the motor-board assembly.

(c) Remove the speed-regulator lever.

(d) Remove the three machine screws that hold the motor in place. The motor may then be removed.

Changing Motor Springs. Should a spring break and require replacement the best method to make a repair is to replace the entire spring barrel. While the cost of the spring barrel is greater than that of the spring alone, the saving in labor will usually justify such replacement. Unless the serviceman is experienced in handling springs of this type, the following directions should be followed carefully:

(a) Disassemble the motor and remove the spring barrel. Remove the winding gear.

(b) Place the gear flat on a piece of metal and file off the ends of the six rivets. Remove the rivets and gear.

(c) Place the palm of the right hand over the closed end of the barrel, making sure that the fingers do not protrude beyond the open side. Firmly hold the barrel, open side downward, over a large can or barrel. With the left hand pull the center turns of the spring out. As soon as the spring starts, pull the left hand clear of the can, holding the spring barrel firmly until the spring is entirely clear.

(d) *A new coiled spring may prove extremely dangerous if not properly handled. Read these instructions and work very carefully, especially if not experienced in work of this kind.* The new spring is furnished coiled and with a heavy wire clamp holding the spring tightly wound. Pull out about one foot of the spring. Then with the spring flat on a table gently tap the ring until it comes to the edge. Do not push the clamp so close to the edge that it will not hold the spring.

Place the hook end of the spring over the barrel hook. Wind the exposed end into the barrel and then insert the entire spring in the barrel, allowing the clamp to be on the outer edge. Place a block over the entire spring and force the spring into the barrel, thereby releasing the clamp.

(f) Place a tablespoonful of spring lubricant between the spring leaves and in the center of the spring.

(g) Place the gear in position and rivet it with six rivets to the spring barrel. Use a small punch for flattening the ends of the rivets. Place the gear on a flat surface while re-riveting the barrel to it.

(h) Reassemble the motor in the reverse manner of that used to dismantle it.

Winding Shaft Binding. A heavy jar may cause the motor to shift slightly on the motor board and produce binding of the winding shaft against the motor board. Loosening the motor mounting screws and shifting the motor to its proper position (center of slot) will correct this condition.

Chassis Wiring

NOTE—If the maximum volume, obtained with the volume control in the extreme clockwise position, is insufficient to meet the requirements of a particular installation, the locking device may be re-adjusted as follows: (1) Remove volume control knob by pulling outward; (2) take off rear panel by removing screws at edges; (3) loosen lock nut holding right angled bracket which serves as stop for metal pointer on shaft; (4) turn shaft clockwise until volume is increased to desired level; (5) lock bracket in new position against pointer, by retightening lock nut; and (6) replace rear panel and knob.

Figure A—Schematic Circuit

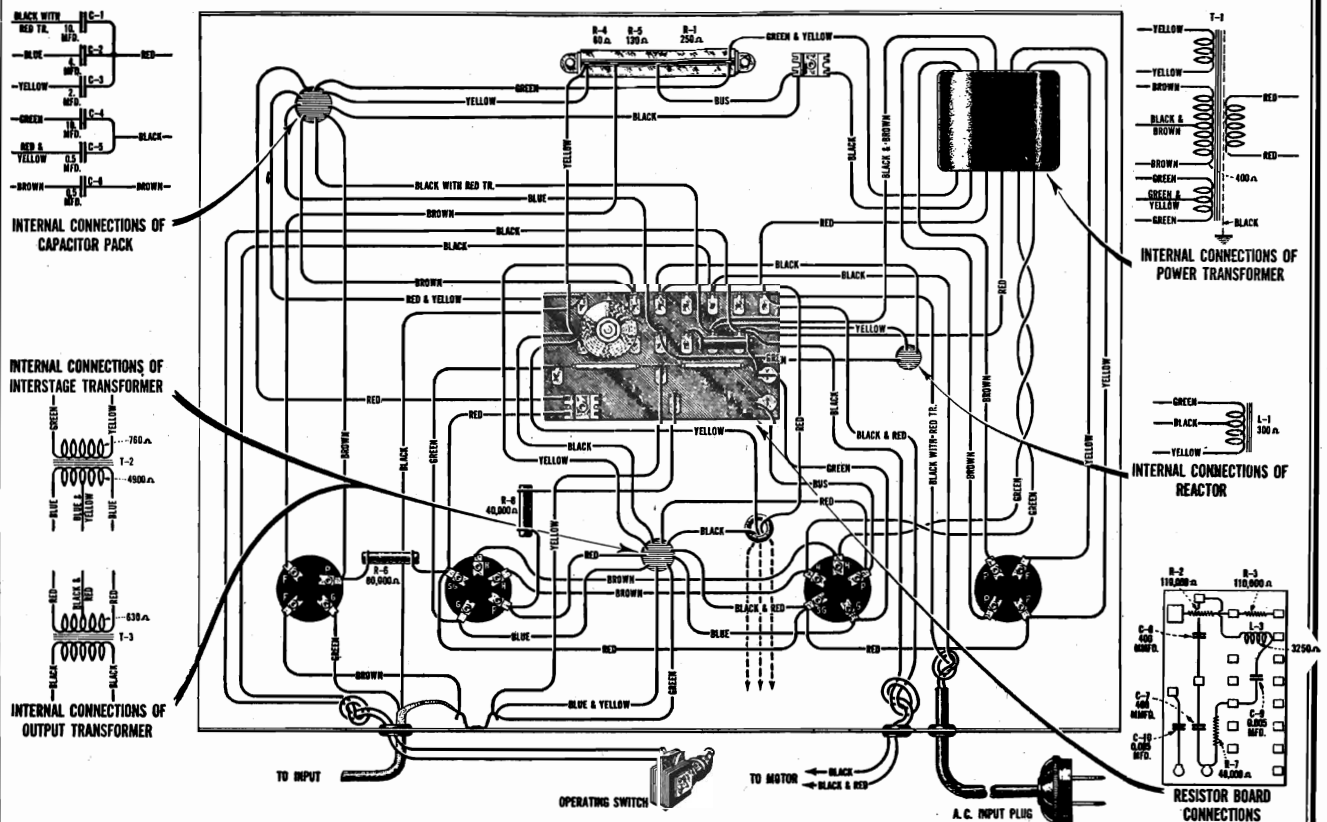

Figure B—Amplifier Wiring

MODEL CRD-9
Assembly Wiring
Parts List

RCA-VICTOR CO., INC.

1. Plug the two wires (which should be equipped with pin terminals) from the external source into the pin jacks located below the Transfer Switch.
2. Set the Power Switch to the "on" position. The Motor Switch should be in the "off" position.
3. Set the Transfer Switch in the downward position. Signals originating in the external input circuit will now be heard through the demonstrator loudspeaker.
4. Adjust the volume to the desired level by means of the demonstrator Volume Control.
5. When through operating, set the Power Switch to the "off" position.

External Input—To use the demonstrator amplifier and loudspeaker for reproduction from an external source of audio frequency input, proceed as follows:

1. Plug the two wires (which should be equipped with pin terminals) from the external source into the pin jacks located below the Transfer Switch.

NOTE—The impedance of the external input circuit should match that of the demonstrator input, which is approximately 10 ohms at 1,000 cycles.

WIRING

The schematic and assembly wiring diagrams are shown in Figure C.

MAGNETIC PICKUP

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or hardened pivot rubbers, it is necessary to proceed as follows:

- Remove the pickup cover by removing the center holding screw and needle screw.
- Remove the pickup magnet and the magnet clamp by pulling them forward.

Figure A

- Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.
- Remove screws A and B, Figure A, and then remove the mechanism assembly from the pole pieces.
- The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.
- The mechanism should now be reassembled except for the magnet, which must be magnetized. After being magnetized the mechanism—with the pole pieces upward, should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be remagnetized thoroughly, being careful not to change the polarity obtained by the initial magnetization.
- After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.

- After remagnetizing, it is necessary to correctly center the armature. This may be done quite accurately by feeling its play after the needle is inserted. A little practice will quickly show which way an adjustment is necessary to have the armature centered properly. The adjustment is made by loosening screws A and B, Figure A, and sliding the mechanism slightly in relation to the pole pieces.

- The cover now may be replaced over the entire assembly, and the pickup returned to the tone arm.

In reassembling, it may be desirable to check the armature air gap by means of a small Feeler Gauge. This air gap should be nine mils on each side of the armature. However, a little practice with the needle in place will quickly disclose whether or not the armature is centered.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.
- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be noted that the hole in the damping block is somewhat smaller than the diameter of the armature. This is done so that a snug fit will be obtained.

Figure B

- After properly locating the damping block, a soldering iron should be applied to the armature so that the block will melt slightly at its point of contact with the armature. A special tip, constructed as shown in Figure B, will prove desirable for fusing the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling. The pickup should then be assembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as a flux a water solution of zinc chloride (commonly called acid flux). After tinning, dip the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (e) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (h) above.

WIRING

The schematic and assembly wiring diagrams are shown in Figure 1.

MAGNETIC PICKUP

Replacing Magnet Coil, Pivot Rubbers, Armature or Damping Block

In order to replace a defective coil or hardened pivot rubbers, it is necessary to proceed as follows:

- Remove the pickup cover by removing the center holding screw and needle screw.
- Remove the pickup magnet and the magnet clamp by pulling them forward.

Figure 2

- Unsolder the coil leads and remove the mechanism assembly from the back plate by releasing the two mounting screws and the damping block clamping screw.
- Remove screws A and B, Figure 2, and then remove the mechanism assembly from the pole pieces.
- The coil or the front pivot rubber may now be removed and replaced. If it is desired to replace the rear pivot rubber, then the end of the armature soldered to the mechanism support must be unsoldered and the damping block removed. The rear pivot rubber now may be replaced. After putting the pivot rubbers in place a new damping block should be fastened to the armature as outlined in instructions on replacing the damping block.

The mechanism should now be reassembled except for the magnet, which must be magnetized. After being magnetized the mechanism—with the pole pieces upward, should be placed so that the magnet may be slid from the magnetizer onto the pole pieces without breaking physical contact. After placing the pole pieces on the magnet, the entire assembly should be magnetized by the initial magnetization.

After assembling to the mechanism, the entire assembly should be fastened to the back plate by means of the screws provided, making sure the damping block is securely clamped. At the same time, the metal dust cover must be placed in position.

Replacing the Damping Block

If it is desired to replace the damping block, it may be done in the following manner:

- Disassemble the pickup as described under the preceding section.
- Remove the armature entirely by unsoldering it at its joint with the mechanism support.
- Remove the damping block from the armature and clean the bushing for holding the damping block with emery paper.
- Insert the armature through the new block so that it occupies the same position as that of the old. Also ascertain that the block is in correct vertical alignment with the armature. It will be necessary to use the diameter of the block as a guide in measuring the diameter of the armature. This is done so that a snug fit will be obtained.

Figure 3

- After properly locating the damping block, a soldering iron should be applied to the armature so that the block will seat slightly at its point of contact with the armature. A special tip, constructed as shown in Figure 3, will prove desirable for fitting the block in place. The iron should be applied long enough to slightly melt the block and cause a small bulge on both sides, but should not be applied long enough to cause any bubbling in the pickup should then be assembled as described in the preceding section.

Only rosin core solder should be used for soldering the coil leads in the pickup. Also rosin core solder should be satisfactory for resoldering the end of the spring in the hole in the mechanism, since both these parts have been previously tinned. In case the parts are not well tinned, it will be necessary to scrape the end of the spring and the hole in the mechanism until bright. These parts may now be tinned by using as flux a few drops of the parts in water to wash off the acid flux and thereby prevent serious subsequent corrosion. After making sure that the pivot rubbers and damping block are properly in place, as described under (c) above, the armature may now be soldered in place in the mechanism by using rosin core solder, since the parts are now tinned. Care must be exercised to get the needle hole perfectly square with respect to the mechanism, or otherwise it will be difficult if not impossible to center the armature in the airgap as explained under (b) above.

RCA-VICTOR CO., INC.

VOLTAGE AMPLIFIER PB23M1

REPLACEMENT OF INPUT TRANSFORMER

Should it become necessary to replace the input transformer in the first stage of the voltage amplifier, care must be used to replace it in such a position that maximum shielding is obtained. The position of the transformer with respect to the amplifier panel which gives minimum hum is the correct position for maximum shielding.

FIDELITY CHARACTERISTICS

In this voltage amplifier the low-frequency booster circuit is located in the plate circuit of the UY-224A, and the voice frequency filter in the cathode circuit of the RCA-56. The voltage amplifier is connected at the factory to operate with 50-inch baffles. The response at 60 cycles is approximately 90% of the 1000-cycle response and at 100 cycles the response is approximately 60 per cent. If it is desired to shift the low-frequency peak either to a lower frequency or higher frequency, or to change the value of the frequency response, proceed as follows:

- (a) To shift the peak to 50 cycles, remove the .02 mfd capacitor C-41 from the low-frequency booster circuit by disconnecting the jumper wire between terminals No. 16 and No. 18 on the capacitor pack. Place the .03 mfd capacitor C-40 in the circuit by connecting a jumper between terminals No. 16 and No. 17.
- (b) To shift the peak to 40 cycles, connect the capacitors C-40 (.03 mfd) and C-41 (.02 mfd) in parallel by connecting jumpers between terminals No. 16, No. 17 and No. 18.
- (c) If 27-inch baffles or doublet baffles are used on the stage, it will be necessary to shift the low-frequency

peak to 80 cycles. To do this, disconnect the jumper wires between terminals No. 16, No. 17 and No. 18 on the capacitor pack. Connect a .02 mfd capacitor (Catalog No. 3639) externally between terminals No. 16 and No. 17 on the capacitor pack. This will connect the .02 mfd capacitor in series with the .03 mfd capacitor C-40 to give .012 mfd across L-30.

- (d) To increase the value of response at any of the peak values used in the foregoing, remove the 100,000 ohm resistor R-81 connected across reactor L-30, between terminals on the tube shelf connected to terminals No. 7 and No. 16 on the capacitor pack. If a still further increase, to a maximum of approximately 400 per cent, is desired, shunt the plate resistor R-18 (125,000 ohm) with the 100,000 ohm resistor.
- (e) To increase the response at 100 cycles, decrease the value of the shunt resistor R-80, and if a decrease in response is desired increase the value of the shunt resistor R-80. If male voices sound boomy it will be necessary to increase the value of the shunt resistor.

Chassis Wiring

Volume Amplifier Wiring (PB23M1)

MODEL PG-59
Units Specifications

RCA-VICTOR CO., INC.

Supplement No. 3 to RCA Victor Photophone Theatre Reproducing Equipment Type PG-59 (High Fidelity)

(1) PA83C1 AMPLIFIER RACK

The PA83C1 Amplifier rack is similar electrically to the PA83B2. The PA83C1 has heavier front panels than previous models of this amplifier type.

(2) PA83C3 AMPLIFIER RACK—PB82C1 AMPLIFIER UNIT

The frequency response characteristic is a modification of that obtained on previous models. The amplifier is connected at the factory so that more pronounced low frequency response is obtained with the 27-inch baffles. The response is such that no loudspeaker filter is required in the loudspeaker voice coil circuit.

A fuse is connected in series with capacitor C-11 in the PK22 exciter lamp supply unit as a protection to the rectox rectifier and transformer.

Figure 1 shows the rack wiring and schematic diagram of the PA83C3 rack.

(3) FIDELITY CHARACTERISTICS—PB82C1

For 27-inch Baffle

The amplifier unit is connected at the factory so that the response is approximately 160 per cent at 80 cycles, 64 per cent between 200 cycles and 300 cycles, 125 per cent between 2000 cycles and 4000 cycles and then drops off to approximately 40 per cent at 10,000 cycles.

To modify the frequency response characteristic, proceed as follows: See Figure 2.

- (a) To reduce the frequency response between 100 cycles and 300 cycles, remove the short circuit which is connected across C-28 and R-40.
- (b) Should the operation performed in (a) reduce the extreme low frequency response too much, remove the resistors R-32 and R-33 (2 megohms each).
- (c) To increase the frequency response between 100 cycles and 300 cycles, remove the 0.1 mfd capacitor C-27 which is shunted across C-3. Open up by-pass circuit on R-9.
- (d) To reduce extreme low frequency response disconnect the resistors R-32 and R-33 (2 megohms each) and connect R-41 and R-42 ($\frac{1}{2}$ megohm each) in place of those removed.

For 50-inch Baffle

- (a) If 50-inch Baffles are used with the PG-59 equipment, disconnect the resistors R-32 and R-33 (2 megohms each) and also replace C-25 and C-26 (.04 mfd each) by C-19 and C-20 (.07 mfd each). The frequency response characteristic will then be approximately 160 per cent at 60 cycles, 64 per cent between 200 cycles and 300 cycles, 125 per cent between 2000 cycles and 4000 cycles, and 40 per cent at 10,000 cycles.
- (b) To reduce the frequency response between 100 cycles and 300 cycles, remove the short circuit which is connected across C-28 and R-40.
- (c) To increase the frequency response between 100 cycles and 300 cycles, remove the 0.1 mfd capacitor C-27 which parallels C-3. Open up the by-pass circuit on R-9.
- (d) To reduce the extreme low frequency response, connect resistors R-32 and R-33 (2 megohms each) across the reactors in the grid circuit of the Radiotrons RCA-2A3.

(4) LOUDSPEAKER—PL52C2

The Model PL52C2 Loudspeaker mechanism has a new type of terminal board for the voice coil circuit as shown in Figure 3. The design of these terminals is such that they are more easily accessible for installation and service work.

PRE-AMPLIFIER PA103A1

Schematic Wiring Diagram

PRE-AMPLIFIER

For program pickup, or where the velocity microphone is used for any purpose except close talking, a pre-amplifier is required for each microphone. The overall gain of this pre-amplifier is 58 DB. The Radiotron voltages for this pre-amplifier are obtained from a PK24B1 power supply unit.

The pre-amplifier is designed to work from a 250-ohm source and into a 250-ohm line.

MODEL PG-62-C
Installation Data

The RCA Victor Portable Public Address System, Type PG-62 is a complete amplifying system consisting of an amplifier, a microphone, and two loudspeakers. It is designed for use as a sound reinforcing system in auditoriums, theatres and churches or for outdoor gatherings. The equipment is entirely A. C. operated, power for its operation being obtained from any 50 or 60 cycle, 110 volt house lighting receptacle. The maximum undistorted power output of this equipment is 20 watts which is sufficient to meet the average requirements of sound reinforcement in auditoriums with a capacity up to 2,500 seats.

The amplifier consists of two units; the voltage and power amplifier units both mounted in a carrying case. The loudspeakers, two of which are supplied with the equipment, are each mounted in a wooden housing. A special carrying case is provided for the loudspeakers when they are to be transported.

A velocity type microphone, the latest type developed by the RCA Victor engineers, is also furnished as a standard part of the equipment. Provision is made for placing microphone and stand together with the microphone interconnecting cables in the amplifier carrying case when the equipment is to be transported. Figure 1 shows the equipment set up for operation.

All the controls except the power control switch are mounted on the voltage amplifier base and are easily accessible to the operator. The controls consist of the power control switch mounted on the power amplifier base, the microphone volume control, amplifier volume control, the speech clarifying switch and the tone switch. Figure 2 shows the location of the various controls.

Facilities are provided for operating the equipment with a phonograph turntable. If it is desired, phonograph music may be played as a background for the microphone pick-up, the volume of each being controlled independently of each other. In the Universal Amplifier Assembly a microphone selector switch is mounted on the voltage amplifier to permit the use of a carbon type microphone with the equipment.

PART I—SETTING UP THE EQUIPMENT

(1) TYPE PG-62 EQUIPMENT

The equipment is set up for operation in the following manner:

- Open the amplifier carrying case and lay the two halves on the floor or a table so that the Radiotrons will be in an upright position. Remove the microphone and microphone stand and support.
- Check and make certain:
 - That all Radiotrons are in their proper sockets and pressed down firmly. Never apply power to the instrument unless all Radiotrons are in place. See Figure 2.
 - That the short flexible lead is connected to the top grid contact of the Radiotron RCA-57.
 - That all shields are rigidly in place over all the tubes in the voltage amplifier and the cap is on the shield over the Radiotron RCA-57.

- Open the loudspeaker carrying case and remove the two loudspeakers. Place the loudspeakers in a position so that the loudspeaker grilles face in the direction in which the sound beams are desired. Interconnect the two loudspeakers with the cable and plug provided. Connect the loudspeakers to the amplifier by means of the four-pole plug provided on the other loudspeaker cord.

- Assemble the microphone and the microphone stand and support. Insert the three-pole plug on the end of the microphone cable into the three-pole receptacle on the voltage amplifier.
- Plug the A. C. power cord into a 105-125 volt, 50-60 cycle A. C. power receptacle. The equipment is now ready for operation.

FUSE: A small cartridge type fuse is located on the end of the power amplifier base. Should it open and the equipment fail to function, replace the Rectifier Tube, RCA-83, and replace the fuse. A deposit of mercury between the elements may have caused the short that burnt out the fuse.

(2) UNIVERSAL AMPLIFIER

Before the equipment may be set up for operation, certain accessories must be obtained. They are as follows:

- Microphone, such as the Type PB-90.
- Microphone stand, such as the table stand, Type PB-96 or the floor stand, Type AZ-4090.
- One, two, or four loudspeakers having a voice coil impedance of 7½ ohms or 15 ohms each. Each loudspeaker should have its own source of supply for field current. The dry disc rectifier type or the vacuum tube rectifier type is suitable for this purpose.
- A two conductor loudspeaker cable.

The equipment is set up for operation in the following manner:

- Insert the Radiotrons in the sockets as shown in Figure 2.
- Place both the voltage and power amplifiers on a table or on the floor so that the Radiotrons will be in an upright position. Check and make certain:
 - That all Radiotrons are in their proper sockets and pressed down firmly. Never apply power to the instruments unless all Radiotrons are in place. Figure 2 shows the proper Radiotron locations.
 - That the short flexible lead is connected to the top grid contact of the Radiotron RCA-57.
 - That all shields are rigidly in place over all the tubes in the voltage amplifier and the cap is on the shield over the Radiotron RCA-57.
- Connect the voltage and power amplifiers together by means of the interconnecting cable as shown in Figure 10.
- Make connections between the loudspeakers and the four pole loudspeaker plug, furnished with the amplifier, as indicated in Figure 3. Insert the loudspeaker plug into the corresponding receptacle on the side of the power amplifier base.

NOTE: If a loudspeaker having a voice coil of 7½ ohms impedance is used, the link between the output transformer and the loudspeaker receptacle should remain connected between terminals 1 and 2, as indicated in Figure 10. If the voice coil impedance is 15 ohms, shift the link so that it connects terminals 2 and 3 on the link terminal board.

- Insert the three-pole plug on the end of the microphone cable into the three-pole receptacle on the voltage amplifier.
- Plug the A. C. power cord into a 105-125 volt, 50-60 cycle A. C. power receptacle. The equipment is now ready for operation.

FUSE: A small cartridge type fuse is located on the end of the power amplifier base. Should it open and the equipment fail to function, replace the rectifier tube, RCA-83, and replace the fuse. A deposit of mercury between the elements may have caused the short that burnt out the fuse.

PART II—OPERATION

After the equipment has been properly located and connected, it may be operated in the following manner. (Refer to Figure 2.) This operating procedure applies to both the PG-62 equipment and the Universal Amplifier.

- Apply power by turning the power control switch "on," located on the base of the power amplifier.

MODEL PG-62-C
Operating Notes

RCA-VICTOR CO., INC.

(2) MULTIPLE OPERATION OF POWER AMPLIFIERS

The Type PB-88 Voltage Amplifier may be used to operate as many as three Type PB-89 Power Amplifiers. The requirements for such operation are as follows:

- (a) In each power amplifier, remove the resistor R-18 (50,000 ohms) and replace with a 100,000 ohm, one-watt resistor, Catalog No. 3058.

Figure 5—Two microphones wired to one plug

Figure 6—Multiple Operation of Power Amplifier

- (b) Connect the power amplifiers to the voltage amplifier as shown in Figure 6.
- (c) If the Model PB89A1 power amplifiers are used, connect a set of loudspeakers to each power amplifier as shown in Figure 8. If the Model PB89B1 power amplifiers are used, connect a set of loudspeakers to each power amplifier as shown in Figure 3.
- (d) Each power amplifier must be connected to a source of A. C. 110 volt, 60 cycle power.

PART IV—SERVICE DATA ON
AMPLIFIER EQUIPMENT

(1) ELECTRICAL DESCRIPTION OF CIRCUIT

The velocity microphone is coupled to the first stage of the voltage amplifier (RCA-57) by means of an input transformer located on the amplifier base. The link circuit between the microphone transformer and the input transformer is of 250 ohms impedance. A potentiometer is provided in the grid circuit of the RCA-57 to vary the input voltage applied to the grid.

The RCA-57 is resistance coupled to the RCA-56 in the second stage. Another potentiometer is provided in the grid circuit of this RCA-56 to control the output volume of the entire equipment. The RCA-56 is in turn resistance coupled to the RCA-56 in the third stage of the voltage amplifier. The last stage of the voltage amplifier is coupled to the single RCA-59 which is the driver for two Radiotrons RCA-59 in the Class "B" output stage. The output stage supplies power to two loudspeakers through a step-down transformer. This transformer has an output impedance of 15 ohms with a tap at $7\frac{1}{2}$ ohms.

2. The microphone should be located adjacent to the person talking and to one side of the loudspeaker. It should preferably not be located either directly in front or at the rear of the loudspeaker as acoustic feedback will result. Turning the microphone, with both volume controls at maximum, until the position where the least sound is produced in the loudspeakers due to feedback, will allow best operation.

NOTE: The Universal Amplifier Assembly is equipped with a microphone selector switch located on one end of the voltage amplifier. Set this switch in the "Velocity" position when a Velocity Type Microphone is used. When a carbon type microphone is used, set the switch at the "Carbon" position.

Set the Microphone Volume Control, located on the voltage amplifier, at its mid-position. Talk into the microphone at a distance of ten to twenty inches and gradually rotate the Amplifier Volume Control until the desired volume is obtained from the loudspeakers.

Figure 4—Wiring changes for two microphone operation

3. If voice only is to be picked up by the microphone, set the speech clarifying switch in the "speech" position. For musical pickup, the "music" position will give better reproduction. In either case, the "tone" dial, located on the base of the voltage amplifier, should be adjusted for most pleasing reproduction.

PART III—SPECIAL OPERATION

In some instances, it may be desirable or necessary to use two velocity microphones or more than one power amplifier operated from one voltage amplifier. The following sections cover these special uses of the equipment.

(1) TWO MICROPHONE OPERATION

In general, the use of more than one velocity microphone with either the PG-62 Equipment or Universal Amplifier is not recommended. This would presume a microphone mixer which is undesirable as the overall gain is insufficient to overcome the attenuation in the mixer.

If it is necessary to use two microphones (not more than two) and keep both in the circuit at the same time, using no fading or mixing arrangement, other than the volume controls on the voltage amplifier, the connections and changes in the amplifier wiring are as follows:

PG-62 Equipment

- (a) Disconnect and tape the two green leads between the microphone receptacle on the voltage amplifier and input transformer.
- (b) Connect the two yellow transformer leads (500 ohms) to the microphone receptacle. See Figure 4.
- (c) Connect the two microphones in series to the microphone plug as shown in Figure 5.

Universal Amplifier

- (a) Disconnect and tape the two green leads between the microphone selector switch on the voltage amplifier and the input transformer.
- (b) Connect the two yellow transformer leads (500 ohms) to the microphone selector switch at the points from which the two green leads were removed. See Figure 4.
- (c) Connect the two microphones in series to the microphone plug as shown in Figure 5.

Operating Notes
Chassis Views
Loud Speaker Data

FIG. 3
LOUD SPEAKER WIRING FOR
VARIOUS VOICE COIL IMPEDANCES.

Figure 2—View of Voltage and Power Amplifiers Showing Parts

(6) PHASING LOUDSPEAKERS (PG-62 Equipment)

If either of the loudspeaker cones are replaced, the two loudspeakers must be properly phased after the replacement work is done. That is, the motion of both cones must be in the same direction at a given instant when a signal is impressed on them. The following procedure may be used to phase the loudspeakers.

1. Place the two loudspeakers side by side and connect them together by means of the cord and plug provided.
2. Turn the equipment on so that field coils are energized. Apply 6 volts D. C. intermittently to the voice coil terminals at one loudspeaker (black lead and yellow lead on PL71A1 or white lead and red lead on PL71B1). If both cones do not move in the same direction, reverse the voice coil leads to the terminal board of one loudspeaker only.

CAUTION: The loudspeaker fields are at approximately 400 volts above ground. Therefore care must be observed in making tests on the loudspeakers.

(7) DIRECTIONAL BAFFLE LOUDSPEAKER

It is sometimes desirable to use a directional baffle type of loudspeaker with this amplifying equipment. In this case it is necessary to compensate for the difference between the response frequency characteristics of the flat baffle and the directional baffle. The compensation should consist of a .0005 MFD capacitor (Catalog No. 21648) connected in series with the .005 MFD capacitor C-1, and a 250,000 ohm resistor (Catalog No. 23114) shunted across the speech clarifying switch.

The power supply for both the voltage and power amplifiers is obtained from the RCA-83 and a filter system located on the power amplifier base. The field coil of one loudspeaker in the PG-62 Equipment is as a filter reactor in the power supply system in the power amplifier. In the Universal Amplifier an additional reactor is used in the filter circuit in place of the loudspeaker field mentioned above.

(2) CARBON MICROPHONE CONNECTIONS (Universal Amplifier Only)

The Universal Amplifier Equipment is designed so that it will operate with a double button carbon microphone of 250 ohms impedance. A three-pole plug, similar to that employed with the velocity microphones, should be used. Each button on the microphone should be connected to each of the symmetrical poles on the plug. The remaining pole on the plug should be used to connect to the midpoint of the microphone. When using the carbon microphone, the microphone selector switch should be placed at the "Carbon" position.

(3) PHONOGRAPH CONNECTIONS

An input jack is provided in the grid circuit of the RCA-57 which permits the use of a phonograph turntable RCA Victor Type PT-34, Type PT-15, Type PT-16 or Type PT-17. The instructions for operation of the turntables are included with the phonograph equipment.

(4) WIRING

The schematic wiring diagram for the PG-62 Equipment is shown in Figures 7. The wiring diagram for the complete PG-62 Equipment is shown in Figure 8. Figures 9 and 10 show the schematic and wiring diagrams respectively for the Universal Amplifier.

(5) RADIOTRON SOCKET VOLTAGES

The Radiotron socket voltages given in the following tabulation are the actual values at which each Radiotron should operate. In circuits containing high resistance, voltages read on a set analyzer will not agree with the values in the table, due to the relatively low resistance of the meter employed. Therefore, a correction must be applied to the meter reading to obtain the correct voltage at each socket. Usually, an application of Ohm's Law will give an approximate value of the voltages at which each Radiotron is operating, assuming that the resistance of the meter is known.

Sealed Vibrator Test
Data

RCA-VICTOR CO., INC.

Sealed-Vibrator Test

In order to properly test the new sealed type vibrators, it is essential that certain test specifications be made. The following bench layout and test information will permit proper tests of vibrators for all important qualities except R.F. interference. R.F. interference must be tested by installing the vibrator in the instrument in which it is to be used and making an operating test. No other test for R.F. interference is conclusive.

The bench test set-up shown uses the following material:—

- 2 Six-volt storage batteries
- 1 7000 Ohm 75-Watt Resistor capped at 5000 Ohms (10,000 Ohms standard stock size)
- 3 Transformers, Stock Nos. 9457, 9049, 9430
- 1 Ammeter 0-20 (Low Resistance)
- 1 Voltmeter 0-10
- 1 Voltmeter 0-500 (1000 Ohm per volt)
- 1 Capacitor, Stock No. 6738
- 1 Bracket

The following tabulation gives the proper transformer, load, resistance and other information for tests:

VIBRATOR UNDER TEST	TRANSFORMER TO BE USED	LOAD RESISTANCE (OHMS)	MINIMUM OUTPUT VOLTAGE AT 6 VOLTS INPUT	MAXIMUM INPUT CURRENT (AMPERES) 8 VOLTS
M-34 (7604)	9430	5000	210*	6.25
M-105 (7689)	9049	5000	180*	5.0
M-116 (7694)	9457	7000	240*	5.0

* In event reading is reversed, interchange either green and red or brown and blue vibrator leads.

Using the test set-up shown, proceed as follows:—

1. The vibrator should start every time the circuit is properly connected across the 6-volt section of battery. Check starting by feeling for a slight vibration or listening for vibrator noise.
2. The output voltage should be above the values given in the table.
3. The input current should be below the values given in the table.

Failure to meet any of these three conditions is sufficient cause for rejection of a unit as defective.

Typical Bench Set-Up for Testing Vibrators

MODEL 951
Alignment
Voltage
RADOLEK CO.

These service notes pertain to two receivers which are identical with the exception that one model had Duola connections incorporated in it. These connections are shown in the schematic drawing by the dotted lines. Where Duola provisions are provided connections marked "X" on the diagram are open. Receivers with Duola connections may be identified by the Duola switch and two tip jacks located on the back of the chassis. Receivers which do not have the Duola connections do not have the switch (Part #9566) or the tip jacks (Part #9565).

ALIGNMENT: Only when an antenna, oscillator or IF transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE TRANSFORMER ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the grid clip disconnected. CONNECT A 50,000 OHM RESISTOR FROM THE CONTROL GRID OF THE 6A7 TUBE TO THE ROTOR FRAME OF THE VARIABLE CONDENSER. The ground side of the test oscillator should be connected to the gang condenser frame and must not be otherwise grounded.
2. Set the oscillator at 265 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer trimmer shields.
4. The second IF transformer should next be adjusted in the same manner as the first intermediate transformer.

TO ALIGN THE VARIABLE CONDENSER:

1. Place the band selector switch for operation on the 1500-540 kilocycle band (right hand position) and tune the receiver to exactly 1400 kilocycles on the dial and set the oscillator to this frequency. Next, adjust the trimmer screws of the oscillator and antenna section of the variable condenser to obtain maximum output reading. These trimmers are mounted on the top of the variable condenser.
2. Tune the receiver and set the oscillator frequency to approximately 600 kilocycles. Adjust the 600 kilocycle padding condenser which is located on the rear of and accessible through the small hole in the chassis for maximum output. Be sure to rock the variable condenser slightly to the right and left so as to obtain the position of greatest output.

NOTE: There is no short wave adjustment. After alignment has been properly made in accordance with the instructions given, the dial calibration will be correct and the receiver will properly track on short wave band.

VOLTAGE TABLE

TYPE OF TUBE	POSITION OF TUBE	FILAMENT VOLTS	PLATE VOLTS	SCREEN VOLTS	CATHODE VOLTS	OSC. GRID NO.1	ANODE GRID NO.2	SCREEN GRID NO.3 & 5
6A7	Oscillator & Modulator	5.2	128		2.00	1.5	125	76
78	Intermediate Frequency	5.1	128	128	2.25			
75	2nd Detector Diode & AVC	5.0	82.5*		2.00			
43	Output	25	115	128	20**			
25Z5	Rectifier	25						

* Triode plate voltage. Comparative only is not the true voltage applied. The voltmeter, when readings are taken at this point, is in series with a very high resistance.

** Bias for the 43 output tube is obtained by the voltage drop across the filter choke. Read bias voltage from cathode to negative side of filter choke.

Voltage

RADOLEK CO.

VOLTAGE TABLE:

Line Voltage : 115
 Volume Control : Full on
 Wave Band : Broadcast

<u>TUBE</u>	<u>FIL.</u>	<u>PLATE</u>	<u>SCREEN</u>	<u>CATHODE VOLTS</u>
57 1st Detector	2.4	230	90	4.5
57 Oscillator	2.4	175	175	1.7
58 I. F.	2.4	230	90	4
2A6 2nd Detector	2.45	160*		3
2A5 A. F.	2.4	218	230	7**
80 Rectifier	4.8	340 ea. plate		

* Comparative voltage only. The voltmeter, when readings are taken at this point, is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis unless otherwise specified.

** Read from grid to chassis.

Only when the antenna, oscillator or I. F. transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the type 57 modulator tube (1st detector) leaving the grid cap disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

NOTE: Some of the IF intermediate transformers used do not have the brass hex nut and the trimmer screw inside of the brass hex nut, but have two parallel trimmers which are likewise accessible through two holes provided in the top of the I. F. shield can.

4. The second I. F. transformer should next be adjusted in the same manner as the first I. F. transformer.

VARIABLE CONDENSER ALIGNMENT: It is important when aligning the variable condenser to follow the procedure given carefully, otherwise the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.
2. Tune the receiver to exactly 1400 kilocycles on the dial, adjust the band selector switch for operation on the broadcast band (1500-540 kilocycles) and set the oscillator to 1400 kilocycles. Then adjust the oscillator variable condenser section trimmer condenser TO BRING THIS SIGNAL IN (maximum output). The oscillator and antenna variable condenser trimmers are mounted on top of the variable condenser. Looking at the front of the receiver the first section of the variable condenser is the oscillator section and the other section tunes the antenna coil.
3. Leave the band selector switch for operation on the same band, set the oscillator at 600 kilocycles and tune the receiver to approximately 600 kilocycles on the dial. Then adjust the 600 kilocycle padding condenser which is the one located towards the front on the right hand side of the chassis and accessible through the small hole in the chassis for maximum output. It is necessary to rock the condenser slightly to the right and left to obtain the correct position. After aligning the 600 kilocycle padding condenser be sure to recheck the 1400 kilocycle adjustment as the 600 kilocycle alignment may have changed the alignment at 1400 kilocycles.
4. Adjust the short wave switch for operation on 1500 kilocycle to 4500 kilocycle band. Set the oscillator at 4 megacycles and the receiver to 4 megacycles on the dial. Turn the receiver on end and BRING THE 4 MEGACYCLE SIGNAL IN (TO MAXIMUM OUTPUT) BY ADJUSTING THE 4 MEGACYCLE TRIMMER located underneath the chassis and adjacent to the band selector switch. Next, tune the receiver to 1600 kilocycles on the dial and set the oscillator frequency to 1600 kilocycles after which adjust the 1600 kilocycle padding condenser which is located on the rear right hand side and accessible through the hole in the chassis for maximum output. It is imperative that after making this adjustment at 1600 kilocycles that the alignment at 4 megacycles be rechecked, as the 1600 kilocycle adjustment may throw the receiver out at 4 megacycles.

MODEL 958

Alignment Data

RADOLEK CO.

TUBE EQUIPMENT: The receiver uses the following tubes:

One (1) type 57 First Detector
 One (1) type 57 Oscillator
 One (1) type 58 I.F. Amplifier
 One (1) type 2A6 Second Detector Diode Triode, AVC.
 One (1) type 2A5 Output.

Only when an antenna, oscillator or IF transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the #57 Modulator tube (1st detector), leaving the grid clip disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the 1st intermediate transformer trimmer up and down until maximum reading is obtained on the output meter, then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.
4. The second I.F. transformer should next be adjusted in the same manner as the first I.F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the variable condenser to follow the procedure given carefully, otherwise the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.
2. Tune the receiver to exactly 4 megacycles on the dial and adjust the band selector switch for operation on this band.

Set the short wave trimmer about one-half the distance between maximum clockwise and counter-clockwise rotation.

Next set the test oscillator to exactly four megacycles and tune the signal in by adjusting the oscillator variable condenser trimmer mounted on top of the variable condenser. Looking at the front of the receiver the first section of the variable condenser is the oscillator section and the other section tunes the antenna coil.

3. Leave the band selector switch for operation on the same band and tune the receiver to 1.6 megacycles on the dial.

Set the oscillator to exactly 1.6 megacycles.

Adjust the padding condenser accessible through the hole in the right hand side of the chassis and the closest to the rear of the chassis to obtain maximum output reading. After making this adjustment recheck the alignment at 4 megacycles. It is advisable to recheck the 1.6 and 4 megacycle adjustment several times.

4. Adjust the band selector switch for operation on the broadcast band.

Tune the receiver to exactly 1400 kilocycles on the dial and set the oscillator to this frequency.

Turn the receiver on end and adjust the trimmer screw on the small trimmer located adjacent to the short-wave switch underneath the chassis for maximum signal after which adjust the antenna variable condenser trimmer mounted on top of the variable condenser for maximum signal strength.

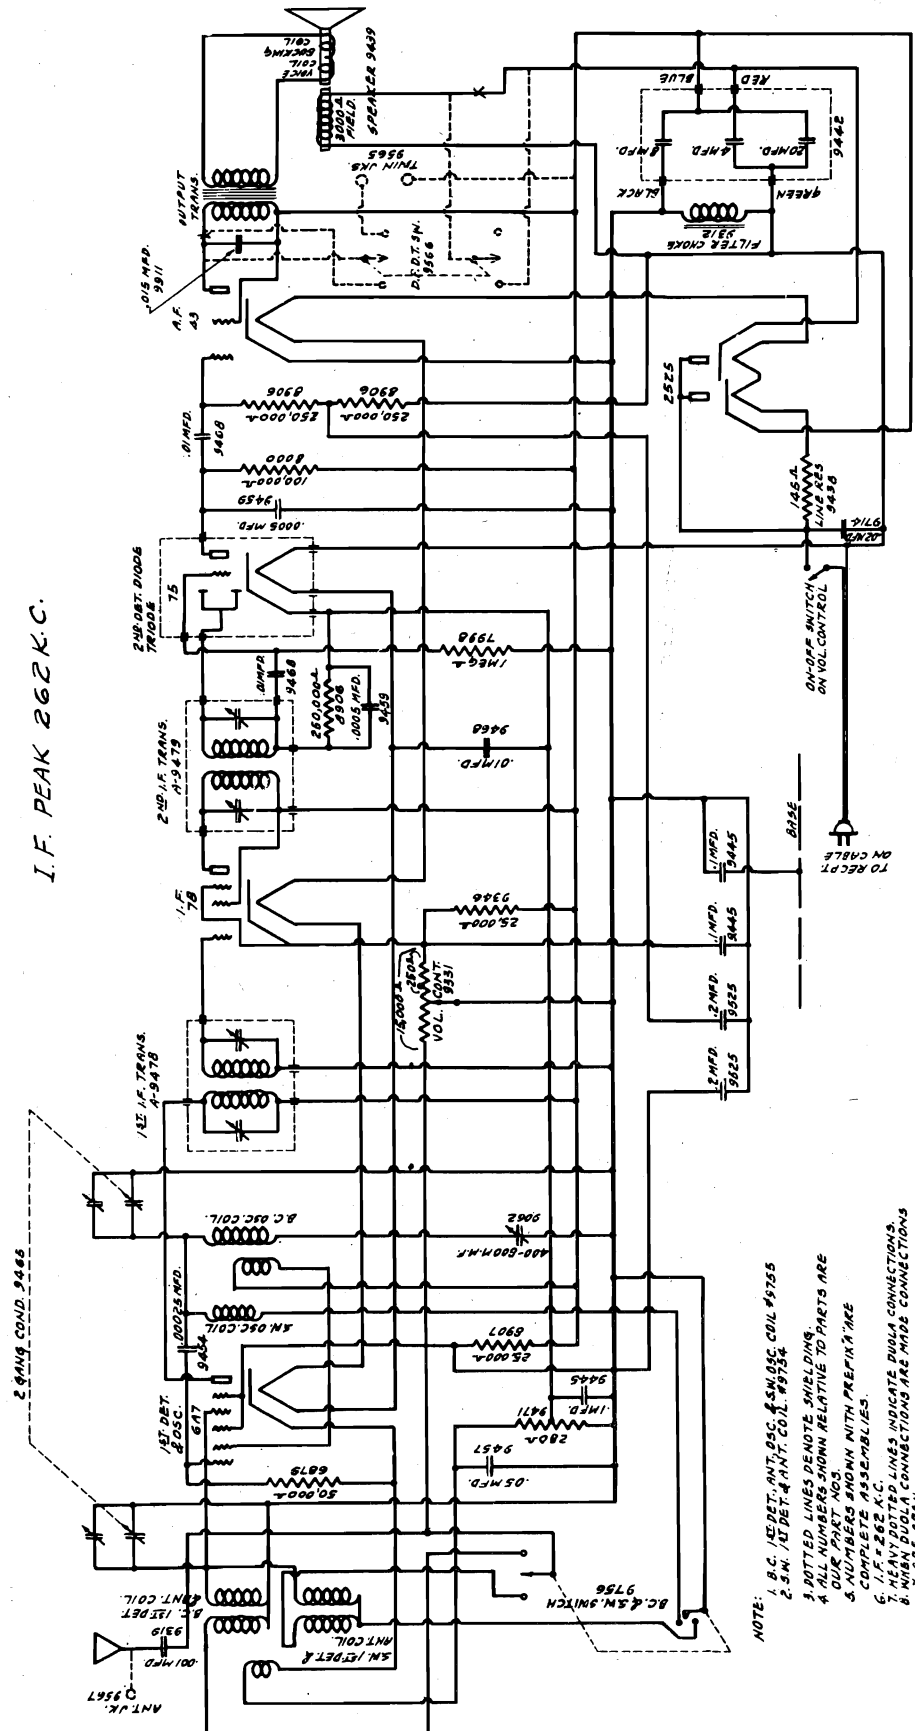

5. Leave the band selector switch for operation on the broadcast band and tune the receiver to approximately 600 kilocycles and adjust the oscillator to this frequency. Then adjust the 600 kilocycle padding condenser which is located on the righthand side next to the 1.6 megacycle padding condenser for maximum output reading. As this adjustment is quite critical it is necessary to rock the condenser slightly to obtain maximum sensitivity.

NOTE: Always recheck the 1400 kilocycle alignment after making the adjustment at 600 kilocycles and the 600 kilocycle adjustment after aligning at 1400 kilocycles. All short-wave bands are properly aligned after correctly aligning at 4 megacycles.

Alignment, Voltage

RADOLEK CO.

These service notes pertain to two receivers which are identical with the exception that one model had Duola connections incorporated in it. These connections are shown in the schematic drawing by the dotted lines. Where Duola provisions are provided connections marked "X" on the diagram are open. Receivers with Duola connections may be identified by the Duola switch and two tip jacks located on the back of the chassis. Receivers which do not have the Duola connections do not have the switch (Part #9566) or the tip jacks (Part #9565).

ALIGNMENT: Only when an antenna, oscillator or IF transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE TRANSFORMER ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the grid clip disconnected. CONNECT A 50,000 OHM RESISTOR FROM THE CONTROL GRID OF THE 6A7 TUBE TO THE ROTOR FRAME OF THE VARIABLE CONDENSER. The ground side of the test oscillator should be connected to the gang condenser frame and must not be otherwise grounded.
2. Set the oscillator at 265 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer trimmer shields.
4. The second IF transformer should next be adjusted in the same manner as the first intermediate transformer.

TO ALIGN THE VARIABLE CONDENSER:

1. Place the band selector switch for operation on the 1500-540 kilocycle band (right hand position) and tune the receiver to exactly 1400 kilocycles on the dial and set the oscillator to this frequency. Next, adjust the trimmer screws of the oscillator and antenna section of the variable condenser to obtain maximum output reading. These trimmers are mounted on the top of the variable condenser.
2. Tune the receiver and set the oscillator frequency to approximately 600 kilocycles. Adjust the 600 kilocycle padding condenser which is located on the rear of and accessible through the small hole in the chassis for maximum output. Be sure to rock the variable condenser slightly to the right and left so as to obtain the position of greatest output.

NOTE: There is no short wave adjustment. After alignment has been properly made in accordance with the instructions given, the dial calibration will be correct and the receiver will properly track on short wave band.

VOLTAGE TABLE

TYPE OF TUBE	POSITION OF TUBE	FILAMENT VOLTS	PLATE VOLTS	SCREEN VOLTS	CATHODE VOLTS	OSC. GRID NO.1	ANODE GRID NO.2	SCREEN GRID NO.3 & 5
6A7	Oscillator & Modulator	5.2	128		2.00	1.5	125	76

* Comparative voltage only. The voltmeter when readings are taken at this point, is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis unless otherwise specified.

** Read from grid to chassis.

Only when the antenna, oscillator or I. F. transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the type 57 modulator tube (1st detector) leaving the grid cap disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

NOTE: Some of the IF intermediate transformers used do not have the brass hex nut and the trimmer screw inside of the brass hex nut, but have two parallel trimmers which are likewise accessible through two holes provided in the top of the I. F. shield can.

4. The second I. F. transformer should next be adjusted in the same manner as the first I. F. transformer.

VARIABLE CONDENSER ALIGNMENT: It is important when aligning the variable condenser to follow the procedure given carefully, otherwise the dial calibration will be incorrect.

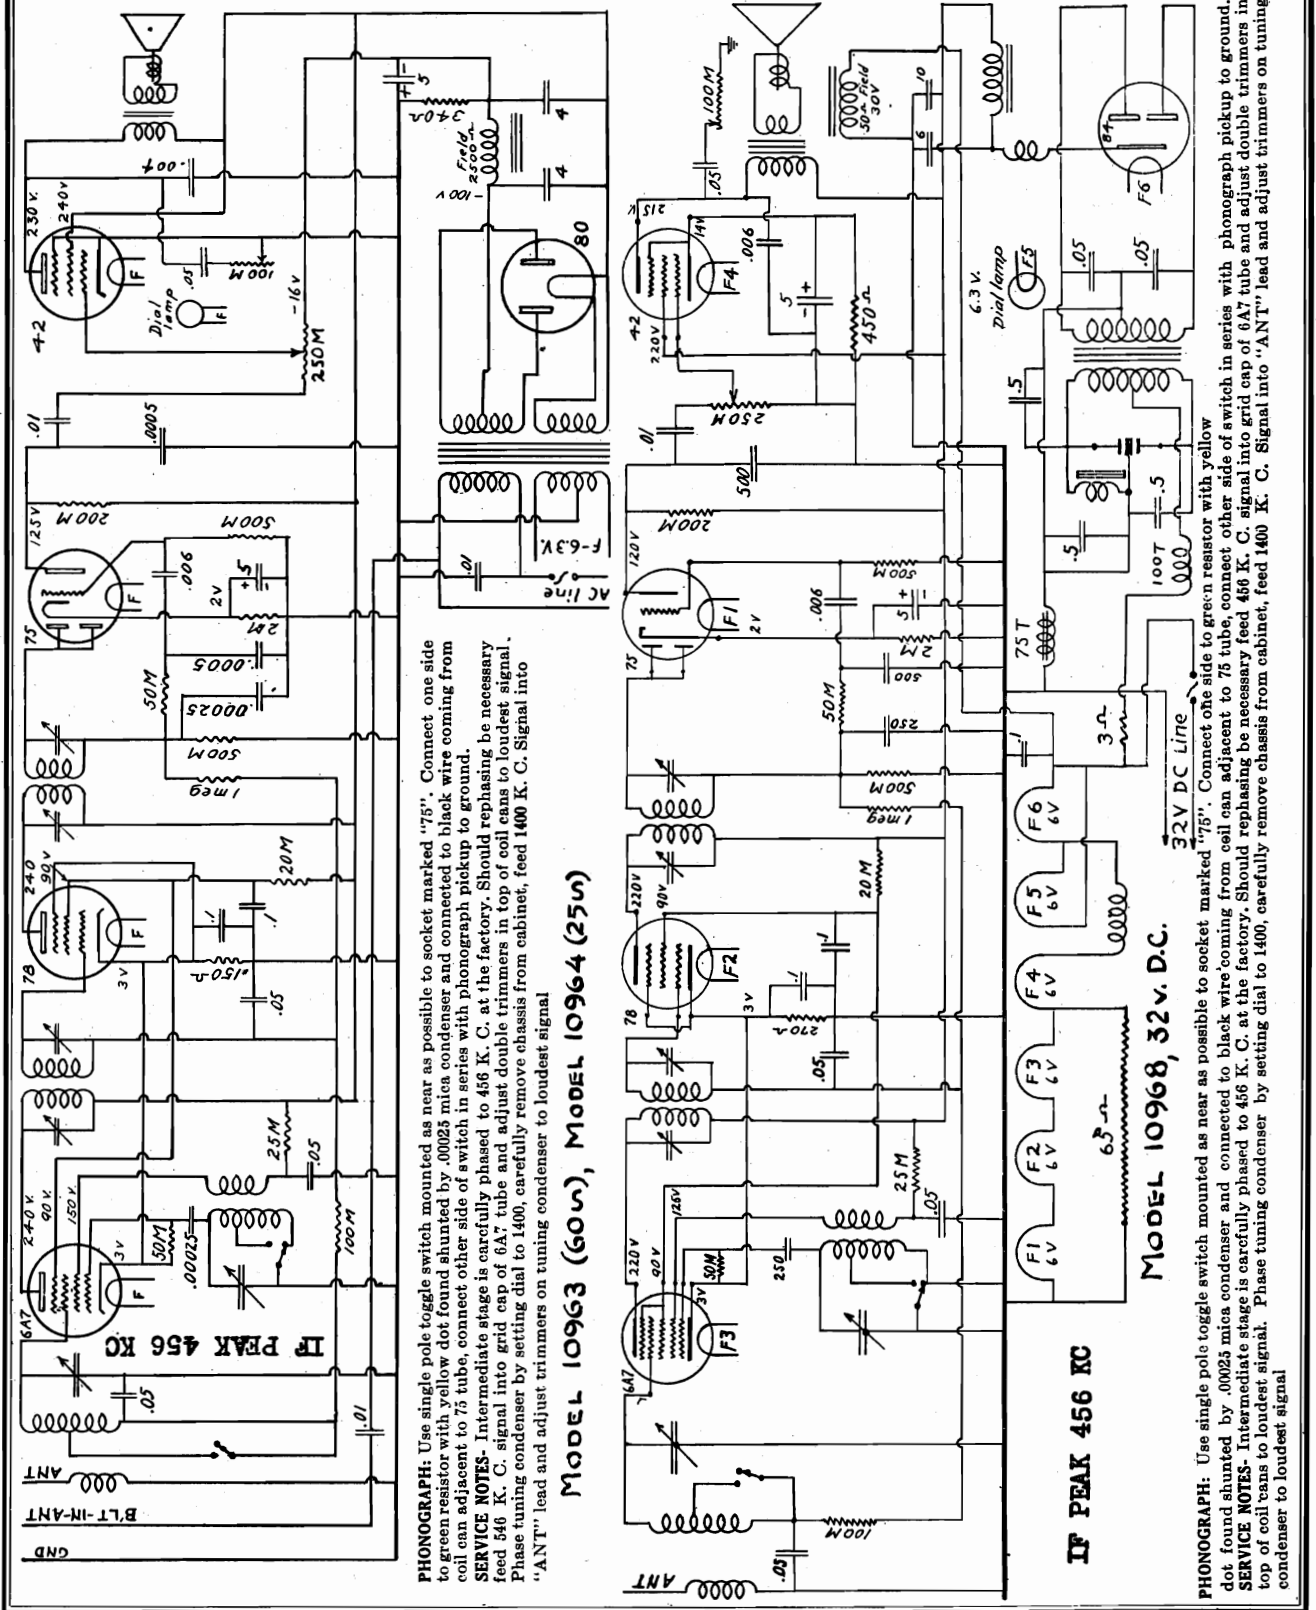

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.
2. Tune the receiver to exactly 1400 kilocycles on the dial, adjust the band selector switch for operation on the broadcast band (1500-540 kilocycles) and set the oscillator to 1400 kilocycles. Then adjust the oscillator variable condenser section trimmer condenser TO BRING THIS SIGNAL IN (maximum output). The oscillator and antenna variable condenser trimmers are mounted on top of the variable condenser. Looking at the front of the receiver the first section of the variable condenser is the oscillator section and the other section tunes the antenna coil.
3. Leave the band selector switch for operation on the same band, set the oscillator at 600 kilocycles and tune the receiver to approximately 600 kilocycles on the dial. Then adjust the 600 kilocycle padding condenser which is the one located towards the front on the right hand side of the chassis and accessible through the small hole in the chassis for maximum output. It is necessary to rock the condenser slightly to the right and left to obtain the correct position. After aligning the 600 kilocycle padding condenser be sure to recheck the 1400 kilocycle adjustment as the 600 kilocycle alignment may have changed the alignment at 1400 kilocycles.
4. Adjust the short wave switch for operation on 1500 kilocycle to 4500 kilocycle band. Set the oscillator at 4 megacycles and the receiver to 4 megacycles on the dial. Turn the receiver on and BRING THE 4 MEGACYCLE SIGNAL IN (TO MAXIMUM OUTPUT) BY ADJUSTING THE 4 MEGACYCLE TRIMMER located underneath the chassis and adjacent to the band selector switch.

Next, tune the receiver to 1600 kilocycles on the dial and set the oscillator frequency to 1600 kilocycles after which adjust the 1600 kilocycle padding condenser which is located on the rear right hand side and accessible through the hole in the chassis for maximum output. It is imperative that after making this adjustment at 1600 kilocycles that the alignment at 4 megacycles be rechecked, as the 1600 kilocycle adjustment may throw the receiver out at 4 megacycles.

INSTALLATION:

This set is designed to operate from a 110 to 125 volt, 50 or 60 cycle alternating current supply.

An outdoor antenna should be used, having a length of from 60 to 100 feet. The antenna should be kept clear of all metal objects, such as pipes and electric circuits. This also applies to the lead-in wire. Shielded wire should not be used for the lead-in. Connect the lead-in to the red wire extending from the back of the set. The ground connection should be made to the black wire. This lead should be as short as possible and preferably connected to a cold water pipe, scraped clean, and a ground clamp used.

Loosen the chassis hold-down screws one turn when installing the set.

The knob on the left controls the volume and also operates the ON and OFF switch.

The center knob controls the station selector, or tuning. This knob operates through a DUAL-RATIO reducing mechanism. When pressed in, the ratio is three and a half to one. This position may be used on the broadcast band, or when it is desired to turn quickly from one band to another. When the knob is pulled out, a ratio of seventeen to one is obtained. This position should be used for tuning on the short wave bands.

The dial is divided into three ranges. The outer range is from 540 to 1900 kilocycles, and is calibrated in tens of kilocycles, or broadcast channels. The bands included in this range are: the regular broadcast band from 540 to 1500 K.C., the police band from 1534 to 1712 K.C., and amateurs from 1715 to 1900 K.C. The middle range covers from 1900 to 6400 K.C. This range includes: amateurs 1900 to 2000 K.C., police stations 2308 to 2490 K.C., aviation 2608 to 3485 and 4110 to 5700 K.C., amateurs 3500 to 4000 K.C., and short wave broadcast 6010 to 6150 K.C. This range is calibrated in hundreds of kilocycles.

The inner range covers the higher frequency bands, extending from 6 to 18 megacycles (6000 to 18,000 kilocycles).

The principal short wave broadcast ranges included are: 6 to 6.15 megacycles, 9.5 to 9.6 megacycles, 11.7 to 11.9 megacycles, 15.1 to 15.35 megacycles, and 17.7 to 17.8 megacycles. Amateur phone transmissions may be tuned in from 14 to 14.4 megacycles. This range on the dial is marked in megacycles, which are thousands of kilocycles. The knob on the right controls the range switch and the pointer, which automatically indicates the range position on the dial.

A continuous type tone control is adjustable from the back of the receiver. This may be adjusted to modify the tone or to reduce noise or static disturbances.

SERVICE DATA:

This is a six tube superheterodyne receiver with automatic volume control. The following tubes are used:

- 6A7 Converter (mixer-oscillator)
- 7B Super-control amplifier, 1st I.F. stage
- 7B Super-control amplifier, 2nd I.F. stage
- 6B7 Diode detector - AF amplifier, Av.C.
- 42 Power amplifier
- 80 Full wave rectifier
- Dial light 6-8 volt Mazda 50

The oscillator, antenna, and mixer coils are wound on the same form for each band. The short wave coils are mounted directly on the switch together with the trimmer capacitors. A variable series trimmer is provided for the broadcast band oscillator circuit. This is accessible from the bottom of the chassis, and is mounted near the broadcast oscillator coil. The I.F. transformers are in the aluminum shields mounted on top of the chassis. The trimmers for these coils may be adjusted from the tops of the shields. The intermediate frequency is 450 kilocycles. Use a weak signal or oscillator input when adjusting the trimmers.

In removing the chassis from the cabinet, take the set screw, spring and brass pin from the tuning knob so that it may be removed from the shaft. The switch and volume knobs may be removed by prying with a wooden screw driver with a piece of cardboard against the cabinet.

Voltage readings for servicing purposes follow:

A. C. VOLTAGES:

Line	180 volts
Filaments - 6A7, 7Bs, 6B7 and 42	6.3 "
Filaments - 80	5.2 "

D. C. VOLTAGES: (No signal)

From ground to:

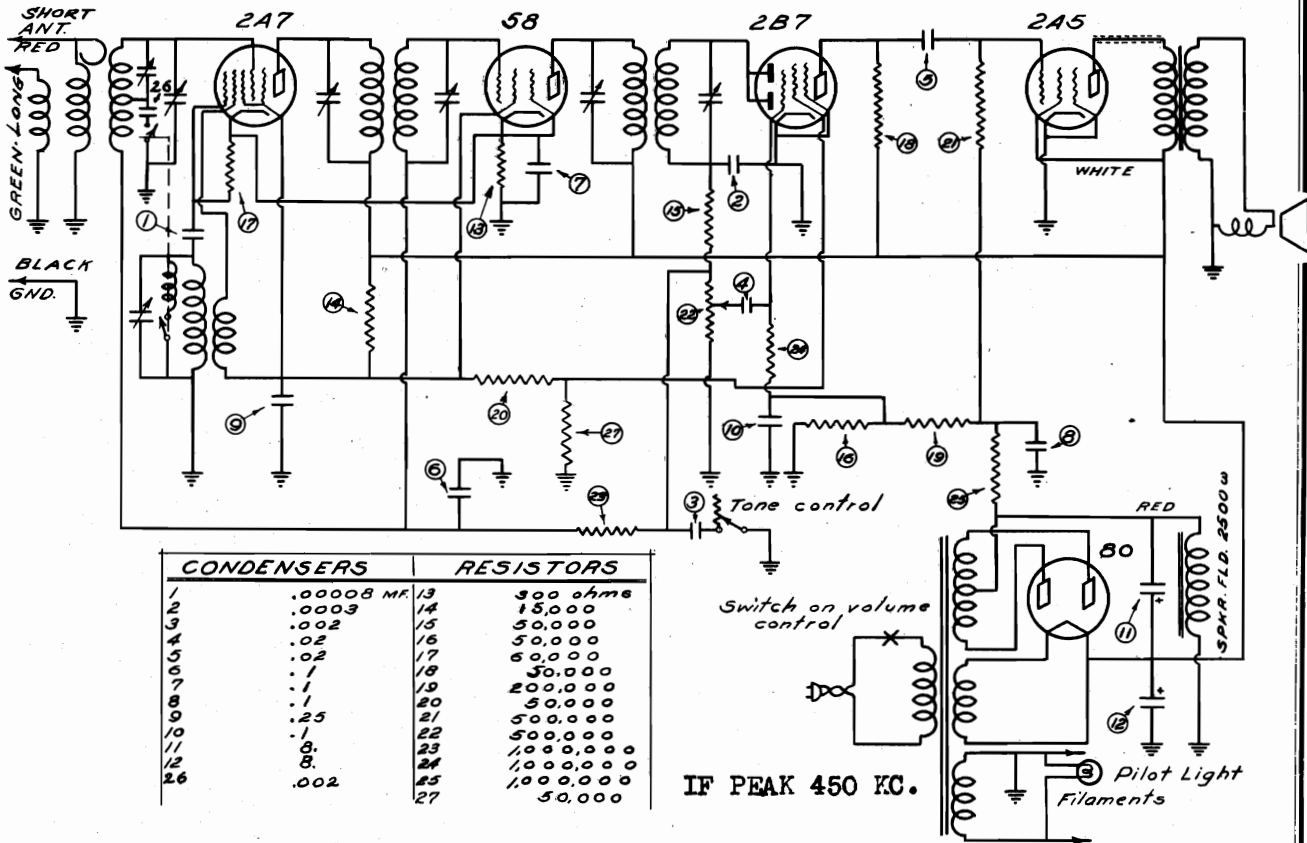

80 Rectifier filament	240 volts
42 Plate	250 "
42 Screen grid	240 "
42 Grid	17 "
6B7 Plate	165 "
6B7 Screen grid	70 "
6B7 Grid	4 "
7B 2nd I.F. plate	240 "
7B 2nd I.F. screen grid	125 "
7B 2nd I.F. cathode	4.5 "
7B 1st I.F. plate	240 "
7B 1st I.F. screen grid	125 "
7B 1st I.F. cathode	6 "
6A7 Plate (mixer)	240 "
6A7 Screen grid	125 "
6A7 Cathode	6 "
6A7 Plate (oscillator)	220 "
Speaker field (red lead)	115 "

Due to current taken by voltmeter used, readings of 6B7 and 42 grid voltages will be less than those above.

MODEL 21-4

Schematic
Voltage, Alignment

REMLER COMPANY, LTD.

REMLER MODEL #21-4

This radio receiver is of the superheterodyne type with automatic volume control.

TUBES:

- 2A7 - Converter (mixer - oscillator)
- 58 - I. F. amplifier
- 2B7 - Diode detector - audio amplifier
- 2A5 - Power amplifier
- 80 - Rectifier
- Dial light, 3.8 volt

INSTALLATION:

This set is designed to operate from a power supply of 110 to 125 volts, 50 or 60 cycle alternating current.

Two antenna connections are provided. The red wire should be connected when the antenna is less than 100 feet in length, and the green wire should be used when the antenna is longer. A good ground connection to the black lead is necessary for best results.

CONTROLS:

The knob at left controls the volume and also operates the ON and OFF switch.

The knob in the center is the station selector. The dial is calibrated in kilocycles for both broadcast and short wave bands. The tone control is operated by the knob on the right. The short wave switch is located on the back of the chassis. In the long wave or broadcast position the receiver covers a band from 540 to 1750 kilocycles. When the switch is moved to the right, or short wave position, the receiver covers from 1700 to 4500 kilocycles. This band includes police, amateur and airport stations as indicated on the dial. The lower frequency band for police calls is from 1714 to 1500 kilocycles. This range is covered with the switch moved to the left or normal broadcast position.

SERVICE DATA:

The antenna and mixer coils are in the aluminum shield nearest the back of the chassis. The trimmer condenser, adjustable through the top of the shield, is for trimming the high frequency end of the short wave position. Trimmers for the broadcast band are located on the variable condenser.

The shield nearest the front of the chassis contains the oscillator coil and first I.F. transformer. The trimmers for this transformer are at the top of this shield.

The second I.F. transformer is within the chassis and is trimmed by the condensers mounted thereon. The intermediate frequency is 450 kilocycles.

A. C. VOLTAGES:

Line	- 120 volts
Filaments - 2A7, 58, 2B7 and 2A5	2.5 "
" - 80	5.2 "

D. C. VOLTAGES:

From ground to:

80 Rectifier filament	- 250 volts
2A5 Plate	235 "
2A5 Screen grid	250 "
2A5 Grid	19 "
2B7 Plate	175 "
2B7 Screen grid	45 "
2B7 Grid	5 "
58 Plate	250 "
58 Screen grid	95 "
58 Cathode	5 "
2A7 Plate	250 "
2A7 Screen grid	95 "
2A7 Cathode	5 "
2A7 Triode plate	95 "
Speaker field (red lead)	105 "

Due to current taken by voltmeter used, readings of 2B7 and 2A5 grid voltages will be less than values shown above.

REMLER COMPANY, LTD.

MODEL 35 Auto Schematic, Socket Voltage, Installation

INSTALLATION:

The receiver unit is intended to be mounted on the bulkhead of the car by the single mounting stud which requires the drilling of one 1/2 inch hole through the bulkhead. When locating the position of this hole consideration should be given to possible interference of the set with the position of control cables and other apparatus between the dash and the bulkhead and also of the mounting stud with apparatus on the motor side of the bulkhead. Preferably the receiver should be mounted so as to allow long easy curves of the flexible control cables and a short lead connection to the antenna.

The location of antenna leads from factory installed antennas depends on the make and model of the car. Usually this lead is brought down one of the front body pillar posts and will be found coiled up at the end of the dash. Connect this lead to the shielded lead from the receiver and tape the joint. Where the car is not factory equipped with antenna, a roof type or plate type may be installed with lead brought to a convenient place for connection to the set. The lead and antenna should be kept as far as possible from wiring circuits and the metal body.

The flexible control cables for the tuning and volume control are fitted with special ends to lock in the control head. Insert the cable with the slotted end into the left or volume control bushing, and the cable with keyed end into the right, or tuning control bushing. Be sure the cable housing extends into the head at least three-eighths of an inch, then tighten the set screws on the bushings. Next insert the cables into the brackets and couplings on the set. The volume control cable in the lower coupling and the tuning cable in the upper coupling, but do not tighten the set screws on the shafts. Next clamp the control head to the steering column, tape the control cables to the column bracket or some solid object under the dash and tighten the clamps on the cable housings at the set. Now turn the volume knob to the position where it is removable from the key slot, and turn the tuning knob to the left till the pointer is on the white line at the low frequency end of the dial. Rotate the couplings projecting from the set to the left till the condenser is against the stop and the switch on the volume control is in the off position. Now the set screws on the shaft couplings may be tightened.

Plug the dial light into the opening at the rear of the control head. Connect the battery wire, the shielded wire with fuse holder and terminal, to the battery side of the ammeter. This terminal on the ammeter usually has only one wire attached.

IGNITION NOISE SUPPRESSION:

The spark plug suppressors should be connected in series with the plugs at each plug and the distributor suppressor should be plugged into the central distributor connection in series with the lead running to this point. The generator condenser should be mounted on the generator and the flexible lead connected to the terminal at the cutout where the wire from the generator is attached. Some cars require special work to further reduce noises due to peculiarities of the wiring systems.

OPERATION:

The left hand knob on the control head operates both the power switch and the volume control. Turn the knob clockwise to increase volume. The dial should become illuminated when the power is on.

Rotate the station selector, or tuning knob until the desired program is heard, reduce the volume, and readjust the selector to the position where quality is the best. The volume control may now be advanced to the desired volume level. The knob on the right side of the set is the tone control. This may be adjusted to modify the tone or to reduce noise and static disturbances.

SHORT WAVE:

The short wave switch is on the left of the speaker. When this knob is turned to the left the regular broadcast band is covered by the station selector dial as well as the lower frequency police band as noted on the dial. When the switch is turned to the right the selector dial covers from 2200 to 6500 K. C. The positions of the higher frequency police band, the 49 meter short wave broadcast band and the major airport and amateur bands are noted on the inner portion of the dial. Many automobile antenna installations are not suitable for receiving these short wave stations from any great distance. When better results or increased range is desired with the car parked, a fifty or sixty foot portable antenna wire, with the far end raised at least fifteen feet from the ground, may be used.

SERVICE DATA:

Tubes:

- 6A7 Converter (mixer-oscillator)
- 7B Super-control amplifier, 1st I.F. stage
- 7B Super-control amplifier, 2nd I.F. stage
- 75 Diode-detector-A F amplifier, A.V.C.
- 41 Power amplifier
- 64 Full wave rectifier
- T-40 Dial light 6.3 v.

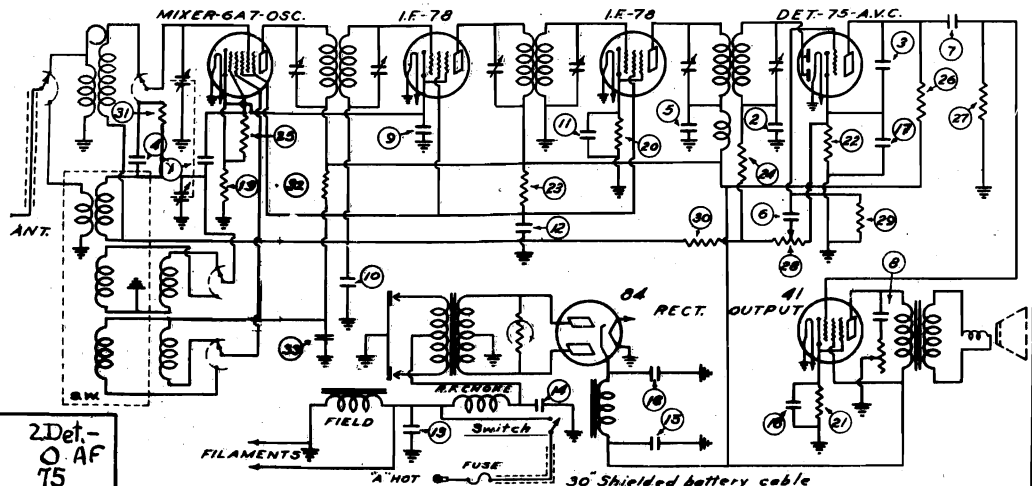

The antenna and mixer coils for the broadcast band are in the shield at the left side of the set. The short wave coils are mounted directly on the short wave switch with the oscillator coil for the broadcast band at the end of the switch. The I.F. transformers are in the aluminum shields adjacent to the antenna-mixer shield. These transformers are peaked at 450 K.C. by the trimmers located at the tops of the shields. Use a weak signal, or oscillator input, and an output meter when aligning the set.

The vibrator type interrupter and transformer are enclosed in the metal box at the right of the receiver. After several hundred hours use the vibrator contacts may require a slight adjustment due to wear. The necessity of this adjustment will be indicated by a marked reduction in plate supply voltage. Vibrator servicing should be done only by a service man with instructions and experience in this work.

Voltages: To chassis - No signal.

General Notes Alignment

SEARS-ROEBUCK & CO.

GENERAL NOTES ON ALIGNMENT

In the service notes on ALIGNMENT PROCEDURE, directions are to couple the test oscillator to the receiver. Since test oscillators of different makes vary considerably in their design and construction, it is not possible to give specific instructions for coupling any particular test oscillator to the receiver. However, the following general method can be applied with practically any test oscillator.

Most test oscillators have two output leads. One of them is the "hot" lead and the other the ground lead. The ground lead should be connected directly to the receiver chassis, except in the case of AC-DC receivers. The connection then should be made through a .1 mfd condenser since the chassis of such receivers is above ground potential. If the test oscillator has only one lead, this information about the ground lead may be disregarded.

As mentioned in all of the service notes, for IF alignment the test oscillator should be connected through a 1 mfd. condenser directly to the control grid cap of the IF or Translator tubes. It is important to leave the grid clip attached to the cap and to leave the tube shields in place. The oscillator tube of the receiver also should be in its socket.

For RF alignment, whether broadcast or short wave, the "hot" lead of the test oscillator should be coupled to the antenna lead of the receiver. The exact means of coupling will depend upon several factors. Among them are the power of the test oscillator, the sensitivity of the receiver, and the extent to which the receiver is out of alignment. If the test oscillator is quite powerful and the receiver one of high sensitivity, merely placing the test oscillator lead parallel to, and several inches away from the receiver's antenna lead may provide sufficient coupling. In some cases it may be necessary to bring the leads very close to each other, or it may even be necessary to twist the antenna lead and the oscillator lead together for several inches. (Of course, the two leads must be separated by their insulation and not make metallic contact.) As the receiver is brought into alignment, thereby increasing its sensitivity, it will be possible to decrease the amount of coupling between the test oscillator lead and the antenna lead. (Move the leads further apart.) Always use the lowest amount of coupling that still will provide a signal strong enough for working purposes. If the test oscillator has a variable control for its power output, it is better to turn this control to its high position and decrease the signal input to the receiver by decreasing the amount of coupling between the test oscillator and the receiver's antenna lead. This procedure will insure the greatest possible accuracy in alignment.

When adjusting the oscillator trimmer condenser, set the variable condenser to the frequency or condenser position

indicated in the service notes. Do not change this position while adjusting the trimmer. However, when adjusting the antenna or translator trimmers, the proper method is to continually "rock" the variable condenser a degree or two both sides of the alignment frequency and, at the same time, adjust the trimmer.

PREVENTING ADJUSTMENT AT THE IMAGE FREQUENCY

When adjusting trimmers for short wave alignment, it sometimes will be found that a peak can be obtained at two different positions of the trimmer. Only one of these peaks is the correct one to use. The other is the image response. The proper procedure follows:

Oscillator Trimmer:

Screw the oscillator trimmer all the way in (maximum capacity). Then reduce the capacity until a peak is reached. Now continue to reduce the capacity until a second peak is reached. Almost always, this second peak is considerably louder than the first one. The first peak is the image frequency adjustment, and must be avoided.

Antenna and Translator Trimmers:

Screw the trimmers all the way in and then reduce capacity until a peak is reached. If the capacity is reduced still further, a second peak will be obtained. However, the correct setting is the first one, the one using the greater amount of capacity. Note that this is exactly opposite to the procedure for the oscillator trimmer.

ALIGNMENT PROCEDURE FOR RECEIVERS USING A WAVE TRAP

If a wave trap is used in Models 1821, 1827, 1828, 1804, 1805, 1820, 1826 or 1840, it must be disconnected before making any RF alignment adjustments on the receiver. This can be done as follows:

1. Connect a jumper between the yellow and blue leads of the wave trap.
2. Disconnect the white lead of the trap. IN SOME TRAPS A GREEN LEAD IS USED INSTEAD OF A WHITE ONE.

After the receiver has been aligned as instructed in the Service Manual for the particular model, reconnect the wave trap. Do not touch the alignment of the receiver after the trap has been reconnected.

MODEL 1802,1803

Socket Layout
Alignment Data

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low voltage scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid cap of the 58 IF tube. Leave the clip attached to the cap and the tube shield in place.
4. Set the test oscillator to 445 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid cap of the 2A7 and tune the IF input transformer.

-6. Repeat the adjustments in order to secure greater accuracy. Always use as low an output as possible from the test oscillator, in order to render the AVC action of the receiver inoperative.

RF Alignment (Broadcast):

1. Screw the padding condenser to about three quarters of its maximum capacity.
2. Set the test oscillator to 1700 kc and couple its output to the green antenna lead of the receiver.
3. Open the variable condenser plates all the way and adjust the broadcast oscillator coil trimmer for maximum output meter reading.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output. The translator section is the one nearest the dial, as shown in the Service Illustration.
5. Set the test oscillator to 600 kc. and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two, and, at the same time, adjust the broadcast oscillator padding condenser for maximum output.
6. Repeat the 1700 kc and 1400 kc adjustments. Always use a low enough output from the test oscillator to render the AVC ineffective.

Short Wave Alignment:

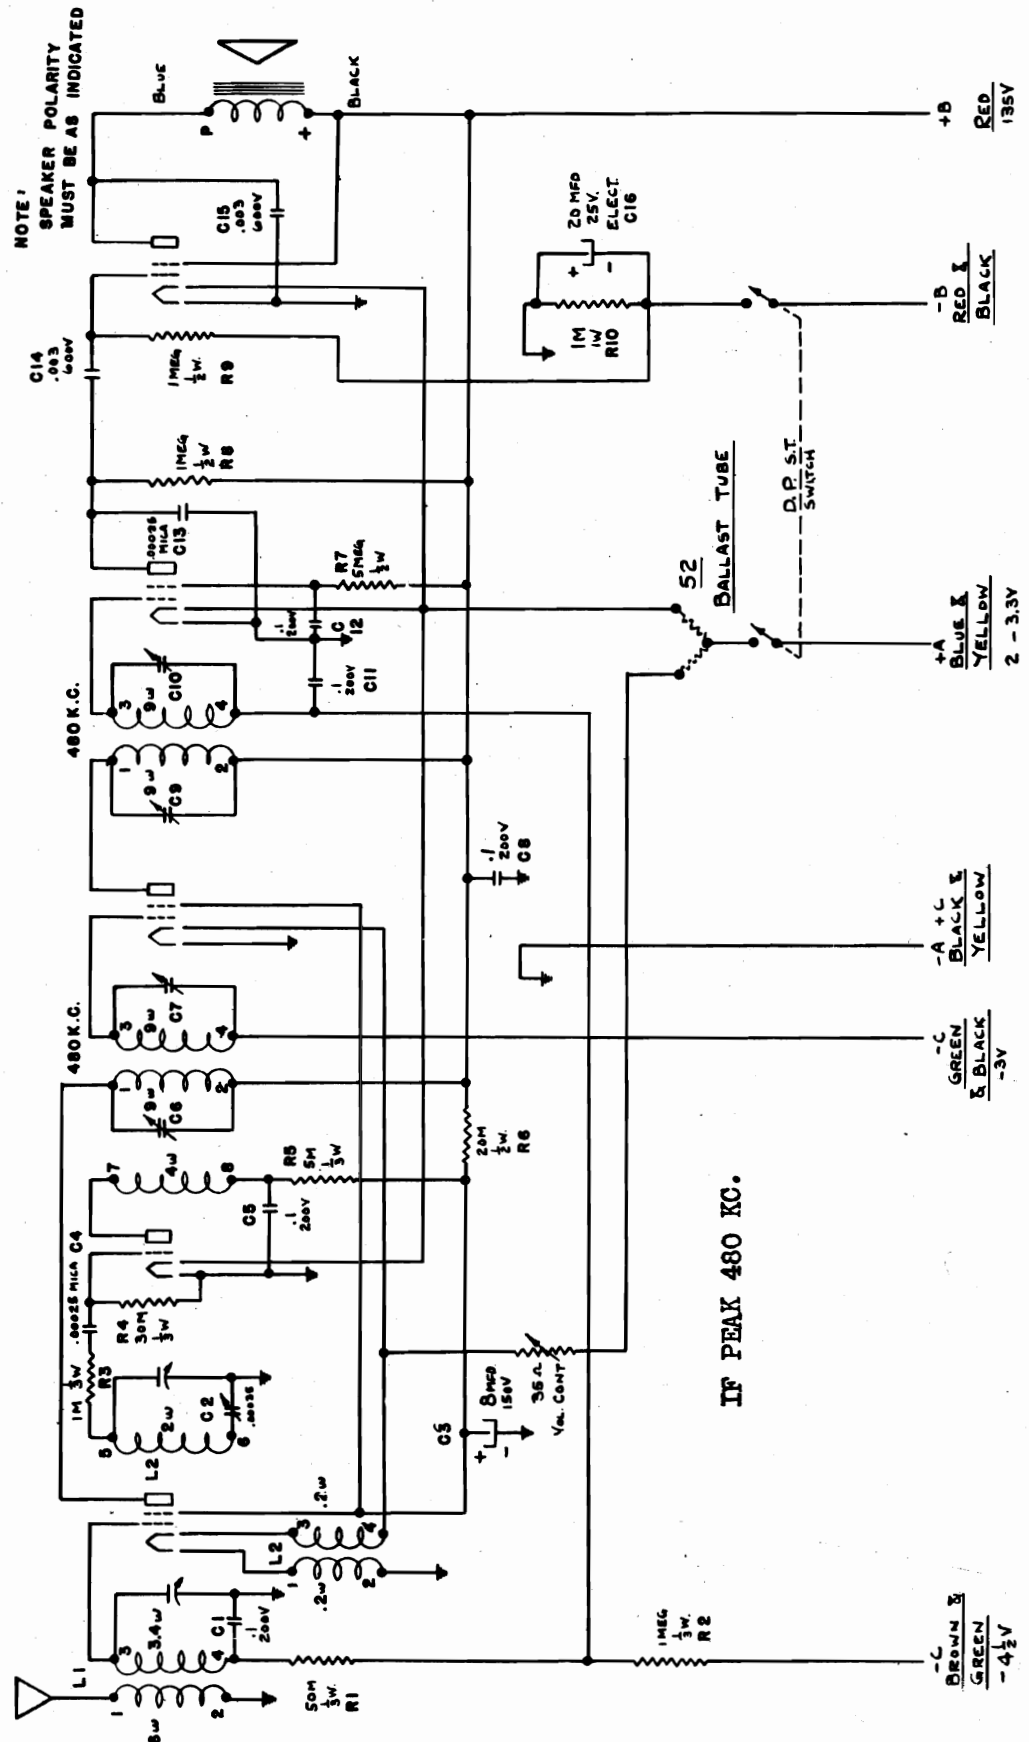

1. Leave the test oscillator loosely coupled to the green antenna lead as for broadcast alignment.
2. Set the test oscillator to 16,400 kc. Its signal should be heard when the condenser plates are all the way out. If the test oscillator cannot be tuned in, wires must be moved to reduce the capacity in the oscillator circuit until this frequency can be reached.
3. Set the test oscillator to 14,000 kc and tune in its signal. Then adjust the short wave translator trimmer for maximum output.

FIG. 3 SERVICE ILLUSTRATION REVISED MODELS 1722 AND 1732

In order to increase the short wave sensitivity of the 1722 and 1732 receivers, certain changes were incorporated in the chassis.

1. A 78 resistance-capacity coupled IF stage was added. However, this stage is used on the short wave bands only.

2. The off-on switch was replaced with a duplex switch combining the functions of off-on switch and the switch to short out the added IF stage on the broadcast band. This shorting out of the stage is accomplished by biasing the 78 IF tube so far negative by means of a 50 M ohm cathode resistor that the amplification of the stage is reduced to a 1:1 ratio. For short wave reception, this duplex control is turned all the way on, shorting out the 50 M ohm cathode resistor, leaving only a 300 ohm bias resistor in the circuit.

3. The 37 detector and 37 first audio tubes are replaced by an 85 tube which fills the same functions.

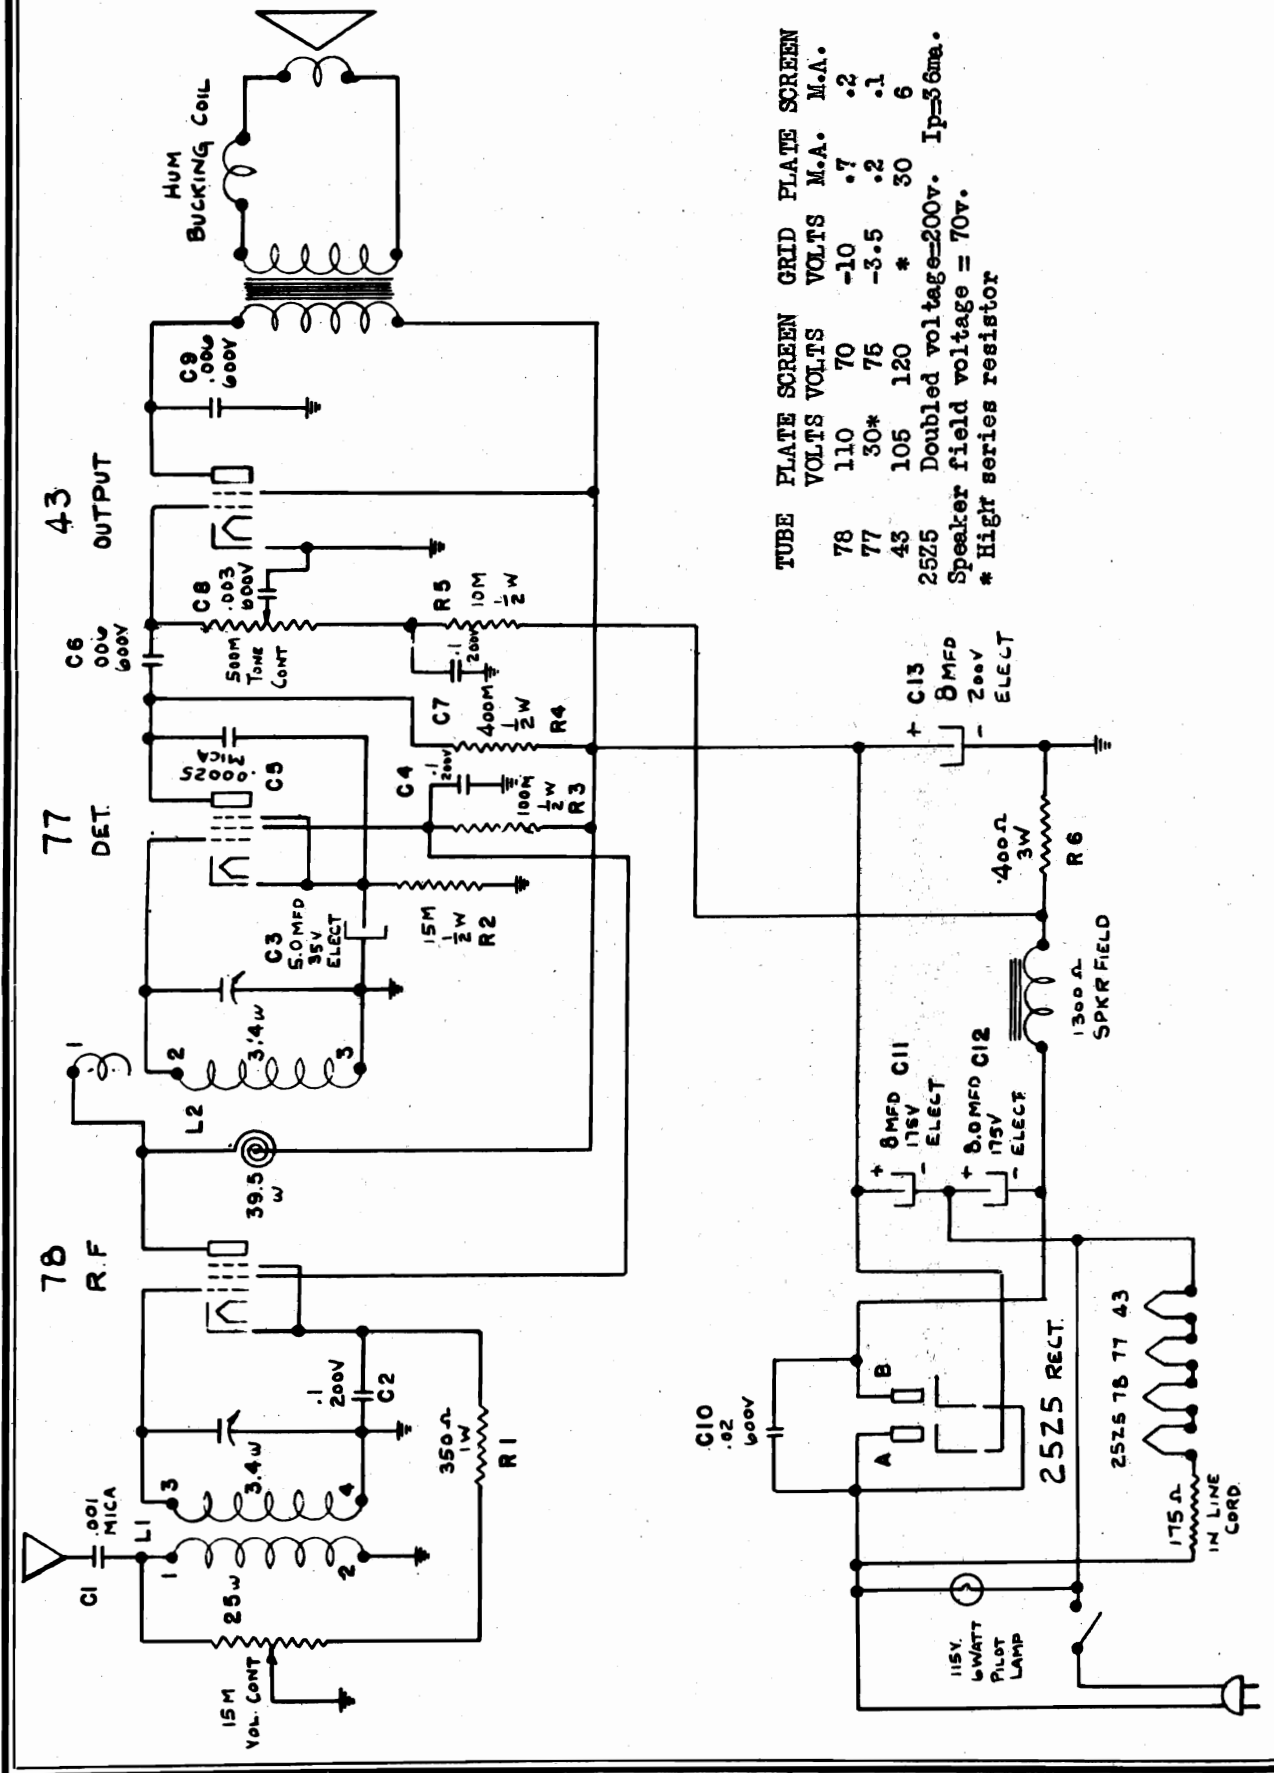

The new block diagram is shown in Fig. 1, the revised schematic in Fig. 2, and the changed top view of the chassis layout in Fig. 3. The rest of the description, explanations, and illustrations given in the original 1722 and 1732 manual, supplement #2, are correct for the revised models.

ADDITIONS TO THE REPLACEMENT PARTS LIST ARE:

Hum Elimination

DOTTED LINES INDICATE ORIGINAL WIRING,
TO BE REMOVED.
SOLID LINES INDICATE CHANGED WIRING.

ELIMINATION OF HUM

in

MODELS 1720, 1725 and 7065

Any trouble due to hum in these models can be eliminated by performing the following operations. The purpose is to add an additional section of filtering to the power supply.

1. Enlarge the hole in the chassis near the power transformer to about 1/4" diameter, as indicated in the illustration.
2. Remove the cover of the power transformer. To do so, it is necessary first to remove the four nuts on the under side of the chassis and then to unscrew the bolts that pass through the laminations. The tone control and switch will have to be demounted in order to get at one of the power transformer nuts.
3. Mount a Part #R10793A choke on top of the power transformer in place of the original transformer cover. Be sure to mount the choke so that its leads can come down through the enlarged hole in the chassis. Also be sure to tighten the bolts well, in order to prevent hum. Then remount the transformer and choke assembly on the chassis and remount the tone control.
4. Make the wiring changes indicated in the illustration. The dotted lines represent the original wiring which is to be changed. The solid lines show the new connections. Note that a new part, a 2 mfd., 440 volt, dry electrolytic condenser, Part #R1114, is added.

PARTS NEEDED

- 1 - R10793A - Audio Choke
- 1 - R1114 - 2 mfd. 440 volt, dry electrolytic condenser.

SPECIAL NOTICE: - The filter system outlined above should be necessary in only a small percentage of the Model #1725 in which the hum condition cannot be corrected by matching the output tubes. Where the condition exists, the trouble is caused by the center tap of the transformer being off. Only in these cases should the filter system be necessary. Dept. 657, Chicago, will ship this filter system out "No Charge", providing the quantity ordered is reasonable.

In ordering, use P-#14326 and mail to Dept. 657, Chicago.

Loud Speakers
Repair Notes

RADIO SERVICE MANUAL

SPEAKER REPAIRS

Speaker repairs fall into two general classifications; those involving replacement of the cone and voice coil assembly and those involving replacement of the field or hum bucking coil. Although there are many models of speakers, all fall into one of four types.

1. INSIDE suspension of voice coil and cone, and pole plate RIVETED to yoke.
2. INSIDE suspension of voice coil and cone, and cone plate WELDED to yoke.
3. OUTSIDE suspension of voice coil and cone, and pole plate BOLTED to yoke.
4. OUTSIDE suspension of voice coil and cone, and pole plate RIVETED to yoke.

·CONE REPLACEMENT OF INSIDE SUSPENSION TYPE SPEAKERS (see Fig. 1)

1. Unsolder the voice coil leads from their terminals.
2. Remove the cone mounting screw.
3. Drill out the cone mounting eyelets or cut off the small head ends with a cold chisel and hammer. If care is used the cardboard mounting rings will not be damaged.

(The 5" Speakers have the cone glued in place instead of being fastened with eyelets. They will have to be torn out).

4. Remove the cone and blow out any dirt or metal chips from the air gap.
5. Replace the new cone and the cardboard mounting rings in their original order.
6. Insert three strips about 3" long, 1/8" wide and .01" thick (cut from a calling card) between the voice coil and the pole stem. They should be spaced evenly around the pole stem. Spacers can be obtained from the factory; part No. S-9177 .0075" thick for 5" and 6" speakers; part No. S-7391 - .01" thick for all other speakers.
7. Replace and tighten the cone mounting screw.
8. Replace the eyelets around the edge of the cone, leaving blank any holes that were originally left blank for speaker to baffle mounting screws. The eyeletting tool illustrated is recommended. (Part No. R-8033).

9. Remove the three inserted spacer strips.
10. Solder the voice coil leads to their terminals.
11. If it should happen that the cone is not properly centered after completing the replacement, loosen the cone mounting screw and move the cone around until proper centering is secured. Then re-tighten the screw. Sometimes several attempts are necessary before proper centering can be had.

Voltage
Alignment Data
Parts List

SEARS-ROEBUCK & CO.

When peaking the IF stages, use a signal from the test oscillator just strong enough to give an audible response from the speaker or readable deflection on an output meter.

The sensitivity control is connected only in the broadcast position. Current is bled through it and the movable arm picks off a portion of the voltage to bias the cathode of the 78 RF tube. The sensitivity control is mounted on the volume control shaft so that sensitivity is decreased at the same time volume is decreased. Without this dual control, the AVC action would make the receiver sensitivity increase to its maximum value when no station was tuned in. By reducing the sensitivity as well as the volume, this dual control keeps between-station-noise at a minimum.

There is a hum control on the rear of the chassis, under the 2A3 tubes. It should be adjusted to the point of minimum hum with the volume control off. In the event that the point for minimum hum appears to be beyond the limit of movement of the control, the 2A3 tubes should be interchanged. If a balance still can not be had, the 2A3 tubes must be replaced by a pair more nearly matched in their characteristics.

In the event that coil replacement makes it necessary to readjust the trimmer condensers, proceed as follows: Tune in a high frequency station (broadcast) of known frequency. Set the dial very accurately to the station's frequency and adjust the isolantite base oscillator trimmer condenser, mounted on the frequency selecting switch assembly, for maximum volume. Greater accuracy can be had if a weak station is selected, or use only a few feet of wire as the antenna with a .00025 mfd. condenser connected between the antenna and ground clips to take the place of the normal antenna capacity. Then tune in a short wave station at about 14,000 kc and adjust the trimmer of the translator section of the ganged tuning condenser (the middle section). Next, tune in the broadcast station used previously and adjust the antenna trimmer on the ganged tuning condenser and the small bakelite base trimmer mounted on the frequency selecting switch. Then tune in a broadcast station at the low frequency end of the dial and adjust the .0012 oscillator padding condenser for maximum volume. Follow this procedure exactly and, having made the adjustment, do not readjust when changing from the broadcast to the short wave station or vice versa.

MODEL 1730
Socket, Trimmers
Adjustments
Parts List

SEARS-ROEBUCK & CO.

SPECIAL NOTE

When peaking the IP transformers, use a low enough output from the test oscillator to render the AVC action inoperative.

THE RF TUNING ADJUSTMENTS

There are three holes at the back of the chassis, giving access to the variable condenser trimmers. The hole nearest the drive end of the condenser is for the RF section trimmer. The next hole is for the translator, and the third one is for the oscillator.

OSCILLATION

Any trouble from oscillation can be cured by connecting a .1 Mfd. 200 volt condenser, (Part #R-8286), from the IP cathode to ground.

THE REMOTE CONTROL UNIT

A few of the first production remote control units used the type clamp shown in Fig. 3. Later production used the type illustrated in Fig. 4. Should trouble be experienced with controls having the type clamp shown in Fig. 3, due to the volume control cable's jumping out of the control head, the type of clamp shown in Fig. 4 should be substituted, (Part #R-10190).

The following procedure will improve the action of the on-off switch, where necessary.

Remove the volume control drum and turn the volume control counter clockwise to its off position. Then turn it clockwise just enough to take up all of the play, so that any further rotation would tend to turn the switch on. Remove the key from the remote control unit and turn the volume control knurled ring to its locked position. Then turn it, as though to switch it on, the slight amount necessary to take up the play. Then replace the volume control drum on the volume control shaft, maintaining a clockwise tension on the rotatable portion of the drum and tighten the set screws. Study of this operation will reveal that its purpose is to take advantage of all of the play in the mechanism in such a way that an increased length of movement is provided for turning the switch off.

It is of vital importance that no twists occur in the cable during the installation. Careful inspection for this point is necessary because in a cable of this type twists are not very obvious. Also, bends should be as gradual as practicable. Sharp bends greatly increase the stiffness of operation.

If, having followed the foregoing suggestions, trouble still is experienced with the remote control, the unit should be considered defective. Return the entire remote control unit, including the cables and the chassis pulleys, for replacement, to the Colonial Radio Corp., 254 Reno St., Buffalo, N.Y.

ADJUSTING THE STATION SELECTOR DRIVE DRUM

1. Fully mesh the variable condenser plates.
2. Turn the Station Selector knurled ring to its low frequency limit.
3. Place the condenser drive drum on the variable condenser shaft and screw the binding strip to the condenser end plate. If necessary, bend the binding strip in such a way that the drive cable runs in as straight a line as possible from the drum to the point where it emerges from the chassis. However, care must be taken that the cable clamp does not touch any part of the chassis. Should it do so, it would render the rubber mounting of the variable condenser ineffective and microphonics would result. Then tighten the drum set screws.
4. After the set has been installed, and the remote control mounted, the calibration can be set more accurately in the following manner. Tune in a station of known frequency. Remove the dial glass retaining spring and set the dial pointer to the station's frequency. Then repress the retaining spring, making sure that the glass does not shift during the operation.

THE GEN-E-MOTOR

The plate and screen voltages for the receiver, are supplied by a Gen-E-Motor. No attempt should be made to repair this unit. It should be returned to the Pioneer Gen-E-Motor Corp., 466 West Superior St., Chicago, Ill. Return only the unit itself. Do not return the complete housing assembly. To remove the Gen-E-Motor from its housing, proceed as follows.

1. Remove the two screws under the chassis, that mount the loud speaker.
2. Remove the three Parker-Kalon screws from the bottom of the Gen-E-Motor housing, and the two screws that hold the electrolytic condenser can to the housing. The Gen-E-Motor and its housing can then be tipped back from the chassis.
3. Unsolder the leads at the base of the housing, so that the Gen-E-Motor and housing can be completely removed from the chassis.
4. Removal of the two screws in each side of the housing, and unsoldering of the Gen-E-Motor leads under the housing, will permit the Gen-E-Motor to be taken from its housing.

POLARITY CHANGING

The receivers are shipped with the polarity changing screws in the proper position for cars having the negative battery terminal grounded. If the car is one with a grounded positive terminal, the positions of the two screws must be changed, as indicated by the sticker on the case, and as shown in Fig. 5.

MODEL 1800
Schematic
Notes, Parts List

G-4-34'

S.R. Model No 1800

GENERAL INFORMATION

This set is designed to operate on 105 to 120 volts AC - 50-60 cycles - also furnished in 25 cycles.

The circuit is of the conventional TRF type, covering the regular broadcast band including police, and short wave from 70 to 200 meters.

An antenna approximately 40' long outside is recommended, but very good results may be obtained with 20' to 25' inside.

Below are listed a few suggestions as to service -

- A - to align set, proceed as follows-
- 1- Tune gang condenser way open and turn compensator adjustment screws to maximum noise level or loudest police signal - 1712 KC.
 - 2- Check again with condenser tuned to 1400 KC.
 - 3- Short Wave - open variable condenser about half way and tune small padder condenser to maximum noise level-rocking variable condenser across midpoint while doing so.

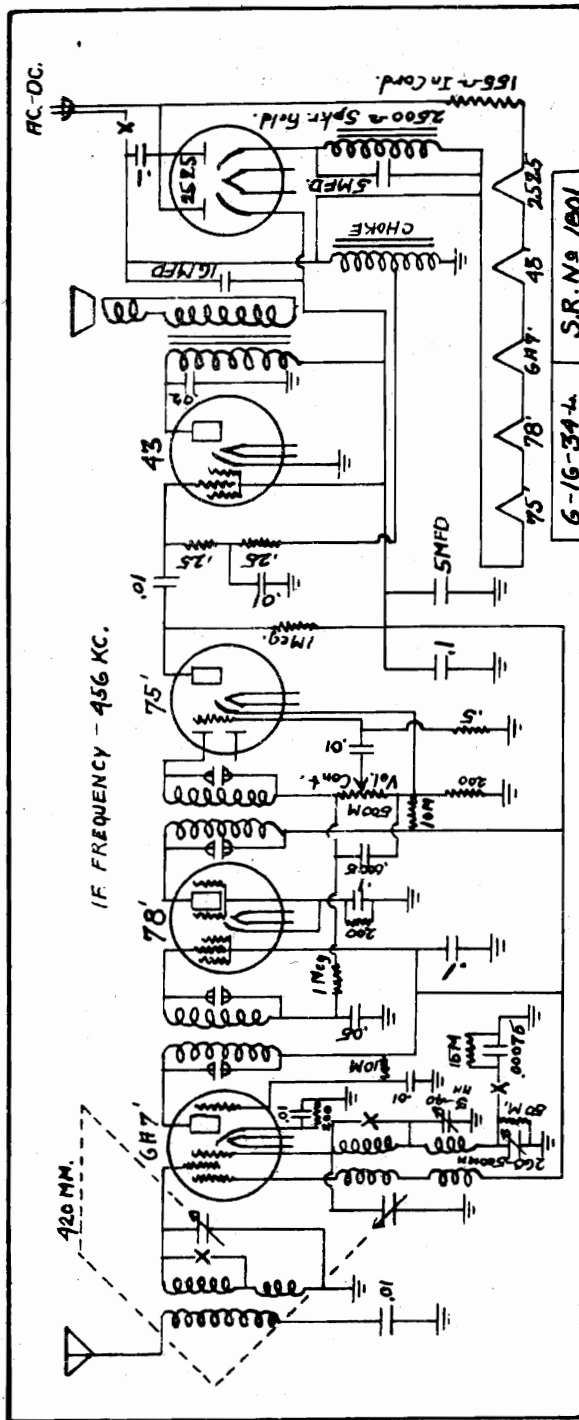

PARTS LIST - S.R.#1800

No.	
73	Terminal strip -3 lug
105	Volume control
152	Dynamic Speaker
153	Variable condenser-2 gang
154	Power transformer
155	Dial scale unit
156	8&4 mfd electrolytic cond.

158	Power cord and plug
159	Knobs
160	Escutcheon plates
165	Set of coils complete
165a	Antenna coil
165b	Interstage coil
307	10 mfd-25v electrolytic
312	4 pole 2 position short wave switch
	Any tube socket (state no. of prongs)
	Any resistor (state ohms & watts)
	Any bypass condenser (state capacity)

MODEL 1801

Alignment
Parts List

SEARS-ROEBUCK & CO.

GENERAL INFORMATION

This set is a superheterodyne designed to operate on AC - DC - 110 volts, 25 to 60 cycles.
To operate, unreel antenna and lay along floor or drop out of window. Turn volume control all the way up and tune in signals. If set does not start operating in two minutes, reverse the plug in wall receptacle.
To rebalance set, proceed as follows:
1 - Align IF transformers at 456 KC, applying 456 note at 6A7 control grid.
2 - Turn variable condenser all the way open - adjust compensators on variable condenser to 1712 KC.
3 - Tune to some weak signal about 1400 KC and readjust the Detector Section only.
4 - Tune set to some signal at 600 KC and while rocking condenser across 600

KC signal, adjust the BC low frequency padder.

To rebalance Short Wave - tune to some signal about center of dial and while rocking variable condenser back and forth adjust 3-40 mm condenser to loudest peak.

Voltage, Alignment,
Socket Layout

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low voltage scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid cap of the 58 IF tube. Leave the clip attached to the cap and the tube shield in place.
4. Set the test oscillator to 445 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid cap of the 2A7 and tune the IF transformer.
6. Repeat the adjustments in order to secure greater accuracy. Always use as low an output as possible from the test oscillator, in order to render the AVC action of the receiver inoperative.

RF Alignment (Broadcast):

1. Screw the padding condenser to about three quarters of its maximum capacity.
2. Set the test oscillator to 1750 kc and couple its output to the green antenna lead of the receiver.
3. Open the variable condenser plates all the way and adjust the broadcast oscillator coil trimmer for maximum output meter reading.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the trimmer on the translator section of the variable condenser for maximum output. The translator section is the one nearer the dial, as shown in the Service Illustration.
5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the broadcast oscillator padding condenser for maximum output.

6. Repeat the 1750 kc and 1400 kc adjustments. Always use a low enough output from the test oscillator to render the AVC ineffective.

Short Wave Alignment:

1. Leave the test oscillator loosely coupled to the green antenna lead as for broadcast alignment.
2. Set the test oscillator to 16000 kc. Its signal should be heard when the variable condenser plates are all the way out. If the test oscillator cannot be tuned in, the grid and plate wires to the short wave oscillator coil and to the oscillator socket should be moved as far away as possible from the metal of the chassis to reduce distributed capacity.
3. Set the test oscillator to 14000 kc and tune in its signal. Then adjust the short wave translator trimmer for maximum output.

TUBE VOLTAGE CHART

All readings should be taken between the chassis and the respective element of each tube.

MODELS 1804 - 1805 -
1820 - 1826

FIG. 1. - SCHEMATIC
MODELS 1804 - 1805 -
1820 - 1826

Some of these sets have the circuit shown in Fig.1; others have that of Fig.2. The difference is in the 75 tube AVC circuit, shown at the left. In Fig.2 one of the diode plates is coupled to the plate of the 78 IF tube through a 15- μ mfd. condenser, thus giving AVC voltage across the 1 megohm resistor connected between this diode plate and the 75 tube's cathode. Note that in sets using Fig. 1 circuit, the green lead of the output transformer secondary connects to the diode plates, whereas in the circuit of Fig. 2, the black lead is connected to the diode plate.

WAVE TRAP CONNECTIONS

In locations near the coast where code interference from ship stations may be experienced, a wave trap can be added. (Part #R11099.)

Some of the receivers have the terminal board shown in Fig. 3 mounted at the rear of the chassis. The wave trap, which may be mounted on the side of the cabinet, should be connected as shown in Fig. 3. In receivers not having this terminal board provided, the wave trap may be added as follows:

1. Unsolder both ends of the green wire which runs from the Wave Switch to one of the lugs on the broadcast antenna coil.
2. Solder the yellow wire of the wave trap to the switch lug in place of the original green wire.
3. Connect the blue wire of the wave trap to the lug of the broadcast antenna coil in place of the original green wire.
4. Connect the white wire of the wave trap to the chassis.

To adjust the wave trap, proceed as follows:

1. With the wave switch in the broadcast position, fully mesh the variable condenser plates.
2. If the interfering signal can be picked up, adjust the two tuning condensers of the wave trap until the interfering signal disappears.
3. If the frequency of the interfering signal is known, the adjustment can be made more quickly and accurately by means of a test oscillator. Set the oscillator to the interfering frequency and couple its output to the antenna lead. The oscillator should be adjusted to give high output. Then adjust the wave trap until the oscillator signal disappears. Usually the frequency of the interfering signal is very close to 500 kc and this frequency should be used if the interference is not heard at the time of the service call.

The IF Stages:

ALIGNMENT PROCEDURE

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator through a .1 mfd. condenser to the control grid of the 7B second IF tube. The grid clip should be left attached to the cap.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustrations.
5. Change the test oscillator connection to the control grid cap of the 7B first IF tube and tune the IF interstage transformer.
6. Change the test oscillator connection to the control grid cap of the 7B translator tube and tune the IF input transformer.

7. In order to secure greater accuracy, repeat all of the operations, starting with the IF output transformer.

RF Alignment (Broadcast):

1. Set the test oscillator to 1785 kc.
2. Couple the output of the oscillator loosely to the antenna lead of the set, with the antenna connected.
3. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output. This trimmer condenser is mounted on the terminal board of the broadcast oscillator coil, as shown in the Service Illustrations.
4. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and at the same time, adjust the broadcast oscillator padder for maximum output. The location of this padding condenser is shown in the Service Illustrations.
5. Repeat the adjustment of the oscillator trimmer at 1785 kilocycles.
6. Set the test oscillator to 1500 kc and tune in its signal. Then adjust the trimmer on the antenna section of the variable condenser for maximum output. In some of the receivers this trimmer has been removed from the variable condenser, in which case this step in the alignment procedure may be omitted.

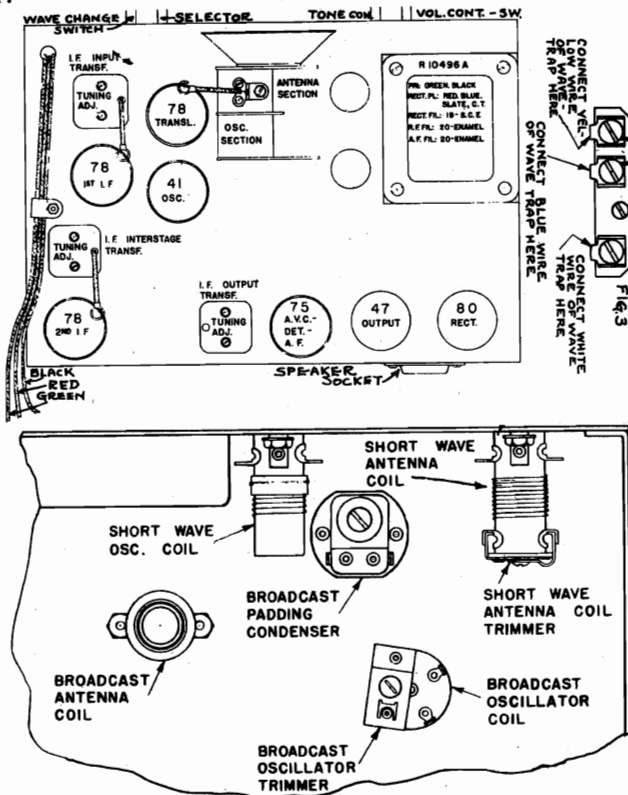

Short Wave Alignment:

1. Set the test oscillator to 16 megacycles, leaving it coupled to the set's antenna lead as for broadcast alignment.
2. Turn the wave band switch to the short wave position and tune in the test oscillator signal. Then adjust the trimmer on the short wave antenna coil for maximum output.
3. Set the test oscillator to 6 megacycles and tune in its signal. If necessary, turns may be shifted on the short wave antenna coil to secure accurate alignment on this frequency. Should it become necessary to shift turns, the translator trimmer will have to be readjusted at 16 megacycles after the turns have been shifted.

The IF Stages:

ALIGNMENT PROCEDURE

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, through a .1 mfd condenser, to the control grid of the 78 IF tube. The grid clip should be left attached to the cap and the tube shield must be in place.
4. Set the test oscillator to 445 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the control grid cap of the 6A7 tube and tune the IF input transformer.
6. In order to secure greater accuracy repeat the adjustments, starting with the IF output transformer.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment; #1 Band (Broadcast):

1. Couple the output of the test oscillator to the antenna lead of the set, with the antenna connected.
2. Set the test oscillator to 1520 kc.
3. Turn the variable condenser plates all the way out. Then adjust the #1 oscillator trimmer for maximum output. The locations of all of the trimmers are shown in the Service Illustrations.
4. Set the test oscillator to 1400 kc and tune in its signal. Then adjust the #1 antenna trimmer and the #1 translator trimmer for maximum output.
5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the #1 oscillator padder for maximum output.
6. Repeat the 1520 kc and 1400 kc adjustments for greater accuracy.

TUBE VOLTAGE CHART

TUBE	PLATE	SCREEN	OSC. SECTION PLATE	CATHODE
78 - RF	220	90		3.1
6A7 - Osc-Transl	220	90	160	2.6
78 - IF	235	90		3
75 - AVC-Det-AP	75			0
37 - Phase Changer	125			9
47 - Output	230	235		16

All readings are to be taken between the chassis and the respective element of each tube.

#2 Band:

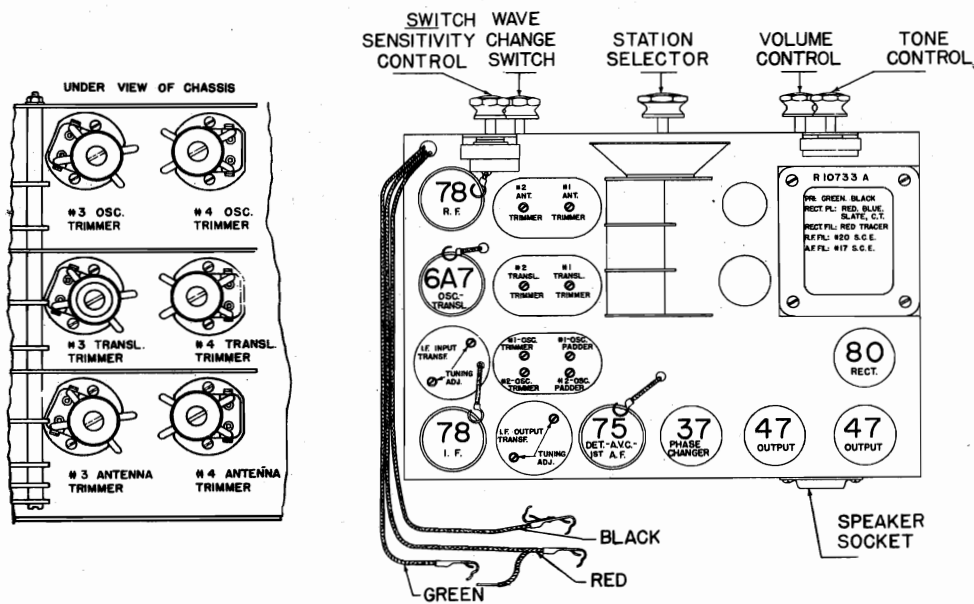

1. Leave the test oscillator coupled to the antenna lead as for broadcast band alignment.
2. Set the test oscillator to 4250 kc.
3. Turn the variable condenser plates all the way out. Then adjust the #2 oscillator trimmer for maximum output.
4. Set the test oscillator to 4000 kc and tune in its signal. Then adjust the #2 antenna trimmer and the #2 translator trimmer for maximum output.
5. Set the test oscillator to 1700 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the #2 oscillator padder for maximum output.
6. Repeat the 4250 kc and 4000 kc adjustments for greater accuracy.

#3 Band:

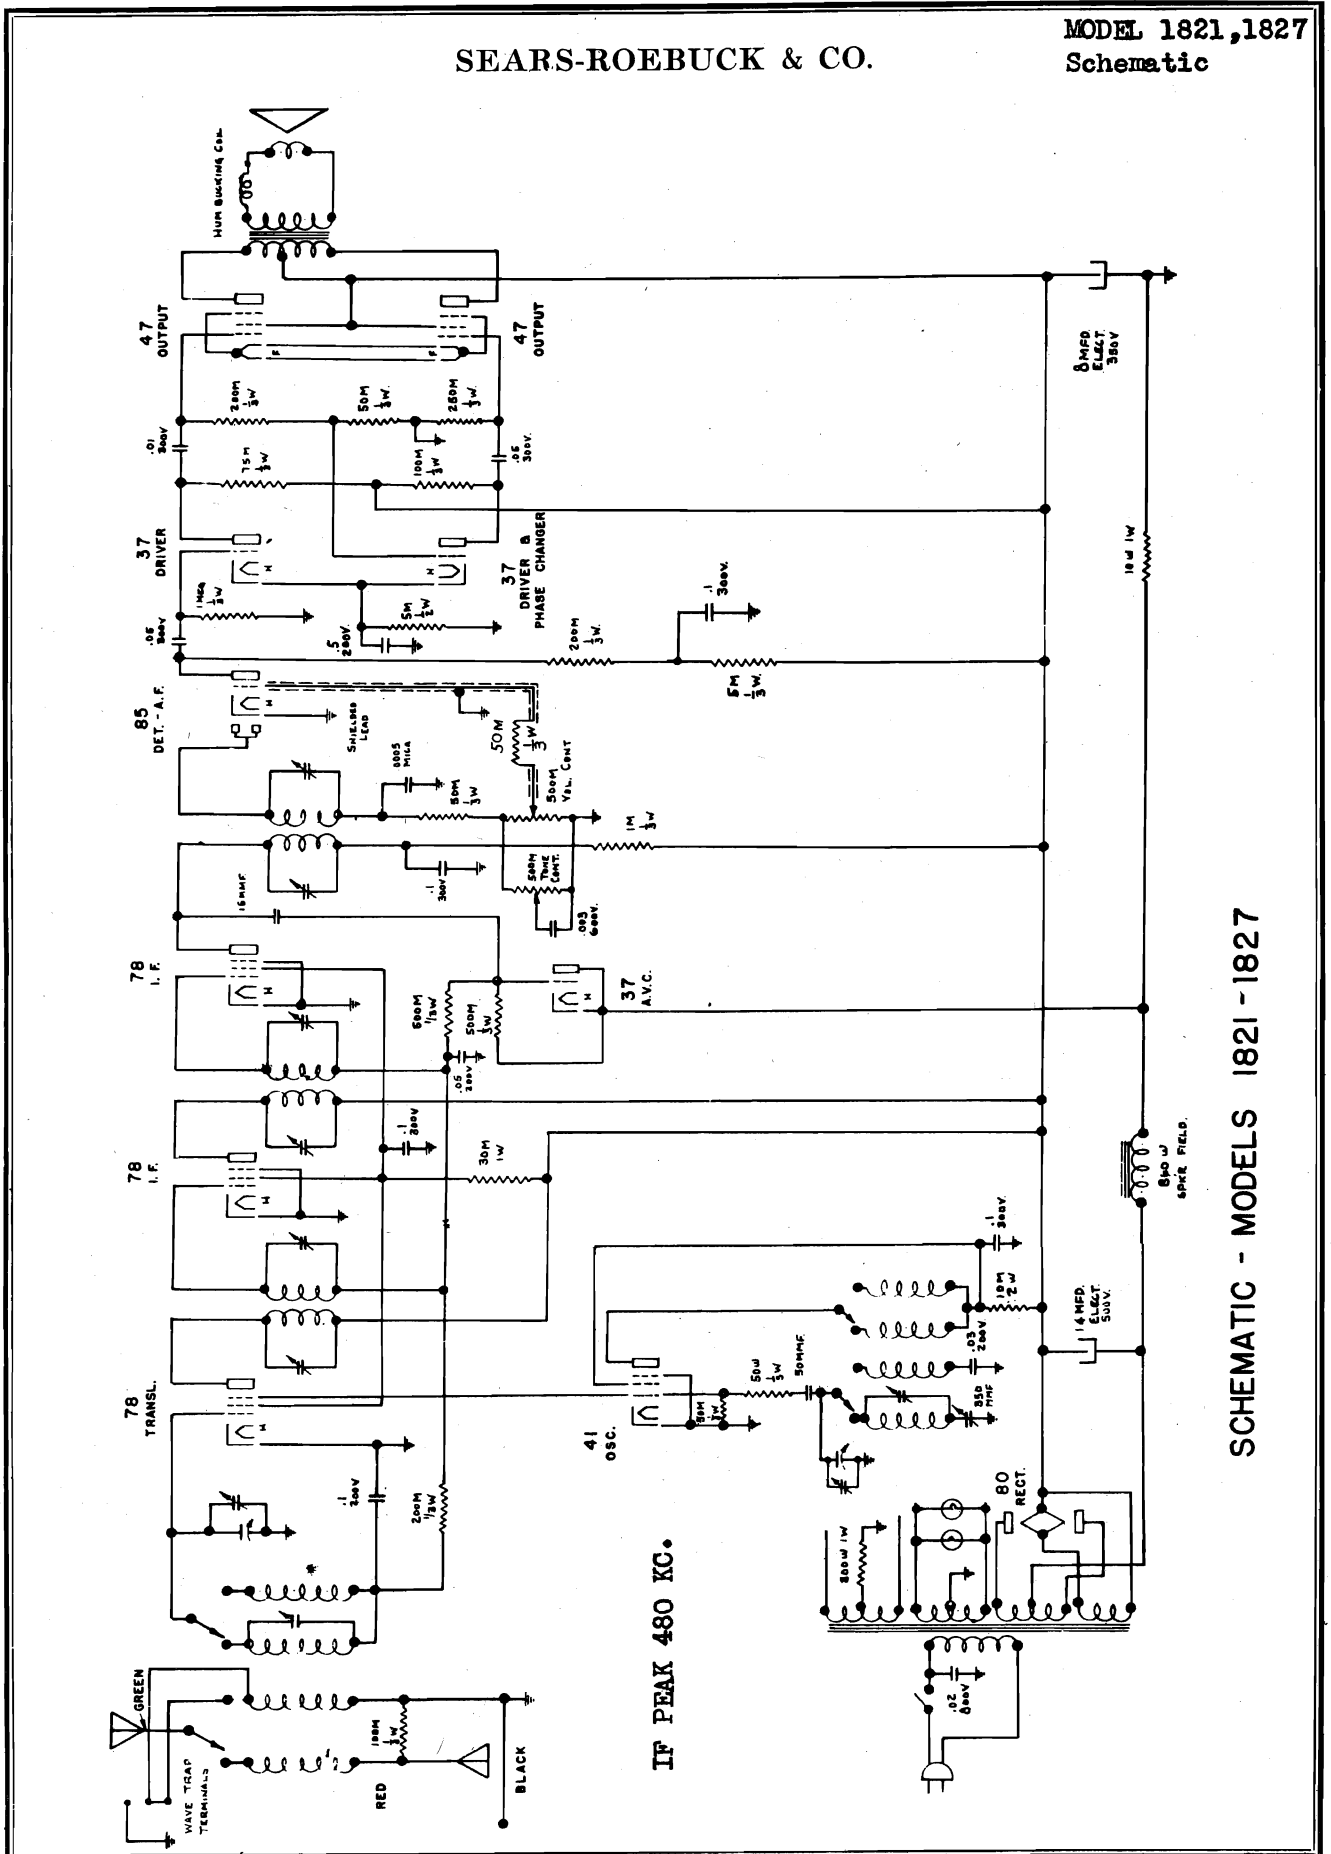

1. Set the test oscillator to 10 megacycles.
2. Turn the variable condenser plates all the way out. Then adjust the #3 oscillator trimmer for maximum output. As shown in the Service Illustrations, this trimmer is mounted inside of its coil, under the chassis.
3. Set the test oscillator to 9 megacycles and tune in its signal. Then adjust the #3 antenna trimmer and the #3 translator trimmer for maximum output.
4. Set the test oscillator to 4.5 megacycles and tune in its signal. If necessary, shift turns on the antenna and translator coils to secure maximum sensitivity. Be sure to cement the turns in place.
5. If turns have been shifted, repeat the 10 megacycle and the 9 megacycle adjustments, since they will have been affected by shifting of the turns.

#4 Band:

1. Set the test oscillator to 19 megacycles.
2. Turn the variable condenser plates all the way out. Then adjust the #4 oscillator trimmer for maximum output.
3. Set the test oscillator to 18 megacycles and tune in its signal. Then adjust the #4 antenna trimmer and the #4 translator trimmer for maximum output.
4. Set the test oscillator to 9 megacycles and tune in its signal. If necessary, shift turns on the antenna and translator coils to secure maximum sensitivity. Be sure to cement the turns in place.
5. If turns have been shifted, repeat the 19 megacycle and 18 megacycle adjustments since they will have been affected by shifting of the turns.

MODEL 1828
Schematic

SCHEMATIC - MODEL 1828

MODEL 1828

Voltage, Alignment
Socket, Parts List

SEARS-ROEBUCK & CO.

To adjust the wave trap, proceed as follows:

1. With the wave switch in the broadcast position, fully mesh the variable condenser plates.
2. If the interfering signal can be picked up, adjust the two tuning condensers of the wave trap until the interfering signal disappears.
3. If the frequency of the interfering signal is known, the adjustment can be made more quickly and accurately by means of a test oscillator. Set the oscillator to the interfering frequency and couple its output to the antenna lead. The oscillator should be adjusted to give high output. Then adjust the wave trap until the oscillator signal disappears. Usually the frequency of the interfering signal is very close to 500 kc and this frequency should be used if the interference is not heard at the time of the service call.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the low scale of the output meter across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator through a .1 mfd. condenser to the control grid of the 78 second IF tube. The grid clip should be left attached to the cap.
4. Set the test oscillator to 480 kc and tune the IF output transformer. The locations of its tuning adjustments are shown in the Service Illustrations.
5. Change the test oscillator connection to the control grid cap of the 78 first IF tube and tune the IF interstage transformer.
6. Change the test oscillator connection to the control grid cap of the 78 translator tube and tune the IF input transformer.
7. In order to secure greater accuracy, repeat all of the operations, starting with the IF output transformer.

RF Alignment (Broadcast):

1. Set the test oscillator to 1785 kc.

2. Couple the output of the oscillator loosely to the antenna lead of the set, with the antenna connected.

3. Turn the variable condenser plates all the way out. Then adjust the oscillator trimmer for maximum output. This trimmer condenser is mounted on the terminal board of the broadcast oscillator coil, as shown in the Service Illustration.

4. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and at the same time, adjust the broadcast oscillator padder for maximum output. The location of this padding condenser is shown in the Service Illustration.

5. Repeat the adjustment of the oscillator trimmer at 1785 kilocycles.

6. Set the test oscillator to 1500 kc and tune in its signal. Then adjust the trimmer on the antenna section of the variable condenser for maximum output. In some of the receivers this trimmer has been removed from the variable condenser, in which case this step in the alignment procedure may be omitted.

Short Wave Alignment:

1. Set the test oscillator to 16 megacycles, leaving it coupled to the set's antenna lead as for broadcast alignment.

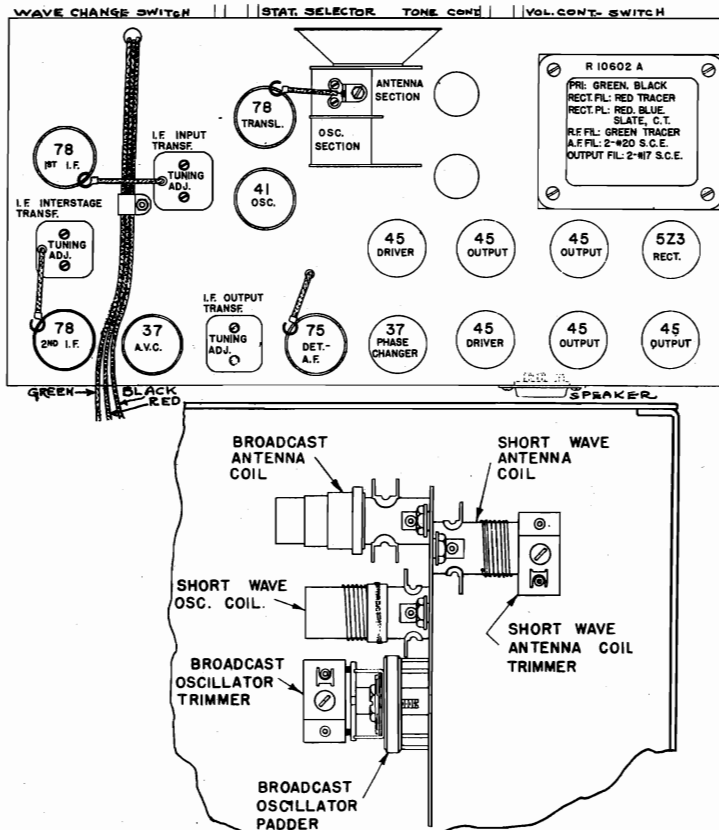

2. Turn the wave band switch to the short wave position and tune in the test oscillator signal. Then adjust the trimmer on the short wave antenna coil for maximum output.

3. Set the test oscillator to 6 megacycles and tune in its signal. If necessary, turns may be shifted on the short wave antenna coil to secure accurate alignment on this frequency. Should it become necessary to shift turns, the translator trimmer will have to be readjusted at 16 megacycles after the turns have been shifted.

TUBE VOLTAGE CHART

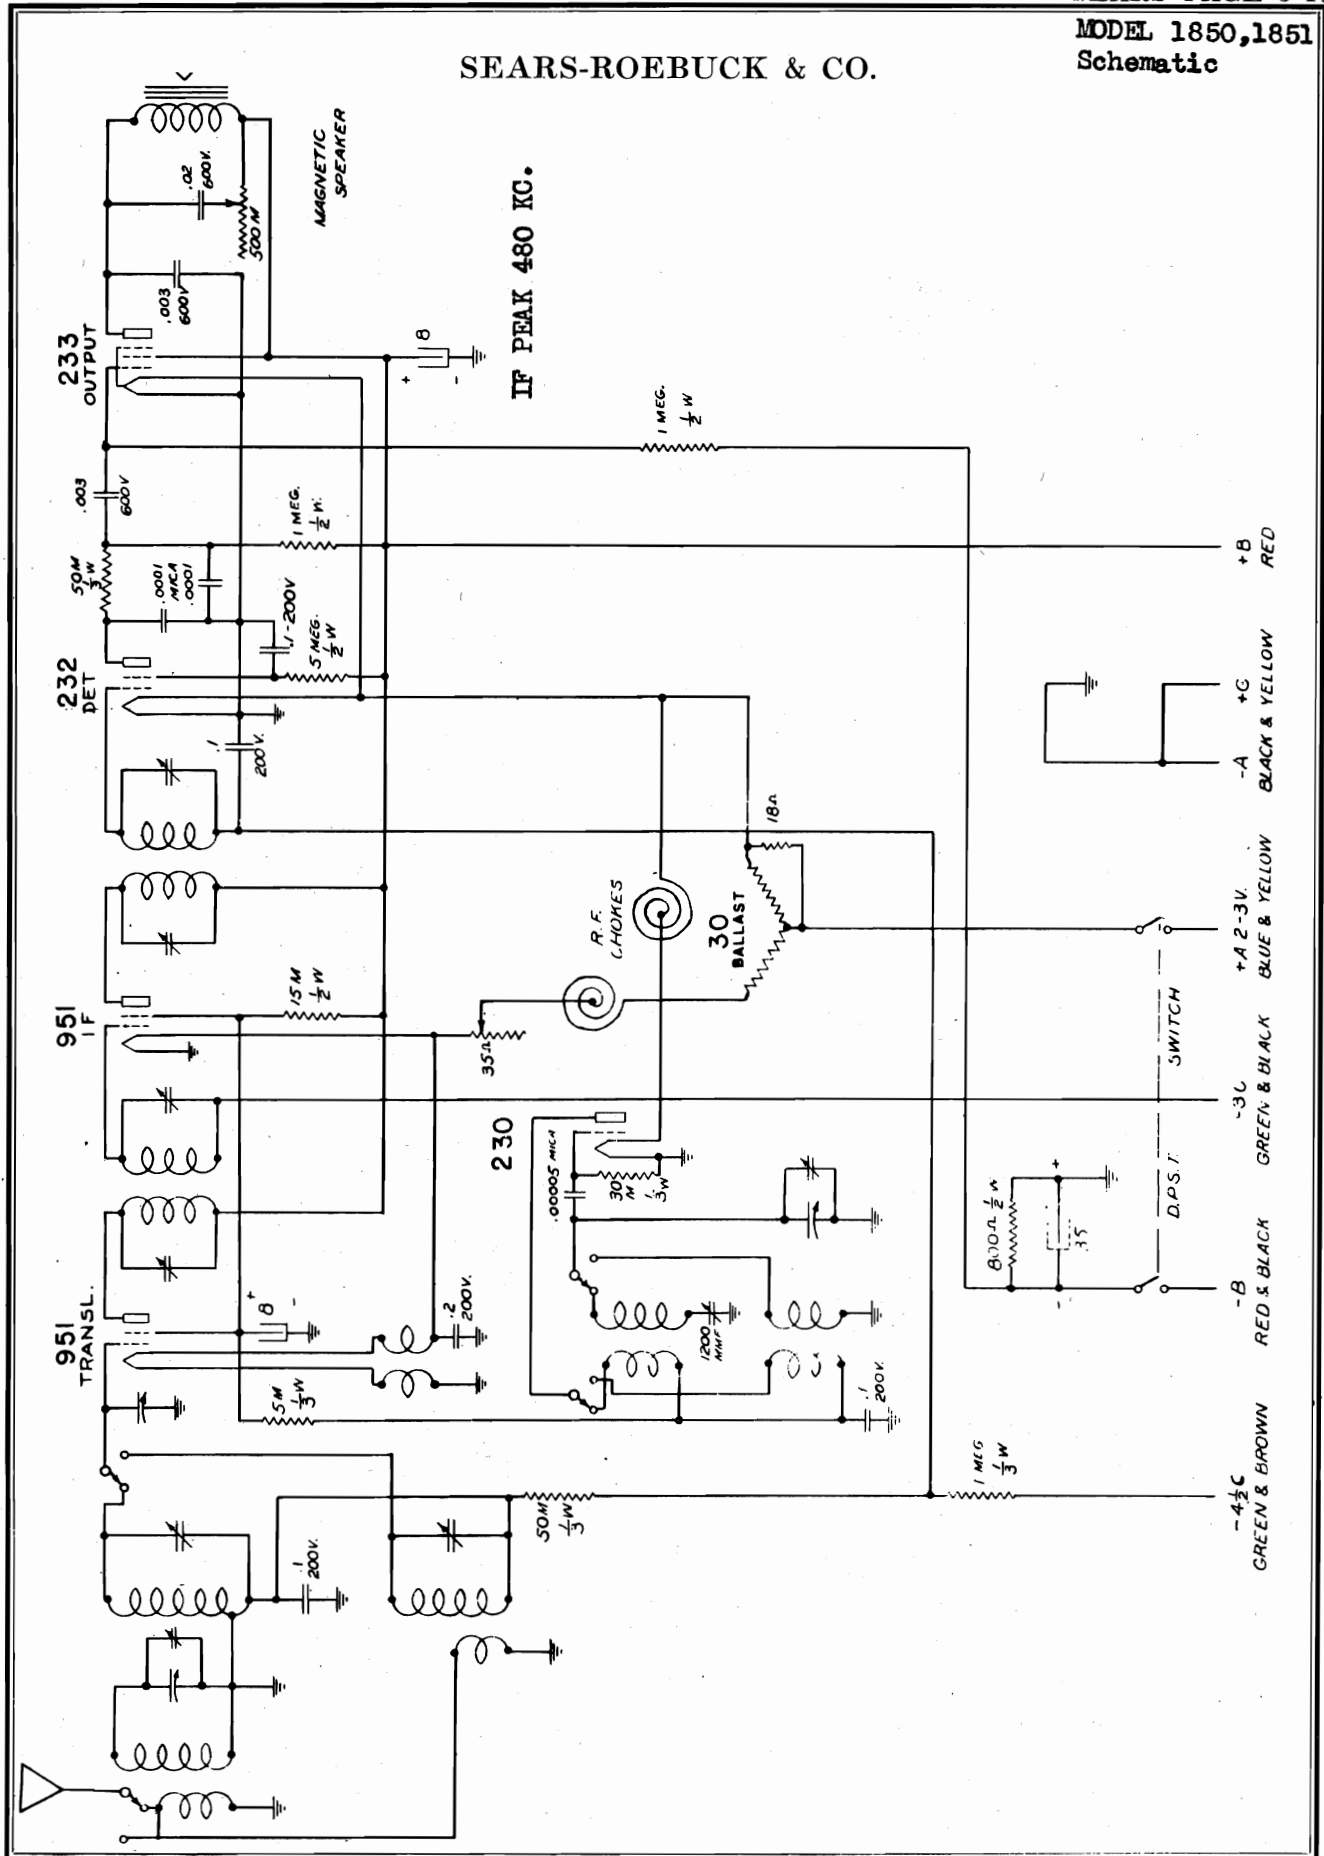

All readings are to be taken between the chassis and the respective element of each tube.

SEARS-ROEBUCK & CO.

MODEL 1850, 1851
Voltage, Alignment
Socket, Parts List

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter across the loud speaker terminals. The high scale (about 100 volts) of the meter should be used.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid of the IF tube, leaving the grid clip attached to the cap.
4. Set the test oscillator to 480 kc. and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.
6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment: (Broadcast)

1. Set the test oscillator to exactly 1600 kc.
2. Couple the output of the oscillator to the antenna lead of the set, with the antenna connected.
3. Turn the dial pointer to exactly 1600 kc. and adjust the oscillator trimmer for maximum output. The oscillator trimmer is on the variable condenser section furthest from the dial.
4. Set the test oscillator to 1400 kc. and tune in its signal. Then adjust the translator and antenna trimmers for maximum output. The translator trimmer is accessible through the hole in the top of the translator coil shield as shown in the Service Illustration. The antenna trimmer is the one on the variable condenser section nearest the dial.
5. Set the test oscillator to 600 kc. and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the peader until maximum output is obtained.
6. Repeat the 1600 kc. and 1400 kc. adjustments.

Short Wave Alignment:

1. Set the test oscillator to 15 megacycles and tune in its signal.
2. Adjust the short wave translator trimmer for maximum output.
3. If necessary, shift the end turns (enamelled wire) of the short wave translator coil to secure accurate alignment and maximum output.
4. Re-adjust the translator trimmer at 15 megacycles.

TUBE VOLTAGE CHART

TUBE	PLATE VOLTAGE	SCREEN VOLTAGE	CONTROL GRID VOLTAGE
951 - Translator	122	70	-.1
230 - Oscillator	60		-.6
951 - IF	122	70	-.8
232 - Detector	22.5*	5*	-.1
233 - Output	115	122	-.1

NOTE: All control grid readings are lower than the actual applied voltage due to high series resistance in the circuit.

* - Indicates low reading due to high series resistance in circuit.

MODEL 1854

Alignment, Voltage
Socket Layout

SEARS-ROEBUCK & CO.

The type 31 Ballast tube maintains the filament voltage at its proper value (2 volts). This will be so whether a 2 volt air cell, a dry cell "A" block or a 6 volt storage battery is used. It is important that the receiver be turned off before removing any tubes. Otherwise the voltage across the remaining tubes will rise, with the possibility of damaging them.

Although the receiver will afford good reception after the "B" batteries have fallen to a lower value, for best results they should be replaced when the total voltage, under load, falls to 100 volts.

THE 230 AVC CIRCUIT

A portion of the IF signal at the plate of the second IF tube is impressed through the .000025 mfd. condenser and the 400 M ohm resistor, upon the 230 AVC tube. This tube is used as a rectifier or diode, with plate connected to filament. During the positive half cycles of the signal voltage, diode current flows through the 400 M ohm resistor which is connected between grid and plate of the 230 AVC tube, creating a voltage drop across it. This voltage is effectively in series with the "C" battery, being connected to it through the 1 megohm resistor which is in the circuit between the 230 grid and the "C" lead. Any increase in signal strength increases the current through the 230 AVC tube, increases the drop across the 400 M ohm resistor and therefore increases the total value of "C" bias. This increased "C" bias is impressed upon the control grids of the translator and IF tubes, decreasing their amplification. Since increases in signal strength are offset by decreases in tube amplification, the output of the second IF tube tends to remain at a constant value.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter across the loud speaker terminals. The high scale (about 100 volts) of the meter should be used.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the second IF tube. Leave the grid clip attached to the cap.
4. Set the test oscillator to 175 kc and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the first IF tube and adjust the inter-stage tuning condenser. This condenser is the Isolantite base one mounted on the back plate of the chassis alongside of the Candohm resistor.
6. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.
7. Repeat all of the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

Broadcast (#1 Band) Alignment:

1. Set the test oscillator to exactly 1600 kc.
2. Couple the output of the oscillator loosely to the antenna lead of the set, with the antenna connected.
3. Turn the dial pointer to exactly 1600 kc and adjust the oscillator trimmer for maximum output. The oscillator trimmer is the bakelite base condenser mounted on the back of the variable condenser end plate.
4. Set the test oscillator to 1500 kc and tune in its signal. Then adjust the translator and antenna trimmers for maximum output. The translator trimmer is the one on the middle section of the variable condenser. The antenna trimmer is the one on the variable condenser section nearest the dial.
5. Set the test oscillator to 600 kc. Tune in its signal and slowly rotate the variable condenser back and forth a degree or two, and at the same time adjust the padder until maximum output is obtained. The padder is the Isolantite base condenser mounted on the end plate of the variable condenser.
6. Since the adjustments are inter-acting to an extent, it is advisable to repeat the entire operation. Always use as low an output from the test oscillator as possible.

Short Wave (#2 Band) Alignment:

1. Set the test oscillator to 4000 kc and couple it loosely to the set's antenna lead, with the antenna connected.
2. Turn the wave band switch to the #2 position and tune in the oscillator signal.
3. If the calibration is out, shift turns (enamel wire) on coil "E" until the proper calibration is obtained. The end plate may be removed from the chassis in order to gain access to the coils.

4. The turns of coils "A" and "B" may be shifted, if necessary, to obtain alignment and maximum output.

5. Check the calibration and alignment at 2000 kc. If they are not correct at this frequency, the 4000 kc adjustment should be repeated to obtain a compromise adjustment for the two frequencies.

6. Cement the coil turns in place.

Short Wave (#3 Band) Alignment:

1. Set the test oscillator to 15 megacycles.
2. Couple its output loosely to the receiver's antenna lead, with the antenna connected. Turn the wave band switch to the #3 position and tune in the oscillator signal.
3. Obtain maximum output and proper calibration by shifting the leads of coils "C", "D" and "F".
4. Tune the test oscillator and the receiver to 6000 kc and shift turns on coils "C", "D" and "F" until maximum sensitivity and proper calibration are obtained.
5. Repeat operation #3 at 15 megacycles.

A loop of #14 wire with its ends soldered together to form a short circuited ring, fastened to a bakelite handle will prove useful for determining whether the end turns of the short wave coils need to be moved toward or away from the other turns. If sensitivity is increased when the loop of wire is slowly inserted inside of a short wave coil, it is an indication that the turns of the coil should be moved apart. If the sensitivity is decreased, it indicates either that the coil adjustment is correct, or that the turns should be moved closer together.

TUBE VOLTAGE CHART

All readings are to be taken between the chassis and the respective element of each tube.

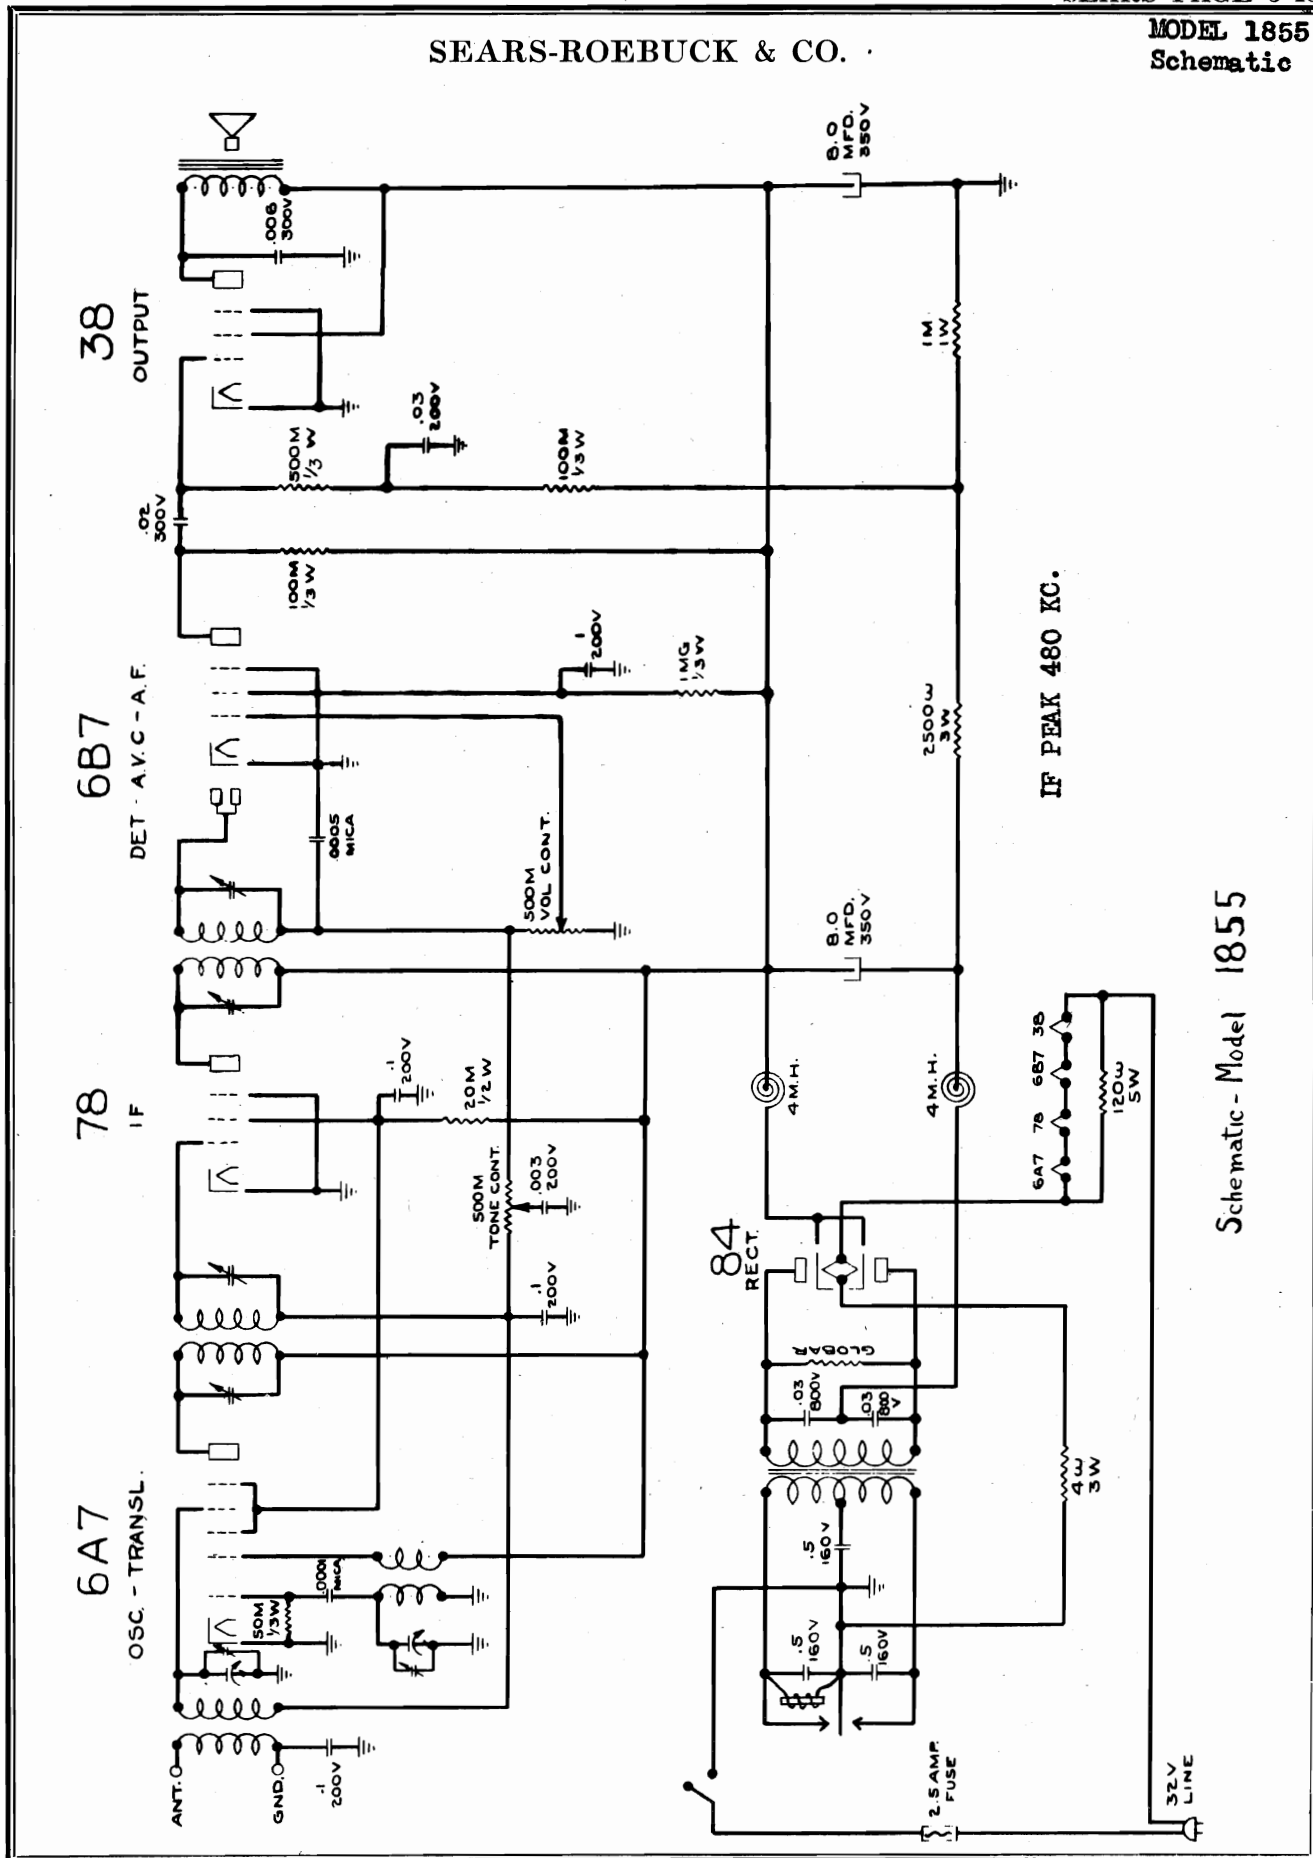

TUBE	PLATE VOLTAGE	SCREEN VOLTAGE	CONTROL GRID VOLTAGE
951 Translator	120	58.5	-1.2
230 Oscillator	44		-2.35
951 1st IF	69	57	-.3
951 2nd IF	120	57	-.3
230 Detector	Used as diode with no applied DC voltage.		
230 AVC	Used as diode with no applied DC voltage.		
230 1st Audio	120		*
950 Output	120	120	-15

* - Extremely low readings due to high series resistance in circuit.

Actual Translator control grid voltage is -4.5 volts.
Actual IF control grid voltage is -1.5 volts.

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter across the loud speaker terminals. The high scale (about 100 volts) of the meter should be used.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the grid of the 78 IF tube. Leave the grid clip attached to the cap.
4. Set the test oscillator to 480 kc. and tune the IF output transformer. The locations of the tuning adjustments are shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.
6. Repeat the adjustments to secure greater accuracy.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment:

1. Set the test oscillator to exactly 1750 kc. Couple the output of the oscillator to the antenna lead of the set, with the antenna connected.
2. Turn the dial to exactly 1750 kc. and adjust the oscillator trimmer for maximum output. The oscillator trimmer is the one on the variable condenser section, furthest from the dial.
3. Set the test oscillator to 1500 kc and tune in its signal. Adjust the antenna trimmer for maximum output.

TUBE VOLTAGE CHART

All readings are to be taken between the chassis and the respective element of each tube. Supply voltage 32 volts.

TUBES	PLATE	SORREN	OSC. PLATE	OSC. GRID	CONTROL GRID
6A7-Osc-Transl -	165	85	165	-5.6	-.4
78-IF -	165	85			-.4
6B7-AVC-Det-AF -	75	20			-.2
38-Output -	165	165			-.6*

* - Extremely low readings due to high series resistance in circuit.

The cover of the power supply unit is fitted with contact fingers to insure good contact with the rest of the power supply case. It is important that this cover makes tight electrical contact with the case to prevent noisy operation due to electrical disturbances from the vibrator.

The resistor marked "Globber", in the schematic, is a special resistor whose value varies with the voltage. When the receiver is first turned on, the output voltage tends to become very high until the tubes heat sufficiently to draw their normal load. Under these conditions, the Globbar resistance drops to a comparatively low value, loading the transformer sufficiently to prevent damage. As the tubes become heated, tending further to lower the voltage, the Globbar resistance increases greatly so that it no longer constitutes a load on the power supply.

Unlike the earlier Model 1733, the polarity of the power cord plug is not of importance.

The antenna coil is not grounded to the chassis, so that the receiver depends entirely upon the installation ground for its ground connection. Accordingly, the best ground possible should be installed.

The polarity of the speaker must be correct. The blue lead connects to the speaker terminal marked "P". The black lead connects to the "N" terminal.

THE 6B7 - AVC-Detector-AF

The 480 kc signal from the IF stage is impressed between the cathode and the diode plates of the 6B7, in series with the 500 M ohms of the volume control. Diode current flows, creating a voltage drop across the control with the grounded end positive with respect to the other end. Since the control grid returns of the 6A7 and 78 tubes are connected to the ungrounded end of the volume control, the negative bias across it is impressed upon the control grids of these tubes. Any increase in signal strength increases the diode current and the drop across the volume control, increases the negative control grid bias and so reduces tube amplification. Since increases in signal strength tend to be offset by decreases in tube amplification, the input to the detector remains substantially at a constant value.

The audio component across the volume control is picked off by the movable arm and fed to the control grid of the pentode portion of the tube. It is there amplified and then coupled to the 38.

SCHEMATIC - MODEL 1857

MODEL 1857
Alignment, Voltage
Parts List

SEARS-ROEBUCK & CO.

ALIGNMENT PROCEDURE

The IF Stages:

Connect the output meter across the loud speaker terminals. The high scale (about 100 volts) of the meter should be used.

1. Connect one lead of the test oscillator to the chassis.
2. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser to the grid of the 1st IF tube. Leave the grid clip attached to the cap.
3. Set the oscillator to 175 kc and tune the 2nd IF output transformer. The locations of the tuning adjustments are shown in the illustration.
4. Connect the oscillator, through the .1 mfd. condenser, to the grid of the translator tube and tune the IF input transformer.
5. Repeat the adjustments for the IF output transformer and then for the IF input transformer.

Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

Broadcast (#1 Band) Alignment:

1. Set the test oscillator to exactly 1600 kc.
2. Couple the output of the oscillator loosely to the antenna lead of the set, with the antenna connected.
3. Turn the dial pointer to exactly 1600 kc and adjust the oscillator trimmer for maximum output. The oscillator trimmer is the bakelite base condenser mounted on the back of the variable condenser end plate.
4. Set the test oscillator to 1500 kc and tune in its signal. Then adjust the translator and antenna trimmers for maximum output. The translator trimmer is the one on the middle section of the variable condenser. The antenna trimmer is the one on the variable condenser section nearest the dial.
5. Set the test oscillator to 600 kc. Tune in its signal and slowly rotate the variable condenser back and forth a degree or two, and at the same time adjust the padder until maximum output is obtained. The padder is the Isolantite base condenser mounted on the end plate of the variable condenser.
6. Since the adjustments are inter-acting to an extent, it is advisable to repeat the entire operation. Always use as low an output from the test oscillator as possible.

Short Wave (#2 Band) Alignment:

1. Set the test oscillator to 4000 kc and couple it loosely to the set's antenna lead, with the antenna connected.
2. Turn the wave band switch to the #2 position and tune in the oscillator signal.
3. If the calibration is out, shift turns (enamelled wire) on coil "E" until the proper calibration is obtained. The end plate may be removed from the chassis in order to gain access to the coils.
4. The turns of coils "A" and "B" may be shifted, if necessary, to obtain alignment and maximum output.
5. Repeat operations #3 and #4 at 2000 kc. If the alignment and calibration are not correct at this frequency, the 4000 kc adjustment should be repeated to obtain a compromise adjustment.
6. Cement the coil turns in place.

Short Wave (#3 Band) Alignment:

1. Set the test oscillator to 15 megacycles.
2. Couple its output loosely to the receiver's antenna lead, with the antenna connected. Turn the wave band switch to the #3 position and tune in the oscillator signal.
3. Obtain maximum output and proper calibration by shifting the leads of coils "C", "D" and "F".
4. Tune the test oscillator and the receiver to 6000 kc and shift turns on coils "C", "D" and "F" until maximum sensitivity and proper calibration are obtained.
5. Repeat operation #3 at 15 megacycles.

A loop of #14 wire with its ends soldered together to form a short circuited ring, fastened to a bakelite handle will prove useful for determining whether the end turns of the short wave coils need to be moved toward or away from the other turns. If sensitivity is increased when the loop of wire is slowly inserted inside of a short wave coil, it is an indication that the turns of the coil should be moved apart. If the sensitivity is decreased, it indicates either that the coil adjustment is correct, or that the turns should be moved closer together.

TUBE VOLTAGE CHART

All readings are to be taken between the chassis and the respective element of each tube.

TUBE	PLATE VOLTAGE	SCREEN VOLTAGE	CONTROL GRID VOLTAGE
951 Translator -	122	55	-1.2
230 Oscillator -	45		-2.75
951 1st. IF -	115	55	- .3
951 2nd. IF -	122	55	- .2
951 Detector -	*	*	-4.5
230 AVC -	No applied DC voltage		
233 Output -	120	122	*

* - Extremely low readings due to high series resistance in circuit

Actual 233 control grid voltage is approximately 13 volts.
 Actual IF control grid voltage is -1.5 volts.
 Actual Translator control grid voltage is -4.5 volts.

MODEL 1858
Alignment, Voltage
Socket, Parts List

SEARS-ROEBUCK & CO.

SILVERTONE - - MODEL 1858

* * *

The Silvertone Model 1858 is a five tube automobile radio receiver almost identical with the Model 1730 described in Service Manual Supplement #25. As an examination of the schematic will show, practically the only circuit difference is in the filtering of the Genemotor. The chief mechanical difference is that the pilot light lead of the Model 1858 is contained in the same covering as the drive cables. The mechanical and general information contained in the Model 1730 manual will apply equally as well to the Model 1858.

The tubes and their functions are:

- 78 - RF
- 6A7 - Oscillator-Translator
- 78 - IF
- 85 - AVC-Detector-AF
- 41 - Output

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter (low voltage scale) across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid cap of the 78 IF tube, leaving the grid clip attached to the cap.
4. Set the test oscillator to 175 kc and tune the IF output transformer. This transformer is mounted under the chassis. The location of its tuning adjustments is shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.
6. Repeat the adjustments to secure greater accuracy. Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment:

1. Connect the test oscillator to the antenna lead through a .00025 mfd. condenser.
2. Open the variable condenser plates to the point where the rotor plates just mesh with the stator plates.
3. Set the test oscillator to exactly 1500 kc and adjust the oscillator trimmer for maximum output.
4. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and at the same time adjust the padder until maximum output is obtained.
5. Repeat operations 1 to 4.
6. Set the test oscillator to 1400 kc and tune in its signal.
7. Adjust the antenna and translator trimmers for maximum output.

TUBE VOLTAGE CHART

All readings are to be taken between the chassis and the respective element of each tube.

TUBE	PLATE	SCREEN	OSC. SECTION		CONTROL GRID	CATHODE
			GRID	PLATE		
78 - RF	- 210	77			.1	3.7
6A7- Osc-Transl	- 210	77	-.2	155	.1	3.7
78 - IF	- 210	77			0	4.8
85 - AVC-Det-AF	- 38				.1	4.8
41 - Output	- 200	210			-.5*	

* - Extremely low reading due to high series resistance in circuit.

MODEL 7043, 7044
Voltage, Parts List
Resistance Test

SEARS-ROEBUCK & CO.

trol grid cap of the first detector tube, to ground. Do not remove any of the tubes from the sockets and it is not necessary to disconnect the grid cap clip from the first detector tube. Reset trimmers No. 5, No. 6, No. 7 and No. 8 for maximum output. While this test oscillator is working into the intermediate frequency stages, no adjustment of the tuning condenser on the receiver will have any effect inasmuch as the intermediate frequency stage is fixed tuned.

If your test oscillator is properly designed, it will supply exactly 175 k.c. and when trimmers No. 5, No. 6, No. 7 and No. 8 are set and tuned for maximum output, they will be correctly adjusted.

Next, disconnect the 175 k.c. test oscillator and connect to the antenna binding post of the receiver, the output lead from your broadcast test oscillator or tune in a broadcast signal around 1400 k.c., then reset trimmer No. 2 and No. 1, respectively, for maximum output. This adjustment will track the first detector and r.f. stages.

To check the calibration of the receiver, whether it be high or low, trimmer No. 3 (oscillator) should be reset until a station of known high frequency is brought in at the correct dial marking with peak volume. If your broadcast test oscillator is accurately calibrated, it might be used in place of the broadcasting station signal. In this adjustment, a broadcast station or test oscillator signal, at about 1400 k.c., should be chosen, the setting of the trimmer at 1400 k.c. is more critical than it would be at 600 k.c.

The next adjustment is important and not easily explained in writing so pay close attention to the following instructions. We will now balance the oscillator to the r.f. and first detector stages.

Tune the external broadcast test oscillator and the receiver both to 600 k.c. then slowly increase or decrease the capacity of No. 4 (oscillator padding trimmer) at the same time and continuously tuning back and forth across the signal with the receiver tuning condenser gang. The output meter needle will now be swinging up and down in step with the variation in tuning. Watch the peak of this swinging closely and readjust No. 4 trimmer until the swinging needle reaches its highest peak.

Retune the receiver and broadcast test oscillator to 1400 k.c. and re-check trimmer No. 3 to make sure that the adjustment of No. 4 has not thrown the receiver out of calibration. If it has, then readjust No. 3 until the calibration is correct, as previously explained, and check on trimmers No. 2 and No. 1, to make sure that the adjustment of No. 4 has not reduced the sensitivity.

CIRCUIT RESISTANCE ANALYSIS

SEARS-ROEBUCK & CO.

MODEL 7048
Schematic, Voltage
Alignment, Resistance

First connect the 175 K. C. Oscillator to the first detector grid and adjust trimmers Nos. 4, 5 and 6 for maximum output as indicated by the loud speaker, or preferably by a regular output meter; next hook up the broadcast oscillator to the antenna and ground binding posts of the set and adjust number 3 (oscillator gang trimmer) at 1500 K. C., for calibration. This is accomplished by using a broadcast oscillator at 1500 K. C. if the calibration of the broadcast oscillator is known to be accurate or by tuning in a broadcasting station, using "crystal control" at a known frequency between 1400 and 1500 K. C., then adjust number 3 trimmer until the receiver's dial reading is exactly the same as the frequency of the broadcasting station; next readjust trimmers number 2 and 1 for maximum output at a point between 1400 and 1500 K. C., since adjusting at these high frequencies is more accurate and critical. No oscillator padding trimmer is employed on this receiver. The special shape of the oscillator tuning condenser rotor makes such a padding trimmer unnecessary.

Output.	570,0001	50,000	50,000
Recti-fier	50,000	1,900

Readings of one megohm and over are given as "infinity". The first three significant figures, only are interpreted from the ohmmeter in each reading; the individual resistance in the circuit can be readily checked upon removal of chassis.
*NOTE: On first few thousand sets the i.f. Suppressor Grid Resistance read .1 ohm and was connected to ground.

Loud Speakers
Cone Replacement Data

SEARS-ROEBUCK & CO.

CONE REPLACEMENT OF OUTSIDE TYPE SUSPENSION SPEAKERS (FIG. 2).

1. Unsolder the voice coil leads from their terminals.
2. Remove the suspension mounting screws.
3. Drill out the cone mounting eyelets or cut off the small head ends with a cold chisel and hammer. If care is used, the cardboard mounting rings will not be damaged.
4. Remove the cone and blow out any dirt or metal chips from the air gap.
5. Re-assemble the cone, suspension, and cardboard mounting rings in their original order. Leave the suspension mounting screws loose enough so that the suspension can be shifted about.
6. Insert four strips about 3" long, 1/8" wide and .01" thick (cut from a calling card) between the inside of the voice coil and the pole stem. They should be evenly spaced around the pole stem. Spacers can be obtained from the factory. Part No. S-8177 for 5" and 6" speakers. Part No. S-7391 for all other speakers.
7. Replace the eyelets around the edge of the cone, leaving blank any holes that were originally left blank for speaker to baffle mounting screws. The eyeletting tool illustrated is recommended (Part No. R-8033).
8. Solder the voice coil leads to their terminals.
9. Tighten the suspension screws.
10. Remove the four spacer strips.

11. If it should happen that the cone is not properly centered after the replacement, loosen the suspension mounting screws and move the cone around until proper centering is secured. Sometimes several attempts are necessary before proper centering can be had.

REPLACING THE FIELD COIL IN SPEAKERS HAVING THE POLE PLATE RIVETED TO THE YOKE (FIG. 3).

1. It is always advisable to remove the cone first, as previously outlined, to avoid damaging it and to facilitate the work of field coil replacement.
2. Make a sketch of the coil connections, paying attention to the polarity, i.e., note whether the start or finish of a winding connects to a particular terminal. This is important since incorrect polarity in speakers with hum bucking coils will increase the hum instead of eliminating it.
3. Drill out the pole-plate-to-yoke-rivets, or cut off the small head ends with a cold chisel and hammer. In some speakers the rivets are aluminum; in others steel. It probably will be easier to drill the steel ones than to cut them off.

4. Dis-assemble the yoke and pole plate and replace the defective coil. Be sure to replace any cardboard spacer rings in their original position.
5. Re-assemble the yoke and pole plate, using nuts and bolts instead of the rivets used originally.
6. Replace the cone and voice coil as outlined previously.

REPLACING THE FIELD COIL IN SPEAKERS HAVING THE POLE PLATE BOLTED TO THE YOKE. (FIG. 4).

The procedure is the same for this type of speaker as for the type with riveted pole plate and yoke, except that the bolts are unscrewed instead of rivets removed. Be sure to keep the pole plate and yoke in the same relative positions as they were in originally, so that the pole stem will remain properly centered in the pole plate.

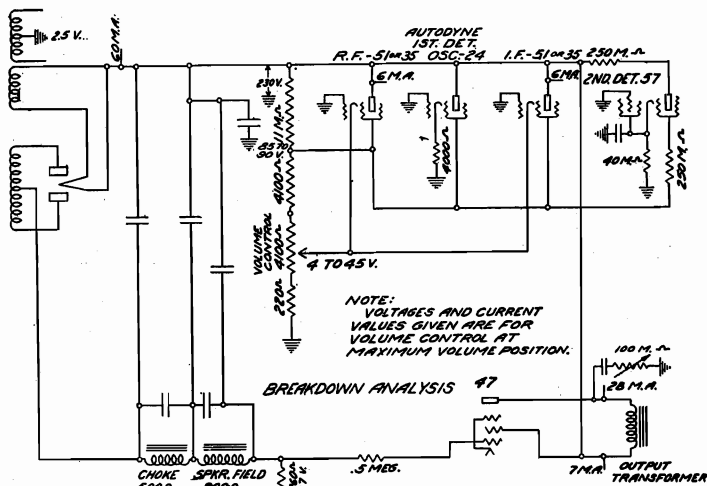

REPLACING THE FIELD COIL IN SPEAKERS HAVING THE POLE PLATE WELDED TO THE YOKE.

1. Remove the cone and voice coil assembly as outlined previously.
2. It will be necessary to break the welds with a cold chisel and hammer, but before doing so, drill four holes through the pole plate and yoke for the bolts and nuts which will replace the welds. Drilling the holes before breaking the welds and making the holes only large enough to pass the bolts will insure proper centering of the pole stem in the pole plate.

SEARS-ROEBUCK & CO.

MODEL 7049 Schematic, Socket Trimmer Data

READJUSTING TRIMMERS

The most important advice we can give you in regard to the adjustment of trimmers would be "don't make 'em." It has been proven conclusively to us that the Factory adjustment of these trimmers will not vary even when the set is severely jarred or dropped. However, if a customer were to tamper with their settings, a readjustment may have to be made. First, let us explain the location of the various trimmers. Diagram No. 3, top view of the series 220 chassis, shows each trimmer numbered. You should be acquainted intimately with each adjustment. A customer would not have to change the settings very much to ruin the sensitivity of the receiver. Further, if a readjustment appears to be necessary, it is imperative to know which circuit is being adjusted when a trimmer is being turned.

It is advisable to use a bakelite screwdriver when making any of these adjustments.

First, connect the 175 k. c. oscillator output leads from the control grid cap of the super-autodyne tube to ground. Do not remove any of the tubes from the sockets, and it is not necessary to disconnect the grid cap clip from the tube. Reset trimmers numbers 5, 6 and 7 for maximum output. While this test oscillator is working into the intermediate frequency stages, no adjustment of the tuning condenser on the receiver will have any effect, inasmuch as the intermediate frequency stage is fixed tuned.

If your test oscillator is properly designed, it will supply exactly 175 k. c., and when trimmers number 5, 6 and 7 are set for maximum output, they will be correctly adjusted and should be sealed.

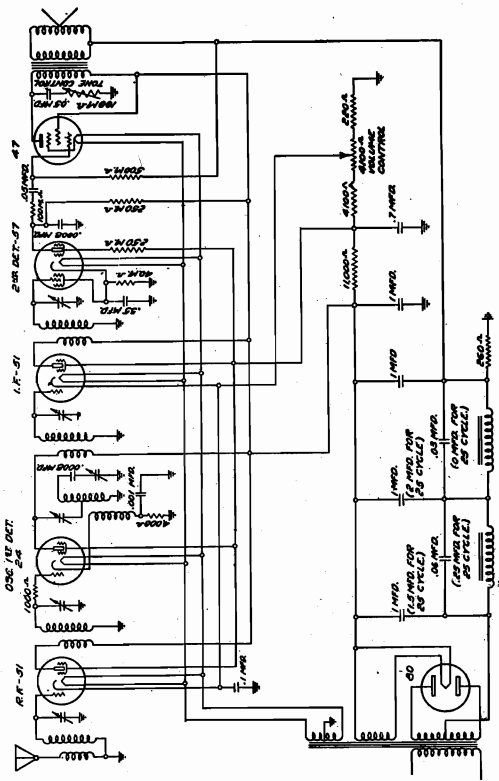

Next, disconnect the 175 k. c. test oscillator and connect to the antenna binding post of the receiver, the output lead from your broadcast test oscillator, or tune in a broadcast signal around 1400 k. c., then reset trimmers numbers 2 and 1 respectively for maximum output. This adjustment will track the super-autodyne grid circuit of the R. F. stage.

To check the calibration of the receiver, whether it be high or low, trimmer number 3 should be reset until a station of known high frequency is brought in on the correct dial marking with peak volume. If your broadcast test oscillator is accurately calibrated it might be used in place of the broadcasting station signal. In this adjustment, a broadcast station or test oscillator signal at about 1400 k. c. should be chosen. The setting of the trimmer at 1400 k. c. is more critical than it would be at 600 k. c.; calibration, therefore more accurate.

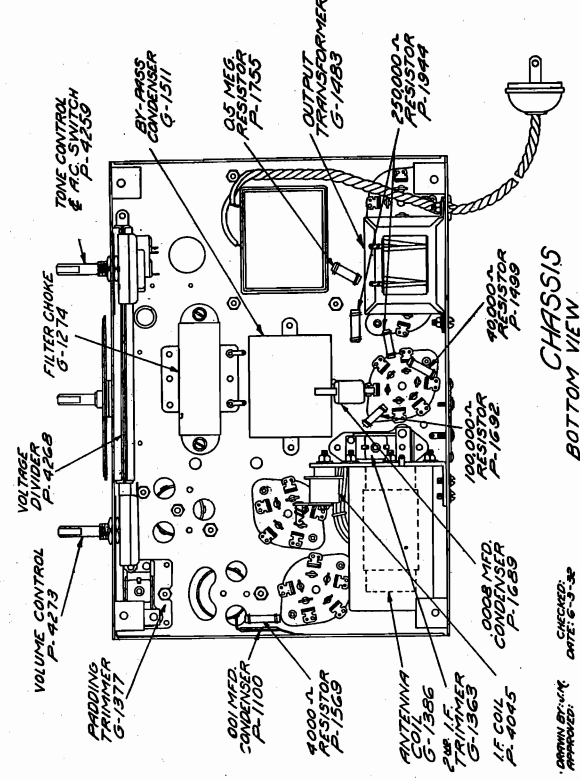

The next adjustment is important and not easily explained in writing, so pay close attention to the following instruction. We will now balance the oscillator to the r. f. and first detector stages.

Tune the external broadcast test oscillator and the receiver both to 600 k.c., then slowly increase or decrease the capacity of No. 4 (oscillator padding trimmer), at the same time and continuously tuning back and forth across the signal with the receiver tuning condenser gang. The output meter needle will now be swinging up and down in step with the variation in tuning. Watch the peak of this swinging closely and readjust No. 4 trimmer until the swinging needle reaches its highest peak.

Retune the receiver and broadcast test oscillator to 1400 k.c. and re-check trimmer No. 3 to make sure that the adjustment of No. 4 has not thrown the receiver out of calibration. If it has, then readjust No. 3 until the calibration is correct, (as previously explained), and check on trimmers No. 2 and No. 1, to make sure that the adjustment of No. 4 has not reduced the sensitivity.

- Number 1 is the antenna trimmer.
- Number 2 is the gang condenser tuning the grid of the Super-autodyne.
- Number 3 is the gang condenser tuning the plate (or oscillator of the super-autodyne).
- Number 4 is the oscillator padding trimmer.
- Number 5 is the Super-autodyne plate trimmer.
- Number 6 is the I. F. grid trimmer.
- Number 7 is the second detector grid trimmer.

MODEL 7110

Schematic

Parts List, Service Notes

SEARS-ROEBUCK & CO.

4-20-'34

S.R. No 7110

GENERAL INFORMATION

This set is designed to operate on 105-120 volts AC or DC from 25 to 60 cycles. The cord of the set will become quite warm in operation. This is a normal condition, the voltage reducing resistor being an integral part of the line cord for rapid dissipation of heat.

The set is of the conventional tuned radio frequency type and is so developed as to give a minimum of trouble and a maximum of enjoyment.

It is recommended that the aerial be used that is supplied with the set. However, if a longer aerial is used, it is advisable to rebalance the antenna stage of the set to the aerial used. To accomplish this, remove the set from the cabinet and set the dial at about 20 on the scale. Turn the compensator screw on the rear section of the variable condenser back and forth until maximum signal strength is obtained.

This set is designed to oscillate across a major portion of the broadcast band. This regeneration is controllable by reducing the volume of the set. Oscillation in a set of this type increases the sensitivity from ten to twenty times.

PARTS LIST

No.	Description
51	Magnetic speaker
52	Variable condenser 2 gang
53	Set of coils - complete

	Any bypass condenser (state capacity)

MODEL 7117,1859-A

Alignment Data
Parts List, Installation

SEARS-ROEBUCK & CO.

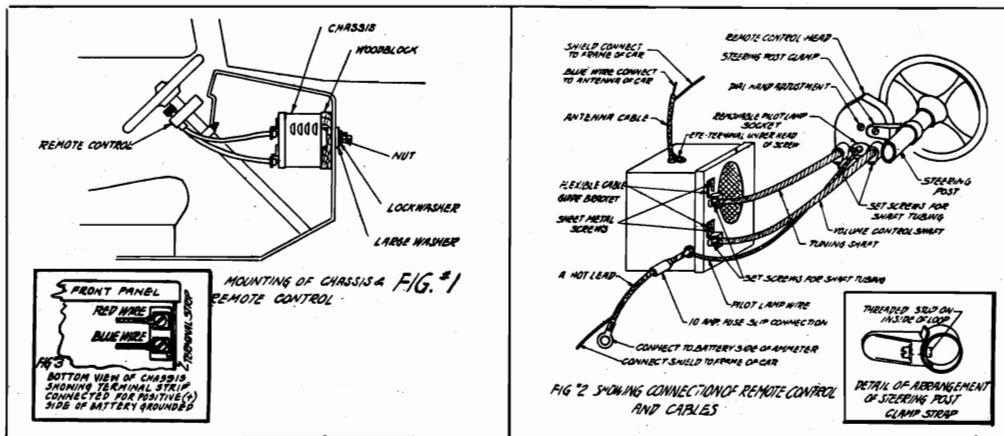

ALIGNMENT PROCEDURE: It should rarely be necessary to realign the intermediate transformers or the variable condenser. As a matter of fact, this should only be necessary when an intermediate transformer, oscillator or R. F. coil has become defective and require replacement. For properly aligning either the intermediate transformer or condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the control grid cap disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 370 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer which is accessible from the top of the I. F. transformer up and down until maximum reading is obtained on the meter, then adjust the trimmer screw located inside of the brass hex nut in the same manner.
4. The second I. F. transformer should next be adjusted in the same manner as the first I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER: To align the variable condenser and padding condenser it is necessary that the receiver chassis be removed from the set housing. After the receiver chassis has been removed connect the remote control flexible drive shafts in their respective couplers, and set the dial needle on the dial face so that the dial calibration is correct.

1. Connect the high output side of the oscillator to the antenna and the ground to the receiver chassis.
2. Tune the receiver to exactly 1500 kilocycles on the dial and adjust the oscillator to this frequency. BRING IN THE 1500 KILOCYCLE SIGNAL (TO MAXIMUM OUTPUT) BY ADJUSTING THE OSCILLATOR VARIABLE CONDENSER TRIMMER MOUNTED ON TOP OF THE VARIABLE CONDENSER. THEN ADJUST THE OTHER VARIABLE CONDENSER TRIMMER FOR MAXIMUM OUTPUT. Looking at the front of the receiver the first section of the variable condenser is the oscillator section and the other section tunes the antenna coil.
3. Tune the receiver to approximately 600 kilocycles on the dial and set the oscillator to this frequency, then adjust the 500 padding condenser which is located on the right hand side and accessible through the hole in the chassis for maximum output. Always rock the condenser slightly to the right and left when making this adjustment, using the position where greatest output is obtained.

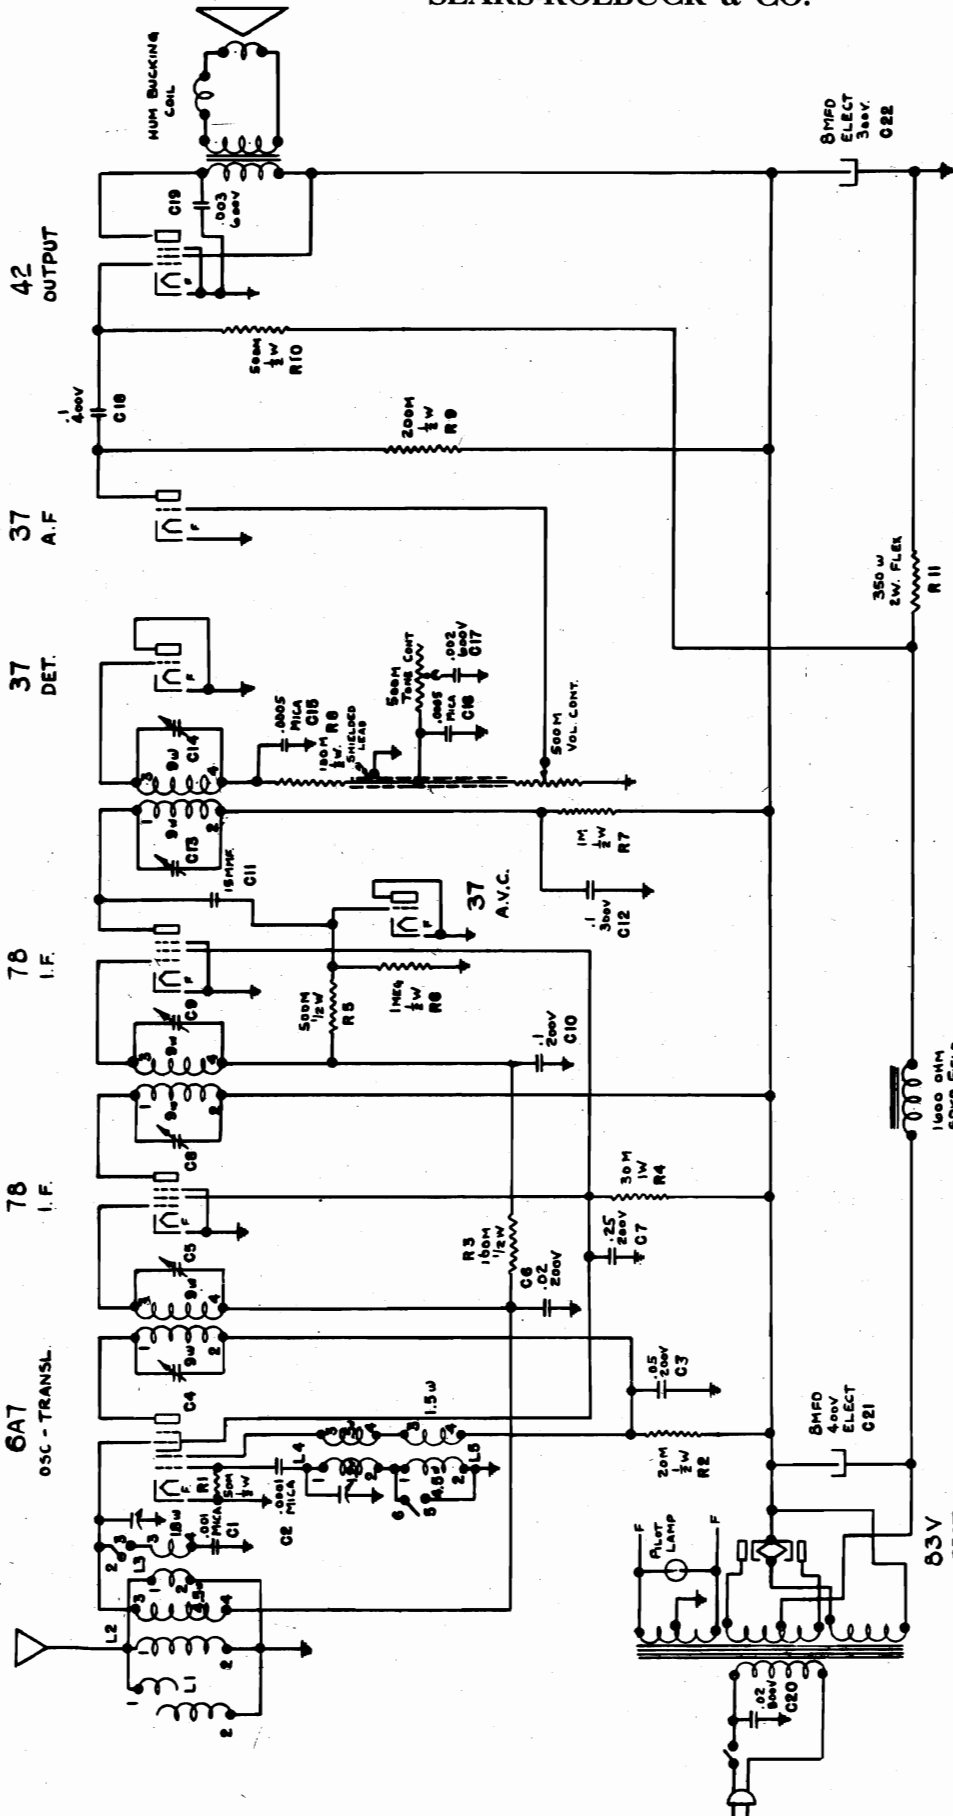

Always determine the polarity of the car battery post which is grounded to the automobile chassis before installing the receiver. When shipped from the factory the receiver is properly connected as illustrated (Fig. 3) for installation in automobiles which have the positive (+) battery post grounded to the car frame. If the negative (-) battery post is grounded, the position of the red and blue leads as shown on the terminal strip diagram must be reversed. As the terminal strip is located underneath and toward the right front corner of the receiver chassis it is necessary to remove the chassis from the set housing to make this change. This is accomplished by removing the sheet metal screw that grounds the antenna shield lead to the housing top, the twelve (12) machine screws around the edge of the housing front, the single machine screw on the bottom of the housing and then grasping the front panel of the housing and pulling outward. Using the receiver in an automobile with improper terminal strip polarity connections will result in damage to the vibrator unit, transformer or electrolytic condenser.

on the variable to 1712 kc.
Now tune the set to some frequency around 1400 kc and read just the detector section only to maximum output. The paddler condenser (which is located beneath the chassis) is now readjusted at 600 kc. Tune the set to some signal around 600kc and with a No.4 Spintite adjust the paddler condenser for maximum output, at the same time rocking the variable condenser back and forth to follow the signal.

PARTS LIST

No.	Description
52	Variable condenser 2 gang
61	Antenna Cord
74	Terminal Strip-7lug
101	Dynamic Speaker

GENERAL INFORMATION

This set is a superheterodyne designed to operate on alternating or direct current of any commercial frequency.

To operate, unreel the aerial to its full length and lay on the floor or drop out of a window. Turn the volume control all the way on. If after a few minutes the set does not function, reverse the plug in the wall socket.

The cord of this set becomes quite warm when the set is in operation. This is a natural condition as the voltage reducing resistor is woven in this cord.

To rebalance the set, first align the I.F. transformers at 456 kc. Then with the variable condenser turned to zero, adjust the trimmers

MODEL 7121
Schematic
Notes, Parts List

SEARS-ROEBUCK & CO.

4-20-34

S.R. No 7121

GENERAL INFORMATION

This set is designed to operate on 105-120 volts, 50-60 cycle, A.C. only. This set is designed to operate trimmers until loudest noise level or if tuned to a police signal at 1720 kc can be heard. Then

The set is of conventional tuned radio frequency type, developed to give best results with a minimum of trouble. tune to some weak signal at 1400 k.c. and check trimmers again.

An antenna approximately 40' outside is recommended, but it is possible to operate this set on 20-25' inside.

Below are listed a few suggestions as to services:

1. Hum-
 - a. Defective filter condenser
 - b. Bad tubes
 - c. Defective bypass condenser
 - d. Open resistor
2. Weak -
 - a. Poor tubes
 - b. Set out of balance
 - c. Shorted bypass condenser
3. Poor tone -
 - a. Speaker off center or dirt in voice coil
 - b. Defective filter condenser
 - c. Poor or defective tubes

This set is designed to oscillate about one-third to half way up the band starting from the police signals - this can be controlled with the volume control.

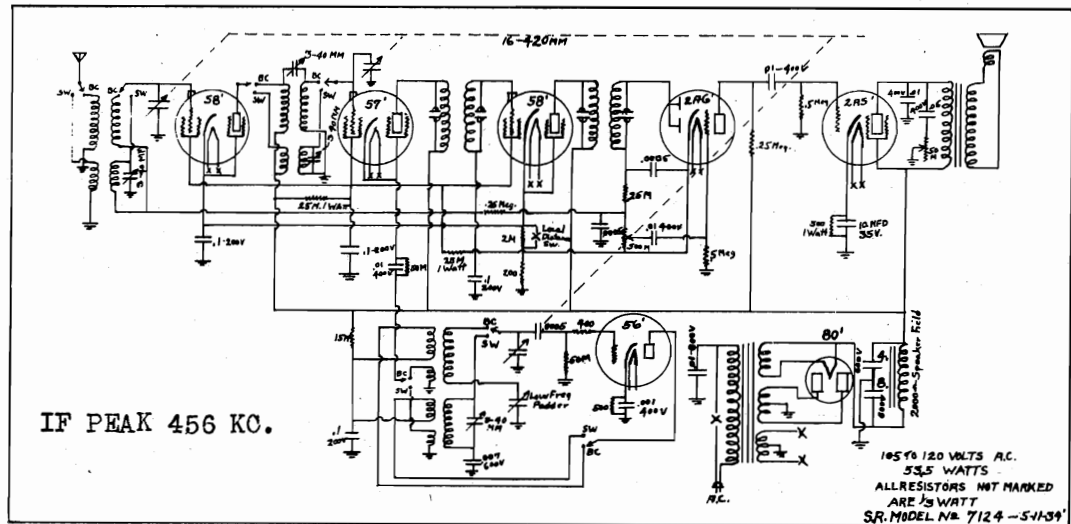

To rebalance set - turn variable condenser all the way open and tune

MODEL 7124
Schematic
Alignment, Parts

GENERAL INFORMATION

This set is designed to operate on 105-120 volts, A.C. The regular band covers from 1712 KC-550 KC and short wave from 15-55 meters.

To align set on broadcast, remove 56 oscillator tube, trim Intermediate Frequency Transformers at 456 KC from an oscillator, feeding same into 57, first detector grid. Secondly, open gang condenser wide open and adjust trimmer condensers on top to maximum noise level, then adjust low frequency padder at approximately 600 KC; after doing this go back and recheck at 1700 KC.

To adjust short wave, turn switch left and tune gang condenser to 31 meters on dial and trim small padders underneath to maximum noise level or some station, checking oscillator coil padder with gang condenser tuned at different points.

SEARS-ROEBUCK & CO.

GENERAL INFORMATION

This set is designed to operate on 105-120 volts AC or DC from 25 to 60 cycles. The cord of the set will become quite warm in operation. This is a normal condition, the voltage reducing resistor being an integral part of the line cord for rapid dissipation of heat.

The set is of the conventional tuned radio frequency type and is so developed as to give a minimum of trouble and a maximum of enjoyment.

It is recommended that the aerial be used that is supplied with the set. However, if a longer aerial is used, it is advisable to rebalance the antenna stage of the set to the aerial used. To accomplish this, remove the set from the cabinet and set the dial to about 20 on the scale. Turn the compensator screw on the rear section of the variable condenser back and forth until maximum signal strength is obtained.

To align Short Wave, open variable condenser about half way and adjust the two short wave padders, one underneath and one on top of chassis, to maximum noise level.

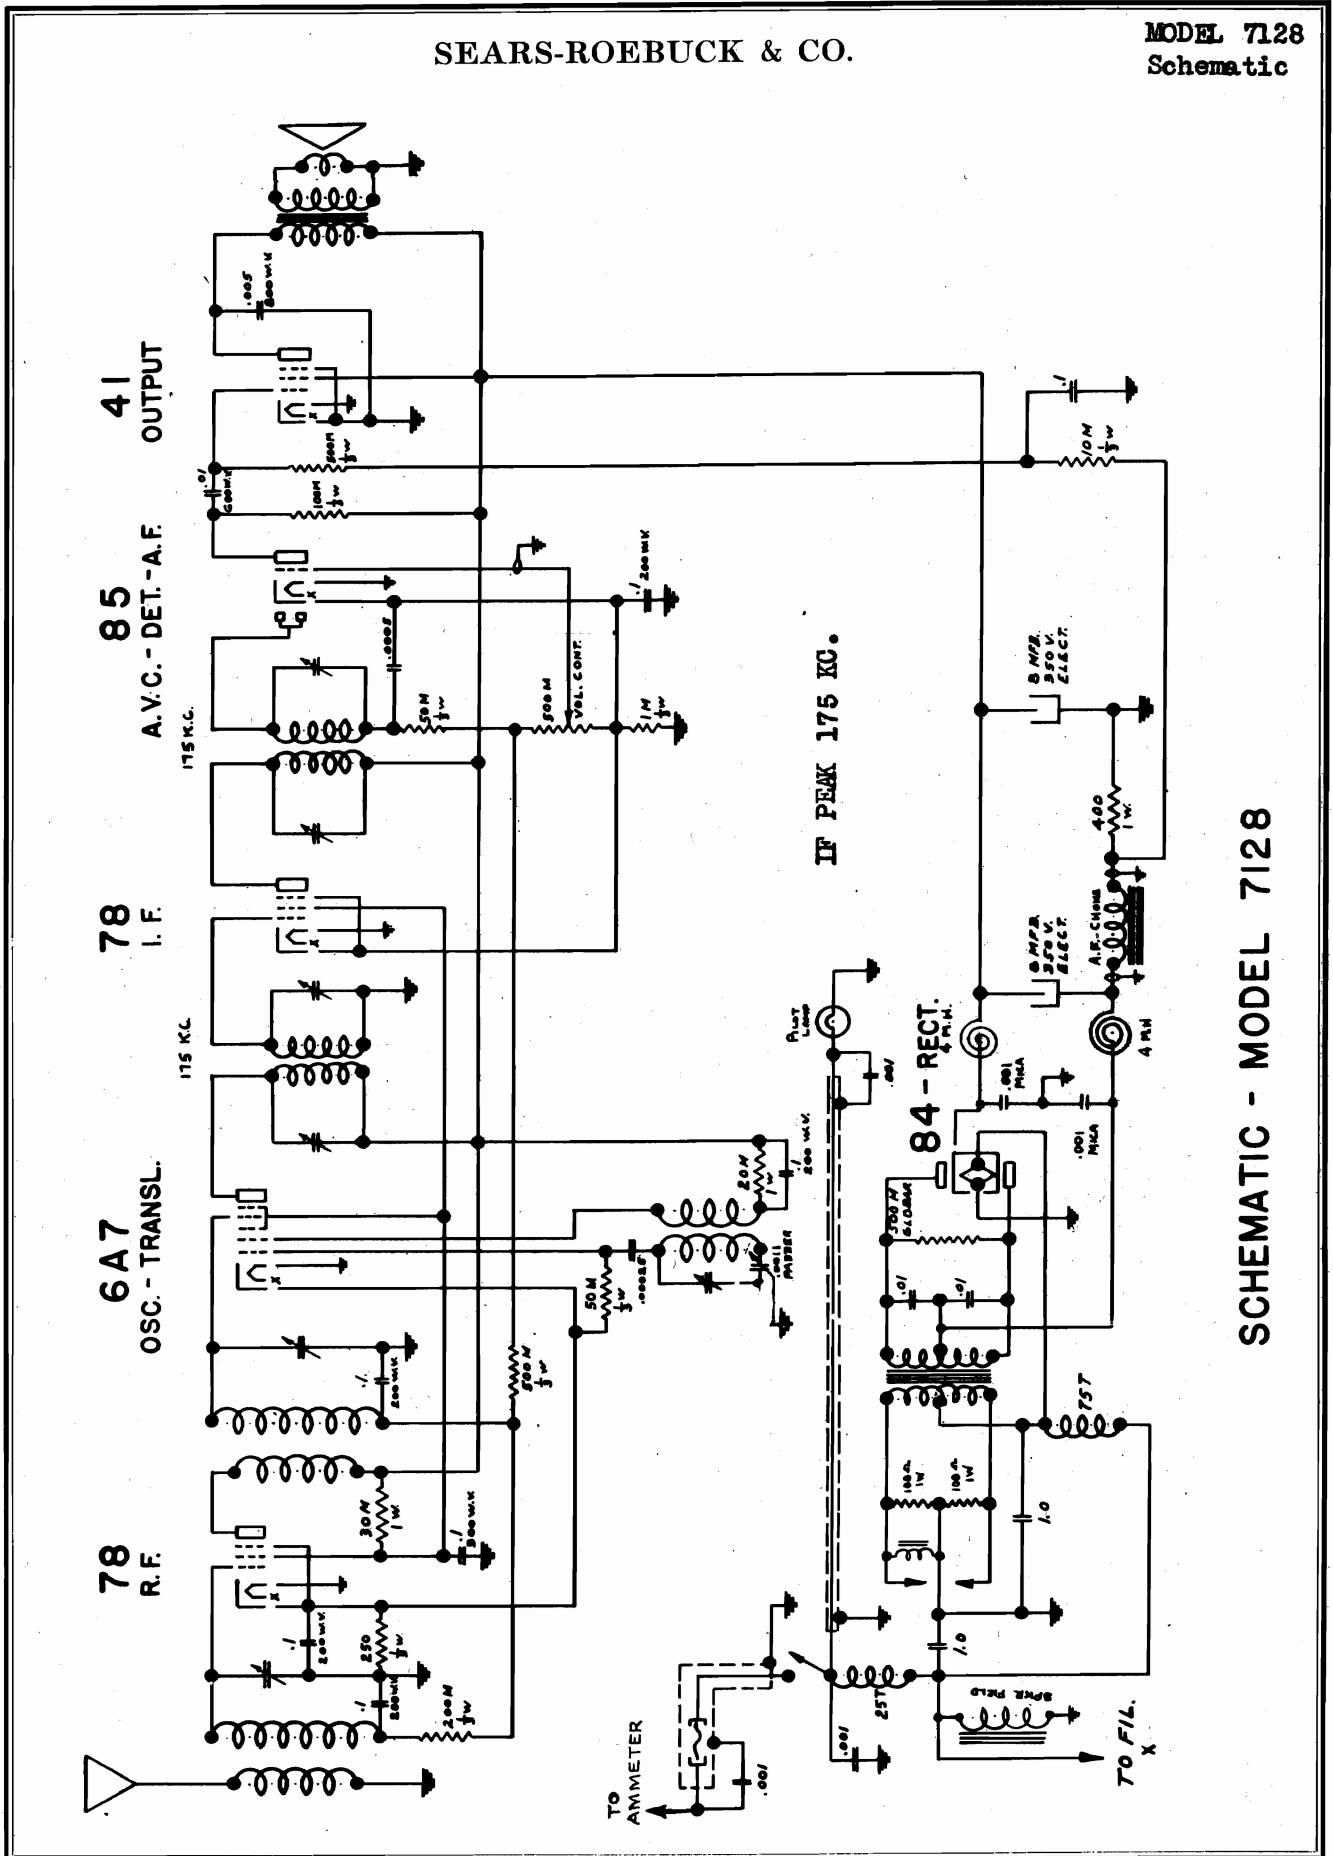

This set is designed to oscillate across a major portion of the broadcast band. This regeneration is controllable by reducing the volume of the set. Oscillation in a set of this type increases the sensitivity from ten to twenty times.

Socket, Parts List

SEARS-ROEBUCK & CO.

SILVERTONE - MODEL 7128

The SILVERTONE Model 7128 is a six tube superheterodyne automobile radio receiver. It uses a full wave vibrator and tube rectifier to supply the "B" voltage.

The tubes and their functions are:

- 78 - RF
- 6A7 - Oscillator-Translator
- 78 - IF
- 85 - AVC-Det-AF
- 41 - Output
- 84 - Rectifier

The resistor marked "Globar" in the schematic, is a special voltage regulating resistor. Its value varies with the voltage applied to it. When the receiver is first turned on, the output voltage from the power supply tends to become very high until the tubes heat sufficiently to draw their normal load. Under these conditions, the Globar resistance drops to a comparatively low value, loading the transformer sufficiently to prevent damage. As the tubes become heated, tending further to lower the voltage, the Globar resistance increases greatly so that it no longer constitutes a load on the power supply.

The voltage drop across the volume control, due to the 85 diode current, is used for AVC voltage.

The general information given in Service Manual Supplement #25, for the Model 1730, will apply as well for the Model 7128.

ALIGNMENT PROCEDURE

The IF Stages:

1. Connect the output meter (low voltage scale) across the loud speaker voice coil.
2. Connect the ground lead of the test oscillator to the chassis.
3. Connect the other lead of the test oscillator, in series with a .1 mfd. condenser, to the control grid cap of the 78 IF tube, leaving the grid clip attached to the cap.
4. Set the test oscillator to 175 kc and tune the IF output transformer. This transformer is mounted under the chassis. The location of its tuning adjustments is shown in the Service Illustration.
5. Change the test oscillator connection to the grid of the translator tube and tune the IF input transformer.
6. Repeat the adjustments to secure greater accuracy. Always use as low an output as possible from the test oscillator in order to render the AVC action of the set inoperative.

RF Alignment:

1. Connect the test oscillator to the antenna lead through a .00025 mfd. condenser.
2. Set the test oscillator to exactly 1500 kc.
3. Turn the variable condenser plates all the way out. Then slip a piece of card about the thickness of a postal card between the stator and the short end of the rotor plates in such a way that the plates cannot be meshed. Turn the rotor plates sufficiently to clamp the piece of paper between them and the stator. With the plates in this position, adjust the oscillator trimmer for maximum output.
4. Adjust the antenna and translator trimmers for maximum output.
5. Set the test oscillator to 600 kc and tune in its signal. Then slowly rotate the variable condenser back and forth a degree or two and, at the same time, adjust the oscillator paddler until maximum output is obtained.
6. Repeat the trimmer adjustments at 1500 kc.

TUBE VOLTAGE CHART

All readings are to be taken between chassis and the respective element of each tube.

TUBE	PLATE	SCREEN	OSC. SEC. PLATE	CATHODE
78 - RF	- 205	75		3.7

115 V. line Volume Control Full On

*These readings are only comparative and are not true voltages applied. The volt meter, when the readings are taken at these points, is in series with a very high resistance.

**To read the 247 bias, read between 247 grid and ground.

ALIGNMENT OF RECEIVER:

Because of the construction and thorough impregnation of the intermediate coils, the intermediate stages should rarely need retracking. Only when an intermediate coil has become defective due to an open or burned out winding, should it be necessary to readjust the intermediate trimmers. Should this occur, it is necessary that an oscillator be used and the intermediate trimmers be adjusted at 175 kilocycles. To align the intermediate stages, connect the high side of the oscillator output to the grid circuit of the first detector, which is done by disconnecting the grid cap of the 224 first detector and connecting the high side of the test oscillator to the control grid of this tube. The ground side of the test oscillator should be connected to the ground post on the chassis. Set the oscillator at 175 kilocycles and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. Be sure that the output from the oscillator is not so large that it will overload the second detector. If during the alignment the meter goes off scale, reduce the output of the test oscillator or adjust the receiver volume control.

The trimmers of the intermediate coils are accessible through the small holes in the bottom of the chassis. There are two trimmers to each intermediate coil. Align the grid trimmer of the first intermediate coil. After a maximum reading is obtained by adjusting the grid trimmer on the first intermediate, adjust the primary for maximum reading and then recheck the grid side to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate coils. After both intermediate coils are properly aligned the adjustment of the intermediate stage is complete and they should not be further disturbed.

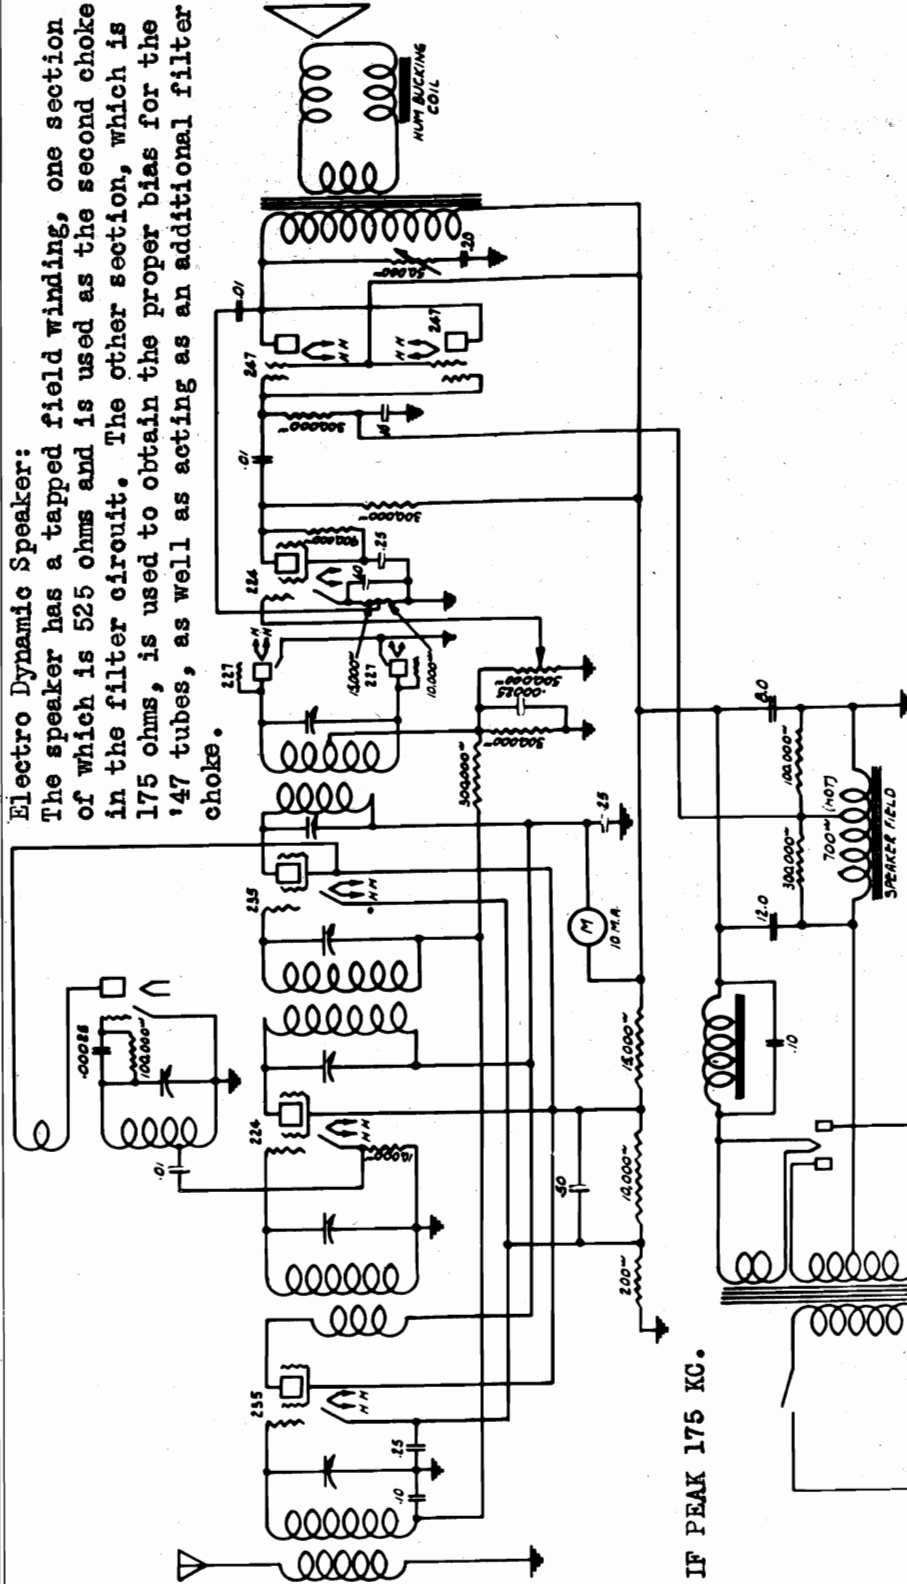

Replace the grid cap on the first detector and connect the oscillator output leads to the antenna and ground posts of the receiver and set the oscillator at 1435 kilocycles. Then tune the receiver to 1435 kilocycles on the dial. It is important that the receiver be tuned to this point. If the receiver is out of the cabinet it will be necessary to use some temporary indicator so that the position 1435 kilocycles on the dial may be accurately located. (This indicator should be set so that when the variable condensers are at the maximum capacity stop the indicator points to the last line on the dial at the low frequency end.) Then track the variable condensers by adjusting the trimmer condensers in the following order: Oscillator, antenna and radio frequency - (reading from the front of the receiver toward the back, the variable condenser sections are: Oscillator, antenna and radio frequency). After the variable condensers have been properly tracked at 1435 kilocycles, adjust the oscillator to 1295 kilocycles. Tune the receiver to this frequency. Check alignment of the condensers at this point by bending the end plate of the rotors in and out, noting the change in reading on the output meter. If when the plates are bent in the reading is increased, it is an indication that that particular section requires more capacity and the end plate should be permanently bent in at this point; or, if when the end plate is bent away the reading is increased, the end plate should be bent away permanently, as it is an indication that that particular section requires less capacity at that particular point. The variable condensers should be checked in this manner at 1295, 880, 650 and 550 kilocycles. These points have been chosen so as to take advantage of the slots in the end plates of the variable condensers. This procedure of bending plates should rarely be necessary on the oscillator section, as the plates of the oscillator section are specially designed to properly track over the broadcast spectrum, providing the antenna and radio frequency stages are correctly aligned.

MODEL 261,521
Battery Data
Parts List

SENTINEL RADIO CORP.

In the first models of the automobile radio the B- and hot "A" leads were connected as shown in diagram "A". In the present model these leads are as shown in diagram "B". All other connections are identical, as shown on the schematic drawing. Connecting the black lead in the cable, designated as B- in the instruction sheet, to the hot 6 volt post of the eliminator will supply the hot 6 volts and provide an "off and on" switch for the B eliminator as well as the receiver itself. In this way no other connection between the hot 6 volt lead of the eliminator and battery should be made and no switch for the hot lead to the eliminator is necessary; the set switch controlling both the B eliminator and receiver.

When using B batteries, the black lead should be connected to the B- of the batteries but under no circumstance should a separate lead from the B- terminal of the batteries be run to the chassis of the car or the shielded cable. In other words, do not ground the B- terminal of the B batteries.

The only difference in the tube equipment between the early and present models is the output tube. The first model utilized a #41 output tube and the present model a #89 tube. Complete complement of tubes is:

MODEL 261,521
Alignment Data

SENTINEL RADIO CORP.

The intermediate frequency transformers are tuned to 175 kilocycles. An oscillator which is accurately set to this frequency and which has an attenuator in its output to control the output can be used. It is of course best to start by retuning the intermediate stage before touching other adjustments. The output of the intermediate frequency generator is connected one side to the grid of the 1st detector (236 tube) after removing the grid cap from this tube. The ground of the oscillator is connected to the chassis base. With the frequency set at 175 K.C. (accurately) the tuning adjustments of the 1st and 2nd I.F. transformers are adjusted to peak resonance. It is very important to use a long bakelite screw-driver for these adjustments. In adjusting, the successive tuning condensers are gone-over several times readjusting the output of the oscillator or the receiver's volume control as required. With the I.F. transformers properly tuned and scaled, the R.F. and oscillator circuits may next be adjusted.

The grid cap of the 1st detector is replaced and a generator or oscillator having frequencies of 1400 and 600 kilocycles is set up and connected to the aerial and ground of the receiver.

Do not attempt to align condenser without a shield. It is extremely important that a shield corresponding to the can be placed around the antenna coil and gang condenser in making adjustments on the r.f. and oscillator circuits, otherwise due to the change in these circuits caused by this shielding a very inaccurate adjustment will be obtained. This shielding may consist of a piece of steel bent to the shape of the corner of the can fitting around the edge of the base from the speaker to the rear right hand corner and extending as high as the speaker with holes in it corresponding to the condenser trimmer locations or a regular can and cover with such holes provided. This shield or can and cover must be in secure and in proper location and not disturbed during these adjustments. From this it is easily seen why if an attempt is made to check the alignment out of the can on this receiver a different or changed adjustment will be had as against the factory setting, which is made with the shielding in place.

With the above shielding in place and tubes which are to be used in chassis, the procedure of circuit alignment is as follows:

Set the generator frequency at 1400 K.C. Set the tuning dial to 15 on the scale, open trimmers slightly on antenna (top) and 1st detector (middle) sections of gang condenser. Then without disturbing dial setting adjust oscillator (bottom) trimmer on gang to greatest signal. After this has been properly set adjust one at a time the antenna and 1st detector trimmers for maximum signals. If these operations are properly set as above, the receiver circuits are correct for the high frequency adjustment. Next change the generator frequency to 600 kilocycles and turn the tuning dial of the receiver to resonate with this signal. This will come in around 82 on the dial. When the 600 kilocycle point is located on the dial next adjust the oscillator low frequency padding condenser, which is at the bottom rear edge of chassis base in right corner. The screw on this condenser is adjusted in and out as the receiver dial is slowly moved across the 600 K.C. resonant point until greatest signal strength is obtained. The combination of the best padding condenser setting with the dial setting giving the greatest signal output is the correct padding condenser adjustment. No change in the gang condenser trimmers adjustment should be made during the 600 K.C. adjustment.

DIAL LIGHT. If the dial light burns out be sure and replace with one of same type 6.3 volts 1000 hrs.

MODEL 550

FIVE TUBE AC-DC SUPERHETERODYNE
(110 V. AC-DC, 6 V. Storage Batteries & 32 V. DC)

VOLTAGE TABLE: Never check voltages until all tubes are fully warmed up to proper operating condition. The voltage table #1 is taken at 115 volts (AC) line with the volume control in the full on position. It must be remembered that the voltage readings vary directly as the line voltage and also with the accuracy of the meters used. A variation of 10% plus or minus is permissible. THE VOLTAGES WILL BE APPROXIMATELY AS GIVEN FOR EITHER DC OR AC OPERATION.

		TUBE VOLTAGES			Table #1
Type of Tube	Position of Tube	Filament Volts	Plate Volts	Screen Volts	C Volts
36	Composite Oscillator & Modulator	5.5	108	21*	2.5
39	Intermediate Frequency	5.6	108	108	2.5
36	Detector	5.7	27*	21*	2.5
38	Output	5.8	103	108	1.5*
25z5	Rectifier	29.0	52.5 MA		

The voltage table #2 is for 6 volt battery operation with a B eliminator which is especially designed for the model #561 receiver. The voltages as given will be correct for 32 volt DC operation in conjunction with a B eliminator of the recommended factory type. It will be found that of certain types of eliminators which do not have sufficient output or a low 6 volt battery, the readings will be lower than that given in the voltage table.

		TUBE VOLTAGES			Table #2
Type of Tube	Position of Tube	Filament Volts	Plate Volts	Screen Volts	C Volts
36	Composite Oscillator & Modulator	5.8	112	25*	2.5
39	Intermediate Frequency	5.8	112	112	2.9
36	Detector	5.8	28*	25*	2.0
38	Output	5.8	108	112	1.5*
25z5	Rectifier	52.5 MA			

* These readings for both Table #1 and #2 are only comparative and are not true voltages applied. The voltmeter, when readings are taken at these points, is in series with a very high resistance.

IMAGE SUPPRESSION: Occasionally in some locations interference in the form of whistles or stations which are tuned in on dial settings other than the station's frequency may be encountered. This is a rare occurrence and is called image interference caused by two signals whose frequencies differ by twice the intermediate frequency. This should not be confused with heterodyne whistles which are caused by two stations being received whose frequencies are the same nor by local stations whose frequencies are close to some out-of-town stations frequency which might result in reception from both stations. To overcome this possibility of image interference an image suppression circuit is incorporated in the receiver. The image adjusting condenser is mounted on the back of the chassis below the first IF transformer shield and is accessible through the hole in the chassis. If a whistle or interfering station is received on a frequency other than its fundamental, tune the receiver to this interference and adjust the image suppression condenser until the interference disappears or until the interference is at the minimum point. UNLESS THERE IS AN ACTUAL IMAGE INTERFERENCE DO NOT ATTEMPT TO ADJUST THE IMAGE SUPPRESSION CIRCUIT.

INTERMEDIATE FREQUENCY ALIGNMENT: Only when an intermediate transformer has become defective, due to an open or burned out winding, should it be necessary to readjust the intermediate stages. Should this occur it is necessary that an oscillator be used with some type of output measuring device so as to correctly tune the transformers. To align the intermediate transformers connect the high side of the oscillator output to the control grid of the 36 oscillator modulator tube leaving the grid cap disconnected from the tube. The ground side of the test oscillator should be connected to the gang condenser frame and MUST NOT OTHERWISE BE GROUNDED. Set the oscillator at 265 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter. BE SURE THAT OUTPUT OF THE OSCILLATOR IS NOT SO HIGH AS TO OVERLOAD THE DETECTOR. IF DURING THE ALIGNMENT THE DETECTOR OVERLOADS REDUCE THE OUTPUT OF THE OSCILLATOR. Align the first intermediate transformer by turning the intermediate-frequency trimmer screw up and down until maximum reading is obtained on the output meter. Both the primary and secondary trimmer screws should be adjusted in this manner. It is always best to recheck the grid side of the intermediate frequency transformer adjustment to make certain the alignment of the secondary has not been changed by the adjustment of the primary. The same procedure is followed in aligning the second intermediate transformer. After both intermediate transformers are adjusted the alignment of the intermediate stage is complete and the trimmer should not be further disturbed, and the grid cap should be connected to the grid of the 36 tube.

VARIABLE CONDENSER ALIGNMENT: If the intermediate frequency stage has been realigned or if an antenna or oscillator coil requires replacement it will be necessary to realign the variable condenser. The front section of the variable condenser (looking at the front of the receiver) is the oscillator section, the other section tunes the antenna stage. Tune the receiver to 1720 kilocycles on the dial and set the oscillator at this frequency. BE SURE THAT OUTPUT OF THE OSCILLATOR IS NOT SO HIGH AS TO OVERLOAD THE DETECTOR. IF DURING THE ALIGNMENT THE DETECTOR OVERLOADS REDUCE THE OUTPUT OF THE OSCILLATOR. Next ad-

SENTINEL RADIO CORP.

Alignment Data
Parts List

Just the trimmer screws of the oscillator and antenna sections which are mounted on top of the variable condensers so as to obtain maximum output reading. It will be found that the oscillator section trimmer condenser will in most cases have to be adjusted to minimum capacity and in some instances it may be necessary to remove the trimmer screw entirely. After the trimmers have been correctly adjusted, at this frequency, tune the receiver to 600 kilocycles and adjust the oscillator to 600 K.C. Next, adjust the oscillator padding condenser (which is located directly below the variable condenser and accessible through the hole in the front of the chassis) to obtain maximum reading on the output meter. If the above is correctly followed the receiver will now track correctly over the entire band from 1720 KC to 550 KC. It is always advisable to align the receiver, whenever possible, with the tubes that are to be used in the set.

32 VOLT FARM LIGHTING SYSTEMS! When the current supply is DC, the 32 volt mains plug must be inserted correctly into the 32 volt DC mains receptacle, otherwise the set will not operate because of reversed polarity. If, after inserting the mains plug into the receptacle, the receiver does not operate for approximately one minute or one and a half minutes, remove the mains plug and turn it half way around and insert it into the receptacle. When operating the receiver on DC it will be found that in most instances the noise interference is greater than when the receiver is used on AC current. DC appliances such as motors, fans, etc., as a general rule cause more interference than similar AC equipment. Unfortunately this interference can only be eliminated at the source of the interference. When operating the receiver on 32 volt DC and using a B eliminator, be sure to keep the set aerial wire as far away from the DC line as possible, to avoid noise pick up from the 32 volt DC line. By connecting the antenna wire to an outside aerial in the event the noise interference is excessive, the interference can generally be minimized, as the increased volume obtained with the longer aerial permits lower minimum volume control setting and a consequent apparent reduction in noise interference. It is not recommended that the 6 volt cable and 6 volt B eliminator be used on the 32 volt system by tapping in at 6 volt as the current consumption will be too large, nor is it recommended that B batteries be used as the life of the battery will be limited. To reduce the drain on the batteries if they are used, it is recommended that only 90 volts of battery be connected to the receiver.

METHOD OF FEEDING STRAP INTO BRACKET & BUCKLE
FIG. 4

SENTINEL RADIO CORP.

MODEL 602
Installation Notes

RECEIVER MOUNTING: The receiver, speaker and "B" eliminator are all contained in a single unit in one steel housing and requires the drilling of but one hole in the bulkhead for mounting. The receiver should be so mounted that the remote control shaft will reach the steering post in as straight a line as possible so as to eliminate any unnecessary bend in the cable. Care should be exercised in choosing the receiver location to avoid interference with the foot pedal, hand brake, clutch pedal and possible interference with the legs of the driver or passenger. A paper drilling template is provided to aid in finding the best location. When the location has been decided on, drill a $3/8"$ to $7/16"$ diameter hole in the motor bulkhead after which the wooden spacer block should be placed on the set mounting bolt and the bolt pushed through the hole in the bulkhead with the wooden spacer block on the driving compartment side. (Fig. No. 1). Place the steel washer, lockwasher and mounting bolt nut (in the order named) on the mounting bolt drawing up the nut loosely. Next, lift the receiver in position so that the square head of the mounting bolt will slip into the lower slotted end of the set mounting plate. Gently lowering the receiver will force the mounting bolt head to the top of the mounting plate slot. The receiver and the mounting bolt will be rigidly locked in position by drawing the mounting bolt up tight. On some installations because of insufficient room under the bulkhead it may be necessary to push the square head of the mounting bolt to the top of the mounting plate and then push the bolt through the hole drilled in the bulkhead.

REMOTE CONTROL: The remote control head, the steering post strap and clamp, the volume control and tuning control shaft tubing and the cable guide brackets are shipped unassembled. No difficulty will be had in properly assembling if the proper procedure is followed in the order given.

1. Mount the two cable guide brackets which are held in position with the two self tapping sheet metal screws, placing the pilot light shield lead under the head of one of these screws (see Fig. 2).

Push the flexible shaft of the volume control tubing through the volume control guide bracket into the volume control coupler mounted on the set until it touches the stop.

Then tighten the two flexible shaft set screws in the volume control coupler firmly.

Next, place the volume control shaft tubing so that it extends about $1/4"$ beyond the guide bracket. Do not permit tubing to touch the coupler. After correctly locating, screw the two guide bracket coupler set screws firmly, but do not force these set screws too tightly otherwise the drive shaft will bind. The tuning control flexible shaft should be mounted in the tuning coupler and the tuning control shaft tubing in the guide bracket in the same manner. Do not put the tuning control flexible shaft in the volume control coupler and vice-versa. Looking at the back of the remote control head the lefthand shaft tubing is the tuning control and the right hand one the volume control (Fig. 2). Looking at the side of the receiver the righthand coupler is the volume control and the lefthand coupler is the tuning control.

2. Loosen the two shaft tubing screws (Fig. 2) underneath the remote control head and insert the slotted end of each shaft tubing in their proper place in the remote control head, after which the set screw should be firmly tightened. If the shaft tubing is properly spaced from

MODEL 602

Installation Notes

SENTINEL RADIO CORP.

Part 2.

the couplers, the volume control and tuning control will move freely. If improperly spaced the shaft tubing may rub on the couplers or may rub in the remote control head thereby making the volume control and tuning control work hard.

3. The steering post clamp strap and clamp bracket should now be mounted on the steering post. The steering post clamp strap has four holes, one of which is threaded. The other three holes are provided so that the clamp may be used on any of the various size steering posts.

The remote control head may be located on the left or righthand side of the steering post column or on the dashboard by using the proper one of the three threaded clamp screw holes on the back of the remote control head. To mount on the lefthand side of the steering post use the lefthand threaded hole, for righthand mounting use the righthand threaded hole and for dashboard mounting the top threaded hole.

Form the clamp with the threaded stud on the inside by placing it around the steering post. Place the slotted end of the clamp against the clamp strap so that the hole in the clamp lines up with the two holes in the strap (Fig. 2.) Push the clamp strap through the hole in the clamp and screw the clamp screw into the threaded strap stud sufficiently tight so that it will be locked firmly in position. The remote control head may now be mounted on the steering post clamp by pushing the machine screw through the hole at the end of the clamp and screwing this machine screw through the threaded hole in the back of the remote control head.

4. The remote control drive is now completely mounted. It is possible that the dial calibration will not be correct. To properly align the dial turn the tuning control knob in the counter clockwise direction until the stop on the variable condenser is reached. This will be indicated by increased tension on the knob. Do not force the dial otherwise the dial needle will jump and the dial calibration will be inaccurate.

PILOT LIGHT: A six to eight volt Mazda type miniature size pilot light is used in the remote control head. The pilot light lead from the remote control head must be inserted in the pilot light receptacle located on the side of the set housing adjacent to the volume control shaft tubing guide bracket. The shielded lead of the pilot light lead should be connected underneath the head of one of the guide bracket mounting screws. To replace the pilot light remove the two control knobs by pulling outward on the knobs. Next, the three small head machine screws on the front of the remote control which hold the front cover of the control box in place should be removed. The cover of the remote control head may now be lifted off the control box and the pilot light socket then becomes accessible.

ANTENNA: A good antenna is very important. An inefficient or insufficient aerial will result in unsatisfactory reception. Most late model cars are factory equipped with an antenna built in the roof of the car. This is generally the most satisfactory type of aerial. If the car is not equipped with a roof type aerial, one may be installed or use may be made of the various aerial kits now available such as plates that are mounted underneath the running board or the strap type aerial which can be fastened between the front and rear axles. THE CLOSER TO THE GROUND THE STRAP OR PLATE TYPE ANTENNA IS SUSPENDED THE GREATER ITS EFFICIENCY.

"B" ELIMINATOR: The "B" eliminator unit which contains the No. 84 rectifier tube is mounted below the receiver and is held in position in the set housing by three machine screws which are accessible from the bottom of the set housing. To replace the rectifier tube it is necessary that the "B" unit be removed from the set housing. To do this unscrew the three "B" unit machine screws in the bottom and the six screws that hold the small detachable plate on the lower back of the set housing. After this plate is removed, the set cable wires which are now accessible should be disconnected from the "B" eliminator terminal strip mounted on the eliminator unit, after which the eliminator may be pulled out of the set housing. Next, remove the cover of the eliminator by unscrewing the six machine screws which hold this in place. After the cover has been taken from the top of the "B" unit the complete mechanism of the "B" eliminator can be lifted out of the eliminator housing and the "B" eliminator tube replaced. Care should be taken when reinstalling the "B" unit in the set housing so that the set cable wires are properly connected to the "B" eliminator terminal strip. Excessive vibration of the "B" unit may be corrected by substituting a new vibrator rubber cover. When changing the rubber cover be sure to place the vibrator unit back in the "B" unit with the vibrator leads toward the "B" eliminator transformer. Continuous blowing of the fuse is indicative of a possible defective "B" unit transformer, a defective vibrator or a defective No. 84 tube. UNDER NO CIRCUMSTANCES ATTEMPT TO ADJUST THE VIBRATOR UNIT. IF THE UNIT BECOMES DEFECTIVE IT SHOULD BE REPLACED WITH A GOOD ONE ONLY. R.F. hash indicated by a constant static-like background noise, which is apparent over the entire tuning range (with the set aerial disconnected) may be due to a defective No. 84 tube or a loose "B" unit cover. If the set antenna lead is run in close proximity with the set "A" leads or the battery "A" hot lead, it is possible to pick up this form of interference. Rerouting the set antenna lead will correct this.

TUBES: The receiver utilizes the following tubes:

One (1) Type 78 - Amplifier Tube
 One (1) Type 6A7 - Detector & Oscillator Tube
 One (1) Type 78 - I. F. Tube
 One (1) Type 75 - Second Detector Diode & AVC Tube
 One (1) Type 41 - Output Tube
 One (1) Type 84 - Rectifier Tube

The tube locations are shown in the diagram attached to the set housing cover. Always be sure that the tubes and their tube shields are firmly pressed down in their sockets. The tubes are readily accessible for removal or for checking by taking off the cover of the metal cabinet. To do this it is only necessary to unscrew the six machine screws which hold the cover to the cabinet and lift the cover off the cabinet. NOTE: In some installations, because of the location of the receiver it may be necessary to remove the set from the motor bulkhead to check the tubes. The tubes used are sturdily constructed and especially designed for use in automobile receivers and under normal conditions will give satisfactory service for a long period of time. Occasionally a tube may become faulty shortly after being placed in service and is generally indicated by low volume or distorted tone. Whenever this condition exists the tubes should be tested and the defective tubes or tube replaced. If the receiver becomes microphonic it can generally be traced to the 6A7, 75 or 41 tube.

MODEL 603

Alignment, Voltage

SENTINEL RADIO CORP.

Parts List

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the control grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.
2. Set the oscillator frequency at 265 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter, and then adjust the other trimmer screw of the intermediate transformer for maximum sensitivity.
4. Adjust the second intermediate transformer in the same manner.

NOTE: Two types of intermediate transformer trimmers have been used in this model receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one intermediate trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is not necessary to remove the receiver chassis from the set housing to align the gang condenser. Regardless of whether or not the receiver is or is not mounted in the set housing the alignment procedure is the same. Three holes are provided in the left hand side of the set housing for the gang condenser trimmers and one in the front of the set housing for the 600 kilocycle padding condenser.

1. Properly connect the remote control head and shafts and adjust the dial needle on the dial face so that the dial calibration is correct.
2. Connect the high output side of the oscillator to the antenna and the ground to the receiver chassis.
3. Tune the receiver to exactly 1400 kilocycles on the dial and adjust the oscillator to this frequency. BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE OSCILLATOR GANG CONDENSER TRIMMER. Looking at the side of the receiver and reading from top to bottom the trimmer condensers are the antenna, R. F. and oscillator sections. Next, adjust the R. F. and antenna sections of the gang condenser for maximum sensitivity
4. Tune the receiver to approximately 600 kilocycles on the dial and set the oscillator to this frequency. Then adjust the 600 kilocycle padding condenser, which is located on and accessible through the hole in the front of the chassis for maximum output. Always rock the condenser slightly to the right and left when making this adjustment using the position of greatest output.

MODEL 660

Alignment Data

SENTINEL RADIO CORP.

Parts List

Whenever this condition is encountered be sure to try other 32 and 34 tubes. Oscillation may also be encountered when the speaker leads come too close to the first detector tube or the antenna, or if the shielding on the I.F. grid leads is loose or pushed back. Sometimes with some tubes oscillation may occur if the pad condenser across the speaker is removed or open. Low battery voltages will be indicated by low volume, signal fading and also motorboating may occur. Motorboating may be corrected by bypassing the "B" batteries from B plus to B minus with a .5 or 1 Mfd. condenser. Be sure to use a condenser that has a DC continuous working rating of not less than 200 volts. An insufficient aerial will reduce the volume and range of the receiver materially. If reception is weak and the tubes and batteries are good, try increasing the overall antenna length. Always keep the aerial as short as possible consistent with satisfactory reception.

INTERMEDIATE ALIGNMENT: Only when an intermediate transformer has become defective due to an open or burned out winding should it be necessary to readjust the intermediate transformer. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device. To align the intermediate transformer:

1. Connect the high side of the oscillator output to the control grid of the No. 30 Modulator tube. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the intermediate transformer trimmer screws up and down until maximum reading is obtained on the output meter. Then adjust the other trimmer screw in the same manner.
4. The second I.F. transformer should next be adjusted in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

To align the variable condenser:

1. Connect the high output side of the oscillator to the set antenna lead and the ground side of the oscillator to the chassis.
2. Tune the receiver to 1400 kilocycles on the dial and set the oscillator to this frequency.
3. Adjust the variable condenser trimmer screws for maximum output reading.
4. Tune the set to approximately 600 kilocycles on the dial and adjust the oscillator frequency to 600 kilocycles. Adjust the padding condenser located on the rear of the chassis adjacent to the antenna and ground leads and accessible through the hole in the chassis for maximum output reading.

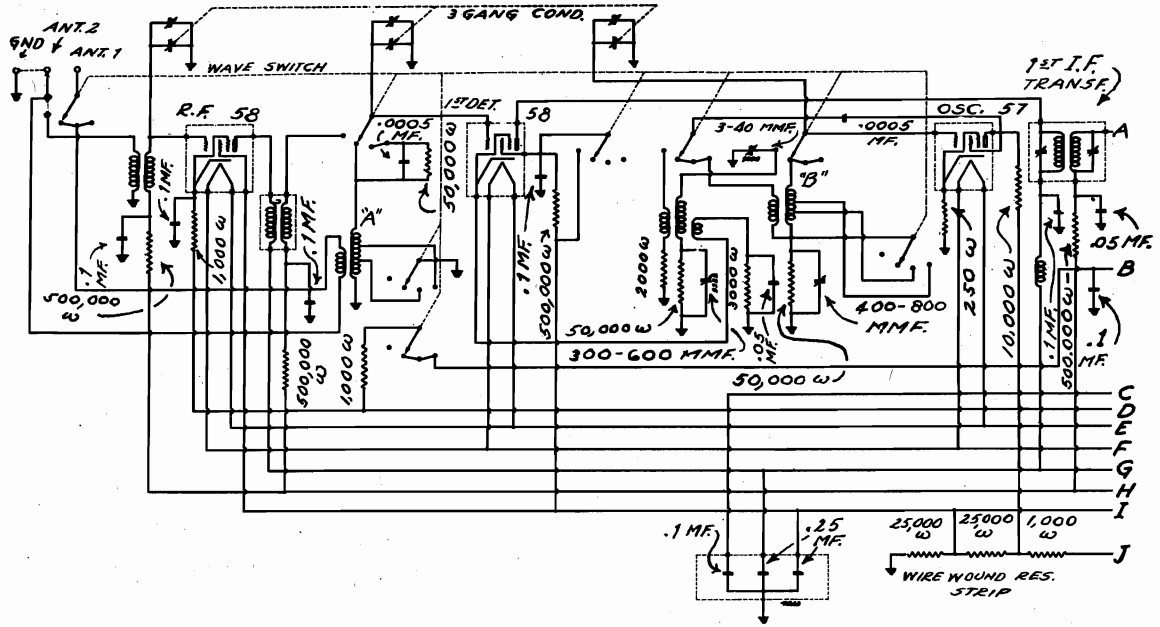

When making this adjustment be sure to rock the variable condenser slightly to the right and left using the position where the greatest output reading is obtained.

* Comparative voltage only. The voltmeter, when readings are taken at this point, is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis, unless otherwise specified.

** Read from grid to chassis.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 58 first detector leaving the grid clip disconnected. The ground side of the oscillator should be connected to the chassis.

2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.

3. Align the first intermediate transformer by turning the brass hex nut (accessible through the hole in top of IF transformer shield) of the first intermediate transformer trimmer screw up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside of the brass hex nut in the same manner.

NOTE: Some receivers utilize the brass hex trimmer nut and inside trimmer screw whereas other receivers of the same type have two parallel trimmer screws accessible through the two small holes in the top of the IF shields. In either case the procedure is the same. The second and third IF transformers are adjusted in the same manner as the first IF transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the variable condenser and padding condensers to follow the procedure given carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The variable condenser sections reading from front to rear are: Antenna, RF & Oscillator.

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.

2. Place the band selector switch for operation on the 1.5 to 4 megacycle band. Tune the receiver to 3.4 megacycles on the dial and adjust the oscillator to this frequency. Bring the 3.4 aligning signal in (maximum output) by adjusting the oscillator section variable condenser trimmer.

3. Tune the receiver to exactly 1.7 on the dial and set the oscillator at this frequency. THE 1.7 MEGACYCLE SIGNAL MUST BE BROUGHT IN (TO MAXIMUM OUTPUT) BY ADJUSTING THE 1.7 MEGACYCLE PADDING CONDENSER WHICH IS LOCATED ON THE FRONT OF THE CHASSIS BELOW THE DIAL. After making the 1.7 megacycle adjustment be sure to recheck the 3.4 megacycle adjustment. It is suggested that the 1.7 and 3.4 adjustments be rechecked several times.

NOTE: This completes the short wave adjustments. Should the dial calibration be too far off, the cause may be due to using the wrong oscillator frequency or dial setting.

4. Set the oscillator to 1400 kilocycles, tune the receiver to 1400 kilocycles on the dial and place the band selector switch for operation on the 1500-540 kilocycle band. Turn the receiver on its right side with the power transformer down and BRING IN (to maximum output) the 1400 kilocycle signal by adjusting the 1400 kilocycle trimmer which is mounted below the chassis on the short wave switch assembly. Next, adjust the antenna and RF variable condenser trimmers located on the top of the variable condenser for maximum output.

5. Leave the band selector switch for operation on the 1500 to 540 kilocycle band and set the oscillator frequency and tuning dial to approximately 600 kilocycles. Then while rocking the variable condenser slightly to the right and left adjust the 600 kilocycle padding condenser located towards the front on the left hand side of the chassis for maximum output, after which recheck the alignment at 1400 kilocycles and then the alignment at 600 kilocycles.

VOLTAGE TABLE
Battery Voltage - 6 Volt
Volume Control - Full on

TYPE OF TUBE	POSITION OF TUBE	FIL. VOLTS	PLATE VOLTS	CATHODE VOLTS	SCREEN VOLTS	GRID NO.1	GRID NO. 2.	GRID NO. 3 & 5
6A7	Modulator & Oscillator	6	220	3	80	5	220	80
6D6	I. F. Amplifier	6	220	2.5	80			
6B7	Second Detector Diode AVC & 1st Audio Triode	6	35##	3.	40			
41	Output	6	215	13	220			
84	Rectifier	6	460-AC	230				

Triode Plate. Comparative voltage only. The voltmeter is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis unless otherwise specified.

ALIGNMENT PROCEDURE: It should rarely be necessary to realign the intermediate transformers or the variable condenser. As a matter of fact, this should only be necessary when an intermediate transformer, oscillator or R. F. coil has become defective and require replacement. For properly aligning either the intermediate transformer or condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 6A7 tube leaving the control grid cap disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 370 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer which is accessible from the top of the I. F. transformer up and down until maximum reading is obtained on the meter, then adjust the trimmer screw located inside of the brass hex nut in the same manner.
4. The second I. F. transformer should next be adjusted in the same manner as the first I. F. transformer.

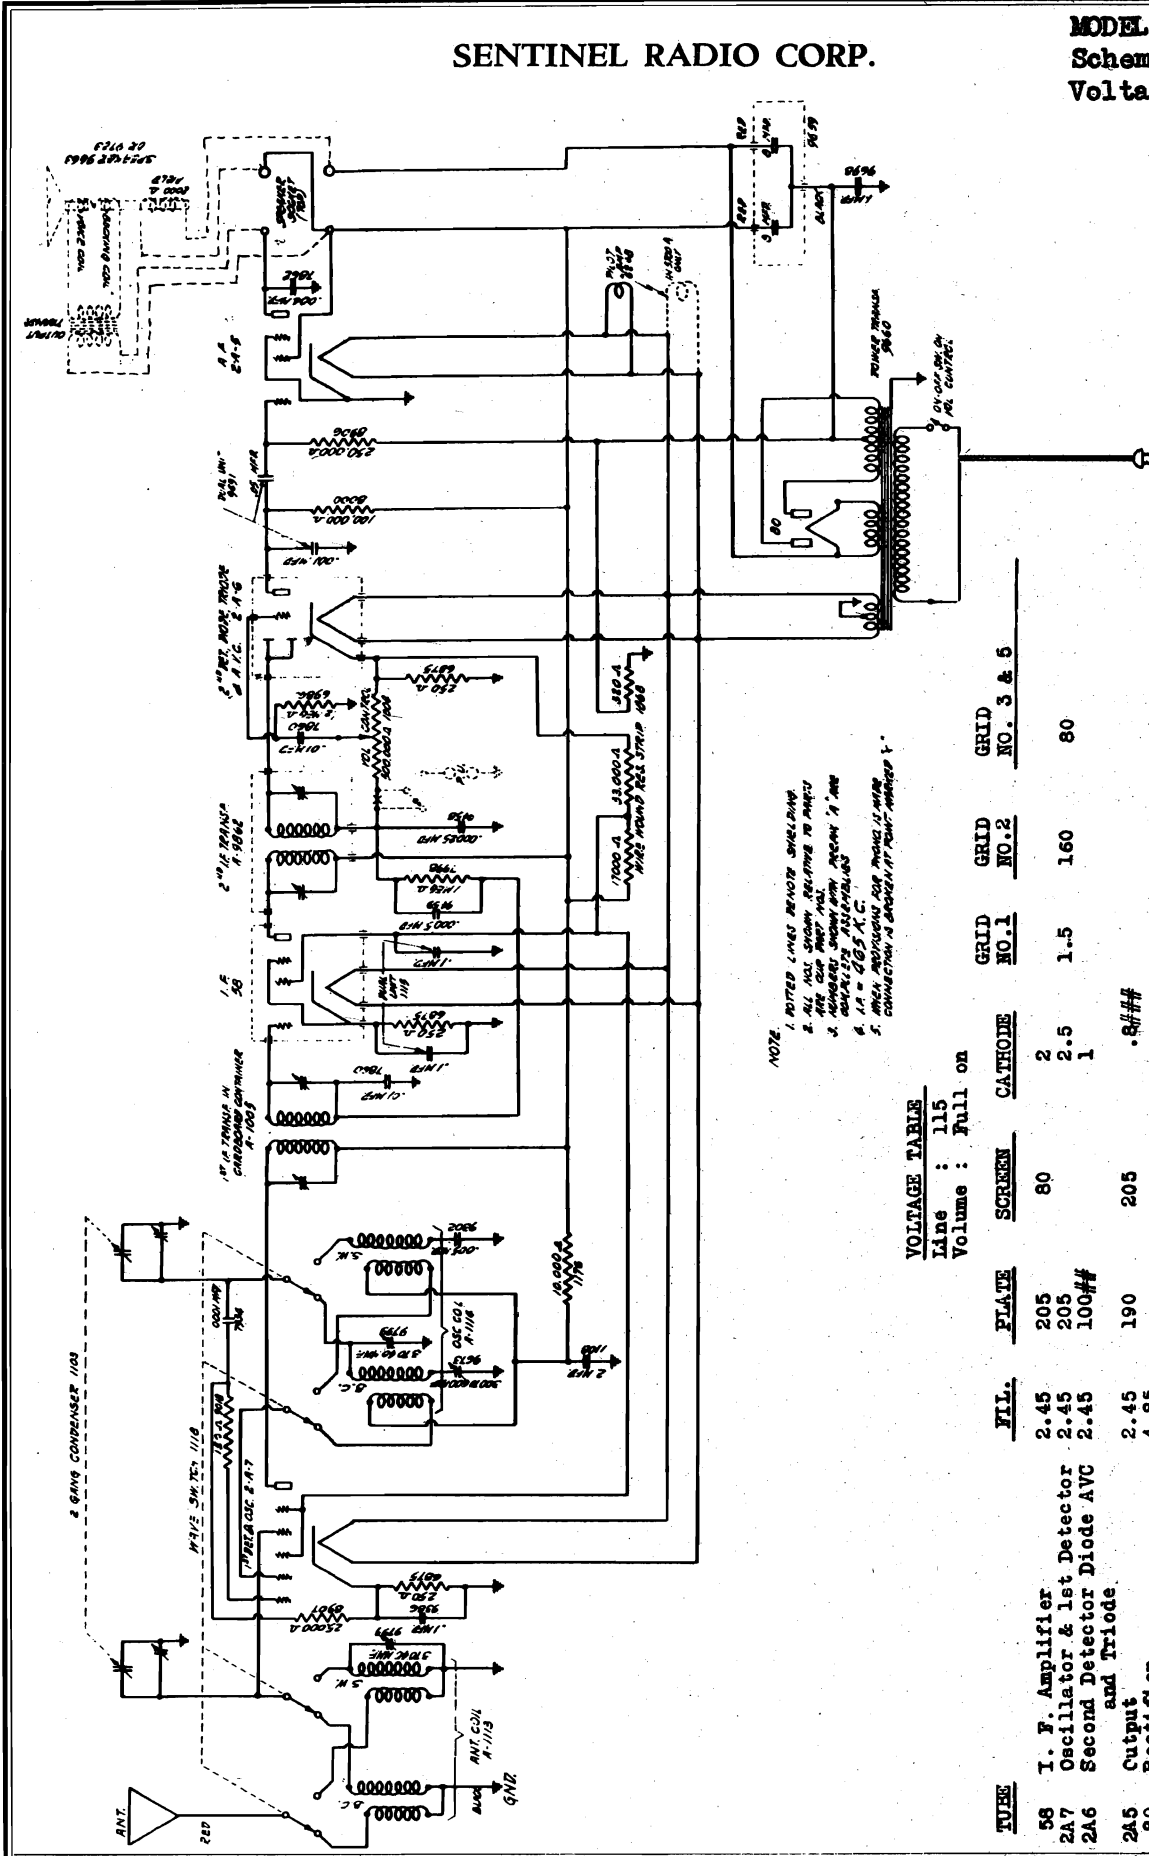

TO ALIGN THE VARIABLE CONDENSER: To align the variable condenser and padding condenser it is necessary that the receiver chassis be removed from the set housing. After the receiver chassis has been removed connect the remote control flexible drive shafts in their respective couplers, and set the dial needle on the dial face so that the dial calibration is correct.

1. Connect the high output side of the oscillator to the antenna and the ground to the receiver chassis.
2. Tune the receiver to exactly 1500 kilocycles on the dial and adjust the oscillator to this frequency. BRING IN THE 1500 KILOCYCLE SIGNAL (TO MAXIMUM OUTPUT) BY ADJUSTING THE OSCILLATOR VARIABLE CONDENSER TRIMMER MOUNTED ON TOP OF THE VARIABLE CONDENSER. THEN ADJUST THE OTHER VARIABLE CONDENSER TRIMMER FOR MAXIMUM OUTPUT. Looking at the front of the receiver the first section of the variable condenser is the oscillator section and the other section tunes the antenna coil.
3. Tune the receiver to approximately 600 kilocycles on the dial and set the oscillator to this frequency, then adjust the 600 padding condenser which is located on the right hand side and accessible through the hole in the chassis for maximum output. Always rock the condenser slightly to the right and left when making this adjustment, using the position where greatest output is obtained.

MODEL 5700,5721
Alignment Data
Parts List

SENTINEL RADIO CORP.

ALIGNMENT PROCEDURE: Only when an IF transformer, antenna or oscillator coil is replaced should it ever be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is absolutely necessary that a good accurate calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 tube leaving the grid cap disconnected. The ground side of the oscillator should be connected to the receiver chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the intermediate transformer brass hex adjusting nut located on top of the intermediate transformer can up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside the brass hex nut for maximum output.
4. Adjust the second I. F. transformer in the same manner as the first I. F. transformer.

VARIABLE CONDENSER ALIGNMENT: It is essential that the following instructions be carefully adhered to in the order given otherwise the receiver will be insensitive and the dial calibration will be inaccurate.

1. Connect the high side of the oscillator output to the set antenna lead and the oscillator ground to the receiver chassis.
2. Place the band selector switch for operation on the 16 to 5.2 megacycle band.
3. Set the oscillator frequency to exactly 15 megacycles and adjust the receiver dial to exactly 15 megacycles. Then BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE trimmer condenser of the oscillator gang condenser section. The oscillator trimmer condenser is mounted on top of the rear section of the variable condenser. The front section of the variable condenser tunes the antenna stage.
4. Place the band selector switch for operation on the 1715 to 535 kilocycle band, set the oscillator to exactly 1400 kilocycles and tune the receiver dial to 1400 kilocycles. BRING IN THIS 1400 KILOCYCLE SIGNAL BY ADJUSTING THE SMALL TRIMMER CONDENSER which is located underneath near the center and towards the front of the chassis.
5. Next adjust the antenna variable gang condenser section trimmer condenser for maximum output (front section).
6. Leave the receiver operating on the same band and set the oscillator frequency to approximately 600 kilocycles and adjust the dial to approximately 600 kilocycles. Then while rocking the variable condenser slightly to the right and left, adjust the 600 kilocycle padding condenser which is located below the speaker and accessible through the front of the chassis for maximum output.
7. Recheck the 1400 kilocycle adjustment.
8. Place the band selector switch for operation on the 16 to 5.2 megacycle band and tune the dial to exactly 15 megacycles and set the oscillator frequency to 15 megacycles. Then adjust the trimmer condenser which is located underneath and toward the center of the right hand side of the chassis for maximum output.

This completes the alignment procedure and it is suggested that all the adjustments be rechecked.

BAND SELECTOR SWITCH: Two different frequency bands are available, the frequency range being:

1715 to 535 Kilocycles- 175 to 560.75 Meters
 16 to 5.2 Megacycles- 18.7 to 57.7 Meters

MODEL 6101, 6102**Service Notes****Voltage****Alignment Data****SENTINEL RADIO CORP.**

This receiver is designed to operate on 32 volt battery plants only and must not be used on 36 volt battery plants without a voltage regulator. Generally, it is not advisable to operate the receiver while the generator is charging the battery due to the fact that considerable radio interference (static noise) may be encountered. This is not a reflection on the receiver, but is due to interference caused by the power plant generator, itself. Some generators have built-in traps to eliminate this interference and when so constructed this particular type of plant generator will not cause interference. If excessive static noise is encountered be sure that it is not caused by the 32 volt plant generator.

THIRTY-TWO VOLT POWER UNIT: Two power units have been furnished with the six tube 32 volt receiver, one unit utilizes a 25Z5 tube and the other an 84 tube. Diagrams for both of these units are shown on the receiver circuit diagram. It will be noted from the parts and price list that all parts with the exception of the power transformer and tube sockets are interchangeable. When ordering these parts be sure to order by part number.

NOTE: The dynamotor type unit supplied with the five tube 32 volt receiver cannot be used with the six tube receiver nor can the power units (utilizing the 84 or 25Z5 tube) furnished with the six tube receiver be used with the five tube 32 volt set.

The 32 volt power unit is shipped unmounted and must be placed in the sound-proof celotex compartment. In the console models this is located below the receiver mounting board and in the table models it is located above the chassis. To install the power unit in the sound-proof box remove the wood screws which hold the celotex back to the box, then place the power unit on the rubber mounting blocks provided inside of this box so that the unit is floating free on these rubber insulators. It is very important that the unit does not touch the side of the box. If excessive vibration is noticed be sure to check the power unit installation, as excessive vibration will result if it is not properly mounted on all of the rubber supports or if it is permitted to touch the side of the celotex housing.

PILOT LIGHT: A type T-3 $\frac{1}{2}$ #40 6.3 volt pilot light is used. The pilot light is readily accessible for removal from the rear of the cabinet.

ANTENNA AND GROUND: Under ordinary conditions an aerial from twenty-five to seventy-five feet in length including lead-in will prove ample. In some locations which are located a considerable distance from broadcast stations it may be necessary to use a longer aerial than this to obtain satisfactory daylight reception. Never place the aerial lead-in in close proximity to the 32 volt lighting lines, as considerable static noise may be picked up if the antenna lead-in is run parallel to the 32 volt power lines for any distance.

INTERMEDIATE ALIGNMENT: Only when an intermediate transformer has become defective due to an open or burned out winding should it be necessary to readjust the intermediate transformer. For aligning either the intermediate transformer or the variable condenser it is necessary that an oscillator be used with some type of output measuring device. To align the intermediate transformer:

1. Connect the high side of the oscillator output to the control grid of the #36 modulator tube. The ground side of the oscillator should be connected to the ground lead.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning one of the intermediate transformer trimmer screws up and down until maximum reading is obtained on the output meter. Then adjust the other trimmer screw in the same manner.
4. The second I. F. transformer should next be adjusted in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.

To align the variable condenser:

1. Connect the high output side of the oscillator to the set antenna lead and the ground side of the oscillator to the ground lead.
2. Tune the receiver to 1400 kilocycles on the dial and set the oscillator to this frequency.
3. Adjust the variable condenser trimmer screws for maximum output reading.
4. Tune the set to approximately 600 kilocycles on the dial and adjust the oscillator frequency to 600 kilocycles. Adjust the padding condenser located on the rear of the chassis adjacent to the antenna and ground leads and accessible through the hole in the chassis for maximum output reading.

When making this adjustment be sure to rock the variable condenser to the right and left using the position where the greatest reading is obtained.

Schematic

SENTINEL RADIO CORP.

SENTINEL RADIO CORP.

MODEL 6315, 6317, 6321

Voltage

Alignment Data

BAND SELECTOR SWITCH: The receiver is designed for operation on four different frequency bands. The frequency range of these bands are:

Band No. 1 - from 10 Megacycles to 24 Megacycles
 Band No. 2 - from 4 Megacycles to 10 Megacycles
 Band No. 3 - from 1.5 Megacycles to 4 Megacycles
 Band No. 4 - from 1500 Kilocycles to 540 Kilocycles

VOLTAGE TABLE

Line Voltage : 115
 Volume Control: Full on
 Wave Band : Broadcast

TUBE	Fil.	Plate	Screen	Cathode Volts	Grid No.1	Grid No.2	Grid No. 3 & 5
2A7 Oscillator 1st Detector	2.45	220		2.2	3.5	200	90
58 First I. F. Amplifier	2.45	220	90	6			
58 Second I. F. Amplifier	2.45	220	90	3.5			
2A6 Second Detector	2.45	120##		1			
2A5 Output	2.45	210	220				
80 Rectifier	4.89						

Triode Plate. Comparative voltage only. The voltmeter is in series with a high resistance and is therefore not the true voltage applied. Read all voltages from socket to chassis unless otherwise specified.

ALIGNMENT PROCEDURE: Only when an antenna, oscillator or I. F. transformer has become defective due to an open or shorted winding should it be necessary to realign the receiver. For aligning either the intermediate transformer or variable condenser it is necessary that an oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 First Detector tube, leaving the grid clip disconnected. The ground side of the oscillator should be connected to the chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the brass hex nut of the first intermediate transformer trimmer up and down until maximum reading is obtained on the output meter, then adjust the trimmer screw located inside of the brass hex nut in the same manner. The intermediate transformer trimmer screws are accessible through the small hole in the top of the intermediate transformer shields.
4. The second and third I. F. transformers should next be adjusted in the same manner as the first I.F. transformer.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning the variable condenser and padding condensers to follow the procedure given carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the antenna and the ground to the chassis.
2. Place the band selector switch for operation on the 1.5 to 4 megacycle band. Tune the receiver to exactly 1.7 megacycles on the dial, set the short wave trimmer about half the distance between maximum clockwise and counter-clockwise rotation and adjust the oscillator frequency to exactly 1.7 megacycles. Next, bring this 1.7 megacycle signal in to maximum output by adjusting the padding condenser accessible through the hole in the right hand side and closest to the rear of the chassis.
3. Leave the band selector switch for operation on the 1.5 to 4 megacycle band and tune the receiver to exactly 3.4 megacycles on the dial.

Next, set the test oscillator to exactly 3.4 megacycles and tune the signal in by adjusting the oscillator variable condenser trimmer mounted on top of the variable condenser. The middle section of the variable condenser is the oscillator section. Recheck the 1.7 megacycle adjustment after making the adjustment at 4 megacycles. For best results it is always advisable to check each adjustment several times. **NOTE:** This completes the short wave adjustment.

4. Adjust the band selector switch for operation on the broadcast band (1500 to 540 kilocycles) and tune the receiver to exactly 1400 kilocycles on the dial and set the oscillator to this frequency. Turn the receiver on end and bring this 1400 kilocycle signal in to maximum output by adjusting the trimmer screw on the small trimmer, which is located adjacent to the short wave switch underneath the chassis.

Next, adjust the antenna and preselector variable condenser section trimmers mounted on top of the variable condenser for maximum signal output. (These are the front and rear gang sections).

5. Leave the band selector switch for operation on the broadcast band (1500 to 540 kilocycles) and tune the receiver and oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser which is located on the right hand side and towards the front of the chassis for maximum output reading. This adjustment is quite critical and it is necessary to rock the condenser slightly to the right and left to obtain maximum sensitivity.

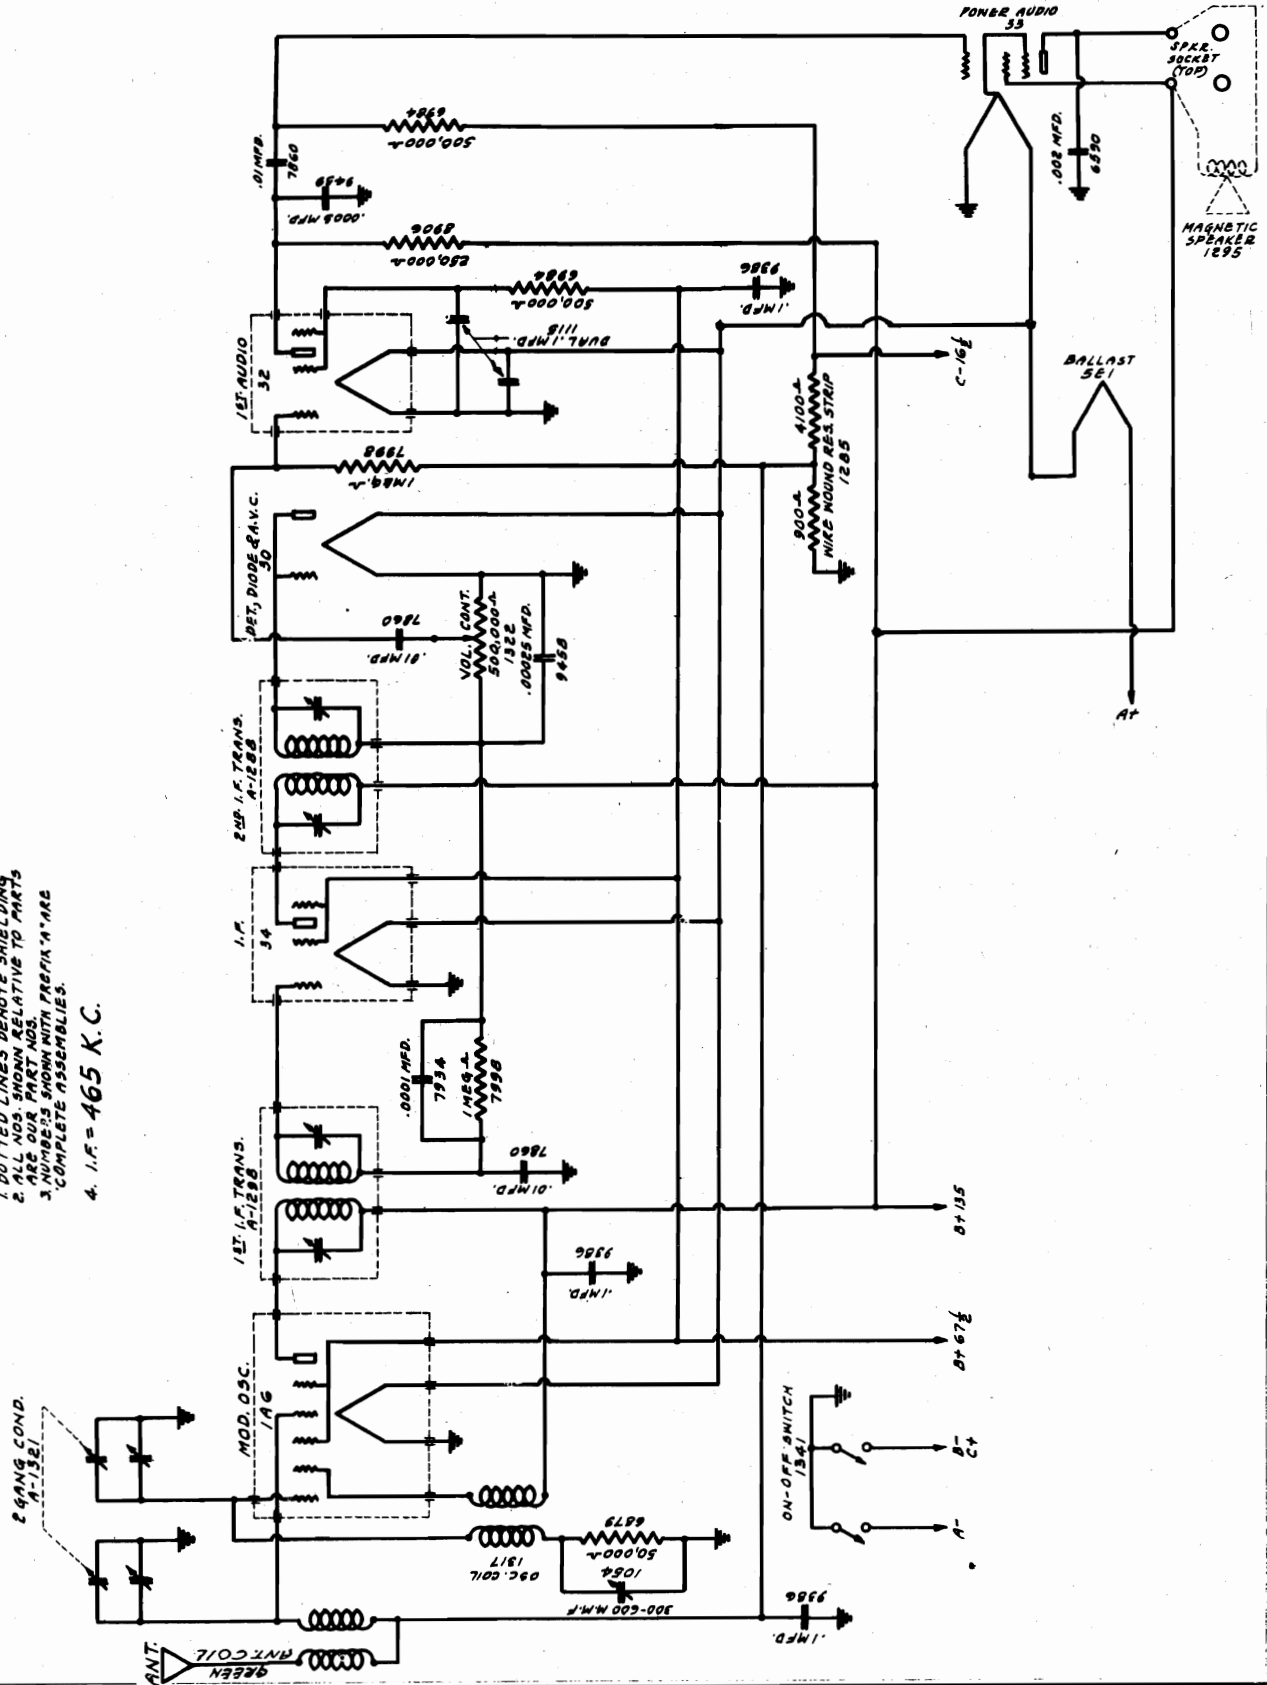

Always recheck the 1400 kilocycle alignment after making the adjustment at 600 kilocycles.

Voltage, Parts List

SENTINEL RADIO CORP.

Alignment Data

1. Connect the high side of the oscillator output to the control grid of the 1C6 tube leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the first intermediate transformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter, and then adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the second intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel HOLES in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning to follow the procedure carefully, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the receiver antenna lead and the ground to the chassis.
2. Place the band selector switch for operation on the short wave band, tune the receiver to exactly 15 megacycles on the dial and set the test oscillator frequency to exactly 15 megacycles. THEN TUNE IN THE 15 MEGACYCLE SIGNAL BY ADJUSTING THE TRIMMER MOUNTED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER TO MAXIMUM OUTPUT.

Looking at the front of the receiver the oscillator section is the rear section of the gang condenser.

3. Set the band selector switch for operation on the broadcast band, adjust the test oscillator frequency to 1400 kilocycles and set the receiver dial to exactly 1400 kilocycles. NEXT, BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED UNDERNEATH AND NEAR THE CENTER FRONT OF THE CHASSIS.
4. After making this adjustment tune the dial to 1720 kilocycles and set the oscillator frequency to 1720 kilocycles. If the 1720 kilocycle signal cannot be received reduce the 1400 kilocycle trimmer capacity until the 1720 kilocycle signal is brought in.
5. Next, set the receiver dial and test oscillator to exactly 1400 kilocycles, and adjust the trimmer located on the front section of the gang condenser for maximum sensitivity.
6. Leave the band selector switch for operation on the broadcast band, tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser, which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity. As this adjustment is quite critical it is necessary to rock the condenser slightly to the right and left to find the point of greatest sensitivity.
7. Place the band selector switch for operation on the short wave band, adjust the test oscillator frequency to exactly 15 megacycles and set the receiver dial to 15 megacycles. Turn the receiver on its back with the dial up and adjust the trimmer, which is mounted on the top of the coil underneath and near the right hand side of the chassis, for maximum output. Be sure to rock the condenser slightly to the right and left when making this adjustment.

This completes the alignment procedure. It is recommended that all of the adjustments be gone over again. Generally it will be found that improved results can be obtained if this is done.

VOLTAGE TABLE

"A" Battery - 3 Volt Dry Cell
 "B" Battery - 3 45 Volt "B" Batteries
 "C" Battery - 1 22½ Volt Battery

MODEL X
Schematic
Voltage

The intermediate stages are carefully phased to 456 kilocycles at the factory. Should rephasing be necessary, feed a 456 kilocycle signal from a test oscillator to the grid cap of the tube marked "78," located at the rear end of the tuning condenser, then adjust the double trimmers in the top of the coil cans nearest this tube, also the single trimmer in the top of the coil can near the "85" tube, to loudest volume, being sure to keep the oscillator signal at a low volume level. In trimming the frequency bands, first set the dial to the third group of figures from the right-hand end. Trim the "red" band first by adjusting the trimmers on the top of the tuning condenser until a signal of the proper frequency is heard at its loudest. Next, trim the "orange" band by adjusting the three-plate trimmers, located on the underside of the chassis, to loudest volume with proper signal frequency applied to the antenna. Next, trim the "blue" band by adjusting the two-plate trimmers located adjacent to the three-plate trimmers, to loudest volume with the proper signal frequency applied to the antenna. In trimming the various bands be sure that the band switch is set to the proper band as indicated by the color of the dial lamp. Also, keep the oscillator signal to as low volume level as possible for accuracy.

PHONOGRAPH: Mount single pole toggle switch at any convenient point on rear flange of chassis, disconnect 5 mfd. condenser from "cathode" of 6C6 socket and connect it to one side of switch, connect other side of switch to "cathode" of socket and connect phonograph across switch.

Alignment Data

Detailed Alignment Instructions for SPARTON Models 53 and 57

(Original) Effective September 28, 1934

Foreword: Before attempting to realign the circuits of the above SPARTON models, the service man should read carefully the information contained in the preceding pages of Bulletin No. 3-E, especially the paragraphs pertaining to the use of a test oscillator, output meter, method of adjusting the various trimming and padding condensers, and the bending of split condenser plate sections.

The use of quality test equipment is highly recommended, and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT NEEDED.

- A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 172.5 to 1710 kilocycles.
- B. Output meter.
- C. Part A-9631 adjusting wrench.

2. STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS.

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

- A. Alignment of Model 53.
 - (1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to adjust any condensers.
 - (2) Connect "antenna" of test oscillator to grid cap of Type 78 First Detector-Oscillator Tube, and "ground" of test oscillator to chassis frame of receiver. Connect output meter (condenser in series) from plate of Type 43 Tube to ground. (See Fig. 1, Page 1, Bulletin No. 3-E.)

Note: It is advisable to read carefully the operating instructions included with test oscillator. A blocking condenser must be in series with the test oscillator antenna lead to prevent damage to the oscillator. If the oscillator construction or equipment does not include this, use a .1 MFD or .2 MFD fixed condenser.

- (3) Tune test oscillator to obtain a signal of 456 kilocycles.
- (4) Turn the Station Selector of the receiver so that the condenser plates are all of the way out.
- (5) Retard the volume control of the receiver as much as possible and still obtain a 1/2 to 3/4 full scale deflection of the output meter. The gain control of the test oscillator should be advanced to obtain sufficiently strong signals.
- (6) Adjust condensers C₁ (reached from the bottom of the chassis) and C₂ (reached from the back of the chassis). These are the first and second intermediate frequency adjustable condensers, respectively.

B. Alignment of Model 57.
Note: The Model 57 is similar to the Model 53 with the exception that it is equipped with the band selector switch and dial light assembly. The alignment procedure for this model is the same as that for the 53 with the following exceptions:

- (7) Set the Station Selector Knob pointer at 540 kilocycles with the variable condenser rotor plates flush with the stator plates.
- (8) Disconnect "antenna" lead of test oscillator from grid cap of first detector oscillator tube and connect to the antenna terminal of the chassis.
- (9) Tune test oscillator to obtain a signal of 1500 kilocycles.
- (10) Tune the station selector of the receiver to 1500 kilocycles.
- (11) Without disturbing the 1500 kilocycles setting of either the test oscillator or the receiver, adjust condenser C₃ and the antenna compensator C₄ for a maximum deflection of the output meter.
- (12) Tune the test oscillator and receiver to 900 kilocycles for calibration check.

- (13) Tune test oscillator and receiver to 600 kilocycles, and again check the calibration.
- (14) Operation of the receiver should also be checked at 1710 kilocycles and 550 kilocycles.

Note: If the test oscillator is crystal-controlled for a frequency of 172.5 kilocycles, harmonics of this frequency may be used to check the dial calibrations at the following readings: 690, 862.5, 1035, 1207.5, 1380, and 1552.5 kilocycles. The end plates of the oscillator section of the two-gang condenser may be bent if necessary to correct dial readings.

(15) The condenser C₄ (antenna compensator) may require readjustment to permit best performance of the receiver after it has been connected to the antenna with which it will be used.

1500 kilocycles should be heard through the receiver when the station selector dial knob is turned to the low-frequency end of the dial between 540 and 600 kilocycles (between 54 and 60).

Note: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration. The condenser C₄ of the Model 57 will also have to be readjusted after the receiver is connected to the regular antenna.

IMPORTANT

SPARTON types 482-A, 482-B and 483 should not be replaced by type '45. Difference in filament voltage will burn out type '45.

SPARTON types 482-B and 483 should never be mixed in a power amplifier. Always use two type 482-B or two type 483. These tubes should be used in SPARTON Models as listed in the above chart.

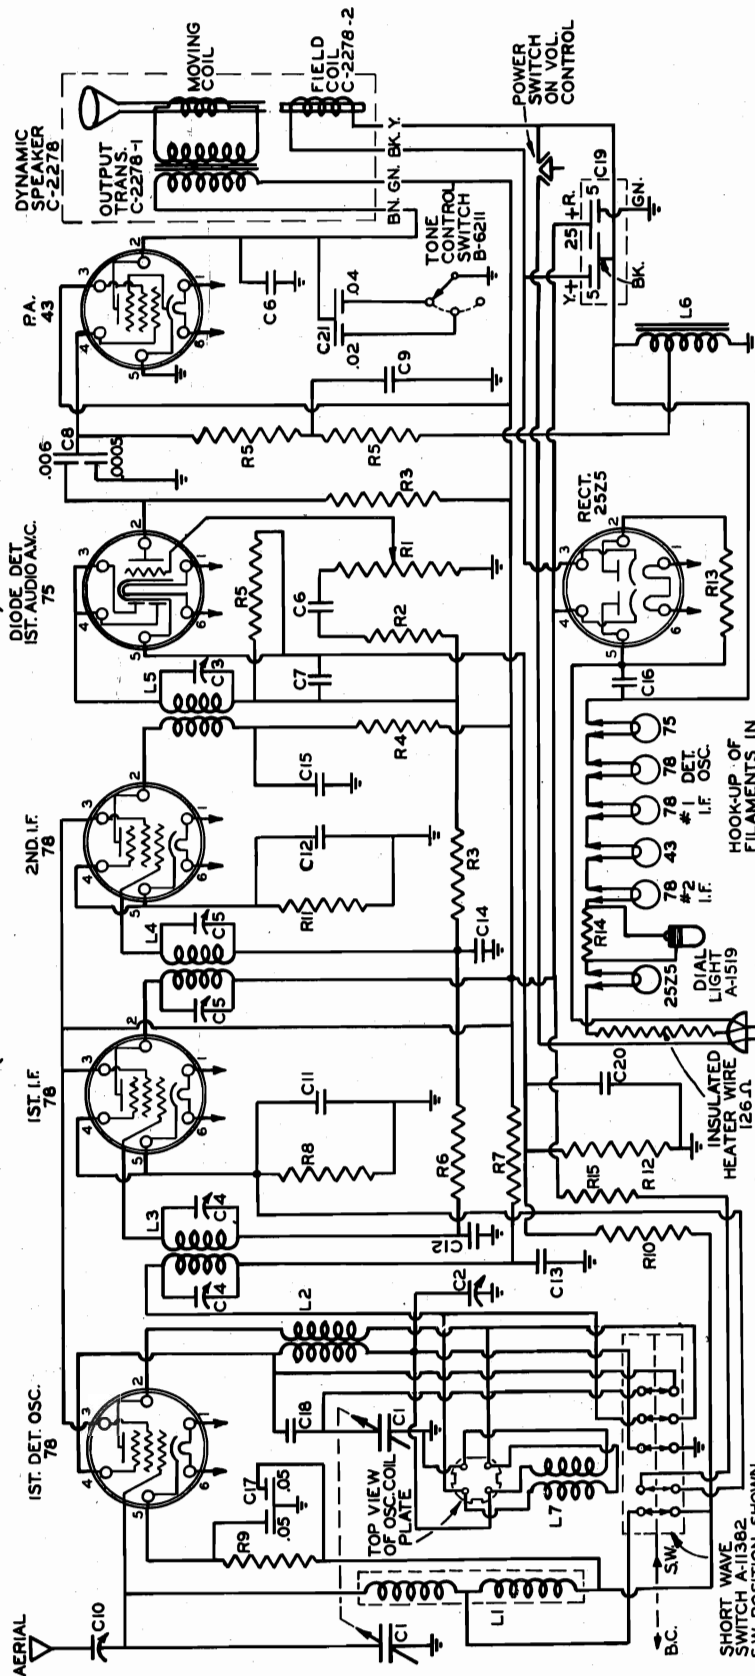

SPARTON types 484-A and 485 should not be replaced by type '27. Difference in characteristics causes overload on both transformer and tube.

NOTE: Best results with SPARTON Equasonne Models are obtained by mixing high and low reading type 485 tubes in the R-F Amplifier unit.

MODELS 65 AND 66 CHASSIS

(ORIGINAL) EFFECTIVE AUGUST 1, 1934

SPARKS-WITHINGTON CO.

MODEL 65, 66, 65T, 66T
Alignment Data

Detailed Alignment Instructions for SPARTON Models
65, 65-T, 66 and 66-T

(Original) Effective August 14, 1934

Note: Models 65 and 66 are A. C.-D. C. receivers; Models 65-T and 66-T are equipped with a power transformer and must be used on A. C. only.

Foreword: Before attempting to realign the circuits of the above SPARTON models, the service man should read carefully the information contained in the preceding pages of this bulletin, especially the paragraph pertaining to the use of a test oscillator, an output meter, method of adjusting the various trimming and padding condensers, and the bending of split condenser plate sections.

The use of quality test equipment is highly recommended, and a good test oscillator becomes a virtual necessity when aligning the all-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED.

- A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 172.5 to 15,000 kilocycles.
- B. Output meter.
- C. Sparton Part A-9631 Adjusting Wrench.

2. STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS.

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

A. Alignment of Broadcast Band.

- (1) The dial pointer should be exactly parallel with the horizontal lines on the scale when the selector rotor plates are completely in mesh with the stator plates. The pointer may be reset, if necessary, by first loosening the nut on the planetary drive

The end plates of the oscillator section of the two gang condenser may be bent if necessary to correct dial readings.

Note: An allowance of 20 kilocycles at 900 kilocycles and 15 kilocycles at 600 kilocycles is permitted.

B. Alignment of Short-Wave Band.

- (1) Adjust Band Selector Switch to Short Wave Position.

- (2) Adjust test oscillator to obtain a wave length of 20 meters (15 megacycles) and tune receiver to this wave length.

Adjust for resonance with antenna tuning condenser (C_A). Calibration should check within 1½ meters. Push or pull the wires that are near the oscillator coil to correct any greater variation in calibration.

- (3) Adjust test oscillator to obtain a wave length of 50 meters (6 megacycles) and tune receiver to this wave length.

Adjust for resonance with antenna tuning condenser (C_A). Calibration should check within 1½ meters. If the error in calibration exceeds this amount, recheck the preceding adjustments.

Adjust oscillator trimmer condenser (C₀). Check calibration of receiver by setting the test oscillator to obtain a signal of 172.5 kilocycles. Harmonics of this frequency should be picked up at the following readings on the dial: 690, 862.5, 1085, 1207.5, 1380 and 1552.5 kilocycles.

Note: All adjustments should be re-checked to assure accuracy and stability of adjustment and calibration.

- C₀ ANTENNA TUNING CONDENSER
- C₁ OSCILLATOR TRIMMER
- C₂ 1ST I.F. CONDENSER
- C₃ 2ND I.F. CONDENSER
- C₃ 3RD I.F. CONDENSER
- * POWER SWITCH FOR 65T AND 66T LOCATED ON SIDE OF CABINET.

Fig. 6. CHASSIS DIAGRAM FOR SPARTON MODELS 65, 65-T, 66 AND 66-T

MODEL 67, 68, 691
Alignment Data

SPARKS-WITHINGTON CO.

- (5) With the test oscillator tuned to 20 meters, adjust condensers C_1 and C_2 .
- (6) Tune the test oscillator to obtain a wave length of 80 meters (6 megacycles) and tune receiver to this wave length for calibration check.
- (7) Tune test oscillator to obtain a wave length of 33.3 meters (9 megacycles) and tune receiver to this wave length for calibration check.
- (8) Tune test oscillator to obtain a wave length of 20 meters (15 megacycles) and tune receiver to this wave length for calibration check.

The end plates of the oscillator section of the two gang condenser may be bent if necessary to correct dial readings.

C. Alignment of Short-Wave Band.

- (1) Turn the Band Selector Switch to the Short-Wave Position.
- (2) Tune the station selector to 1500 kilocycles in the broadcast band.
- (3) Tune test oscillator to obtain a signal of 20 meters wave length (15 megacycles).
- (4) Without changing the station selector setting of 1500 kilocycles, adjust condenser C_3 . The station selector should show the same reading of 1500 kilocycles when the receiver is tuned to signals of 1500 kilocycles or 20 meters (15000 kilocycles.)

Note: All adjustments should be re-checked to assure accuracy and stability of adjustment and calibration.

Detailed Alignment Instructions for SPARTON Models 67, 68 and 691

Foreword: Before attempting to realign the circuits of the above SPARTON models, the service man should read carefully the information contained in the preceding pages of this bulletin, especially the paragraphs pertaining to the use of a test oscillator, an output meter, method of adjusting the various trimming and padding condensers, and the bending of split condenser plate sections.

The use of quality test equipment is highly recommended, and a good test oscillator becomes a virtual necessity when aligning the all-wave or short-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers.

Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED.

- A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 172.5 to 15,000 kilocycles.
- B. Output meter.
- C. Sparton Part A-5732 or A-8737 adjusting wrench.

2. STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS.

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given.

A. Alignment of Intermediate-Frequency Stages.

- (1) Turn on receiver and test oscillator, and allow both to operate several minutes before attempting to align any condensers.
- (2) Connect "antenna" of test oscillator to grid cap of type 6A7 first detector-oscillator tube, and "ground" of test oscillator to chassis frame of receiver. Connect output meter as in Fig. 1, page 1, Bulletin No. 3-E.

Note: It is advisable to read carefully the operating instructions included with test oscillator.

- (3) Tune test oscillator to obtain a signal of 345 kilocycles.
- (4) Turn the volume control of receiver on full, and place Band Selector Switch in Broadcast Position.
- (5) Adjust I. F. condensers C_1 and C_2 . (See Fig. 7.)
- (6) The dial pointer should point to the lowest calibrated frequency mark on the broadcast section of the kilocycle scale (dial division between 55 and horizontal line). If the dial pointer reads incorrectly, it may be reset by first loosening the nut on the planetary drive and drum (back of the Station Selector knob), then resetting the pointer while holding the rotor plates completely in mesh with the stator plates, and then tightening the nut.

B. Alignment of Broadcast Band.

- (1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect to the antenna terminal of the chassis.
- (2) Tune test oscillator and receiver to frequency of 1500 kilocycles.
- (3) Adjust Condenser C_3 .
- (4) Adjust Condensers C_2 and C_4 .
- (5) Tune test oscillator and receiver to 600 kilocycles.
- (6) Adjust condenser C_3 for maximum output.

Note: Slight readjustments of the station selector and condenser C_3 may be required to obtain the greatest deflection on the output meter. A variation of 5 kilocycles from the value of 600 kilocycles is permitted in this procedure.

Check calibration of receiver by tuning the test oscillator to obtain a signal of 172.5 kilocycles. Harmonics of this frequency should be picked up at the following readings of the dial: 690, 862.5, 1035, 1207.5, 1380, and 1552.5 kilocycles.

NOTES: Voltage and resistance readings are for schematic diagram shown. See note under schematic diagram. Allow 15% + or — on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665, Type 1.

**Cannot be measured with Weston No. 665, Type 1.

MODELS 67, 68, AND 691 CHASSIS

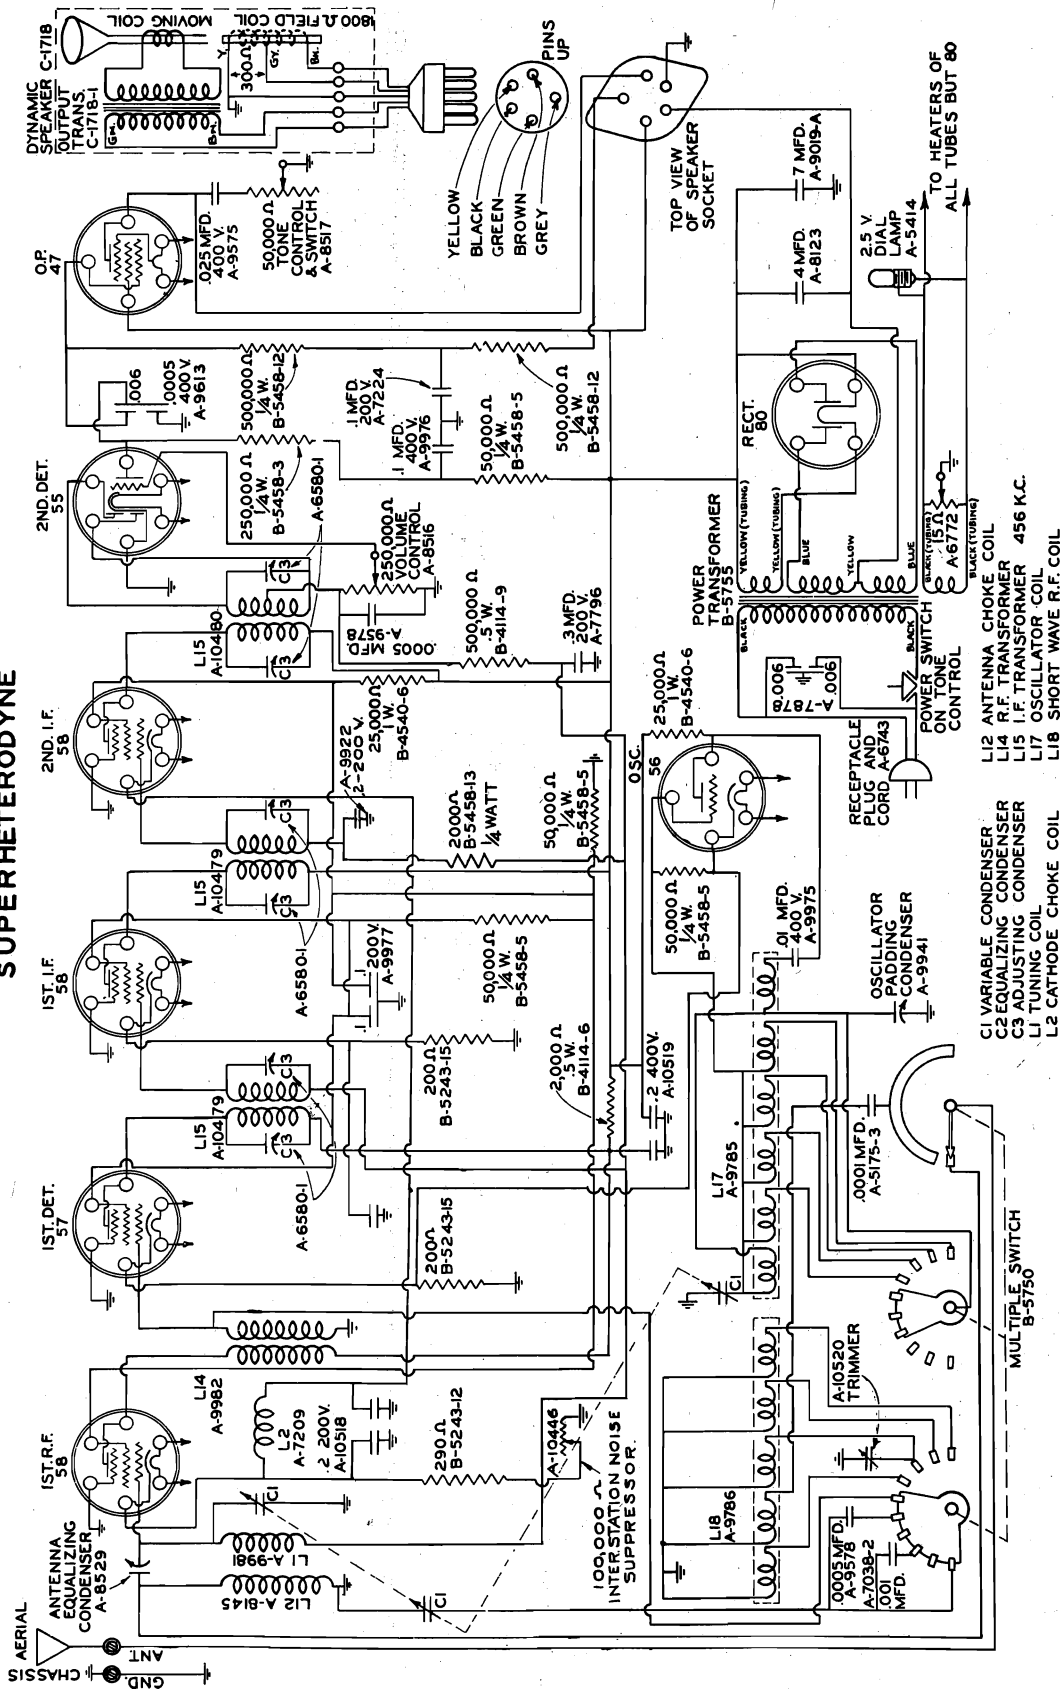

CIRCUIT FOR PHONOGRAPH PICK-UP

Break connection between Condenser C7 and Volume Control R1 (see Schematic Diagram) and install toggle switch (SPARTON Part A-11561 may be used). Toggle switch may be mounted by drilling a 1/2" hole in the back of the chassis, 4 inches from the right hand side and 1 inch up from the bottom.

in Jewell 444 Set Analyzer.

SPARTON MODEL 75-A

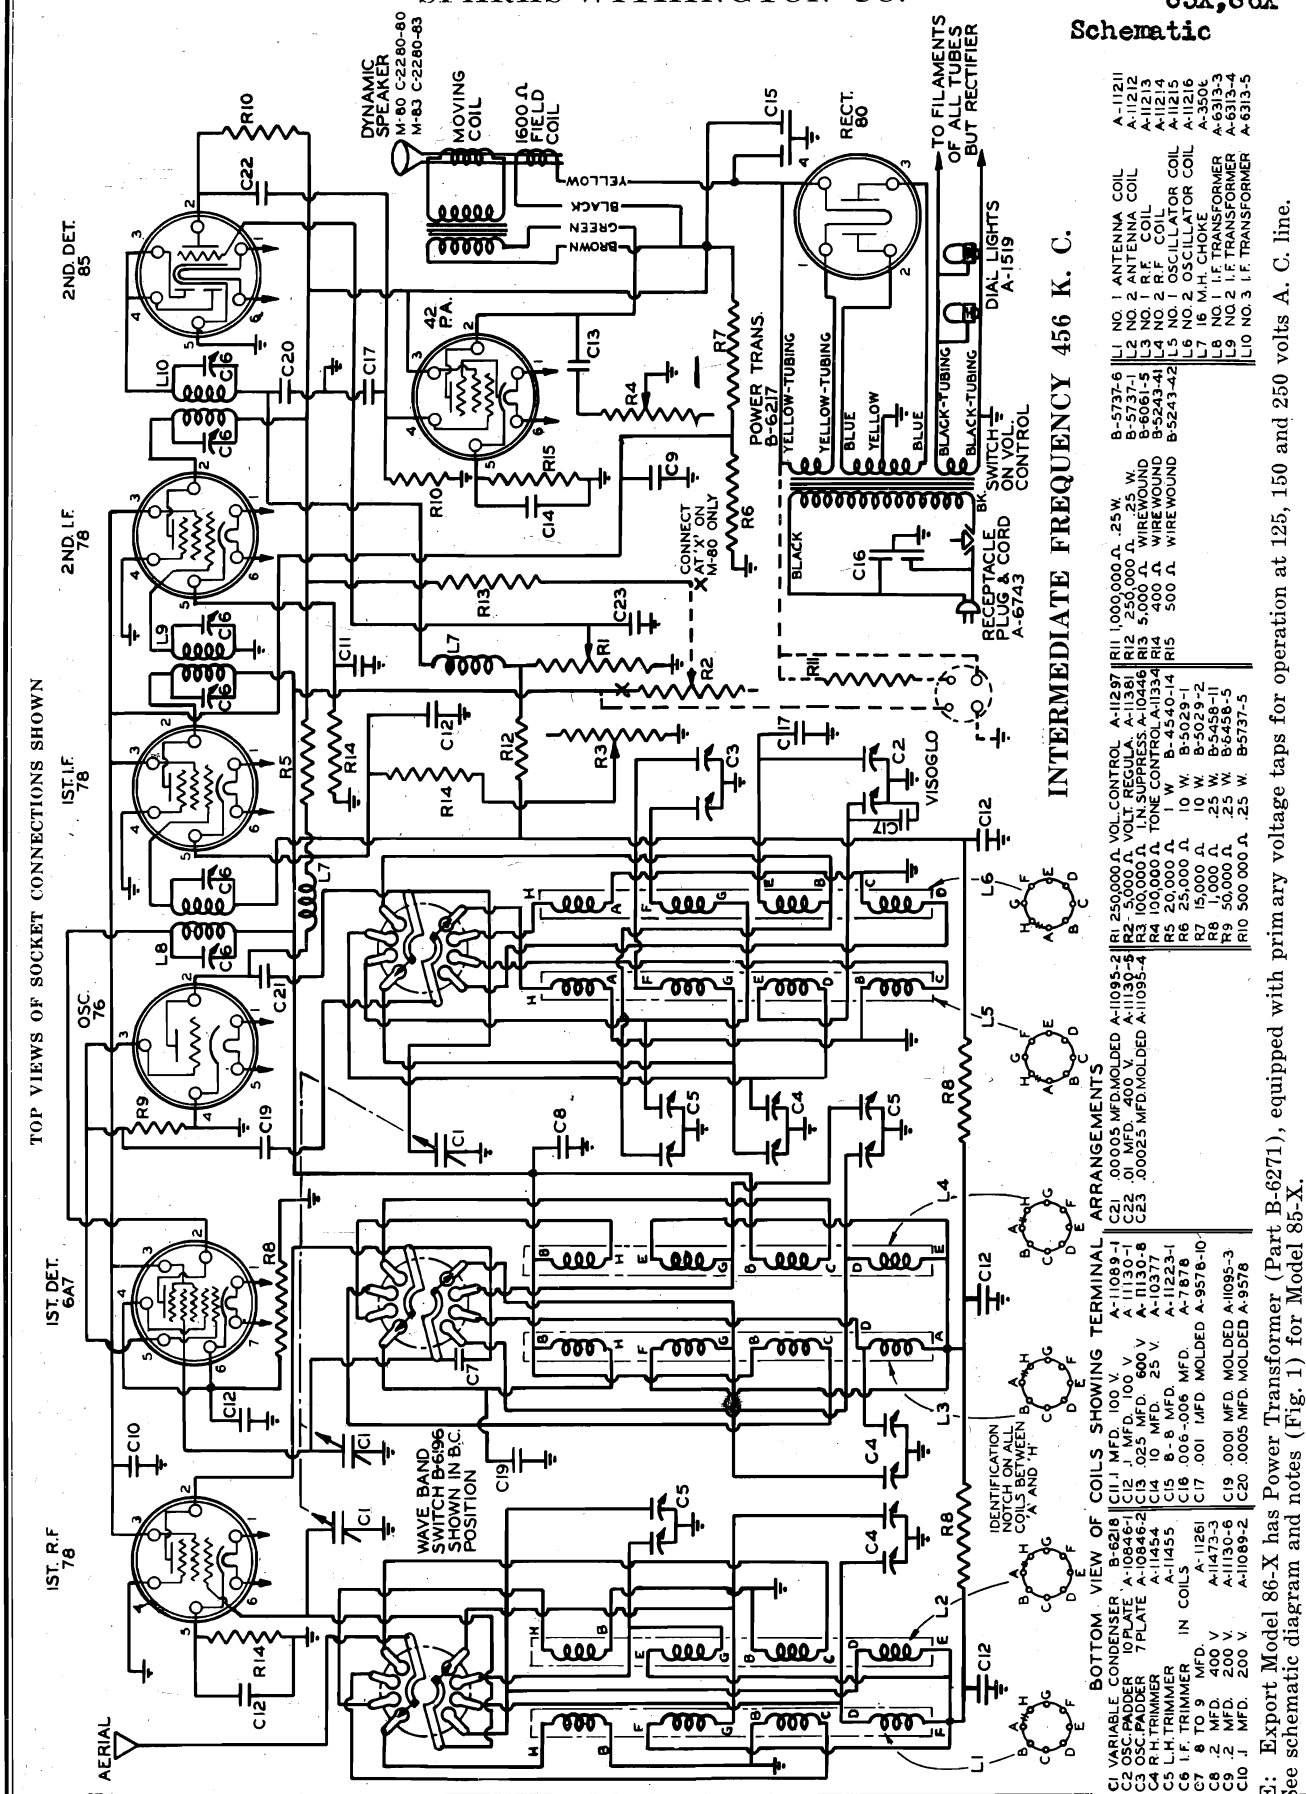

NOTE: SPARTON MODEL 475-A has Model 75-A chassis and Model 74 cabinet.
SPARTON MODEL 478-A has Model 75-A chassis and Model 478 cabinet.

NOTE: The 8,000 ohm Resistor (B-5458-23) and .006 mfd. condenser (A-9916) are included in the Type 57 1st Detector circuit as above in all chassis having light brown color tuning scales. These receivers will have -3.0 volts on Type 57 Control Grid instead of -1.9 and 8,000 ohms cathode resistance to ground instead of 200 ohms as shown in the above table.

NOTES: Voltage and resistance readings are for schematic diagram shown. Allow 15% + or - on all measurements. Always use meter scale which will give greatest deflection within scale limits. All measurements made with Weston Selective Analyzer No. 665, Type 1.
*Zero or 6.0 volts A. C., depending on twist of filament hook-up wire. When Prong No. 1 reads zero, Prong No. 6 (Prong No. 7 of Type 6A7 Tube) should read 6.0, and vice versa.
**Cannot be measured with Weston No. 665, Type 1.

MODELS 80, 83, 84, 85-X, AND 86-X CHASSIS

FIG. 1

THE MODEL 85-X PHONOGRAPH COMBINATION has the circuit changes shown in Fig. 1 in addition to the regular schematic diagram. The dotted lines in Sections (B) and (C) are shown solid in the regular schematic diagram and toggle switch (D. P. D. T.), condenser C24 and resistor R16 are added. Section (A) shows connections of toggle switch, Part A-5905, and phono motor on Model 85-X.
A PHONOGRAPH PICK-UP may be used with the Models 80, 83, 84 and 85-X by incorporating the toggle switch (D.P.D.T.), Part A-11561, condenser C24 (10 MFD., Part A-10877), resistor R-16 (5,000 ohms, 1/4 watt, Part B-5458-16), and the circuit changes shown in Fig. 1, Sections (B) and (C) only. The toggle switch may be mounted by drilling a 1/2-inch hole in the back of the chassis, 4 inches from the left hand side and 1 inch up from the bottom.

MODELS 80, 83, 84, 85X,
86X, 104
Alignment Data

(Original) Effective September 28, 1934

Detailed Alignment Instructions for SPARTON All-Wave Models 80, 83, 84, 85-X, 86-X, and 104

Note: The Models 80, 83, 84, 85-X and 86-X employ an eight-tube chassis. The Model 104 employs a ten-tube chassis.

The Model 85-X is a radio-phonograph combination and the Model 86-X is an export receiver equipped with a special power transformer permitting operation on line voltages of 125, 150, and 250 volts A. C.

The alignment procedure is the same for all of the above models.

Foreword: Before attempting to realign the circuits of the above SPARTON models, the service man should read carefully the information contained in the preceding pages of Bulletin No. 3-E, especially the paragraphs pertaining to the use of a test oscillator, output meter, method of adjusting the various trimming and padding condensers, and the bending of split condenser plate sections.

The use of quality test equipment is highly recommended and a good test oscillator becomes a virtual necessity when aligning the all-wave type of receiver. Due to the fact that the ear cannot distinguish small changes in sound intensity, an output meter is essential to the proper adjustment of the various condensers. Unless otherwise specified, the adjusting of any condenser consists of turning the adjusting screw or nut to the right or left until the output meter registers the greatest deflection.

1. EQUIPMENT REQUIRED

A. Modulated test oscillator (crystal controlled or accurately calibrated) capable of generating frequencies from 172.5 to 20,000 kilocycles.

B. Output meter.

C. Part: A-7613 adjusting wrench.

2. STEP BY STEP PROCEDURE FOR COMPLETE ALIGNMENT OF MODELS

Note: For proper alignment of these chassis, the procedure should be followed in the same order as given. In the following procedure, the broadcast band will be termed Band No. 1; the first short-wave band (green section of the dial), Band No. 2; the second short-wave band (red section of the dial), Band No. 3; the third short-wave band (blue section of the dial),

disturbing the setting of the test oscillator or the station selector, adjust condensers C_{13} , C_9 , and C_6 in the order given.

- (4) Tune test oscillator and receiver to 600 kilocycles and adjust condenser C_{14} .
- (5) Retune test oscillator and receiver to 1350 kilocycles and check the adjustments of condensers C_{12} , C_8 , and C_4 .
- (6) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Band No. 2 (1.2 to 3.6 Megacycles)

- (1) Turn the band selector switch to the first short-wave band (green section of the dial).
- (2) Tune test oscillator and receiver to 3,000 kilocycles and adjust Condensers C_{13} , C_9 , and C_6 in the order given.
- (3) Tune test oscillator and receiver to 1650 kilocycles and adjust condenser C_{11} .
- (4) Retune the test oscillator and receiver to 3,000 kilocycles and check the adjustments of Condensers C_{13} , C_9 , and C_6 .

D. Alignment of Band No. 3 (3.1 to 8.0 Megacycles)

- Caution:** On the third and fourth bands (second and third short-wave bands) care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image frequency is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band with the Inter-station Noise Suppressor turned full on, allowing maximum sensitivity of the receiver. If a "dead spot" appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.
- On Band No. 4 this type of misalignment may be more easily de-

fect by turning the set to full sensitivity and with the test oscillator generating a frequency of 15,000 kilocycles, tune the dial to approximately 15,900 kilocycles. If a strong signal is found at approximately this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 1500 kilocycles would be 1500 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore a signal on this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

- (1) Turn band selector switch to the second short-wave position (red section of the dial).
- (2) Tune test oscillator and receiver to 7,200 kilocycles and adjust condensers C_{14} , C_{10} , and C_7 in the order given.
- (3) Tune test oscillator and receiver to 3,600 kilocycles and adjust condenser C_{10} .
- (4) Retune test oscillator and receiver to 7,200 kilocycles and check the adjustments of condensers C_{14} , C_{10} , and C_7 .

D. Alignment of Band No. 4 (7.5 to 20 Megacycles)

- (1) Turn the band selector switch to the third short-wave position (blue section of the dial).
- (2) Tune the test oscillator and receiver to 15,000 kilocycles and adjust condensers C_{15} , C_{11} , and C_7 in the order given.
- (3) Tune test oscillator and receiver to 9,000 kilocycles and adjust condenser C_{10} .
- (4) Retune test oscillator and receiver to 15,000 kilocycles and check the adjustments of condensers C_{15} , C_{11} , and C_7 .
- (5) The calibration of the receiver should also be checked at a frequency of 12,000 kilocycles.

Note: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

MODEL 104 CHASSIS

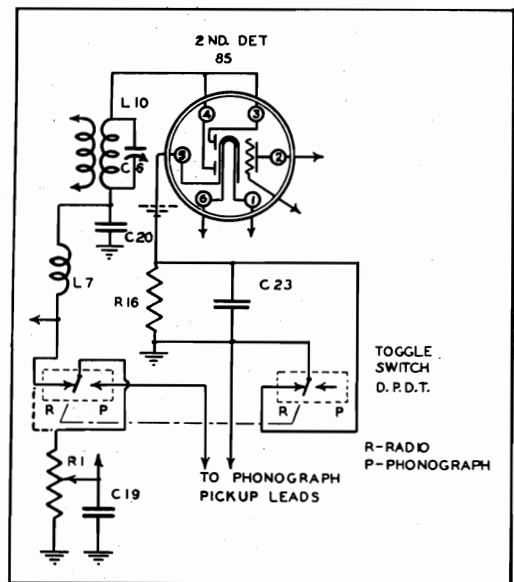

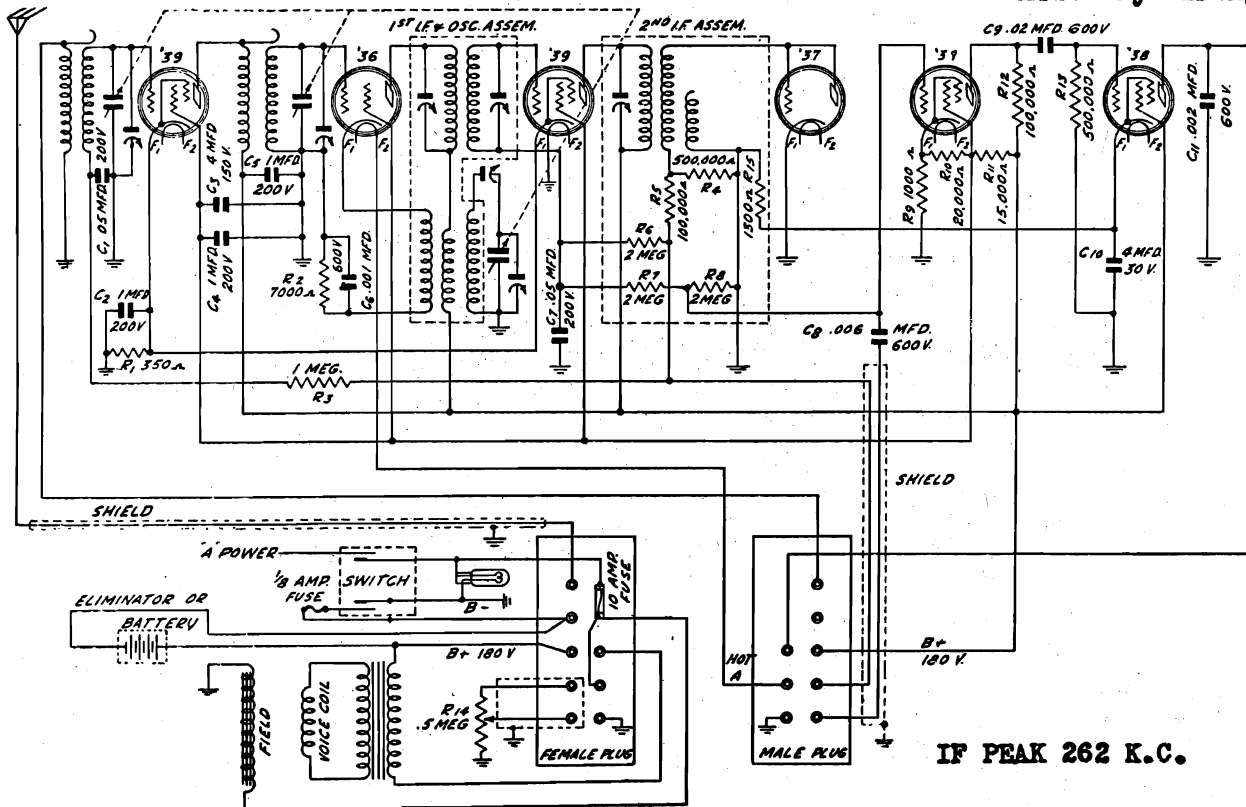

DIAGRAM OF CONNECTIONS FOR PHONOGRAPH PICKUP

Parts required: 1 Toggle Switch (D. P. D. T.), Part A-11561; 1 Condenser (C23), Part A-10377, 10 MFD., 25 V.; 1 Resistor (R-16), Part B-5458-16, 5000 ohms, 1/4 watt.

Dotted line between R1 and L7 and dotted ground at Prong No. 5 of Type 85 tube indicate original connections. See schematic diagram on back of sheet. Toggle switch may be mounted by drilling 1/2" hole in back of chassis 4 inches from left hand side and 1 inch up from bottom.

MODEL 1171, 1172

STEWART - WARNER CORP.

**Voltage Data
Alignment Data**

The Stewart-Warner 6 Tube Superheterodyne Model No. R-117 Chassis is used in the Model 1171 and 1172 Auto Radio receivers. These two sets are identical with the exception of the remote control head and the flexible shafts.

The Model 1171 remote control uses a key to operate the volume control and a knob for tuning while the 1172 control uses a different type of head with knobs for both the volume control and tuning. Sets with serial numbers below 15000 are Models 1171's, while those above 15000 are 1172's.

The only difference in the chassis used is the omission of the dial light dimming resistor (diagram No. 51) in the 1172 sets.

DIAL CALIBRATION

In the Model 1171, the dial can be calibrated by tuning in a station of known frequency and then setting the pointer to give the correct reading by turning the adjusting screw which is located on the middle of the back of the remote control head. In the Model 1172, the dial is calibrated by turning the tuning knob after the pointer has stopped at the last dial division. Turning the knob in a clockwise direction, after the pointer reaches 15.4, will lower the dial reading, while turning it counter clockwise after the pointer is at 5.3, will increase the dial reading.

CIRCUIT DESCRIPTION

In the R-117 Chassis, the incoming signal is tuned and amplified by the 78 R. F. amplifier tube and then it is further amplified and its frequency is converted to 177.5 K. C. in the 6A7 combination first detector and oscillator tube.

The 177.5 K. C. signal is amplified by the I. F. stage, using a 78 type tube and is then rectified by the diodes of the 75 second detector tube. The rectified current produces a modulated D. C. voltage drop across the diode load resistor No. 11. The audio frequency modulation is impressed across the 500,000 ohm volume control from where it goes to the triode section of the 75 which acts as an audio amplifier.

The modulated drop across resistor No. 11 is filtered and applied to the grids of the 78 and 6-A-7 tubes to provide A.V.C. action.

LOCAL-DISTANCE SWITCH

A local-distance switch is provided in the R. F. stage to reduce the sensitivity in locations where there is excessive noise in tuning between stations. When this switch is in the open or "local" position, a high bias is placed on the 78 R. F. tube by means of the 6000 ohm resistor No. 2. This resistor is shorted out when the switch is thrown to the distance position (with white dot showing) thus reducing the bias to its normal value.

POWER SUPPLY PROTECTIVE RESISTOR

The filter system and the rectifier tube are protected against breakdown during the warming-up period by the Globar resistor connected across the high voltage secondary of the power transformer (No. 21 in the circuit diagram). This resistor drops rapidly in resistance as the voltage across it rises, so that it acts as a load on the power transformer and keeps the voltage below the danger point until the tubes warm up and take their normal current. Because of its unique voltage characteristics, the Globar resistor cannot be tested with an ordinary ohmmeter, since it will show a resistance of several megohms.

ALIGNMENT

A good modulated oscillator and a sensitive output meter are necessary for proper alignment of the R. F. and I. F. stages of this receiver. The output of the oscillator must be adjustable to give a very weak signal which will not actuate the A. V. C. of the receiver. The output meter must be sensitive enough to give sufficient reading with such a weak signal.

The output meter should be connected from the 42 plate to ground through a .25 mfd. condenser or across the voice coil, depending upon its sensitivity. A convenient point to connect to the 42 plate is the terminal of the tone control which is wired to the speaker plug.

During all alignment adjustments, keep the volume control full on and the local-distance switch in the "distance" position.

7-18-34

IMPORTANT: Use high resistance voltmeter of 1000 ohms per volt. Readings will vary depending upon range of meter. Make allowances for battery voltage variations.

NOTE A: The oscillator grid voltage varies from 0 at 1500 K. C. to -5.0 at 530 K. C.

NOTE B: The oscillator anode voltage may vary from 118 at 1500 K. C. to 128 at 530 K. C.

NOTE C: The actual bias on the grid of the 42 tube is -15.5 volts which must be measured from chassis to the ungrounded filter choke terminal. Due to the high resistance of the grid leak, the voltmeter will show only about -1 volt at the grid.

I. F. ALIGNMENT

The I. F. trimmers are located on the top of the I. F. transformers which may be reached by removing the front cover. The modulated oscillator should be set to exactly 177.5 K. C. and connected from the 6-A-7 control grid to ground. Adjust the oscillator output to give about half-scale reading of the output meter. Adjust all three I. F. trimmers to give maximum output reading.

The first I. F. transformer has a double trimmer consisting of a slotted screw for one trimmer and a hex nut around it for the other. In adjusting the second I. F. transformer single trimmer, it is desirable to use a bakelite screwdriver or one having only a small metal tip. After the I. F. trimmers have been aligned once, go back and repeat the procedure, since any adjustment of one will affect the others to some extent.

R. F. ALIGNMENT

The gang condenser trimmers can be reached by removing the back cover. Connect a .00025 mfd. mica condenser in series with the output of the test oscillator and the aerial lead of the receiver. This condenser is absolutely necessary to secure proper alignment of the antenna stage. Adjust the receiver to approximately 1400 K. C. and carefully tune the service oscillator to give maximum receiver output. Adjust the output of the oscillator to the minimum value which will give sufficient output meter deflection. Adjust the two trimmers nearest to the shaft end of the gang condenser to give maximum output meter reading. The trimmer on the other condenser section (oscillator section) should not be touched unless the set does not calibrate properly.

ALIGNING THE PADDING CIRCUIT

The low-frequency oscillator padding trimmer located on the side of the chassis does not require adjustment in most cases. However, if the set does not align properly at the low frequency end proceed as follows: Remove the chassis from the case. To do this it is necessary to unsolder the braided shield from the outside of the case at the antenna plug opening and then remove the screws holding the chassis to the case. Set the test oscillator to exactly 600 K. C. and tune the set to the signal. Adjust the padding trimmer which is mounted on the side of the chassis while turning the gang condenser back and forth over a small range. The correct setting is the one which gives maximum output. If the pointer is not exactly at 6.0 (600 K. C.) for maximum output, re-adjust the pointer calibration to get the proper reading. After adjusting the padding trimmer check up the alignment and calibration at 1400 K. C.

ADJUSTMENT OF OSCILLATOR TRIMMER

If the receiver is badly out of calibration, particularly at the high frequency end, the following procedure should be followed.

Set the test oscillator to exactly 1400 K. C. Turn the tuning knob until the dial pointer indicates 14.0 (1400 K. C.) and then adjust the oscillator trimmer (third one from shaft end of the variable condenser) until the signal is received with maximum output. Then adjust the other two gang condenser trimmers as directed under R. F. alignment.

Wave Trap
Installation Data

STEWART WARNER CORP.

INSTRUCTIONS FOR INSTALLATION OF WAVE TRAP

This wave trap is designed to be used with any Stewart-Warner chassis using an intermediate frequency of 456 kilocycles. The trap will reduce or prevent code interference caused by powerful code stations which operate at or near this frequency.

It is made for easy installation by any service man. In the Model R-123, two holes for mounting it are provided on the rear of the chassis so that the wave trap may be attached by means of the two self-tapping screws which are included in the kit. These holes are normally covered by the paper name plate, but they can easily be found by punching through the paper sticker with a point at the positions shown on the diagram.

On all other models, the trap should be screwed to the inside of the cabinet near the receiver antenna lead.

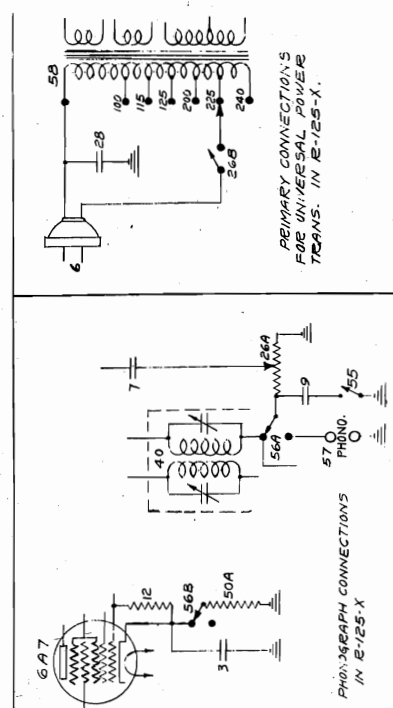

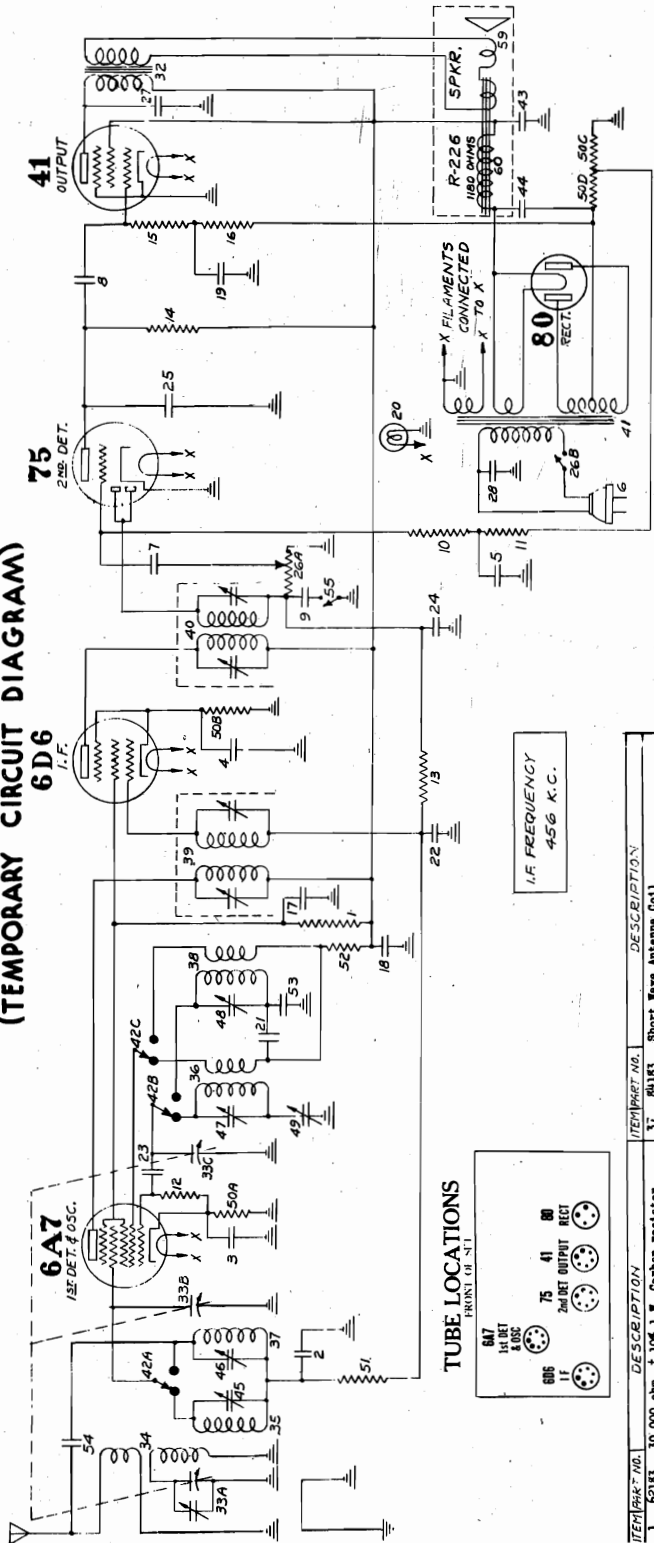

After mounting the trap, connect the blue antenna wire from the set to one of the wave trap leads and connect the antenna lead-in to the other wave trap lead.

Usually the wave trap will not require adjustment, but if some particular code station continues to cause excessive interference after installing the trap, it can be adjusted to diminish the unwanted signal. To make this adjustment, turn the slotted screw extending from the back of the wave trap with a screwdriver. Turn it slowly, first in one direction and then in the other, until the interfering signal disappears or has minimum volume.

Alignment Data

RADIO SERVICE NOTES - MODEL R-125 CHASSIS (RECEIVER MODELS 1251 TO 1259)NO. 3 - ALIGNMENT OF MODEL R-125 CHASSIS

Experience has definitely shown that a selective radio chassis such as the Stewart-Warner Model R-125 cannot be properly aligned by ear or "on the air." An output meter and a high grade modulated service oscillator are absolutely essential. The oscillator should be capable of generating the frequencies of 456 K.C., 600 K.C., 1400 K.C. and a short wave range extending to 4000 K.C. or more. This oscillator must provide a wide range of signal output -- very weak for proper alignment of the various bands so that the A.V.C. circuit will not be actuated and very strong for use when the receiver is badly out of adjustment or for shortwave alignment where harmonics are used.

When using your oscillator do not rely on calibration curves for frequency determination but check the frequencies by comparison with broadcast station signals.

PRELIMINARY STEPS.

To align the R-125 chassis, proceed as follows:

1. Remove the chassis from the cabinet.
2. Connect the output metal across the primary of the output transformer on the dynamic speaker. (Center and blue terminals)
3. Turn the volume control to maximum volume position.
4. For all adjustments use an all-bakelite aligning tool which has only a small meter screwdriver tip.
5. At all times during alignment use the lowest output meter scale which will provide a steady reading and adjust the oscillator output so that the output meter reads near the center of the scale.
6. Refer to the diagram for the location of trimmer condensers.

VERY IMPORTANT: In aligning all but the I.F. stages it is absolutely necessary to have a 400 to 500 ohm resistor in series with the antenna lead to the oscillator. Do not omit this resistor or the alignment will be incorrect!

I.F. ALIGNMENT

1. Set the test oscillator to exactly 456 K.C. Connect the output leads of oscillator from the 6A7 control grid to ground and set the range switch (right hand knob) to the broadcast position (clockwise). Carefully adjust the I.F. transformer trimmers No. 1,2,3, and 4 for maximum output meter deflection. Repeat the four adjustments since the adjustment of each trimmer has some effect on the others.

BROADCAST BAND ALIGNMENT

1. Check the position of the dial on the condenser shaft by pushing the rotor plates of the gang condenser to full mesh. The dial should then read 530 K.C. Please note that the plates should be pushed with the fingers and not turned by means of the dial for this check.

2. Turn the range switch (right hand knob) to the maximum clockwise position, which is the broadcast setting.

3. Whenever possible, use a broadcast station signal between 1300 and 1420 K.C. to calibrate the receiver dial. If no such station can be heard, you can use a 1400 K.C. signal from your oscillator provided that it is properly calibrated. To calibrate the set turn its dial to the exact frequency setting of the signal (either a station or the oscillator) then carefully adjust trimmer No. 5 (broadcast oscillator shunt trimmer) until the signal is tuned in with maximum volume at its correct frequency setting.

4. Connect a 400 or 500 ohm, 1 watt carbon resistor in series with the test oscillator output and the receiver antenna lead. This resistor must remain connected for all broadcast and short wave adjustments in order to secure proper alignment of the antenna stage. Ground the receiver chassis and connect the oscillator ground lead to the chassis.

5. Set the test oscillator to approximately 1400 K.C. and carefully tune the receiver to the signal. Adjust trimmer No. 6 (broadcast detector shunt trimmer) and trimmer No. 7 (broadcast pre-selector shunt trimmer) for maximum output meter reading. Retune the receiver and check the adjustments. Do not touch trimmer No. 5 since this will change the calibration.

6. Set the test oscillator to approximately 600 K.C. and tune the receiver to the signal. Adjust trimmer No. 8 (broadcast oscillator padding

MODELS 1251 to 1259
Chassis R-125 Series
Alignment Data, Part 3

STEWART WARNER CORP.

trimmer) to get maximum output meter deflection. Retune the receiver dial to a peak and readjust the trimmer. Continue this procedure of adjusting the trimmer and retuning the set until the output meter reading cannot be increased. This procedure must be followed or the receiver will not be properly aligned.

7. With a 1400 K.C. test oscillator signal, check alignment of trimmers No. 6 and 7.

SHORT WAVE BAND ALIGNMENT.

1. Turn the receiver range switch to the short wave band position (counter-clockwise).

2. Set the test oscillator to give a 16,000 K.C. signal. If your oscillator cannot reach this frequency, use the 2nd harmonic of 8,000 K.C., the third harmonic of 5333 K.C., or the fourth harmonic of 4000 K.C., all of which will give a 16,000 K.C. signal.

3. To calibrate this point turn the receiver dial to 16 M.C. on the inner dial scale and adjust Trimmer No. 9 (shortwave oscillator shunt trimmer) to give maximum output. Generally two peaks will be found. Align on the peak secured with the trimmer screw farthest out. Then adjust trimmer No. 10 (short-wave detector shunt trimmer) to a peak. After this is done, try detuning No. 10 in either direction and retune the receiver dial. If this gives a higher output, continue detuning No. 10 and retuning the dial until the maximum output meter reading is reached. If this procedure results in a lower output, detune the trimmer in the opposite direction and retune the dial, etc.

IMPORTANT: The antenna coupling condenser marked "A" in the diagram is adjusted to a definite capacity at the factory and should not require any further adjustment. Therefore do not adjust trimmer "A" unless it is found that trimmer No. 10 will not peak or if maximum output is obtained with No. 10 either all the way out or all the way in. If it is necessary to adjust trimmer "A" turn its adjusting screw all the way in and then turn it out just far enough to give a satisfactory peak on No. 10 when trimmer No. 10's adjusting screw is almost all the way out.

Always readjust No. 10 after adjusting trimmer "A".

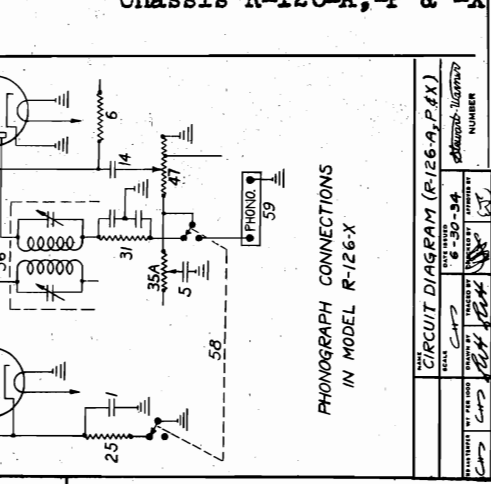

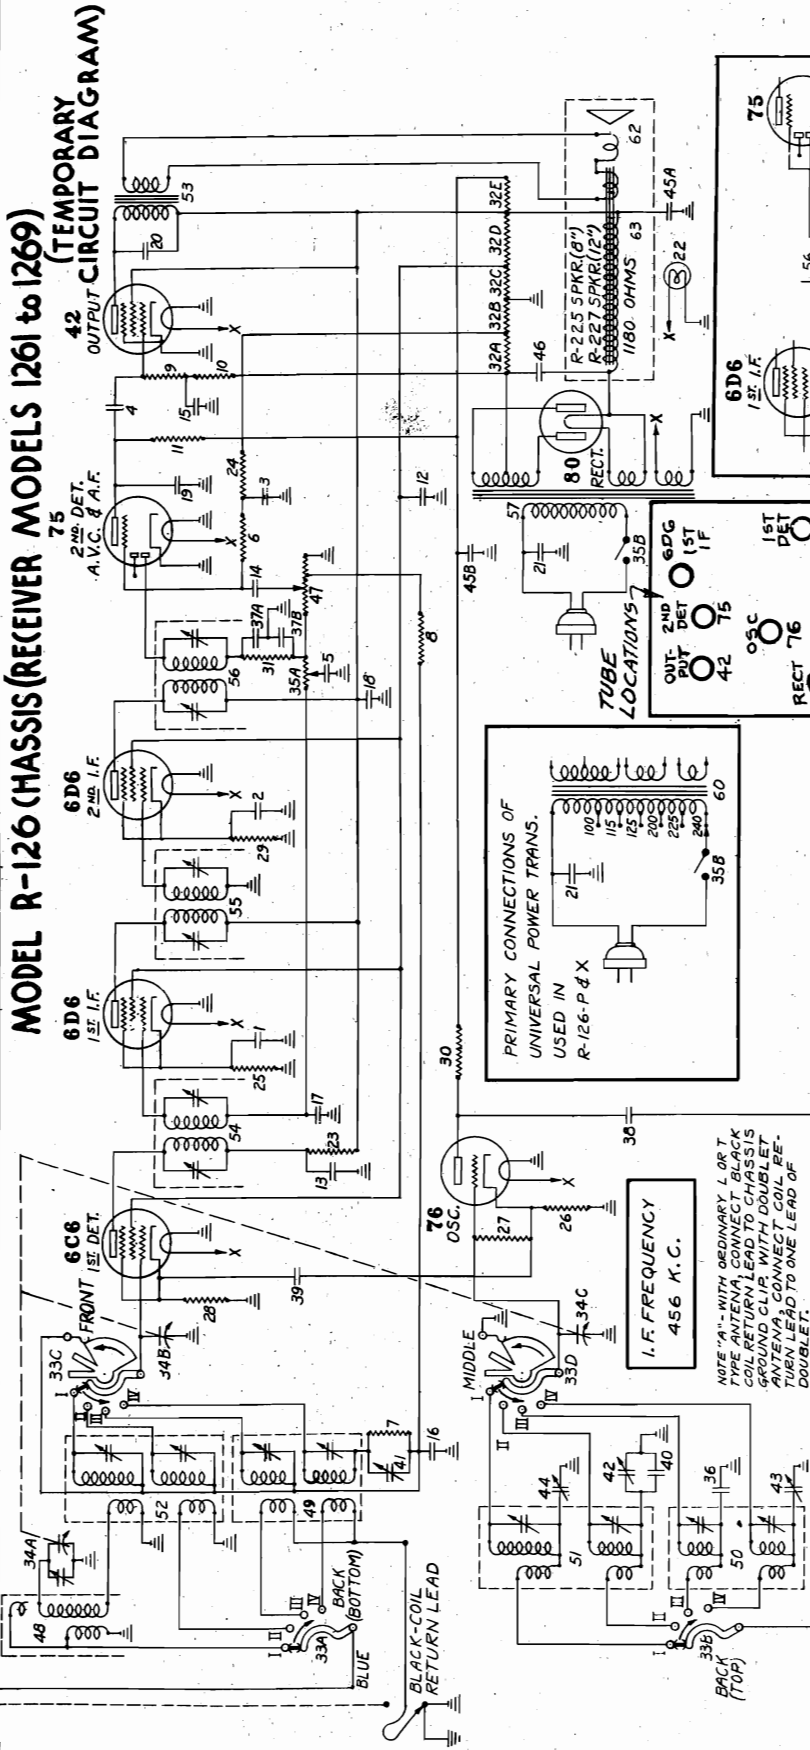

4. Tune the receiver to about 15.1 M.C. and check for the image signal which should be weaker than the 16.0 M.C. signal. If the image is as strong as the signal it shows that trimmer No. 10 is not properly adjusted. No signal at 15.1 M.C. but one at 16.9 M.C. shows that trimmer No. 9 is aligned on the image frequency and thus both No. 9 and 10 must be readjusted at the proper frequency.

Note: After completing the alignment, all of the trimmers except the padding and I.F. trimmers should be locked in place with Ambroid or some similar type cement in order that they will not be jarred out of adjustment.

RADIO SERVICE NOTES - MODEL R-126 CHASSIS (RECEIVER MODELS 1261 TO 1269)NO. 3 - ALIGNMENT OF MODEL R-126 CHASSIS

Experience has definitely shown that a selective radio chassis such as the Stewart-Warner Model R-126 cannot be properly aligned by ear or "on the air". An output meter and a high grade modulated service oscillator are absolutely essential. The oscillator should be capable of generating the frequencies of 456 K.C., 600 K.C., 1400 K.C. and a short wave range extending to 4000 K.C. or more. This oscillator must provide a wide range of signal output -- very weak for proper alignment of the various bands so that the A.V.C. circuit will not be actuated and very strong for use when the receiver is badly out of adjustment or for short wave alignment where harmonics are used.

When using your oscillator do not rely on calibration curves for frequency determination but check the frequencies by comparison with broadcast station signals.

PRELIMINARY STEPS

To align the R-126 chassis, proceed as follows:

1. Remove the chassis from the cabinet.
2. Connect the output meter across the primary of the output transformer on the dynamic speaker. (Center and blue terminals)
3. Turn the volume control to maximum volume position.
4. For all adjustments use an all-bakelite aligning tool which has only a small metal screw driver tip.
5. At all times during alignment use the lowest output meter scale which will provide a steady reading and adjust the oscillator output so that output-meter reads near the center of the scale.
6. Refer to the diagram for location of trimmer condensers.

VERY IMPORTANT: In aligning all but the I.F. stages it is absolutely necessary to have a 400 to 500 ohm resistor in series with the antenna lead to the oscillator. Do not omit this resistor or the alignment will be incorrect!

I.F. ALIGNMENT

1. Set the test oscillator to exactly 456 K.C. Connect the output leads of oscillator from the 6C6 control grid to ground and set the range switch (lower center knob) to the broadcast position (dial pointer on black dial scale). Carefully adjust the I.F. transformer trimmers No. 1, 2, 3, 4, 5 and 6 for maximum output meter deflection. Repeat the six adjustments since the adjustment of each trimmer has some effect on the others.

BROADCAST BAND ALIGNMENT

1. Check the position of the dial on the condenser shaft by pushing the rotor plates of the gang condenser to full mesh. The dial should then read 530 K.C. Please note that the plates should be pushed with the fingers and not turned by means of the dial for this check.

 - 18 3rd. Shortwave Band oscillator padding trimmer
 - 19 3rd. Shortwave Band detector padding trimmer

2. Turn the range switch (lower center knob) to the maximum counter-clockwise position, which is the broadcast setting.

3. Whenever possible, use a broadcast station signal between 1300 and 1420 K.C. to calibrate the receiver dial. If no such station can be heard, you can use a 1400 K.C. signal from your oscillator provided that it is properly calibrated. To calibrate the set, turn its dial pointer to the exact frequency setting of the signal (either a station or the oscillator). Carefully adjust trimmer No. 7 (broadcast oscillator shunt trimmer) until the signal is tuned in with maximum volume at its correct frequency setting.

4. Connect a 400 or 500 ohm, 1 watt carbon resistor in series with the test oscillator output and the receiver antenna lead. This resistor must remain connected for all broadcast and short wave adjustments in order to secure proper alignment of the antenna stage. Ground the receiver chassis and connect the oscillator ground lead to the chassis.

5. With the test oscillator adjusted to approximately 1400 K.C. carefully tune the receiver to the signal. Adjust trimmer No. 8 (broadcast detector shunt trimmer) and No. 9 (broadcast pre-selector shunt trimmer) for maximum output meter reading. Retune the receiver and check the adjustments. Do not touch trimmer No. 7 since this will change the calibration.

6. Set the test oscillator to approximately 600 K.C. and tune the receiver to the signal. Adjust the broadcast oscillator padding trimmer No. 10 to get maximum output meter deflection. Then retune the receiver dial to a peak and readjust the trimmer. Continue this procedure of adjusting the trimmer and retuning the set until the output meter reading cannot be increased. This procedure must be followed or the receiver will not be properly aligned.

7. With a 1400 K.C. test oscillator signal, check alignment of trimmers No. 8 and 9.

MODELS 1261 to 1269
Chassis R-126 Series STEWART WARNER CORP.
Alignment Data, Part 3

FIRST SHORT WAVE BAND ALIGNMENT

1. Turn receiver range switch to the first short wave band position (dial pointer on red dial scale).
2. Adjust the oscillator to exactly 4000 K.C.
3. To calibrate this point set the receiver dial pointer to 4000 K.C. on the red dial scale and adjust trimmer No. 11 (first shortwave band oscillator shunt trimmer) to a peak. If there are two peaks, the proper one is the one with the trimmer screw farthest out. Then tune trimmer No. 12 (first short wave band detector shunt trimmer) to a peak. Try detuning No. 12 in either direction and retune the receiver dial. If this gives a higher output meter reading, continue detuning No. 12 and retuning the dial until the maximum output meter reading is reached. If this procedure results in a lower output detune the trimmer in the opposite direction, retune the receiver, etc.
4. To check the above adjustment, leave the test oscillator set at 4.0 M.C. and increase its output. Then tune in the image signal at about 3.1 M.C. on the receiver dial. This image signal should be weak compared to the correct signal at 4.0 M.C. If it is almost as strong as the 4.0 M.C. signal, it is a sign that trimmer No. 12 is not properly adjusted and it will be necessary to repeat the procedure for aligning this trimmer. If no signal can be heard at 3.1 M.C. even with greatly increased oscillator output, tune the set at 4.9 M.C. A signal heard at this point shows that trimmer No. 11 is aligned on the image frequency and so both No. 11 and 12 must be readjusted at the proper signal frequency.
5. Set the test oscillator to about 1750 K.C. and tune the receiver to the signal. Adjust trimmer No. 13 (first shortwave band oscillator padding trimmer) for maximum output. Then retune the receiver dial to a peak and again adjust the trimmer. Continue this procedure of adjusting the trimmer and retuning the set until the output meter reading cannot be increased.
6. Check the alignment of trimmer 12 with a 4000 K.C. signal.

SECOND SHORT WAVE BAND ALIGNMENT

1. Turn the receiver range switch to the second short wave band position (dial pointer on green dial scale).
2. Adjust the test oscillator to exactly 12,000 K.C. If you cannot obtain this frequency on your oscillator, you may use the second harmonic of 6000 K.C., the third harmonic of 4000 K.C., or the fourth harmonic of 3000 K.C., all of which will give a 12,000 K.C. signal.
3. To calibrate, set the receiver dial pointer to 12 M.C. on the green dial scale and then adjust trimmer No. 14 (second shortwave band oscillator shunt trimmer) for maximum output. Generally two peaks will be found. Align on the one with the trimmer screw farthest out. Adjust trimmer No. 15 (second shortwave band detector trimmer) to a peak. After this is done, try to increase the output meter reading by detuning trimmer No. 15 and retuning the dial.

STEWART WARNER CORP.

MODELS 1261 to 1269
Chassis R-126 Series
Alignment Data, Part 4

4. Tune the receiver to about 11.1 M.C. and check for reception of the image which should be weaker than the 12.0 M.C. signal. If the image is almost as strong as the correct signal, it shows that trimmer No. 15 has not been properly adjusted. If the signal cannot be heard at 11.1 M.C., but can be received at 12.9 M.C., then trimmer No. 14 is aligned on the image frequency and No. 14 and 15 must be realigned at the proper signal frequency.

THIRD SHORT WAVE BAND ALIGNMENT

1. Turn the receiver range switch to the third short wave band (pointer on purple dial scale).

2. Set the test oscillator to give a 20,000 K.C. signal. If your oscillator cannot reach this frequency, use the 2nd harmonic of 10,000 K.C., the third harmonic of 6666 K.C., the fourth harmonic of 5000 K.C., or the fifth harmonic of 4000 K.C., all of which will give a 20,000 K.C. signal.

3. To calibrate this point, turn the receiver dial pointer to 20 M.C. on the purple dial scale and adjust trimmer No. 16 (third shortwave band oscillator shunt trimmer) to give maximum output. If there are two peaks, align on the one with the trimmer screw farthest out. Then adjust trimmer No. 17 (third shortwave band detector shunt trimmer) to a peak. After this is done, try to increase the output meter reading by detuning No. 17 and retuning the receiver dial.

4. Tune the receiver to about 19.1 M.C. and check for the image signal which should be weaker than the 20.0 M.C. signal. If the image is almost as strong as the signal, it indicates that trimmer No. 17 has not been properly adjusted. No signal at 19.1 M.C. but one at 20.9 M.C. shows that trimmer No. 16 is aligned on the image frequency and thus both No. 16 and 17 must be readjusted.

5. Adjust test oscillator to 12,000 K.C., or use the second harmonic of 6000 K.C., the third harmonic of 4000 K.C., or the fourth harmonic of 3000 K.C., all of which will give a 12000 K.C. signal.

Calibrate this point by setting the dial pointer to 12.0 M.C. on the purple scale and adjusting trimmer No. 18 (third shortwave band oscillator padding trimmer) to give maximum output. Retune the dial and then adjust trimmer No. 19 (third shortwave band detector padding trimmer) to a peak. Retune the dial and readjust No. 19. Repeat this procedure of adjusting No. 19 and retuning the dial until it does not increase the output meter reading.

6. Check the reception of the image signal at 11.1 M.C. If the image is almost as strong as the 12 M.C. signal but was found to be satisfactory at 19.1 M.C. with a 20,000 K.C. signal, No. 18 or 19 are aligned on the wrong peak and should be readjusted.

7. Check adjustment of No. 17 with a 20,000 K.C. signal.

NOTE: To prevent the trimmers from being jarred out of adjustment, use Ambroid or some similar cement to fasten the trimmer screws in position after completing the alignment. This should be done to all adjusting screws except the padding and I.F. trimmers.

RADIO SERVICE NOTES - MODEL R-127 CHASSIS (RECEIVER MODELS 1271 TO 1279)

NO. 3 - ALIGNMENT OF MODEL R-127 CHASSIS

Experience has definitely shown that a selective radio chassis such as the Stewart-Warner Model R-127 cannot be properly aligned by ear or "on the air". An output meter and a high grade modulated service oscillator are absolutely essential. The oscillator should be capable of generating the frequencies of 456 K.C., 600 K.C., 1400 K.C., and a short wave range extending to 4000 K.C. or more. This oscillator must provide a wide range of signal output -- very weak for proper alignment of the various bands so that the A.V.C. circuit will not be actuated and very strong for use when the receiver is badly out of adjustment or for shortwave alignment where harmonics are used.

When using your oscillator do not rely on calibration curves for frequency determination but check the frequencies by comparison with broadcast station signals.

PRELIMINARY STEPS

To align the R-127 chassis proceed as follows:

1. Remove the chassis from the cabinet.
2. Connect the output meter across the primary of the output transformer on the dynamic speaker. (Center and blue terminals)
3. Turn the volume control to maximum volume position.
4. For all adjustments use an all-bakelite aligning tool which has only a small metal screw driver tip.
5. At all times during alignment use the lowest output meter scale which will provide a steady reading and adjust the oscillator output so that output meter reads near the center of the scale.
6. Refer to the diagram for the location of the trimmer condensers.

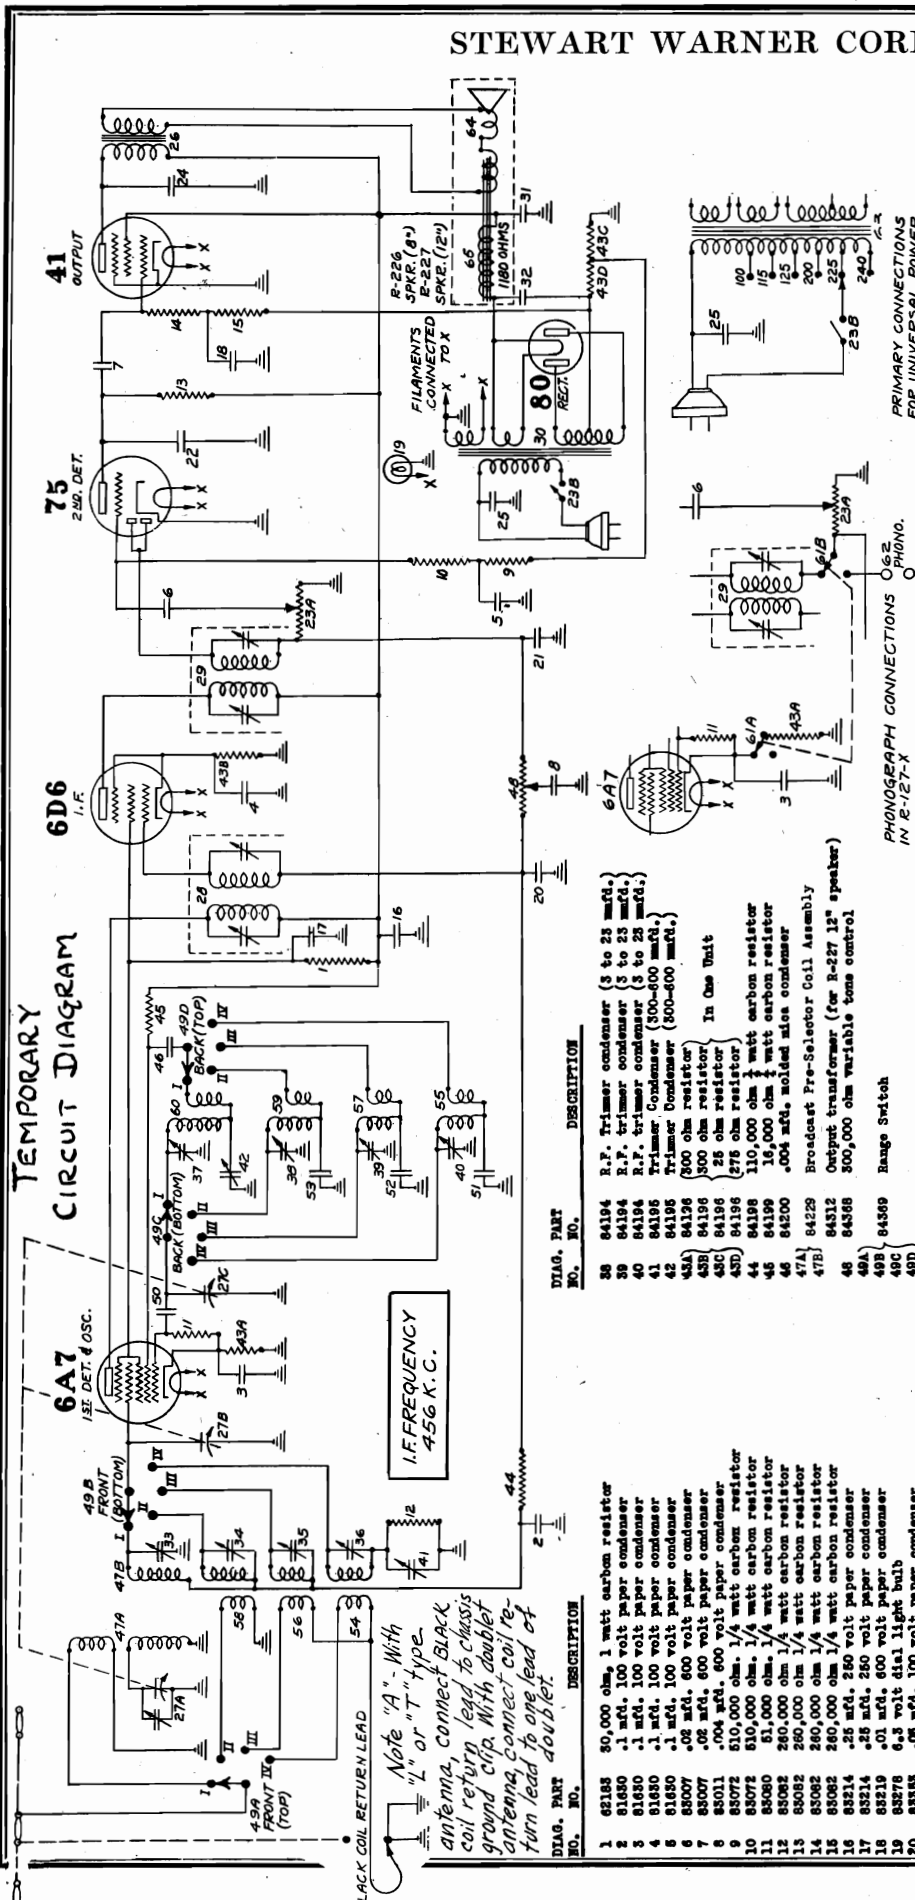

VERY IMPORTANT: In aligning all but the I.F. stages it is absolutely necessary to have a 400 to 500 ohm resistor in series with the antenna lead to the oscillator. Do not omit this resistor or the alignment will be incorrect!

I.F. ALIGNMENT

1. Set the test oscillator to exactly 456 K.C. Connect the output loads of oscillator from the 6A7 control grid to ground and set the range switch (right hand knob) to the broadcast position (fully clockwise). Carefully adjust the I.F. transformer trimmers No. 1, 2, 3, and 4 for maximum output meter deflection. Repeat the four adjustments since the adjustment of each trimmer has some effect on the others.

BROADCAST BAND ALIGNMENT

1. Check the position of the dial on the condenser shaft by pushing the rotor plates of the gang condenser to full mesh. The dial should then read 5.3 (530 K.C.). Please note that the plates should be pushed with the fingers and not turned by means of the dial for this check.

2. Turn the range switch (right hand knob) to the maximum clockwise position, which is the broadcast setting.

3. Whenever possible, use a broadcast station signal between 1300 and 1420 K.C. to calibrate the receiver dial. If no such station can be heard, you can use a 1400 K.C. signal from your oscillator provided it is accurately calibrated. To calibrate the set, turn its dial to the exact frequency setting of the signal (either a station or the oscillator). Then carefully adjust trimmer No. 5 (broadcast oscillator shunt trimmer) until the signal is tuned in with maximum volume at its correct frequency setting.

4. Connect a 400 or 500 ohm, 1 watt carbon resistor in series with the test oscillator output and the receiver antenna lead. This resistor must remain connected for all broadcast and short wave adjustments in order to secure proper alignment of the antenna stage. Ground the receiver chassis and connect the oscillator ground lead to the chassis.

5. With the test oscillator adjusted to approximately 1400 K.C., carefully tune the receiver to the signal. Adjust trimmer No. 6 (broadcast detector shunt trimmer) and No. 7 (broadcast pre-selector shunt trimmer) for maximum output meter reading. Retune the receiver and check the adjustments. Do not touch trimmer No. 5 since this will change the calibration.

STEWART WARNER CORP.

MODELS 1271 to 1279
Chassis R-127 Series
Alignment Data, Part 3

6. Set the test oscillator to approximately 600 K.C. and tune the receiver to the signal. Adjust trimmer No. 8 (broadcast oscillator padding trimmer) to get maximum output meter deflection. Then retune the receiver dial to a peak and readjust the trimmer. Continue this procedure of adjusting the trimmer and retuning the set until the output meter reading cannot be increased. This procedure must be followed or the receiver will not be properly aligned.

7. With a 1400 K.C. test oscillator signal, check alignment of trimmers No. 6 and 7.

FIRST SHORT WAVE BAND ALIGNMENT

1. Turn receiver range switch to the first short wave band position, which is the third position of the right hand knob when turning it in a clockwise direction.

2. Adjust the oscillator to exactly 4000 K.C.

3. To calibrate this point set the receiver dial to 4.0 megacycles on the red dial scale and adjust trimmer No. 9 (first shortwave band oscillator shunt trimmer) to a peak. If there are two peaks, the proper one is the one with the trimmer screw farthest out. Then tune No. 10 (first shortwave band detector shunt trimmer) to a peak. Try detuning No. 10 in either direction and retune the receiver dial. If this gives a higher output meter reading, continue detuning No. 10 and retuning the dial until the maximum output meter reading is reached. If this procedure results in a lower output detune the trimmer in the opposite direction and retune the receiver to secure the maximum output.

4. To check the above adjustment, leave the test oscillator set at 4.0 M.C. and increase its output. Then tune in the image signal at about 3.1 M.C. on the receiver dial. This image signal should be weak compared to the correct signal at 4.0 M.C. If it is almost as strong as the 4.0 M.C. signal, it is a sign that trimmer No. 10 is not properly adjusted and it will be necessary to repeat the procedure for aligning this trimmer. If no signal can be heard at 3.1 M.C. even with greatly increased oscillator output, tune the set to 4.9 M.C. A signal heard at this point, shows that trimmer No. 9 is aligned on the image frequency and so both No. 9 and 10 must be readjusted at the proper signal frequency.

SECOND SHORT WAVE BAND ALIGNMENT

1. Turn the receiver range switch to the second short wave band position, which is the second position in a clockwise direction.

2. Adjust the test oscillator to exactly 12,000 K.C. If you cannot obtain this frequency on your oscillator, you may use the second harmonic of 6000 K.C., the third harmonic of 4000 K.C., or the fourth harmonic of 3000 K.C., all of which will give a 12,000 K.C. signal.

3. To calibrate this point turn the receiver dial to 12 M.C. on the green dial scale and then adjust trimmer No. 11 (second short wave band oscillator shunt trimmer). Generally, there will be two peaks, so align on the one with the trimmer screw farthest out. Adjust trimmer No. 12 (second shortwave detector shunt trimmer) to a peak. After this is done, try to increase the output meter deflection by detuning trimmer No. 12 and retuning the receiver dial. Continue detuning No. 12 and retuning the dial until the maximum output meter reading is reached.

MODELS 1271 to 1279
Chassis R-127 Series
Alignment Data, Part 4

STEWART WARNER CORP.

4. Tune the receiver to about 11.1 M.C. and check for reception of the image signal which should be weaker than the 12.0 M.C. signal. If the image is almost as strong as the 12 M.C. signal, it shows that No. 12 is not adjusted properly. If the signal cannot be heard at 11.1 M.C., but can be received at 12.9 M.C., then trimmer No. 11 is aligned on the image frequency and No. 11 and 12 must be realigned at the proper signal frequency.

THIRD SHORT WAVE BAND ALIGNMENT

1. Turn the receiver range switch to the third shortwave band position, which is the furthest counter-clockwise position.

2. Set the test oscillator to give a 20,000 K.C. signal. If your oscillator cannot reach this frequency, use the 2nd harmonic of 10,000 K.C., the third harmonic of 6666 K.C., the fourth harmonic of 5000 K.C., or the fifth harmonic of 4000 K.C., all of which will give a 20,000 K.C. signal.

3. To calibrate this point turn the receiver dial to 20 M.C. on the purple dial scale and adjust Trimmer No. 13 (third shortwave band oscillator shunt trimmer) to give maximum output. Generally there will be two peaks, so align on the one with the trimmer screw farthest out. Then adjust trimmer No. 14 (third short wave band detector shunt trimmer) to a peak. After this is done, try to increase the output meter deflection by detuning No. 14 and retuning the receiver dial. Continue detuning No. 14 and retuning the dial until the maximum output meter reading is reached.

4. Tune the receiver to about 19.1 M.C. and check for the image signal which should be weaker than the 20.0 M.C. Signal. If the image is almost as strong as the 20 M.C. signal, it shows that No. 14 is not adjusted correctly. No signal at 19.1 M.C. but one at 20.9 M.C. shows that trimmer No. 13 is aligned on the image frequency and thus both No. 13 and 14 must be readjusted.

5. Adjust test oscillator to 12,000 K.C., or use the second harmonic of 6000 K.C., the third harmonic of 4000 K.C., or the fourth harmonic of 3000 K.C., all of which will give a 12,000 K.C. signal. Carefully tune the dial to the signal at about 12 M.C. on the purple dial scale. Adjust trimmer No. 15 (third shortwave band detector padding trimmer) for maximum output meter reading and then retune the dial. Repeat this procedure of adjusting the trimmer and retuning the dial until it does not increase the output meter reading.

6. Check reception of the image signal at 11.1 M.C. If the image is almost as strong as the 12 M.C. signal, but was found to be satisfactory at 19.1 M.C. with a 20,000 K.C. signal, No. 15 should be readjusted.

7. Check the adjustment of No. 14 with a 20,000 K.C. signal.

NOTE: To prevent the trimmers from being jarred out of adjustment use Ambroid or some similar cement to fasten the trimmer screws in position after completing the alignment. This should be done to all trimmers except the padding and I.F. trimmers.

STROMBERG-CARLSON TEL. MFG. CO.

MODEL 60
Specifications
Schematic

Stromberg-Carlson No. 60 Type Radio Receivers

ELECTRICAL SPECIFICATIONS

Type of Circuit	Superheterodyne
Tuning Ranges	540—1570 k. c. and 5.5 to 15.5 mc.
Type and Number of Tubes	1 No. 6D6, 1 No. 6A7, 1 No. 6B7, 1 No. 37, 2 No. 41, 1 No. 80
Voltage Rating	105-125 volts
Frequency Rating	50-60 Cycles
Power Consumption Rating	80 Watts

CIRCUIT DESCRIPTION

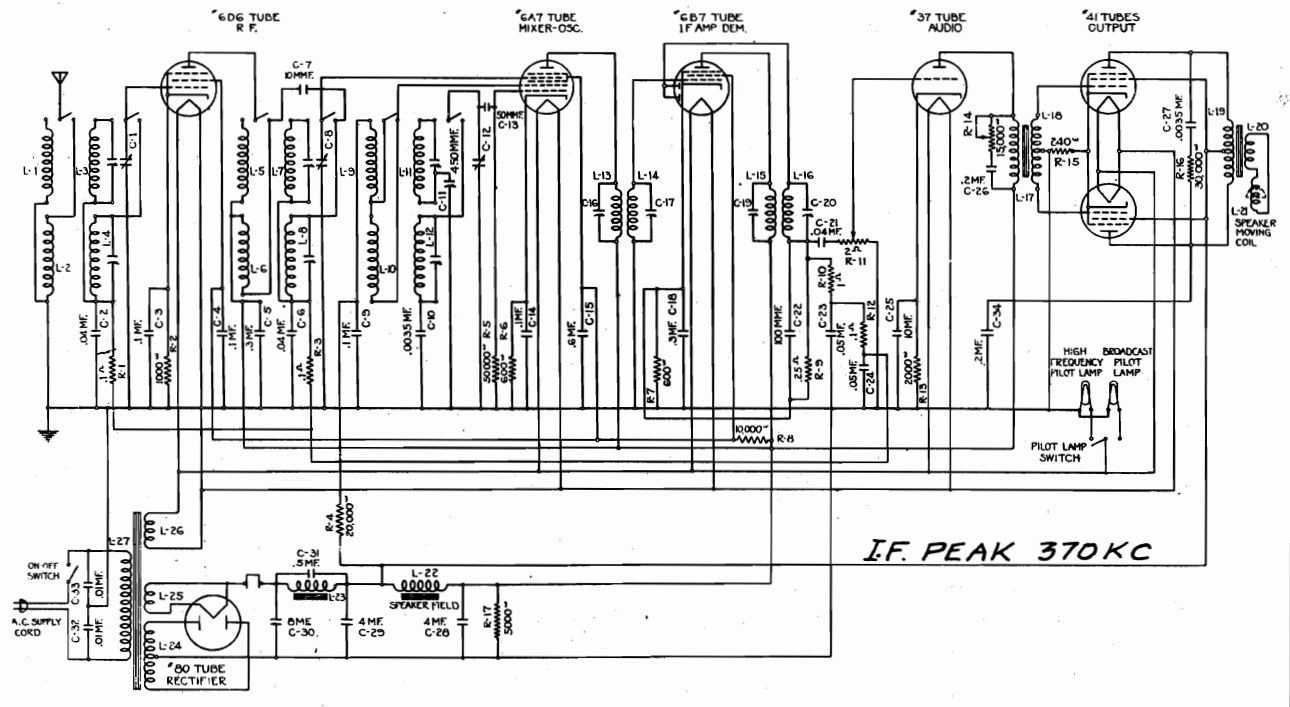

These receivers are seven tube A. C. operated Superheterodynes with two tuning ranges; standard broadcast and short-wave broadcast. See P-24418 Instructions for Installation and Operation to details of controls, installation and operating procedure.

The No. 6D6 tube is used as the R. F. amplifier. The No. 6A7 tube is used for the oscillator-mixer. The No. 6B7 tube serves as the I. F. amplifier, A. V. C., and demodulator. The No. 37 tube is the first audio amplifier and the two No. 41 tubes function as the power output stage. The No. 80 is the rectifier in the power supply circuit.

NORMAL VOLTAGE READINGS

These voltage readings are obtained by measuring between the various tube socket contacts and the bases with the tubes and speaker plug in place. The set is therefore in operation when the measurements are made. Fig. 2 shows the terminal layout of the sockets with the proper terminal numbers. The terminals of each socket are numbered, starting with one heater or filament pin and proceeding around the pin circle clockwise to the other heater or filament pin. This is done looking at the bottom of the socket. Tune Receiver to 1500 k. c.

Voltages are given for a line voltage of 120 volts and allowance should be made for differences when the line voltage is higher or lower. A meter with a resistance of 1,000 ohms per volt should be used for measuring the D. C. voltages. The Volume Control should be set all "On" (clockwise) before measuring voltages. See page 2.

Stromberg-Carlson No. 68 All-Wave Radio Receiver

STROMBERG-CARLSON TELEPHONE MANUFACTURING COMPANY
 Rochester, New York

ELECTRICAL SPECIFICATIONS

Type of Circuit	Superheterodyne
Tuning Ranges	A—520 to 1500 kc.; B—1400 to 4200 kc.; C—3.7 to 10.5 mc.; D—8.9 to 25 mc.
Type and Number of Tubes	2 No. 6D6, 1 No. 6A7, 1 No. 6B7, 1 No. 5Z3, 3 No. 42, 1 No. 76, 1 No. 85
Voltage Rating	105-125 Volts
Frequency Rating	50-60 Cycles
Power Consumption Rating (Maximum line voltage)	160 Watts
Intermediate Frequency	370 kc.

CIRCUIT DESCRIPTION

This receiver is a ten tube A. C. operated all-wave superheterodyne having four tuning ranges. See P-24689, Installation and Operating Instructions, for installation and operating procedure.

One No. 6D6 tube is used as an R. F. amplifier, the No. 6A7 tube is used as a modulator, and the No. 76 acts as the oscillator in the Tuner Unit. In the Amplifier Chassis the other No. 6D6 acts as the I. F. amplifier. The No. 6B7 is in the A. V. C. circuit, while the No. 85 acts as demodulator and first audio amplifier. One No. 42 operates as a second or driver audio stage and the other two constitute the power output stage. The No. 5Z3 is the rectifier in the power supply.

NORMAL VOLTAGE READINGS

These voltage readings are obtained by measuring between the various tube socket contacts and the bases with the tubes in place. The Receiver is therefore in operation when the measurements are made. Fig. 1 shows the terminal layout of the sockets with the proper terminal numbers. The terminals of each socket are numbered, starting with one heater or filament pin and proceeding around the pin circle clockwise to the other heater or filament pin. This is done looking at the bottom of the socket.

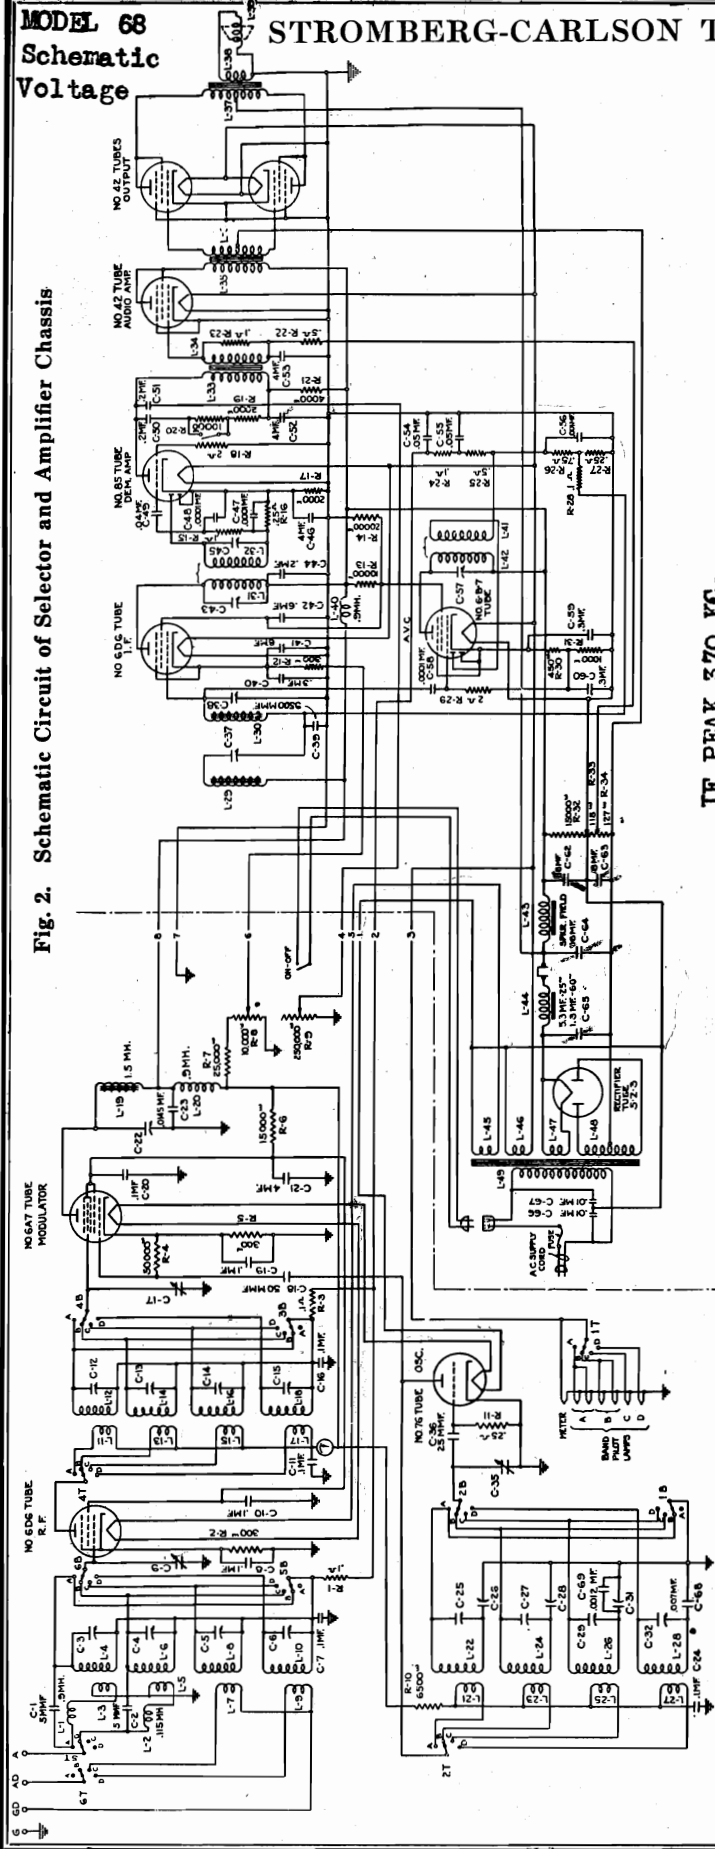

Voltages are given for a line voltage of 119 volts and allowance should be made for differences when the line voltage is higher or lower. A meter with a resistance of 1,000 ohms per volt should be used for measuring the D. C. voltages. See page 2.

ELECTRICAL SPECIFICATIONS

Type of Circuit.....	Superheterodyne Frequency Changer
Tuning Ranges (in Selector).....	B—1430 to 4200 kc.; C—3.7 to 10.5 mc.; D—9 to 25 mc.
Type and Number of Tubes.....	1 No. 6D6 1 No. 6A7, 1 No. 76, 1 No. 84
Voltage Rating.....	105-125 Volts
Frequency Rating.....	50-60 Cycles
Power Consumption Rating.....	28 Watts
Frequency of Signal Output to Receiver.....	545 Kc.

CIRCUIT DESCRIPTION

The No. 69 All-Wave Selector contains the frequency changer circuits of a superheterodyne system which connected to the input (Ant. and Gnd. connections) of a good standard broadcast receiver gives an extension of the tuning range from 1500 kilocycles to 25 megacycles. Thus all frequencies between 550 kilocycles and 25 megacycles can be readily tuned. See P-24692 Installation and Operating Instructions for details of controls, installation and operating procedures.

The No. 6D6 tube is used as the R. F. Amplifier. The No. 6A7 tube is used as the Modulator. The No. 76 tube is used as the Oscillator. The No. 84 tube is the Rectifier in the self-contained power supply.

NORMAL VOLTAGE READINGS

These voltage readings are obtained by measuring between the various tube socket contacts and the bases with the tubes in place. The Selector is therefore in operation when the measurements are made. Fig. 2 shows the terminal layout of the sockets with the proper terminal numbers. The terminals of each socket are numbered, starting with one heater or filament pin and proceeding around the pin circle clockwise to the other heater or filament pin. This is done looking at the bottom of the socket.

Voltages are given for a line voltage of 120 volts and allowance should be made for differences when the line voltage is higher or lower. A meter with a resistance of 1,000 ohms per volt should be used for measuring the D. C. voltages. See page 2.

ALIGNMENT- Connect a test oscillator to the antenna wire of the receiver and set the oscillator and receiver to 1400 K.C. Adjust either trimmer on the tuning condenser for maximum output.

MODEL TC-20, TC-21

Alignment Data

TRANSFORMER CORP. OF AMER. (New Co.)

Parts List

ALIGNMENT PROCEDURE: Only when an IF transformer, antenna or oscillator coil is replaced should it ever be necessary to realign the receiver. For aligning either the intermediate transformer or the variable condenser it is absolutely necessary that a good accurate calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 2A7 tube leaving the grid cap disconnected. The ground side of the oscillator should be connected to the receiver chassis.
2. Set the oscillator at 465 kilocycles (this must be accurate) and adjust the output of the oscillator so that a convenient reading is obtained on the output meter.
3. Align the first intermediate transformer by turning the intermediate transformer brass hex adjusting nut located on top of the intermediate transformer can up and down until maximum reading is obtained on the output meter. Then adjust the trimmer screw located inside the brass hex nut for maximum output.
4. Adjust the second I. F. transformer in the same manner as the first I. F. transformer.

VARIABLE CONDENSER ALIGNMENT: It is essential that the following instructions be carefully adhered to in the order given otherwise the receiver will be insensitive and the dial calibration will be inaccurate.

1. Connect the high side of the oscillator output to the set antenna lead and the oscillator ground to the receiver chassis.
2. Place the band selector switch for operation on the 16 to 5.2 megacycle band.
3. Set the oscillator frequency to exactly 15 megacycles and adjust the receiver dial to exactly 15 megacycles. Then BRING IN THE 15 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE trimmer condenser of the oscillator gang condenser section. The oscillator trimmer condenser is mounted on top of the rear section of the variable condenser. The front section of the variable condenser tunes the antenna stage.
4. Place the band selector switch for operation on the 1715 to 535 kilocycle band, set the oscillator to exactly 1400 kilocycles and tune the receiver dial to 1400 kilocycles. BRING IN THIS 1400 KILOCYCLE SIGNAL BY ADJUSTING THE SMALL TRIMMER CONDENSER which is located underneath near the center and towards the front of the chassis.
5. Next adjust the antenna variable gang condenser section trimmer condenser for maximum output (front section).
6. Leave the receiver operating on the same band and set the oscillator frequency to approximately 600 kilocycles and adjust the dial to approximately 600 kilocycles. Then while rocking the variable condenser slightly to the right and left, adjust the 600 kilocycle padding condenser which is located below the speaker and accessible through the front of the chassis for maximum output.
7. Recheck the 1400 kilocycle adjustment.
8. Place the band selector switch for operation on the 16 to 5.2 megacycle band and tune the dial to exactly 15 megacycles and set the oscillator frequency to 15 megacycles. Then adjust the trimmer condenser which is located underneath and toward the center of the right hand side of the chassis for maximum output.

This completes the alignment procedure and it is suggested that all the adjustments be rechecked.

IF PEAK 175 KC.

R-F. ADJUSTMENT: Remove chassis from case, couple the output of a modulated oscillator from antenna to ground, set the dial at 1400 and the oscillator at 1400 KC.

Place the oscillator and receiver in operation and adjust the oscillator output so that a weak signal is heard in the loudspeaker when the volume control is at its maximum position.

Adjust trimming condensers, starting with C3, C2 and then C1, until maximum output is obtained. Readjust a second time as there is a slight interlocking of adjustments. Greater accuracy can be obtained with an output meter.

I-F. ADJUSTMENT: The four I-F. trimming condensers are adjusted at 175 KC.

Connect a modulated oscillator set at 175 KC. between the first detector grid and ground. Connect output meter.

Adjust the tuning condenser so that no signal except the I-F. oscillator is heard at maximum volume, with the volume control set at maximum, reduce the output of the oscillator until a small deflection is obtained. Unless this is done, the AVC action will make correct adjustments impossible.

Trim in order C4, C5, C6 and C7. Repeat adjustments and then follow with the R-F. adjustments.

Alignment Data
Parts List

TRANSFORMER CORP. OF AMER. (New Co.)

The action of the A.V.C. will defeat the purpose of an output meter if used in the normal manner. To obviate this, the oscillator output should be turned to as low a setting as will cause a reading on the output meter with the volume control on the set turned to maximum. This will allow the out meter to function correctly. Adjust the test oscillator to 456 K.C. and connect to the grid cap of the 6A7 tube and adjust the trimmers on the three I.F. stages. (There are two adjustments in each coil; a screw and a nut.)

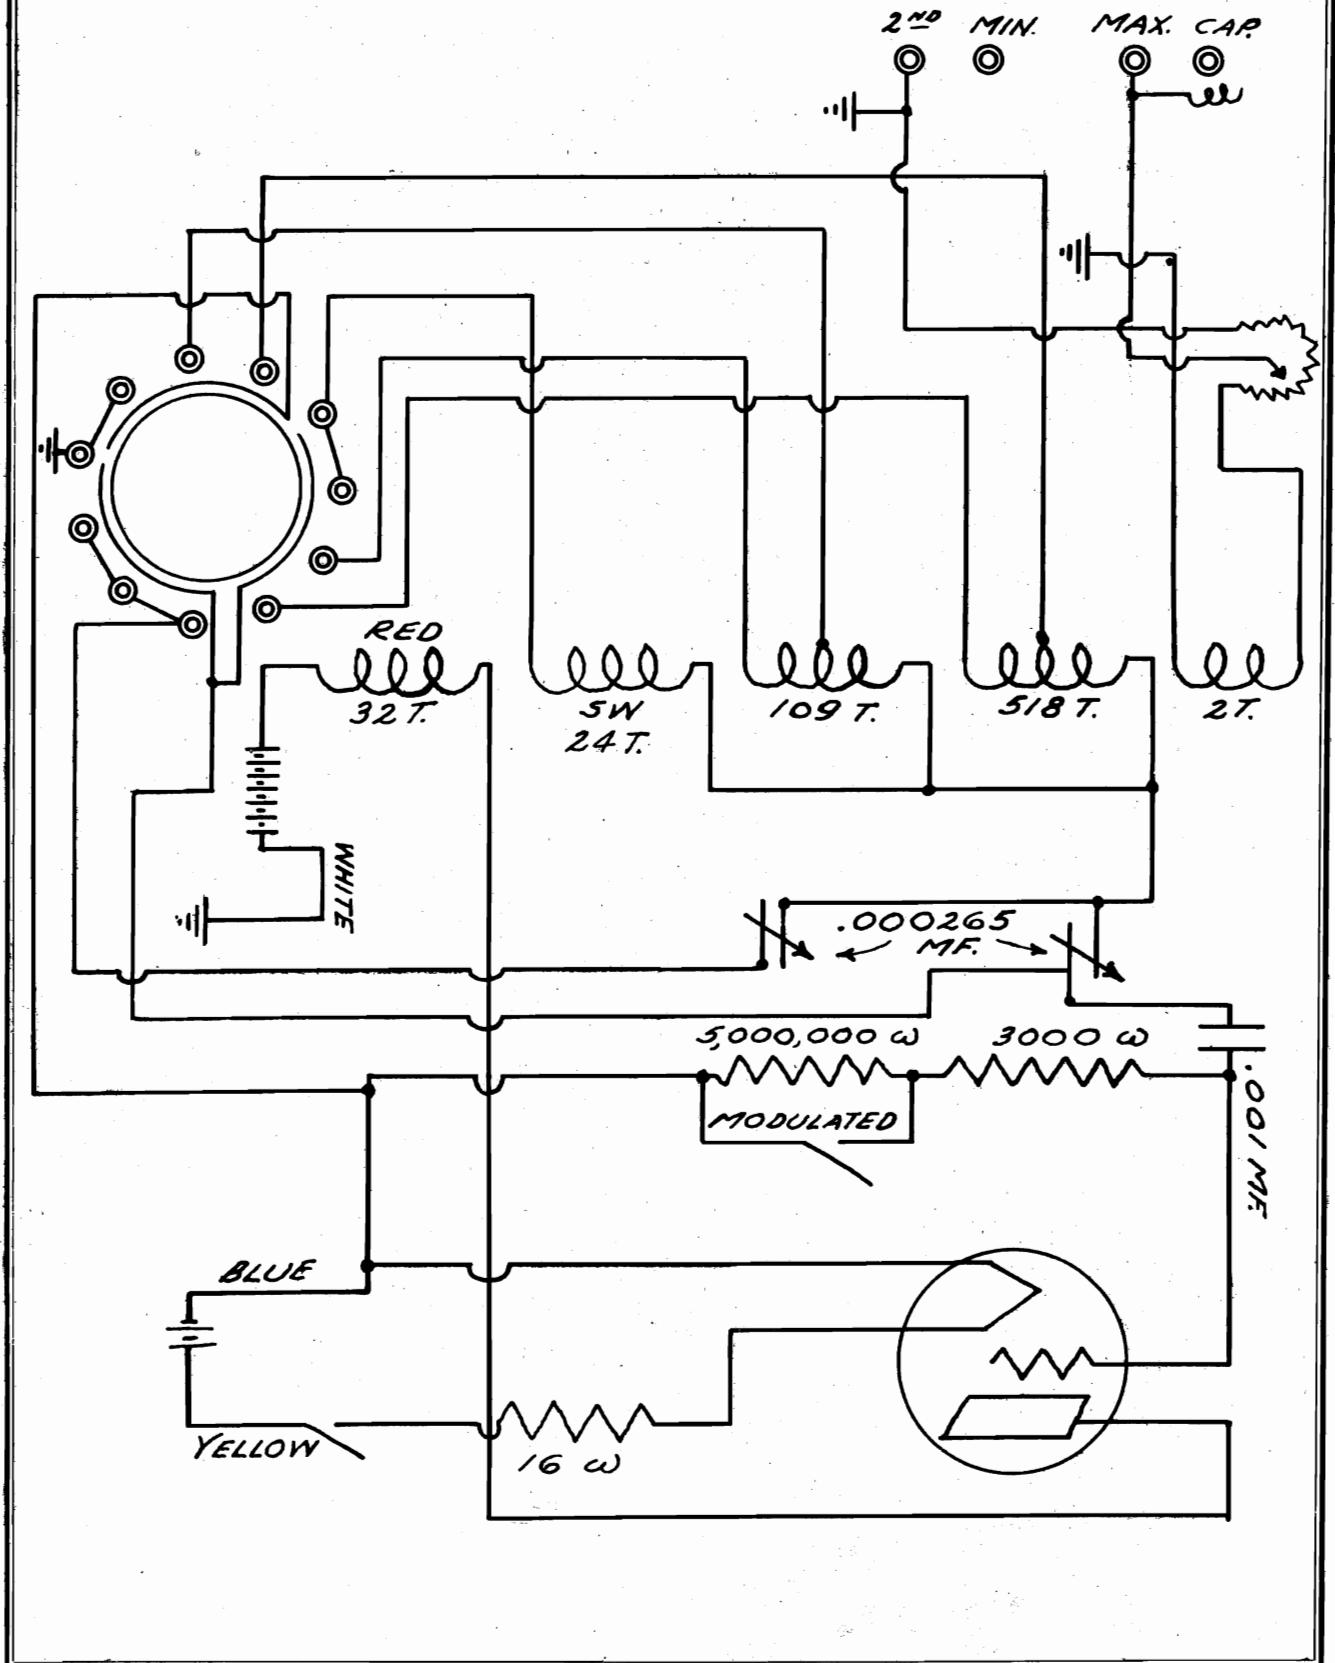

R.F. ALIGNMENT-Connect oscillator to antenna wire on set and adjust oscillator to 1400 K.C. Set receiver dial to 1400 K.C. and wave band switch to the broadcast position. Adjust output of oscillator as outlined under I.F. alignment. Adjust trimmers on sections 1 and 2 for maximum output. Then adjust section 3 of the variable condenser for maximum output. The oscillator padder condenser is the center one of three located on the back of the chassis. In the event that the oscillator section does not track through the broadcast band; this trimmer should be adjusted.

No adjustments are necessary on the other wave bands. All the coils are correctly matched so that they will be in alignment if the above adjustments are correctly made.

ADJUSTING AND ALIGNING INSTRUCTIONS

All of the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustments unless a coil or I.F. transformer is changed, or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a test oscillator is available, then proceed as follows:

1. Connect output meter across voice coil of speaker terminals #49 and #51 (Fig. #1).
2. Set test oscillator at 175 kilocycles (using .1 mfd. antenna condenser).
3. Connect test oscillator lead to grid of the first I. F. tube.
4. Adjust condenser on primary of second I. F. transformer on top of set to peak on output meter.
5. Connect test oscillator lead to grid of first detector tube.
6. Adjust condenser on primary of first I. F. transformer (under set) to peak.
7. Adjust condenser on secondary of first I.F. transformer to peak. (There are two small holes on side of housing for adjustment #6 and #7.)

The above procedure lines up the I. F. stages properly and our attention can now be turned to the oscillator and R. F. adjustments, which are made as follows:

1. Set test-oscillator at 1500 kilocycles (using .1 mfd. antenna condenser).
2. Connect test-oscillator lead to grid of first detector.
3. Set gang condenser at 1500 kilocycles as follows:
 - (a) Open gang to fullest extent.
 - (b) Close slowly to thickness of approximately .015".
4. Peak oscillator trimmer on end of condenser gang.
5. Set test-oscillator at 1400 kilocycles.
6. Connect test-oscillator to antenna lead (using .0002 mfd. antenna condenser).
7. Peak other two condensers on gang.
8. Do not touch oscillator trimmer at 1400 kilocycles setting of gang.

This set should now be fully aligned and normal sensitivity prevail.

UNITED AMERICAN BOSCH CORP.

Testing Data
Parts List

TESTING

(d) SPEAKER: Check field supply with voltohmmeter at speaker, reading between points #49 and #50 (Fig. #1) on speaker terminals (5.8 volts or over). Unsolder blue lead from speaker (#51) and test across terminals #49 and #51 for continuity of voice coil. (Reading full scale ohmmeter.)

(e) SECONDARY OUTPUT TRANSFORMER: After unsoldering blue lead from terminal (#51) Fig. #1, test with ohmmeter between blue lead and terminal #49 (full scale reading - ohmmeter).

(f) CHASSIS: After checking the components listed above, test the voltages as they appear on voltage chart and Fig. #4. The resistance measurements as found in "Resistance Chart" and Fig. #5. If any particular reading obtained is very different from the chart reading, the trouble is located in the portion of the circuit associated with the points at which this discrepancy occurs. Referring to circuit diagram and location drawings (Figs. #1, #2, #3), each part making up the circuit may be individually tested until the faulty part is specifically located.

 Data

UNITED AMERICAN BOSCH CORP.

The tubes employed in this circuit are as follows:

- 1 type 77 radio frequency amplifier.
- 1 type 77 detector oscillator.
- 1 type 78 intermediate frequency amplifier.
- 1 type 75 second detector, A.V.C. and audio amplifier.
- 1 type 41 output tube.

The antenna is coupled to the first stage by means of a transformer. The R.F. stage is coupled to the oscillator by means of a transformer. Resistance coupling is employed between the audio portion of the type 75 tube and the output tube. The first I.F. transformer is doubly tuned and the second I.F. transformer has a tuned primary.

Automatic volume control is provided by utilizing the potential drop in the collector circuit of the type 75 tube. The A.V.C. is made a part of the D.C. grid circuits of the R.F. amplifier and the I.F. amplifier. The intermediate frequency employed is 175 kilocycles.

An electro-dynamic speaker is used with this set. This speaker has a field resistance of 4 ohms and a voice coil resistance of 3.9 ohms.

Automatic volume control is provided by utilizing the potential drop in the collector circuit of the type 75 tube. The A.V.C. is made a part of the D.C. grid circuits of the R.F. and I.F. amplifiers.

An electro-dynamic speaker is used with this set. This speaker has a field resistance of 5.6 ohms and a voice coil resistance of approximately 3 ohms.

A tone control is provided in the plate circuit of the output tube. This consists of a condenser and variable resistor in series.

UNITED AMERICAN BOSCH CORP.

ALIGNMENT INSTRUCTIONS

All the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustment unless a coil or I.F. transformer is changed, or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a test oscillator is available, then proceed as follows and refer to Fig. #1.

(A) I.F. ADJUSTMENT

(Use .1 mfd. antenna condenser)

1. Connect test oscillator to grid of 1st I.F. (78) tube.
2. Adjust small I.F. coil (between 78 and 75 tube) to maximum output.
3. Connect test oscillator to grid of 1st detector (77) tube.
4. Adjust condensers on coil in left hand corner of receiver for maximum output.
5. Repeat the above operations for accuracy.

(B) OSCILLATOR ADJUSTMENT

(Use .1 mfd. condenser on grid - .002 mfd. on antenna)

1. Connect test oscillator to grid of 1st detector (77) tube. Set at 1500 K.C.
2. Set gang to 1500 K.C. as follows:
 - (a) Open gang to fullest extent.
 - (b) Close slowly to thickness of approximately .015 of an inch.
3. Peak oscillator condenser on end of gang.
4. Connect test oscillator to antenna lead.
5. Peak other two condensers on gang.
6. Check sensitivity at several points on dial scale.

The set is now fully aligned and normal sensitivity prevails.

Fig. #1

MODEL 119,129

Installation Data

UNITED AMERICAN BOSCH CORP.

INSTALLATION

In order to mount this receiver on a motorcycle, certain fittings are required. The fittings recommended are contained in a kit supplied by the Indian Motorcycle Company and known as the "Indian Radio Support and Antenna Kit Assembly" (#92344).

Contained in this kit are complete instructions covering the mounting of this receiver on a motorcycle, using the parts in the kit.

When installing the receiver, the shielded cable must be passed in front of the handlebars, (this is very important), then downward past the front head lug and along the frame front tube under the tank to the battery. The cable should be attached to the tubes of the frame by clips.

CONNECTIONS

The power supply unit contained in the receiver is arranged for operation on a motorcycle where the negative side of the battery is grounded. In cases where the receiver is to be used on a motorcycle where the positive side of the battery is grounded, it will be necessary to reverse the red and black wires inside of the power supply unit. With the negative side of the storage battery grounded, the red wire should be connected to the "+" terminal and the black wire should be connected to the "-" terminal. With the positive side of the storage battery grounded, the red wire should be connected to the "-" terminal and the black wire should be connected to the "+" terminal.

The terminal of the battery cable marked "hot" should be connected to the ungrounded side of the storage battery. The other terminal should be connected to the grounded side of the storage battery. A fuse is contained in a spring-bayonet cartridge located in the battery cable near the receiver. The fuse is the standard type used for automotive purposes and is rated at 10 amperes. To replace the fuse, force the rubber tube covering the fuse container along the cable toward the receiver until the end of the fuse cartridge can be grasped and removed. The rubber tube should be held firmly to keep the cartridge from receding into the tube while the fuse is being replaced so that the two halves of the cartridge can be conveniently refitted.

All screws, nuts, and washers must be firmly set and all electrical connections are to be tight and clean even to the possible necessity of removing a slight amount of paint to accomplish this.

"B" POWER SUPPLY UNIT

The "B" power for operation of the receiver is supplied by the American-Bosch magmotor. This magmotor unit is turned on and off simultaneously with the receiver and receives its energy from the storage battery of the motorcycle.

The magmotor is essentially a dynamotor, the armature having two windings, one to supply the driving force for rotating the armature and the other for generating the desired "B" power. The armature is fitted with a commutator at each end. The brushes which contact the commutators look alike, but the material of those operating at the 6-volt end is quite different from that of those operating at the high voltage end. If, for any reason, the brush holders are removed from the frame, they must be returned to their original positions when re-assembled. Failure to do this will cause shortened commutator life and improper operation of the magmotor unit.

The magmotor is provided with a permanent magnet, rather than field coils, for excitation. This makes possible the extreme compactness of the unit and also conserves the battery energy. Should it be necessary to remove the magnet during service operations, some marking should be made on adjacent sides of the frame and magnet so that the magnet can be returned to its original position and not inverted. If it is assembled in an inverted position, the polarity of the output will be reversed and the radio receiver will not function. A large soft iron "keeper" should be placed across the poles of the magnet when it is removed in order to conserve the magnetism. It is well to re-magnetize the magnet after re-assembling the magmotor in order that it may give completely satisfactory service. If the magnet is not remagnetized, the output of the magmotor will be reduced.

The armature shaft rotates in ball bearings which are carried in the endplates. An oil cup is provided in the top edge of each of the endplates. Six (6) drops of Bosch Oil US-506, or a light mineral oil should be put in each cup at the expiration of each 1000 hours use. The term "light mineral oil" applies to the so-called household oils sold in small spout cans by the large refiners of petroleum products. This light mineral oil should not be confused with the light household oils of the "sperm" variety so widely advertised. These "sperm" oils must not be used on the light ball bearings of the magmotor - to do so will gum the bearings and cause unsatisfactory operation.

UNITED AMERICAN BOSCH CORP.

MODEL 119,129
Tuning Notes
Suppression Notes

- (2) Shield the cables, spark plugs, etc., from radiating to the antenna by enclosing them in grounded metal shields.
- (3) Minimize the effect of auxiliary or secondary radiating systems by a judicious choice of grounding points and by making ground connections in the proper way. A ground connection for high frequency currents cannot be made by running wires between the cable shield to be grounded and the engine block or the frame of the machine. The cable shield to be grounded must be brought down against the distributor cap or the rotor electrode. The choice of ground points is commonly accomplished by trial and error-experience with the phenomena governing such circuits being extremely helpful.

Before proceeding with the work of suppressing ignition noise, the ignition system of the motorcycle should be checked thoroughly to make certain that all high-tension leads take good connections at their terminals and that the wiring of the plug between the distributor electrode and the rotor electrode is a minimum, that all leaky high-tension cables are replaced, etc.

The specific procedure for suppressing ignition noise with either two or four cylinder motorcycles and with either battery or magneto ignition is as stated below:

A. Two-Cylinder Motorcycle - Battery Ignition:

- (1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.
- (2) Replace each spark plug lead with a shielded cable.
- (3) Connect .5 mfd. bypass condenser from the generator to ground.
- (4) Disconnect the lead between coil and breaker and replace with a shielded lead running directly from the coil to the breaker (length approximately 10").
- (5) Ground the housing of the ignition coil to the frame.
- (6) Install a spark plug shield on each spark plug whenever possible.

B. Two-Cylinder Motorcycle - Magneto Ignition:

- (1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.
- (2) Replace each spark plug lead with a shielded cable.
- (3) Connect .5 mfd. bypass condenser from the generator to ground.
- (4) Install a spark plug shield on each spark plug whenever possible.

C. Four-Cylinder Motorcycle - Battery Ignition:

- (1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.
- (2) Install suppressor in series with the lead to the center contact of the distributor as close as possible to the distributor.
- (3) Replace each spark plug lead with a shielded cable.
- (4) Ground the spark plug cables in the tube which carries them over the motor.
- (5) Connect .5 mfd. bypass condenser from the generator to ground.
- (6) Install a spark plug shield on each spark plug.
- (7) Connect .5 mfd. bypass condenser from the "hot" side of the ignition coil to ground.

D. Four-Cylinder Motorcycle - Magneto Ignition:

- (1) Install suppressor in series with each spark plug lead as close as possible to the spark plug.
- (2) Replace each spark plug lead with a shielded cable.
- (3) Ground the spark plug cables in the tube which carries them over the motor.
- (4) Connect .5 mfd. bypass condenser from the generator to ground.
- (5) Install a spark plug shield on each spark plug.

TUNING

The receiver as delivered will be tuned to the station frequency requested. Due to unavoidable differences between the frequency adjustment made at the factory and that of the station, it may be necessary to make minor adjustments. The following method of tuning is available. The method of tuning using a tuning meter is preferable since more accurate adjustment is possible.

A. With Tuning Meter: With the receiver installed on the motorcycle and turned on, plug the tuning meter into the jack provided for the purpose. If the station desired is to be tuned, the driver should turn the volume control knob of the tuning meter in the direction indicated by the arrow on the dial is obtained for the station being tuned.

- (1) Remove both small circular cover plates from the top of the receiver housing, thus exposing the tuning adjustment screws.
- (2) Loosen the brass lock nuts (which can be seen through the two holes), using a 7/16" socket wrench. The alignment is attempted with a screw driver.
- (3) Insert a screw driver into the slot in the shaft of the left hand condenser (when the receiver is in such a position that the volume control is toward the operator), and adjust this condenser until maximum deflection of the tuning meter in the direction indicated by the arrow on the dial is obtained for the station being tuned.
- (4) Repeat operation "3" with the right hand condenser.
- (5) Lock the condensers with the 7/16" socket wrench and replace the circular cover plates.

B. Without Tuning Meter: With the receiver installed on the motorcycle and turned on, drive the machine toward the broadcasting station. When the station is heard faintly, stop the motorcycle and proceed as follows:

- (1) Remove both small circular cover plates from the top of the receiver housing, thus exposing the tuning adjustment screws.
- (2) Loosen the brass lock nuts (which can be seen through the two holes), using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.
- (3) Insert a screw driver into the slot in the shaft of the left hand condenser (when the receiver is in such a position that the volume control knob is toward the operator), and adjust this condenser until the station is heard loudest.
- (4) Reduce the volume with the volume control.
- (5) Repeat operations "3" and "4" with the right hand condenser.
- (6) Lock the condensers with the 7/16" socket wrench and replace the circular cover plates.

Alignment by the above operations will be approximate only. To obtain the exact alignment required for successful operation, proceed as follows:

Drive the motorcycle with the receiver operating at maximum volume to a "dead" spot on the station. The station frequency should be noted. Then, with the volume control knob, in such a location repeat operations "1", "2", "3", "4", "5", and "6" under the same circumstances should the volume of the signal be reduced by adjusting the volume control knob. Keep the volume control in its maximum position. Do not neglect to lock the condensers with the socket wrench after alignment and before replacing the cover plates.

When these tuning operations have been properly executed, the receiver installation on the motorcycle is then ready for suppression of ignition interference and subsequently ready for service.

IGNITION NOISE SUPPRESSION

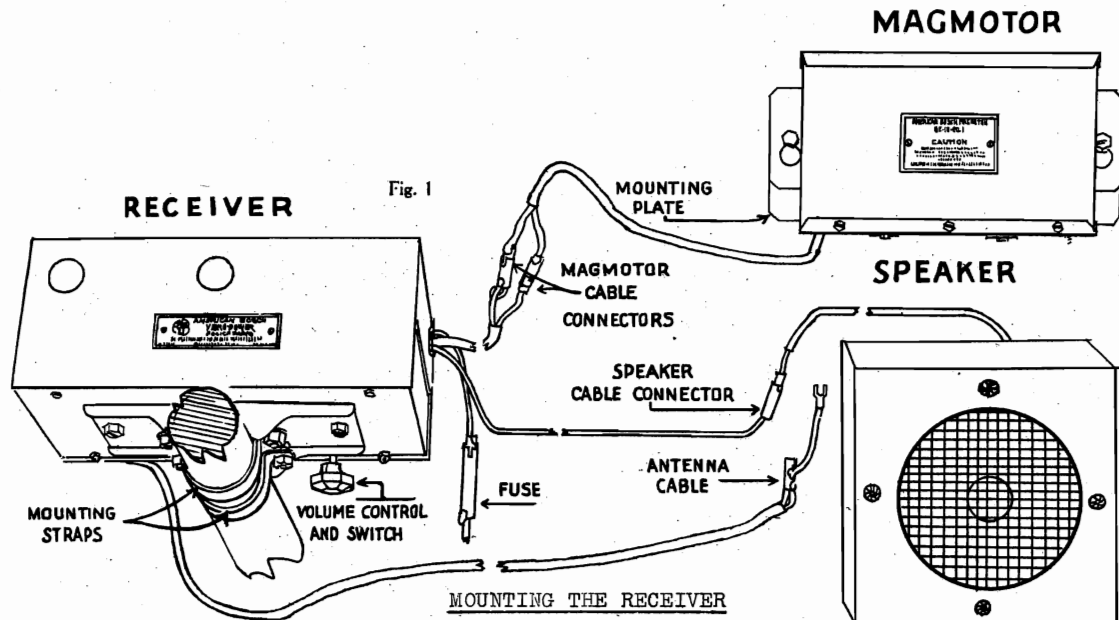

Shielded ignition cable, spark plug suppressor, spark plug shields, and bypass condensers are furnished as auxiliary equipment with the Model 119 and 129 Receivers. These items are necessary for the suppression of ignition interference.

In attempting to suppress ignition interference, the following must be observed:

- (1) Damp the oscillations at the spark plugs and across distributor caps by putting resistors (suppressors) in the cables at these points.

MODEL 139,149
Installation Data

UNITED AMERICAN BOSCH CORP.

A mounting plate is provided for the receiver which fastens to the steering column with two large straps. This plate should be placed on the upper side of the steering column below the instrument panel with the large ends of the keyhole slots at the top. The nuts on the small carriage bolts fastening the straps to the mounting plate should be securely tightened so that the mounting plate will not slip on the steering column. The two screws in the bushings in the receiver housing should then be loosened and the receiver placed on top of the mounting plate with the heads of the screws entering the keyhole slots in the mounting plate. The screws should be allowed to engage the narrow portions of the keyhole slots and the screws should then be tightened securely so that the receiver is held rigidly in place. (See Figure #1).

For cases where mounting on the steering column is not feasible, a bulkhead mounting plate has been provided which is fastened to the bulkhead with three carriage bolts. The adapter plate which is provided for use in conjunction with the mounting plate should be attached with screws to the opposite side of the receiver housing from that through which the volume control shaft projects. It should be placed so that the small ends of the keyhole slots are at the top. The receiver should then be placed on the mounting plate so that the screws in the bushings on the mounting plate enter the keyhole slots in the adapter plate. When the screws engage the small portions of the keyhole slots they should be tightened so that the receiver unit will be held securely.

MOUNTING THE MAGMOTOR

The magmotor or the "B" power supply unit is provided with a mounting plate which is fastened to the operator's side of the bulkhead with three carriage bolts. The two screws in the bushings in the mounting plate should be loosened and the power supply unit placed so that these screws enter the keyhole slots in the bracket fastened to the back of the housing. When the screws engage the small portions of the keyhole slots, they should be tightened so that the unit will be held securely in place.

MOUNTING THE SPEAKER

Two studs are provided on the speaker unit which fasten it to the bulkhead in a position where it will not interfere with the operation of the vehicle but where it will permit a good signal to be heard.

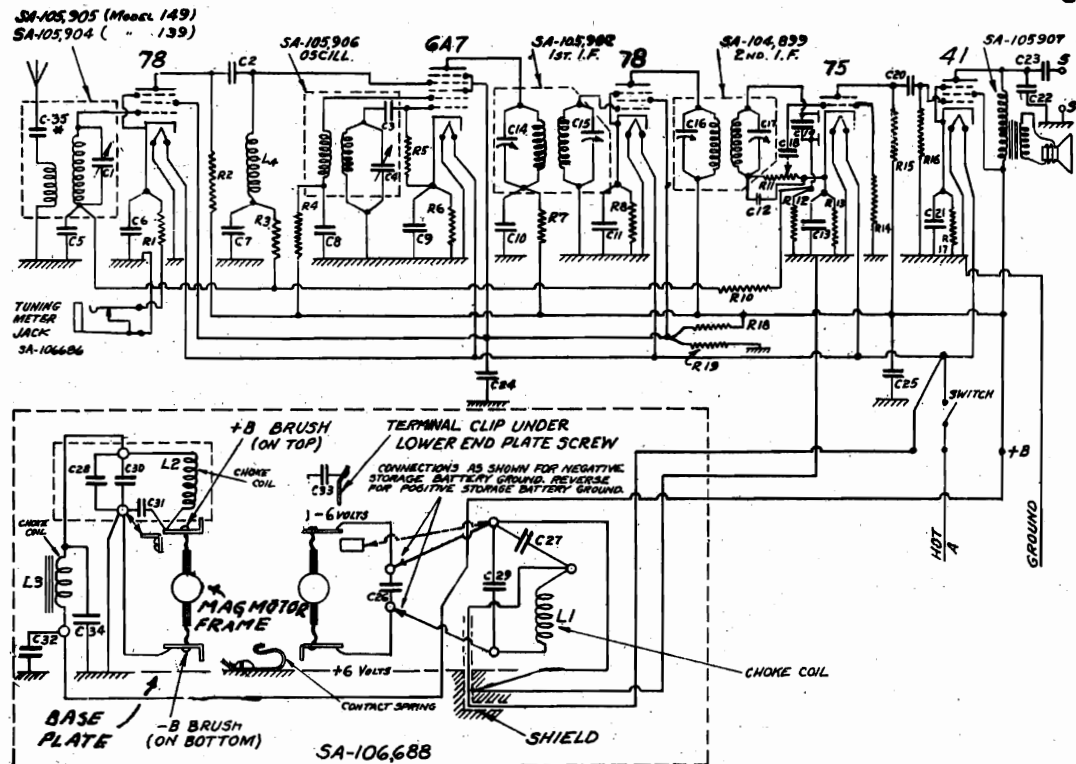

CONNECTIONS

The power supply unit, as provided, is arranged for operation in a motor car where the negative side of the battery is grounded. In cases where this unit is to be used in a motor car where the positive side of the battery is grounded, it will be necessary to reverse the red and black wires inside of the unit. With the negative side of the storage battery grounded, the red wire should be connected to the "+" terminal and the black wire should be connected to the "-" terminal. With the positive side of the storage battery grounded, the red wire should be connected to the "-" terminal and the black wire should be connected to the "+" terminal.

A duplex cable is provided between the receiver and the power supply unit. The two sections of this cable should be connected together. A battery cable containing a fuse is provided. The terminal marked "hot" should be connected to the ungrounded side of the storage battery. The other terminal should be connected to the grounded side of the storage battery. The other shielded cable which enters the receiver housing at the same point as the battery cable and the power supply cable should be connected to the loud speaker. At the other end of the receiver housing a black cotton covered cable is provided which should be connected to the antenna lead-in. Refer to Figure #1 for these cable connections. The antenna lead-in should be shielded and the shield soldered to the bayonet connection beyond the junction.

NOTE:- These readings were taken from the various socket points to ground using a Weston Model 663 volt-ohmmeter which has a resistance as a voltmeter of 1000 ohms per volt full scale. For meters of other ratings, these voltages may not be as indicated.

MODEL 139,149
Testing Data

UNITED AMERICAN BOSCH CORP.

Fig. 4

Fig. 5

TESTING

- (a) **ANTENNA:** Substitute a piece of insulated wire 6 to 8 feet long and lay on ground; if reception is normal, the regular antenna is at fault and should be checked for grounds, opens, etc. (Somewhat better reception should be expected with wire antenna than with car antenna.)
- (b) **TUBES:** Remove and test, or substitute known good tubes, one at a time.
- (c) **SPEAKER:** Disconnect speaker cable from chassis by means of bayonet connector. Test across terminals of speaker with volt-ohmmeter for continuity of voice coil. Reading of 4.5 ohms should be obtained on ohmmeter.
- (d) **SECONDARY OF OUTPUT TRANSFORMER:** With speaker cable disconnected, test with ohmmeter between terminal #1 and ground. Reading of 0.5 ohms should be obtained on ohmmeter.
- (e) **CHASSIS:** After checking the components listed above, test the voltages as they appear on voltage chart and the resistance measurements as found in "Chassis Resistance Chart". If any particular reading obtained is very different from the chart reading, the trouble is located in the portion of the circuit associated with the points at which this discrepancy occurs. Referring to the circuit diagram and location drawings, each part making up the circuit may be individually tested until the faulty part is specifically located.
- (f) **MAGMOTOR:** See section giving complete magmotor service information.

UNITED AMERICAN BOSCH CORP.

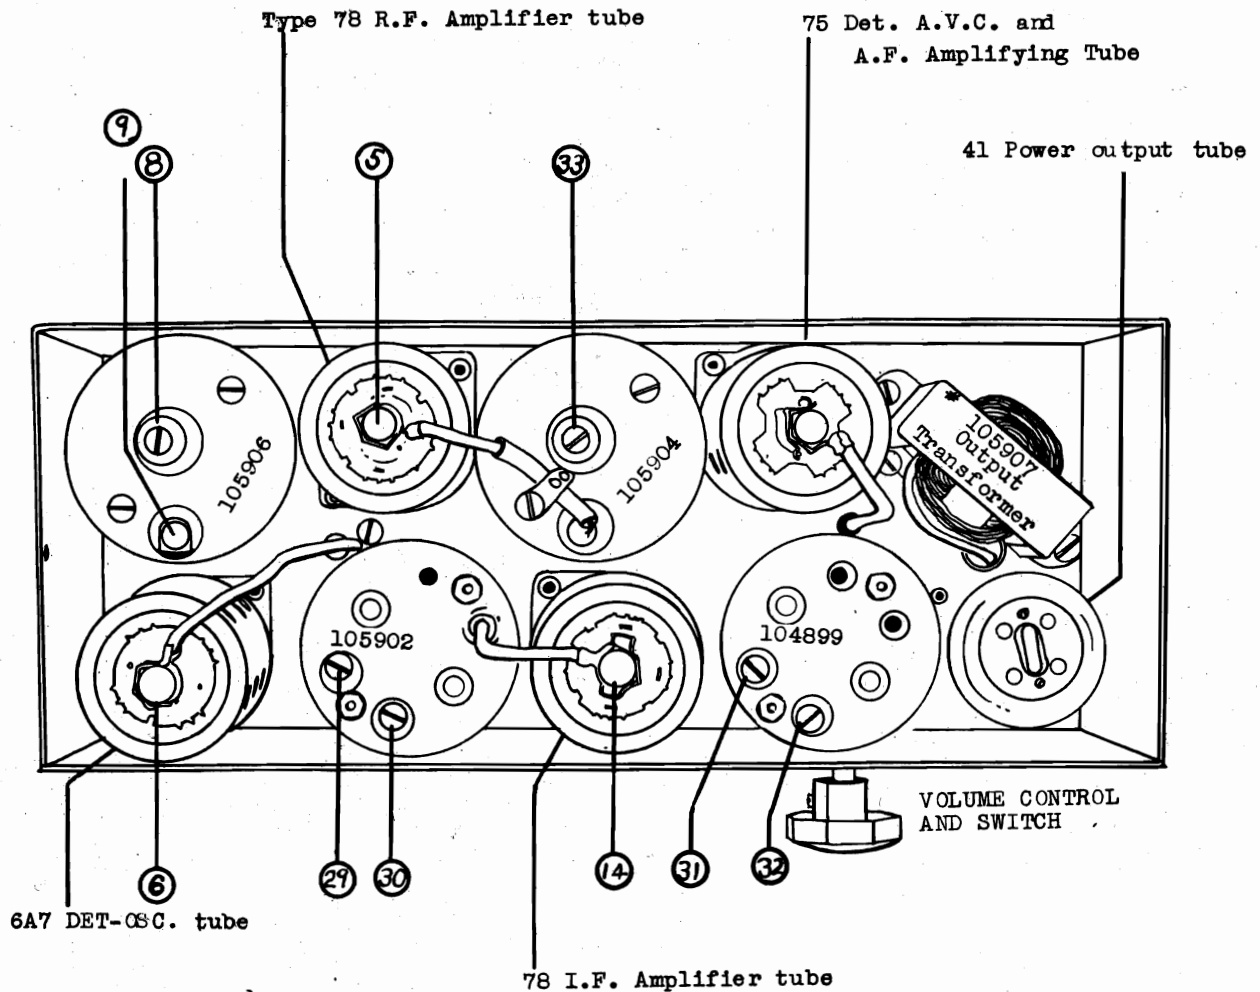

Fig. 2

ALIGNMENT INSTRUCTIONS

All of the adjustable condensers, commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustments unless an I.F. transformer is changed, or the adjustments tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a test oscillator is available, then proceed as follows: See Fig. #2.

1. Connect output meter across terminals of speaker voice coil.
2. Set test oscillator at 456 kilocycles.
3. Connect test oscillator lead to grid of I.F. amplifier tube, type 78. (Point #14).
4. Adjust condenser on primary of second I.F. transformer, (Point #31) to peak on output meter.
5. Adjust condenser on secondary of second I.F. transformer, (Point #32) to peak on output meter.
6. Connect test oscillator lead to grid of detector-oscillator tube, type 6A7 (Point #6)
7. Adjust condenser on primary of first I. F. transformer (Point #29) to peak on output meter.
8. Adjust condenser on secondary of first I. F. transformer, (Point #30) to peak on output meter.

The above procedure lines up the I. F. stages properly, so that all that remains is to tune the oscillator and preselector circuits to the frequency of the station it is desired to receive. This has been covered in the section headed - TUNING

MODEL 139,149

Tuning Data

UNITED AMERICAN BOSCH CORP.

TUNING

The radio receiver as delivered will be tuned to the station frequency requested. Due to unavoidable differences between the frequency adjustment made at the factory and that of the station, it will be necessary to realign the tuning condensers slightly. One of the following methods of procedure should be followed depending upon whether or not a tuning meter is available. The method of tuning using a tuning meter is preferable since more accurate adjustment is possible.

A. With Tuning Meter.

With the receiver in the motor car, and connected to the car antenna and battery, turn the receiver fully on and allow it to get into operation which will be indicated by a slight hum heard in the speaker. Plug the tuning meter into the jack in the receiver housing. If the station desired is not heard, drive the machine (with the radio set in operation), toward the broadcasting station. When the station is heard, stop the motor car and proceed as follows:

- (a) Loosen the brass condenser lock nuts (which can be seen through the two holes in the top cover of the housing) using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.
- (b) With a screw driver inserted into the slot in the shaft of the left hand condenser (when the receiver is in such a position that the volume control is toward the operator), adjust this condenser until maximum deflection of the tuning meter in the direction indicated by the arrow on the dial is obtained on the station being heard.
- (c) Repeat operation "b" with the right hand condenser.
- (d) Lock the condensers with the 7/16" socket wrench.

B. Without Tuning Meter.

With the receiver in the motor car, and connected to the car antenna and battery, turn the receiver fully on and allow it to get into operation which will be indicated by a slight hum heard in the speaker.

If the station desired is not heard, drive the machine (with radio set in operation) toward the broadcasting station. When the station is heard faintly, stop the motor car and proceed as follows:

- (a) Loosen the brass condenser lock nuts (which can be seen through the two holes in the top cover of the housing) using a 7/16" socket wrench. This operation must be observed or damage will be done to the tuning condensers when alignment is attempted with a screw driver.
- (b) With a screw driver inserted into the slot in the shaft of the left hand condenser, when the receiver is in a position such that the volume control knob is toward the operator, adjust this condenser until the station is heard loudest.
- (c) Reduce the volume by rotating the volume control knob on the face of the receiver housing counter-clockwise.
- (d) Repeat operations (b) and (c) with the right hand condenser.
- (e) Lock the condensers with the 7/16" socket wrench.

Alignment by the above operations will be only approximate. To attain the exact alignment required for successful operation proceed as follows:

- (a) Drive the motor car (with radio operating with volume control on full) to a "dead" spot or to a place sufficiently remote from the transmitter to produce a weak signal. In such a location repeat operations "a", "b", "d" and "e". In this case under no circumstances should the volume of the signal be reduced by adjusting the volume control knob. Keep the volume control in its maximum position. Do not neglect to lock the condensers with the socket wrench after alignment and before replacing cover plates.

* This measurement should not be made with the tuning meter connected in the circuit.

MODEL 139,149
Magmotor Notes

UNITED AMERICAN BOSCH CORP.

MAGNETIZING

The magnet should retain its original magnetic strength for an indefinite period but there are factors that may cause dissipation of the magnetism as, for example, the removal of the armature. A reduction in the magnetism will cause the magmotor to operate at a higher speed to deliver the same voltage which will result in a greatly reduced life. For this reason it is well to remagnetize the magnet after any work has been done on the power unit especially if the armature has been removed.

The unit should be completely assembled when the magnetizing is done in order to obtain the proper field excitation. This can be done on a standard Bosch or American-Bosch magnetizing stand.

Should it be necessary to remove the magnet during the service operations, some marking should be made on adjacent sides of the frame and magnet so that the magnet can be located to its original position and the polarity of the output will be reversed and the receiver will not function.

CONDENSERS AND CHOKE COILS

The position in which the condensers and choke coils are placed has a direct bearing on the efficiency of the magmotor and if it is necessary to replace any of these parts, it is of the utmost importance that they be placed in exactly the same positions as the parts removed. The leads must also be of the same length and gauge, or larger and must be placed in the same position as the ones removed.

COMMUTATORS

When the armature has been removed for inspection, and the commutators are found to be dirty, they may be cleaned by using a clean cloth saturated with gasoline or if necessary, by using very fine sandpaper. If the commutators are badly worn and pitted, it will be necessary to turn them down in a lathe. Extreme care should be observed in performing this operation, removing only enough material to provide a good surface.

TESTING

(Refer to Figs. 4 and 5)

With voltage of 6.6 volts measured between point #35 and ground, the "B" voltage, measured between Point #34 and ground with the receiver connected, should be approximately 176 volts.

If the magmotor armature fails to rotate when the cable connections have been made properly and the switch in the chassis has been turned on, the continuity of the circuit through the motor portion of the magmotor should be checked with an ohmmeter in accordance with the following resistance chart:

If the magmotor armature rotates but no "B" voltage is obtained between #34 and ground, the continuity of the circuit through the generator portion of the magmotor and the associated filters, should be checked with an ohmmeter in accordance with the following resistance chart:

MAGMOTOR RESISTANCE CHART

All measurements made with Weston Model 665 Volt-ohmmeter. (Refer to Figs. 4 & 5)

SECTION OF CIRCUIT	MEASURE BETWEEN POINTS	OHMMETER READING
Complete Motor Circuit	#35 and GND	1 ohm
"A" Circuit R.F. choke	#35 and #36	Full scale
Complete Generator Circuit	#34 and GND	800 ohms
"B" Circuit A.P. Choke	#34 and #36	280 ohms
"B" Circuit R.F. Choke	#36 and #37	Full scale

Whenever possible, a direct comparison should be made with a magmotor which is definitely known to be in good operating condition in order to avoid the misinterpretation of variations of readings due to variations in storage battery voltages, load conditions, meter accuracies, etc.

MAGMOTOR SERVICE INFORMATION

LUBRICATION

The armature shaft rotates in ball bearings which are carried in the end plates. An oil cup is provided in the top edge of each of the end plates. Six drops of Bosch oil US-506, or a light mineral oil should be put in each cup at the expiration of each 1000 hours of use. See Fig. 5 for the location of the oil cups. The term "light mineral oil" applies to the so-called household oils sold in small spout cans by the large refiners of petroleum products. This light mineral oil should not be confused with the light household oils of the "spum" variety so widely advertised. These "spum" oils must not be used on the light ball bearings of the magmotor - to do so will gum the bearings and cause unsatisfactory operation.

BALL BEARINGS

The ball bearings are held in place by means of set screws located in the top of each end plate. There are two set screws in each end plate. The set screws are tightened by screwing them down too tightly will distort the ball bearings sufficiently to increase the friction in the bearings with a resultant increase in current drain from the storage battery. The set screws should be carefully tightened while the magmotor is connected to the receiver and while the armature is rotating. An ammeter should be inserted in the battery circuit so that the current drain may be observed. When the set screws have been properly tightened with the magmotor connected to the receiver, the current drain should be approximately 3.0 amperes. Both of the set screws must be removed when dismantling the unit.

BRUSHES

The magmotor has four brushes, two in the input or motor end and two in the output or generator end. The brushes in the input or motor end are made of copper graphite and can be distinguished by their copper color. Under no circumstances must the output or generator end brushes be replaced with brushes of any other material. The brushes should be replaced after 3000 hours of operation. The brushes more than 3000 hours will result in their wearing down so that they make intermittent contact with the commutators, producing excessive sparking and resulting in damage to the commutators. To remove the brushes, first remove the brush holder by removing the screws which fasten the holders to the magmotor frame. Then melt the solder on the brush holder terminal clip so that the flexible wire connection to the brush is loosened and while the solder is molten pull the brush out of the holder. It is very important that the proper grade of brushes are used and no brushes should be used except those furnished by the United American Bosch Corporation.

DISMANTLING AND ASSEMBLING THE MAGMOTOR

In order to inspect and service the armature it is necessary to remove the armature from the magmotor frame. To do this the following procedure should be observed:

- Disconnect the red and black wires connected to the polarity terminal plate and also the two green wires connected to the brushes on the sides of the magmotor.
- Remove the filter assembly mounted on the brass plate fastened to the top of the magmotor by removing the two screws #38 and #39 in Fig. #5.
- Remove the other filter assembly fastened to the top of the magmotor by removing the two self-tapping screws #40 and #41 shown in Fig. #5.
- Remove the filter assembly on the end of the magmotor by removing the four end plate fastening screws.
- Remove the two upper ball bearing set screws and loosen the two lower set screws in the end plates.
- Remove the end plate to which the filter assembly is attached.
- Withdraw the armature.

All parts of the power unit are now available for inspection. To assemble the unit, reverse the sequence of operations given above. Make certain that the wires to the low voltage side are connected as they were originally and use extreme care in tightening the ball bearing set screws (see the special instructions for adjusting the ball bearing set screws).

UNITED AMERICAN BOSCH CORP.

MODEL 260
Alignment DataADJUSTMENT INSTRUCTIONS OF MODEL 260

I. F. Adjustment - The intermediate frequency amplifier is tuned to 517.5 K. C. With this frequency supplied from an approved standard signal generator, place the output terminals of the generator on the input to the 3rd I. F. amplifier tube, i. e. high side on the grid cap and low side on metal frame of receiver. Tune the adjustment screw of the diode transformer for maximum deflection of the output meter (connected across the voice coil terminals of the loud speakers). A sensitivity of approximately 50,000 microvolts should be indicated. Next, connect the signal generator terminals to the 2nd I. F. tube. Tune the adjustment screws of the 3rd I. F. transformer for maximum deflection of the output meter. A sensitivity of 3,000 microvolts should be indicated. Next, connect the signal generator to the 1st I. F. tube and tune the adjustments of the 2nd I. F. transformer for maximum. A sensitivity of 100 microvolts should be indicated. Next, connect the signal generator to the 1st detector tube and tune the first I. F. transformer. A sensitivity of 10 microvolts should be indicated. Leaving signal generator on 1st detector, recheck all the I. F. stages.

R. F. Adjustment - (a) Broadcast Band

Check position of pointer to make sure it is at the marking line just beyond the 540 K. C. calibration mark when variable condenser plates are fully engaged. Then adjust set to the 1400 K. C. marking on scale. Adjust signal generator to 1400 K. C. and connect its output terminals through a dummy antenna to antenna and ground connections. With about 1,000 microvolts from signal generator (to make for ease of finding signal) adjust the broadcast oscillator trim condenser (B. C. Osc. Coil - Trimmer) as indicated in Figure #1. Reduce signal generator input as signal is tuned in so as to keep within a useful deflection of the output meter. When signal is tuned in, adjust the screws marked R. F. TRIMMER and ANT-TRIMMER in Figure #1. These last two need not be touched throughout further adjustments of the radio set. Next, place the set at the 600 K. C. marking with signal generator likewise and adjust the screw of the B. C. OSC. COIL LAGGING condenser until the signal is tuned in. Return the pointer to 1400 K. C., the signal generator likewise, and make the slight readjustment of the B. C. OSC. TRIM condenser for good accuracy of calibration.

When all the adjustments as described are correctly made, the following sensitivity should be maintained for a standard output of 100 milliwatts on a carrier input modulated 30% at 400 cycles.

Frequency (KC)	1400	1000	600
Sensitivity (MV)	3	5	7

(b) Green Band (1600 - 3500 K. C.)

By means of wavechange switch, place pointer on this band. Place pointer on 3.5 mark, set the signal generator to 3500 K. C. and with sufficient input to receiver from standard signal generator, tune the screw adjustment labelled GREEN BAND TRIMMER until the signal is a maximum. Then place pointer to the 1.6MC mark, adjust signal generator to 1600 K. C. and tune the screw marked GREEN BAND LAGGING CONDENSER until the signal output is a maximum.

Return set and signal generator to 3.5MC and readjust GREEN BAND TRIMMER the slight amount necessary. Check the sensitivity. The following readings should obtain for 100 milliwatts output.

Frequency (KC)	3500	2400	1600
Sensitivity (MV)	5	5	5

NOTE: Each oscillator coil is provided with means of adjusting its inductance. This comprises a copper vane placed in the field of the coil and made movable by means of a screw adjustment. On the green, red and blue bands, the adjustment may be made through holes in the side plate adjacent to the oscillator trimmer condensers. While primarily a factory adjustment, these vanes may be used for adjustment in the field where it has been found necessary to make repairs to an oscillator coil. The method is as follows: Having gone through the adjustment of the GREEN BAND as described above, it is found that the sensitivity, particularly in mid-scale (2.4 megacycles) is not up to standard; say, for example, it indicates a sensitivity of 20 microvolts.

MODEL 260

Alignment Data
Socket and
Trimmer Layout

UNITED AMERICAN BOSCH CORP.

Give the vane adjustment screw two turns in a clockwise direction and repeat the adjustments given above at 3.5MC, 1.6MC, and back to 3.5MC. Then tune set and signal generator to 2400 K.C. and observe sensitivity. If this has improved, the adjustment is in the correct direction and a few more trials should be made exactly as described until the correct sensitivity is obtained. If on the other hand a poorer sensitivity is obtained at 2400 K. C., return setting two turns to its original position and repeat procedure making vane adjust in counterclockwise direction, until correct sensitivity is obtained.

It should be mentioned again that this tedious procedure is never necessary unless an oscillator coil has in some way become damaged. In the factory, special test equipment is provided which makes for quick adjustment of inductances to the correct value before the coil is mounted in the radio set.

(c) Red Band (4000 - 9000 K. C.)

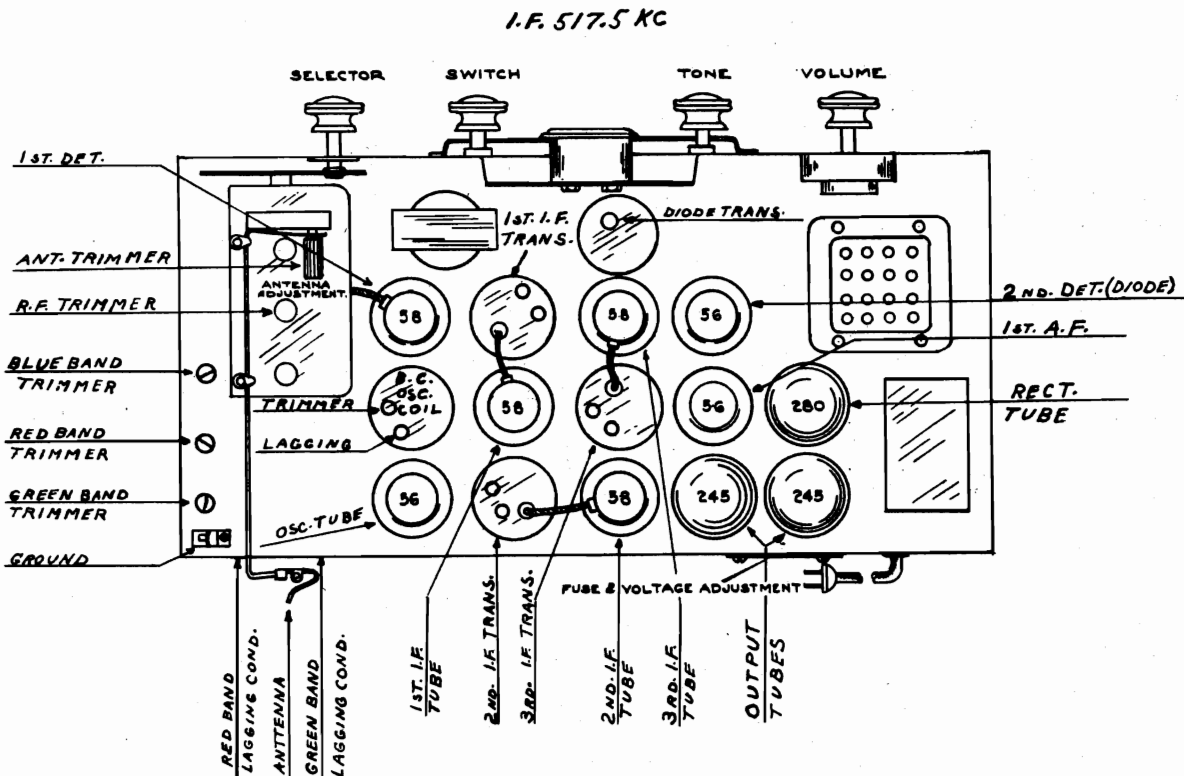

Adjustments in this band are made exactly as described for the green band except that the appropriate trimmer and lagging condensers are used. In Figure #1, reference is made to RED BAND TRIMMER and RED BAND LAGGING CONDENSER. Sensitivity should be in the neighborhood of 5 microvolts across the scale..

(d) Blue Band (10,000 - 20,000 K. C.)

Adjustments in this band should be made starting at the highest frequency end, say 18 MC if obtainable on signal generator. A frequency not lower than 15 MC is desirable. At this highest frequency, set pointer on radio set to calibration and tune BLUE BAND TRIMMER until signal is correctly received. Then place the signal generator at 10 MC and tune radio set until signal is received. If this tuning point deviates from the correct calibration point, the vane regulating the oscillator coil inductance may be reset and the tuning process repeated until scale is adjusted to calibration and the correct sensitivity is obtained. Care should be taken to see that the adjustment is made for the signal itself and not the image. That is, a 15 MC signal should be tuned in at 15 on dial and its image, with more input from standard signal generator, at 14 MC. Five microvolts across scale corresponds to the correct sensitivity.

* Depending upon setting of noise control.

Due to high resistance in grid circuit, this voltage cannot be measured at the socket therefore, readings shown here were taken at "C Stick."

NOTE: These values are readings of a high resistance volt meter from each socket terminal to ground. The filament voltages are, of course, an exception. Cathode readings are given for those tubes having the grid at ground. The valves are only approximate and will vary with the line voltage and type of meter employed.

**MODEL 352
Alignment
Parts List**

UNITED AMERICAN BOSCH CORP.

ALIGNING S. W. OSC.

1. Set wave change switch to short wave or RED band position.
2. Set test oscillator to 1900 KC and adjust #13 and tuning control to a "max-max" as per instructions given under Broadcast Band Alignment.
3. Check sensitivity across band.

GENERAL DESCRIPTION

The American-Bosch Model 352 is a five-tube superheterodyne dual wave receiver. This model is for 110 volt, 60 cycle operation.

The tuning of this receiver is divided between two illuminated scales. The BLACK scale covers the standard broadcast band (560 to 1600 kilocycles) and the RED scale covers the short wave band including the frequencies between 1600 kilocycles and 4800 kilocycles.

ALIGNING

To align the 352 chassis, it is essential to use a high grade modulated oscillator and sensitive output meter. The R.F. signal fed into the receiver must be very weak or it will cause the A.V.C. to function, making correct alignment impossible. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align a receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment components. A top view of the chassis is shown on page R100B and should be carefully studied before the actual work is started.

ALIGNING THE I. F. (175 KC)

1. Set volume control on full.
2. Tune control should be on bass position.
3. Short circuit antenna and ground leads to prevent local stations from interfering with subsequent alignment operations.
4. Connect output meter across voice coil of loud speaker (speaker impedance is 3.5 ohms).
5. Set test oscillator to 175 KC and adjust its output to produce measurable reading on output meter when test oscillator is connected between frame of the chassis and the grid of 58 I. F. tube #6.
6. Adjust #4 and #5 to maximum output, reducing signal oscillator output as stage is brought into resonance.
7. Connect test oscillator to grid of 2A7 (#9) and adjust #7 and #8 to maximum output.

ALIGNING B.C. OSC. AND R.F.

1. Set wave change switch to broadcast or BLACK scale position.
2. Connect test oscillator to grid of first detector tube 2A7 (#9) and adjust test oscillator to 1400 KC.
3. Set dial scale to maximum mark beyond 550 KC calibration point when gang is entirely closed.
4. Set scale at 1400 KC and adjust #10 to maximum output. NOTE: Two peaks will be heard as trimmer condenser is tuned. The second peak from maximum capacity should be used.
5. Connect test oscillator to antenna through 100. mmf. condenser and with scale still set at 1400 KC adjust condensers #10, 11 and 12 to maximum output.
6. Set scale and test oscillator to 600 KC and adjust #14 simultaneously changing this adjustment and the tuning control of chassis for maximum output. This type of adjustment is known as "max-max" and is obtained in the following manner:
Tune receiver with left hand by means of tuning knob and adjust #14 in either direction and then without changing it, tune the receiver through a maximum, noting the value of output meter reading. If change #14 further in same direction, tune receiver and note reading. If output drops with second adjustment, reverse direction of #14 adjustment. If output drops with this type of adjustment, reverse direction of #14 adjustment. NOTE: When the tuning control of #14 is adjusted, the tuning control of #14 are changed. While this procedure may appear difficult, facility can be easily acquired by practice and the operation requires only a few moments.
7. With test oscillator and scale set at 1400 KC readjust #10, 11 and 12, since previous operation may have altered oscillator trimmer setting.
8. Check sensitivity across band.

UNITED AMERICAN BOSCH CORP.

The adjustment of the receiver may be divided into five divisions: (1) adjustment of the I. F. amplifier (2) adjustment of the broadcast band (black) (3) adjustment of the 1500-4000 K. C. band (green) (4) adjustment of the 3500-9000 K. C. band (red) and (5) adjustment of the 8000-20,000 band (blue).

The procedure is as follows:

(A) I. F. Adjustment

- (1) Set signal generator to 476 K. C. with attenuator well ahead (20,000mv).
- (2) Introduce signal to grid of second I. F. amplifier (see diagram).
- (3) Adjust small screws in front side of third I. F. transformer for loudest signal, reducing attenuator as required. Final sensitivity about 5000 microvolts.
- (4) Decrease signal generator attenuator to about 1000mv and introduce signal to grid of first I. F. amplifier.
- (5) Adjust alignment screws of second I. F. transformer for loudest signal, reducing attenuator as stage is brought into resonance. Final sensitivity about 300 microvolts.
- (6) Decrease signal generator attenuator to about 50 microvolt setting, and introduce signal to grid of first detector.
- (7) Repeat alignment procedure on 1st I. F. transformer (see diagram) until best adjustment is obtained. Sensitivity about 20 microvolts.

(B) R. F. Adjustment

- (1) Set signal generator to 1500 K. C. with input from signal generator to grid of first detector. Place pointer of radio set to 1.5 mark on dial. Adjust screw of trim condenser in top of right rear shield container until signal is tuned in. This screw is usually designated by a red color code. Having obtained tune at this point set signal generator to 600 K. C. and set pointer to .6 mark on station indicator and adjust other screw in the shield container until the signal is tuned in. Now return to the 1500 K. C. point with set and signal generator and make the slight resetting of the first named screw to obtain accurate adjustment to scale reading.
- (2) Connect signal generator to antenna lead, making sure the antenna equivalent (200 mmf) is in the circuit.
- (3) Continue setting of 1500 K. C. Adjust alignment condensers on variable condenser gang (1st and 2nd sections from front of set) for loudest signal. Check sensitivity, and calibration at several points on dial. Set should come correctly to kilocycles settings of important broadcasting stations, and its sensitivity on the signal generator should be within the limits specified here.

K. C. - - -	1500	1000	600
M. V. - - -	5	5	10

MODEL 360

Alignment Data

UNITED AMERICAN BOSCH CORP.

Having placed the broadcast band in correct setting, we are now ready to adjust the short wave bands. In order to attempt this a reliable signal generator is required. Examples are the Ferris Instrument Co. type 10B, General Radio 603-A, R. C. A. type TMV-18. Do not try to make adjustments on the short wave bands by means of harmonic obtained from a set tester designed for use only on 500 to 1500 K. C. band. Such a procedure will usually end in getting so far off correct adjustment as to require factory service.

(C) Adjustment of the Green Band

Place signal generator on 3600 K. C. and pointer of radio set at the 3.6 mark on the dial.

Adjust trim condenser in right hand front shield container until signal is tuned in. This trim condenser is usually red color coded. Place signal generator on 1600 K.C. and adjust dial scale pointer of set to 1.6 mark. Adjust opposite condenser in shield container to best signal. Return to 3600 K. C. and repeat adjustment. In adjusting to the 3600 K. C. point it is possible to obtain two settings for different positions of the trim condenser in the shield container. This denotes merely the plus and minus frequency between oscillator and signal generator which will give the correct I. F. frequency. The correct setting of the trim condenser is the one wherein the screw is turned furthest out. In any event, an incorrect setting will always be denoted by lack of sensitivity when the set and signal generator are tuned to 2500 K. C. (mid-band). This check is usually quite valuable. The sensitivities should be as follows:

K. C. - - -	3600	2400	1600
M. V. - - -	10	10	5

(D) Adjustment of the Red Band

Place signal generator on 8000 K. C. marking and tune receiver in region of 8.0 on scale. Note where signal is received. Next place signal generator on its 4000 K. C. setting and tune set to 4.0 on scale. Adjust oscillator lag condenser (rear unit on right hand side plate) until signal is received. Return set and signal generator to 8000 K. C. and observe pointer setting and sensitivity. Slight deviations from calibration can be compensated by manipulating the stiff wires connecting the oscillator coil to the switch.

(E) Adjustment of the Blue Band

Place signal generator at 20,000 K. C. or if this is not available, then adjust to highest possible frequency, which preferably should be at least 15,000 K. C. Tune set to this frequency and note where signal generator is received on the dial scale. Then place signal generator on 10,000 K. C. and adjust oscillator lag condenser (front unit on side plate) until signal generator is tuned in at 10 on dial scale. Now return both signal generator and radio set to the high frequency setting. Located on the under side of the base and adjacent to the switch and high frequency selector coils are two trim condensers which are used for correct adjustment at this high frequency. Increase setting of attenuator until signal generator can be tuned in at two points on dial (say 20 and 19). Then with set pointer at 20 adjust these trim condensers for best signal decreasing signal generator attenuator as signal becomes better tuned. At correct adjustment a very loud signal will be obtained at 20 while a feeble signal or none at all is observed at 19. This is a practical illustration of the effectiveness of pre-selection as outlined in the first part of this description.

The adjustment instructions just given apply to a Model 360 receiver which is in reasonable operating condition, but in some manner has been thrown out of adjustment. Obviously, before the radio technician can go thru with the adjustments given here, he must assure himself that defective tubes, injured parts, such as punctured condensers, shorted variable condensers, open resistors, scratched high frequency coils, etc. are not such as to cause the set to be inoperative on one or more bands of frequencies.

UNITED AMERICAN BOSCH CORP.

MODEL 370
Alignment Data

SERVICE INSTRUCTIONS FOR ADJUSTMENT OF MODEL 370

Note: Signal generators may vary as much as 50% in accuracy of attenuation and for this reason, the sensitivity data should be regarded as an approximate guide to correct performance.

- (4) Decrease signal generator output to about 500 microvolts and connect signal generator to control grid cap of first i.f. amplifier tube (58).
- (5) Adjust alignment screws of second i.f. transformer for loudest signal, reducing output of signal generator as stage is brought into resonance. This adjustment is made by using a small screw driver inserted thru the hole provided in the dial scale. Final sensitivity should be about 300 microvolts.

- (6) Decrease signal generator output to about 50 microvolts and connect signal generator to control grid cap of first detector tube (2A7).

- (7) Adjust alignment screws of first i.f. transformer until loudest signal is obtained, reducing attenuator as stage is brought into resonance. Readjust second and third i.f. transformer alignment screws to assure perfect alignment of the entire amplifier. This should be done without removing signal generator lead from first detector. Over-all sensitivity of the i.f. amplifier should be approximately 51 microvolts.

The tube complement of the Model 370 follows:

- 1 Type 2A7, oscillator and first detector
- 1 Type 58, first intermediate frequency amplifier
- 1 Type 2B7, second intermediate frequency amplifier, detector and a.v.c.
- 1 Type 58, controlled audio amplifier
- 1 Type 53, driver stage
- 1 Type 53, push pull output stage
- 1 Type 83V, rectifier

The adjustment of the receiver will be described under three headings - (A) intermediate frequency amplifier, (B) broadcast band (black), (C) short wave band (red).

Alignment procedure should always be in the order given below:

(A) INTERMEDIATE FREQUENCY AMPLIFIER ADJUSTMENT

- (1) Set signal generator or alignment oscillator to 265 kc. and adjust its output to produce a measurable signal on the output meter when the generator is connected to the control grid cap of the second i.f. (2B7).
- (2) Set volume control at maximum volume position, tone control at bass and wave change switch so that the black scale or broadcast band is in operation.
- (3) With signal generator connected between frame of the receiver and grid cap of the second i.f. amplifier, adjust small screws in front side of their i.f. transformer for loudest signal, adjusting attenuator of signal generator as required. Note: If calibrated output meter and accurate signal generator are being used, the sensitivity should be approximately 8000 microvolts for an output voltage of .6 volts measured across the moving coil of the speaker. This corresponds to 100 milliwatt standard output.

(B) BROADCAST BAND ADJUSTMENT

- (1) Rotate tuning control until gang condenser is fully closed. The pointer should now be in line with the fine black mark approximately 1/8" beyond the 550 kc. calibration mark (5.5 on dial). The travel of the pointer from this mark to the position which it occupies when the condenser is fully open, should be 3-1/16 inches. When the indicator mechanism is so adjusted that this travel is obtained alignment of preselector and oscillator circuits will then assure the best calibration.

- (2) Set signal generator to 1400 kc. with input connected to grid cathode of first detector tube (2A7).

- (3) Adjust tuning control until point is at 1400 kc. calibration mark. Adjust screw of the oscillator section of the gang condenser (see diagram), until maximum output is obtained. Sensitivity should be about 50 microvolts.

- (4) Connect signal generator to antenna ground terminal using an antenna equivalent of 200 mmf. condenser in series with antenna lead to signal generator.

- (5) Adjust all trimmer screws of the gang condenser to a maximum. Sensitivity should be approximately 10 microvolts.

- (6) Set signal generator to 600 kc. with connections made to antenna and ground terminals.

- (7) Tune in signal by means of tuning control and then adjust both tuning control and broadcast band oscillator lagging adjustment simultaneously for a maximum. Note: This type of adjustment is known as "max-max" and is obtained in the following manner.

MODEL 370

Alignment Data

UNITED AMERICAN BOSCH CORP.

Tune receiver with left hand by means of tuning knob and adjust oscillator lag condenser with right hand. Make slight change in oscillator lag condenser in either direction and then, without changing it, tune the receiver thru a maximum noting the value of output meter reading obtained. Change oscillator lag condenser further in the same direction, retune receiver and note reading. If output drops with second adjustment, reverse direction of the adjustment of the oscillator lag condenser. Continue this type of trial and error adjustment until no improvement can be made when either tuning control or oscillator lag condenser are changed. While this procedure may appear difficult, facility can be easily acquired by practice and the operation required only a few moments.

(8) Recheck 1400 kc. adjustment since oscillator lagging procedure may have slightly detuned oscillator. Check sensitivity at various settings along broadcast band. Sensitivity should be approximately 10 microvolts or less.

(C) SHORT WAVE ADJUSTMENT

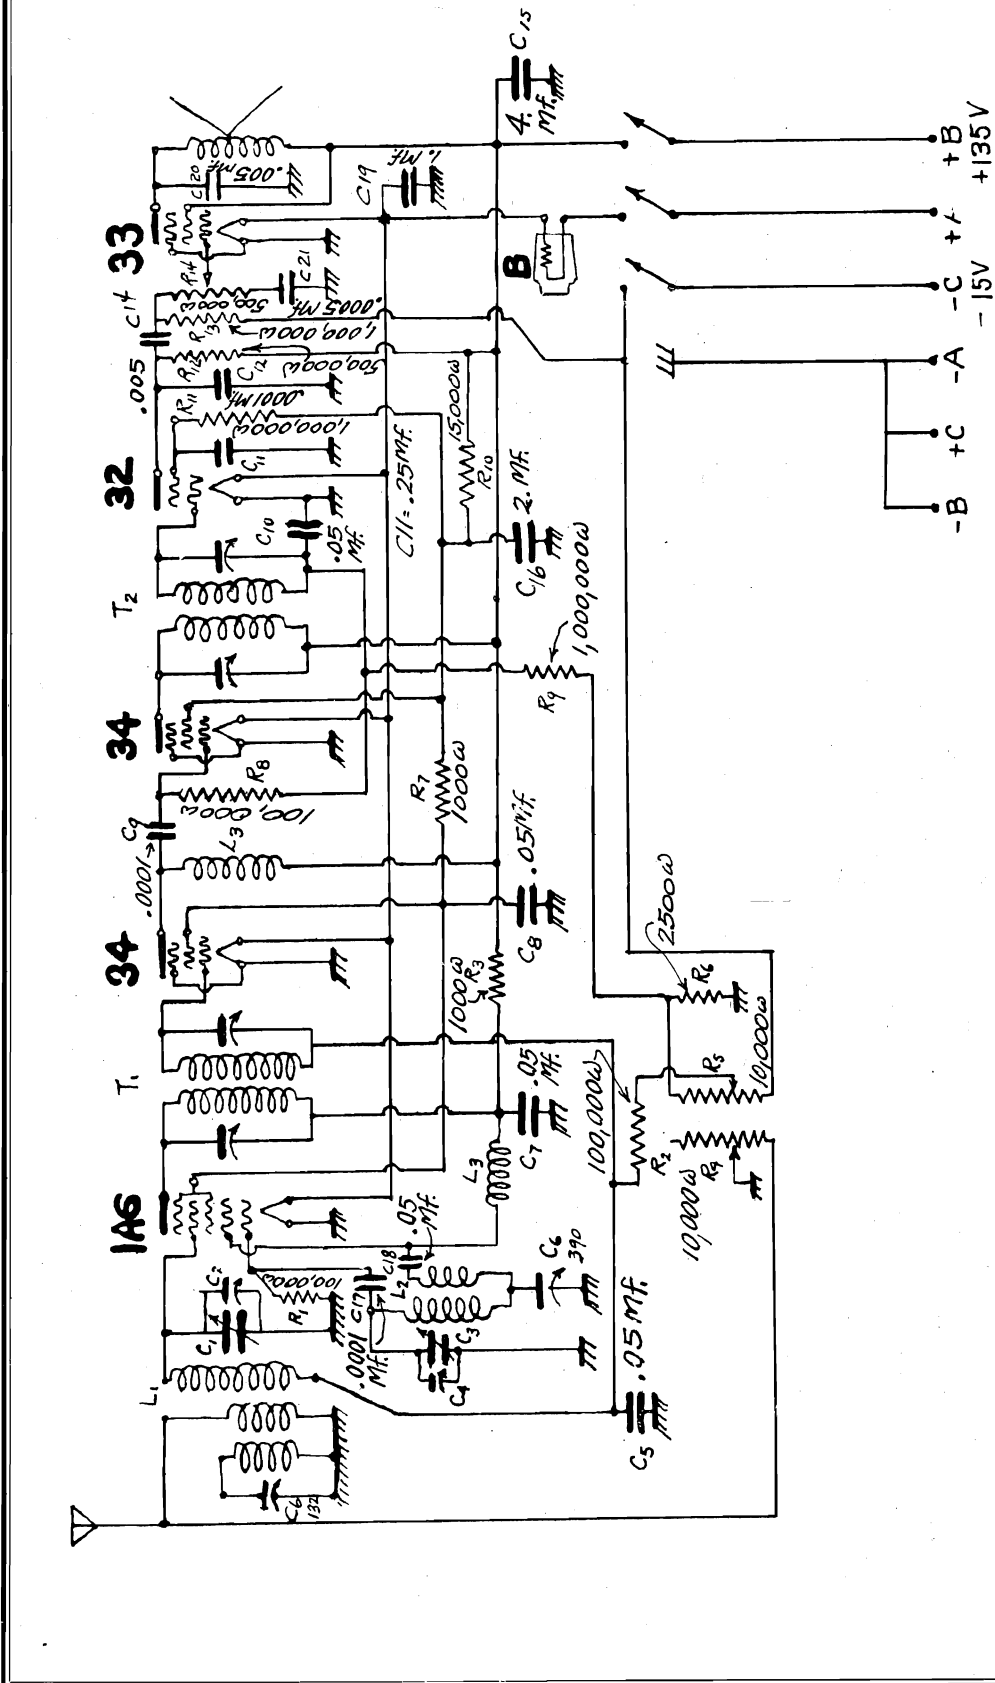

(1) Set signal generator at 2400 kc. with output connected to antenna and ground terminals.

(2) Change wave band switch to red band, tune in signal at 2400 kc. and "max-max" oscillator as described above, using short-wave oscillator lagging condensers as shown on diagram.

(3) Check sensitivity of entire short-wave band which should be 50 microvolts or less.

Voltage
Alignment Data

UNITED AMERICAN BOSCH CORP.

VOLTAGE READINGS

Note: Since no circuits are directly connected to the metal chassis as in the usual A. C. radio sets, it is necessary to measure voltages to the negative side of the circuit designated as "A" on the wiring diagram. A high resistance voltmeter must be used or readings will be inaccurate.

The following voltage readings were taken with the receiver supplied by 115 volts 60 cycle alternating current. Voltage readings will be slightly lower when D. C. is used and will vary with the type of meter used.

1. (Rectifier 25Z5)	Voltage across C16	120 V
	" " C12	120 V
	" " Heater	25 V
2. (Power tube 43)	" Screw to point A	105 V
	" Plate " " "	96 V
	" Bias across L9	15 V
	" Heater	25 V
3. (Second Detector 75)	" Plate to point A	37 V
	" Bias cathode to A	.5 V
	" Heater	6 V
4. (Intermediate 78)	" Screen to point A	105V
	" Plate to point A	105V
	" Bias Cathode point A	1.3V
	" Heater	6V
5. (Osc. Det. 78)	" Screen to point A	105 V
	" Plate " " A	105 V
	" Grid bias Cathode to coil lug across R.	2.8 V
	" Suppressor bias cathode to point A	16.5 V
	" Heater	6 V

The heater voltages may vary considerably because the series connection maintains constant current rather than constant voltage.

Alignment Instructions - Model 500

I. F. Adjustment 456 K. C.

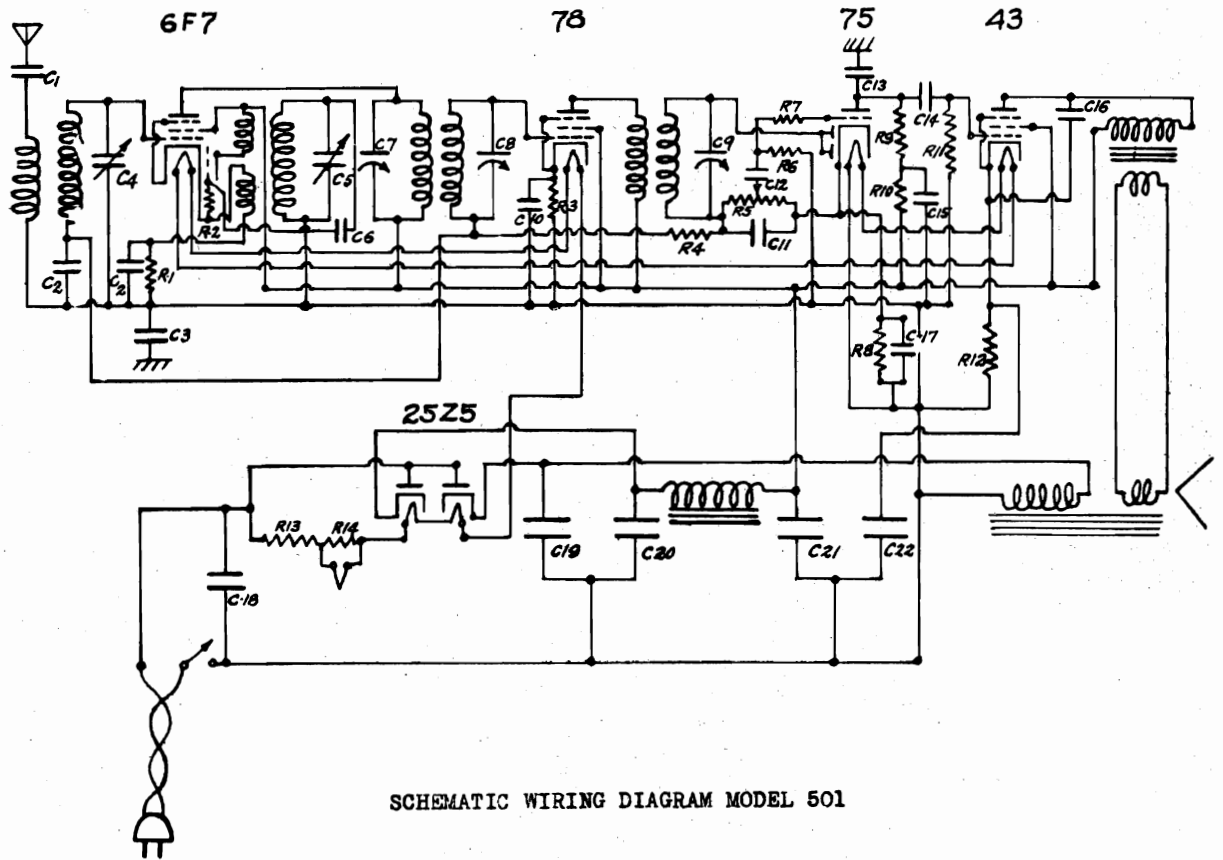

Note: The signal generator or alignment oscillator should have no external ground connection of the low potential side of its output either to ground or to the power line and the low potential output terminal may be connected to the frame of the receiver. An external ground of the receiver frame will result in a loud hum making alignment impossible.

1. Connect volume indicator across moving coil of speaker (speaker impedance is 4.5 ohms)
2. Set volume control at maximum
3. Connect signal generator to grid of I. F. tube (78) and adjust the trim condenser in the top of the small I. F. housing which is located above the chassis between the tubes, to maximum output.
4. Connect signal generator to grid of 1st detector and adjust both condensers to a maximum output. These adjustments are made by means of slotted screws at the rear of the housing at center of set.

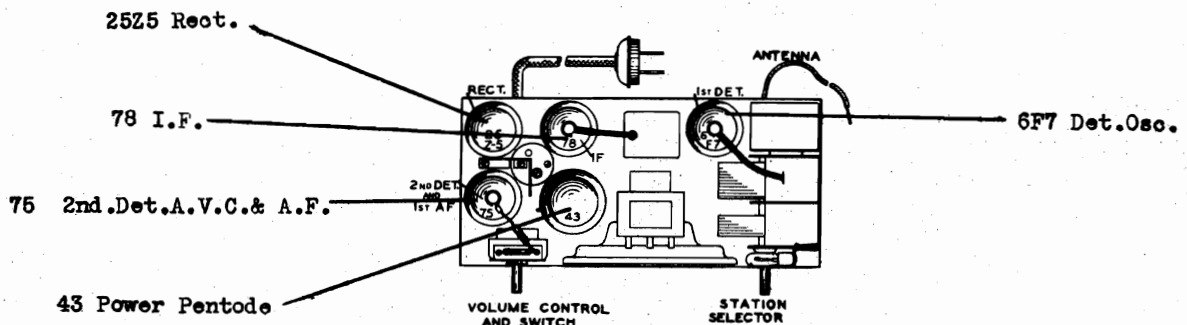

Oscillator and R. F. Adjustment

1. Connect R. F. signal generator to antenna wire thru 100 mf mica condenser. Antenna should be heaked.
2. Set dial scale to maximum mark beyond the 550 kilocycle calibration point when gang is entirely closed.
3. Trim both condenser sections to a maximum with the signal generator and scale set at 1500 kilocycles.

To replace tubes it is necessary to remove the chassis from the cabinet. Remove the screws which fasten the back. Remove the knobs and the screws holding the bottom of the chassis in place. The chassis may then be moved back from the front of the cabinet until the tubes are accessible.

CAUTION: Disconnect the receiver from the power supply before touching the chassis, tubes, or any metal parts inside the cabinet.

I. F. Amp.	78	6.0	112	112	3.6
2nd Det.	75	6.0	50*	-	.5
Power Amp.	43	25	112	180	x21 (bias across 400 ohms)
Rectifier	12Z3	12	Voltage across plate to cathode 248 volts		
Line Voltage	220	Resistor Strip Volts..... 40		
Power in Watts	80	Resistor Cord Volts 117		
Dial Lamp Volts	6.0	Dynamic Field 96		

All above voltage measurements taken with reference to "neutral" line marked "AA" on diagram. *Voltmeter of 1000 ohms per volt must be used especially for type 75 tube plate. This bias measured from Junction R12, C22 and Junction R11, R12. Since filaments in series run constant current, filament voltages may vary considerably from those given above without affecting receiver operation.

II. VOLTAGE MEASUREMENTS WHEN USING 220 VOLT D. C. LINE

Stage	Tube	File	Plate	Screen	Cathode
1st Det.	6F7	6.0	108	96	9.9
I. F. Amp.	78	6.0	96	96	2.8
2nd Det.	75	6.0	*45	-	-
Power Amp.	43	25	96	108	17.5
Rectifier	12Z3	12	Voltage across plate to cathode 221 volts		
Line Voltage	220	Resistor Strip Volts 43		
Power in Watts	80	Resistor Cord Volts 120		
Dial Lamp Volts	6.0	Dynamic Field 81		

TUBES

The receiver employs five tubes of the following types:

- 1 type 6F7 detector oscillator
- 1 type 78 intermediate frequency amplifier
- 1 type 75 second detector, A. V. C., and audio amplifier
- 1 type 43 power pentode
- 1 type 12Z3 rectifier

To replace tubes it is necessary to remove the chassis from the cabinet. Remove the screws which fasten the back. Remove the knobs and the screws holding the bottom of the chassis in place. The chassis may then be moved back from the front of the cabinet until the tubes are accessible.

CAUTION: Disconnect the receiver from the power supply before touching the chassis, tubes, or any metal parts inside the cabinet.

SERVICE INSTRUCTIONS FOR AMERICAN-BOSCH VIBRO-POWER RECEIVER

MODEL 503

INTRODUCTION

The Model 503 is an extremely compact five-tube, automatic volume control superheterodyne which may be operated from any (200 to 240 Volt) A.C. or D.C. supply service.

An important feature of this receiver is its extended tuning range (540 to 1,650 kilocycles). This range includes not only the complete broadcast band, but also many of the important state and city police assignments.

INSTALLATION

The Model 503 is supplied with an attached antenna of the proper length which when fully extended, will provide adequate pick-up unless the receiver is operated in a shielded building.

No ground connection is provided and an external ground from the chassis must not be used, as this may result in damage to the receiver.

If insufficient signal is received with the aerial indoors it may be connected to a conventional single-wire outdoor antenna of from 40 to 100 feet in length. The latter should be as high as possible, and not too close to other aerials or to electric light or power wires.

A lightning arrester is usually required by the electrical code on an outdoor antenna. This arrester may be connected between any point on the "lead-in" and any grounded object, such as a water pipe or a length of pipe driven into moist earth. The connection is best made with a standard copper ground clamp.

When used with alternating current, to complete the installation it is only necessary to insert the attachment plug in any convenient electric light socket or outlet.

When used with direct current the attachment plug must be inserted in the outlet in a definite manner. If after the receiver has been connected to a direct current source, it fails to function and its loud speaker has absolutely no background of sound, reverse the attachment plug in the outlet.

Information regarding your power supply may be obtained from your local electric light company.

OPERATION

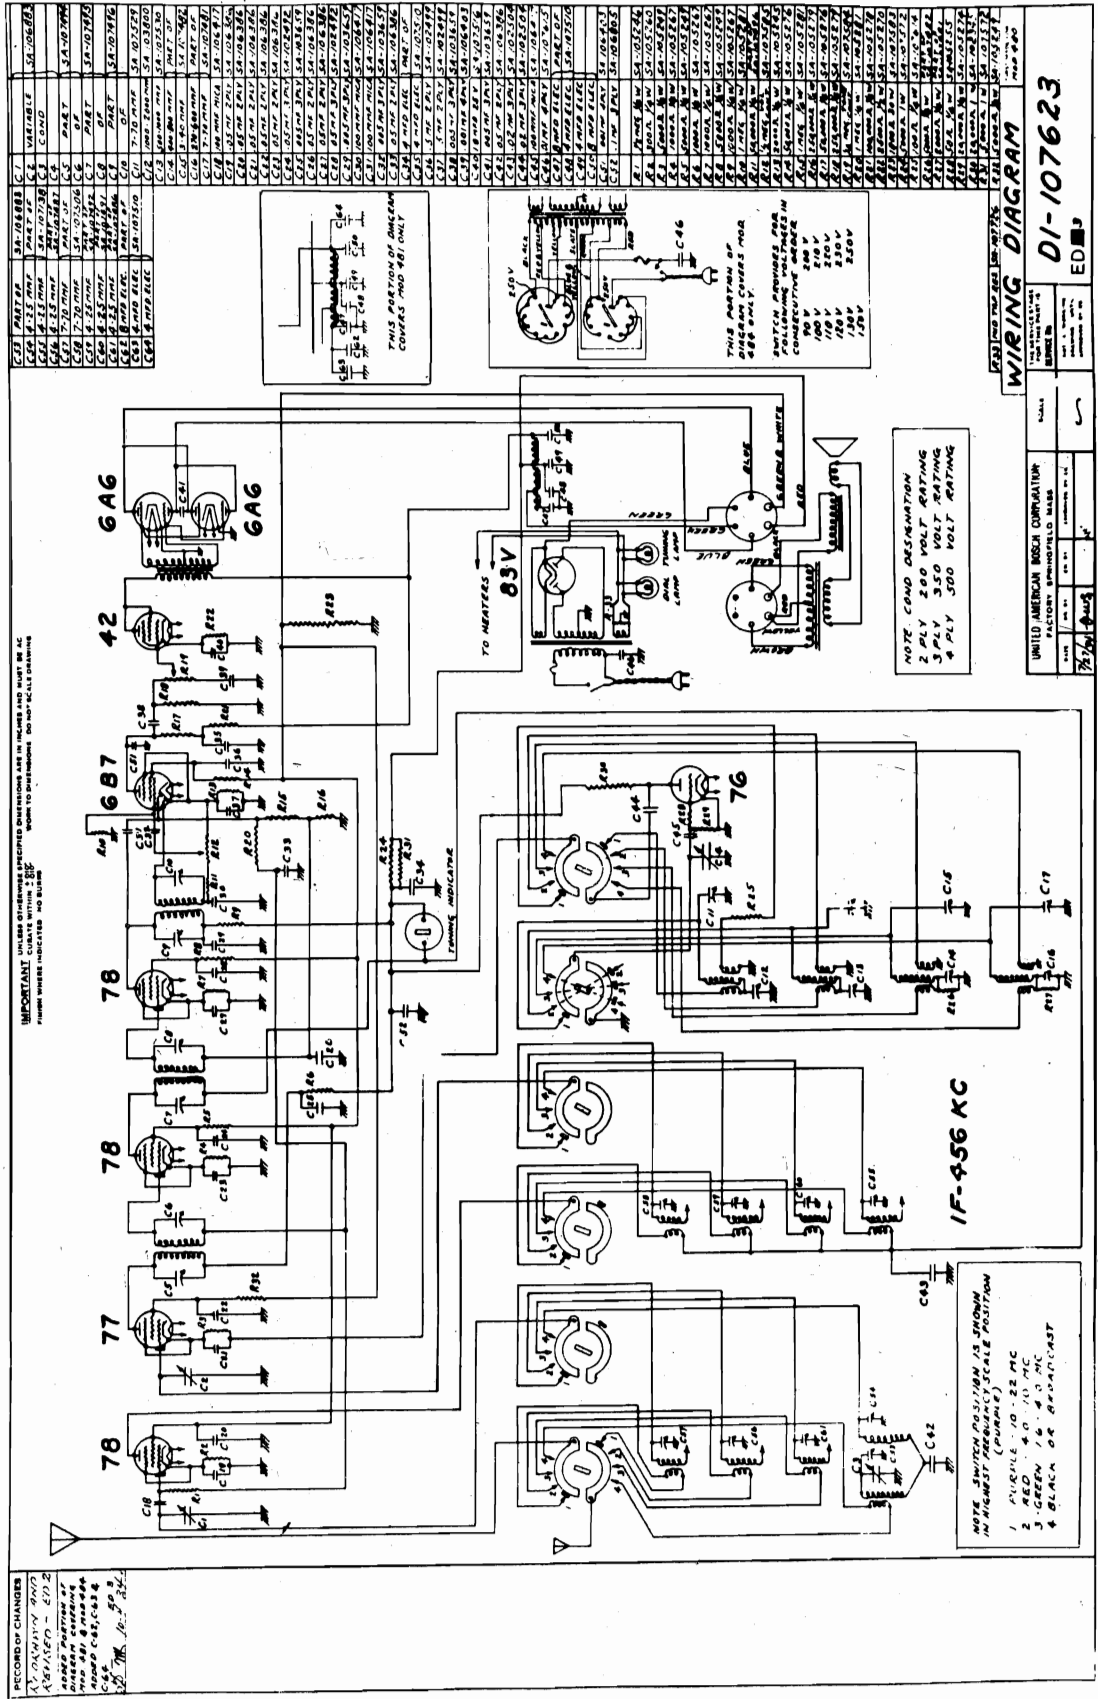

VOLUME CONTROL AND SWITCH. Two operating controls appear on the front panel. The left-hand knob is the combination switch and volume control. In the extreme counter-clockwise position of the knob (curved to the left) the receiver is "off". When the control is turned in a clockwise direction (to the right) the receiver is switched "on" and the scale is illuminated.

Further movement of the knob increases the volume to any desired point. When locating weak or distant stations it is advisable to advance the control to the "fully on" position.

Automatic Volume Control is provided within the receiver and prevents any noticeable change in volume from fading signals. All stations are tuned in with practically the same room volume. "Blasting" from powerful locals is eliminated when tuning, and the operation of the receiver is greatly simplified.

STATION SELECTOR. The right-hand knob is the tuning control. It operates the illuminated tuning dial which is calibrated in channel markings and corresponds to the kilocycle markings given for stations in newspapers and log books, except that for convenience in tuning and conservation of space on the dial, the last cypher has been dropped. For example, a station on 700 kilocycles is received at 70 on the scale.

UNITED MOTORS SERVICE

Peaking Gang Condenser at 1400 K.C.

(a) In order that the 1400 K.C. position of the condenser plates can be accurately determined the chassis must be placed back in the cabinet. The dial pointer should be placed on the sleeve of the condenser gang and the condenser plates turned until they are entirely out of mesh. The pointer should then be moved to the 1750 K.C. position approximately 1/8" below bottom of the numeral "170" (which is slightly off the end of the dial) care being taken to see that the condenser plates are not moved. The tuning knob should be turned until the dial pointer sets on 1400 K.C. This will set the condenser plates in the proper position for aligning at 1400 K.C.

(b) Coil up the antenna lead to within a foot of the chassis and set the oscillator at 1400 K.C. Feed the oscillator output into the antenna wire. This may be done by connecting the shielding on the oscillator output lead to the chassis frame and by simply wrapping a few turns of the portion of the antenna wire nearest the chassis around the oscillator output lead. This will ordinarily provide sufficient coupling between the test oscillator and the antenna circuit of the set. A direct connection with the antenna wire can be made by inserting a pin into the wire close to the chassis.

(c) Peak the oscillator trimmer condenser shown as C-1-B on figure 2 until the oscillator output can be heard in the speaker. Then the trimmer C-1-A located on the adjacent section of the gang condenser, making all adjustments for maximum deflection on the output meter scale.

NOTE: To avoid A.V.C. action and to insure sharp peaking of all trimmers, reduce the oscillator output to the lowest level that will give a reasonable deflection on the output meter scale.

VOLTAGE CHART

All readings are taken from each of the tube socket connections to the chassis frame. The socket contact numbers are in accordance with those found on the circuit diagram.

TUBE	#1	#2	#3	#4	#5	#6	#7	Cap
6A7	32	32	18.5	32	0	.5	26	0
6D6	19.5	32	32	.5	.5	26	--	0
85	13.5	29	0	0	.9	19.7	--	0
48	6	31.5	32	0	6.5	32	--	--
48	6	31.5	32	0	6.5	32	--	--

R-5 RESISTOR ADJUSTMENT

The R-5 resistor shown on figure 3 is a cathode bias resistor variable from 50 to 200 ohms. This resistor controls the residual bias on the 6A7 and 6D6 tubes and must be carefully adjusted. This may be accomplished by tuning the set to an extremely weak station and adjusting R-5 for maximum volume in the speaker.

CIRCUIT GROUND

If an external ground is used it must be connected to the green wire on chassis to guard against short circuits when used on 32 Volt systems with positive grounds.

PEAKING

All of the adjustable condensers, commonly called "trimmer" condensers are very accurately adjusted at the factory and will not need any further adjustment unless they are tampered with in the field or a defective coil has been replaced. DO NOT attempt to change the setting of any trimmer condensers unless it is definitely known that the adjustment is necessary. If re-alignment is found necessary, the only way the circuits can be properly adjusted is with the use of an oscillator and output meter. Connect the output meter to the plate prong of one of the type 48 output tubes and to the chassis frame. Make sure that the output meter is protected with a series condenser to prevent the D.C. from flowing through the meter circuit. If the meter is not protected, connect a 1/10 mfd. condenser in series with the lead to the chassis frame.

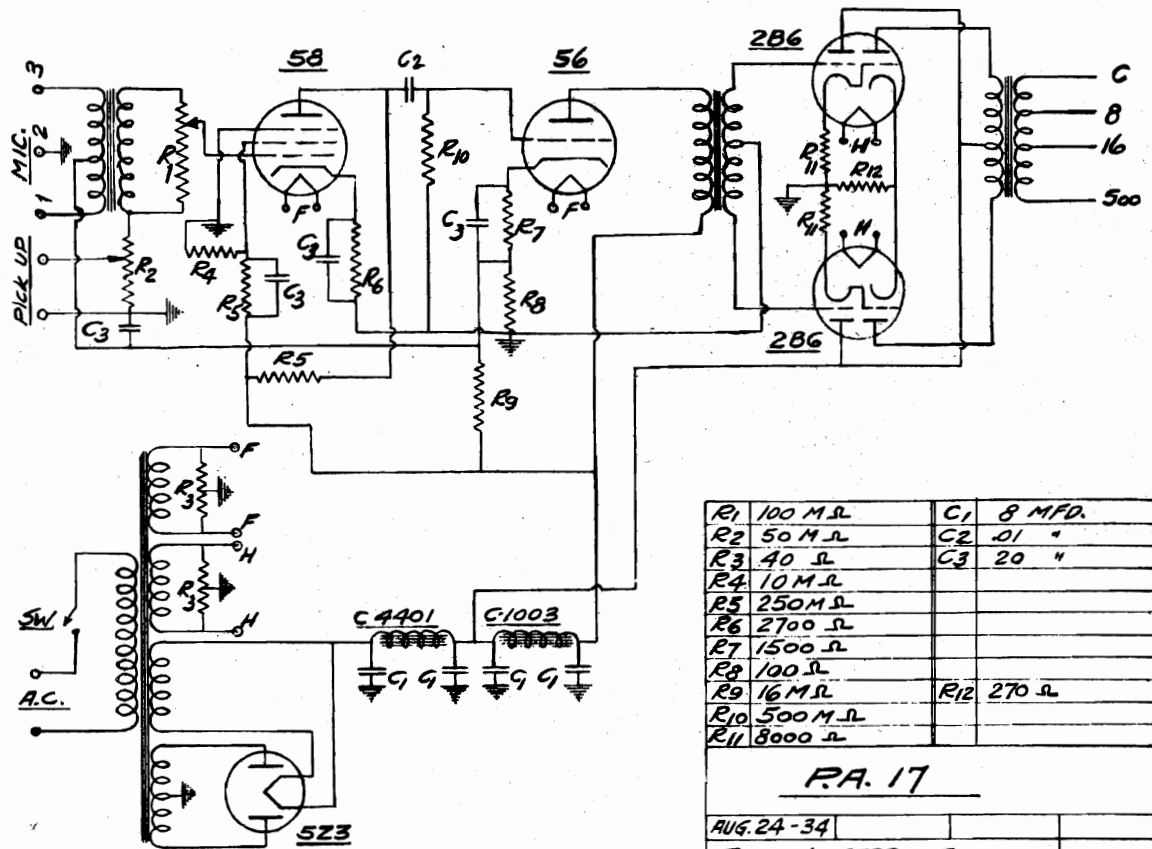

PEAKING I.F. STAGES AT 262 K.C.

- (a) Connect the output of the oscillator to the grid cap of the 6A7 tube (leave 6A7 grid lead clip in place) and to the chassis frame.
- (b) Turn the condenser gang until the plates are entirely out of mesh
- (c) Set the oscillator on 262 K.C. and feed this signal through the I.F. stages of the set.
- (d) Peak the I.F. trimmer located on the top of the 1st I.F. Coil, designated as "D" on figure 3. Then peak the trimmer located on the bottom of the same coil designated as "C" on figure 2. Due to the detuning effect the primary winding exerts over the secondary, it will then be necessary to reset trimmer "D" for maximum output.
- (e) Peak the I.F. trimmer located on the top of the 2nd I.F. coil, designated as "F" on figure 3. Then peak the trimmer located on the bottom of the same coil designated as "E" on figure 2. Then reset trimmer "F" on top of the coil making all adjustments for maximum output.

NOTE: In the event that the I.F. stages are badly out of alignment at 262 K.C. the operation outlined in paragraphs (d) and (e) should be repeated.

MODEL 5-B Series

Voltage Alignment Data.

WELLS-GARDNER & CO., INC.

Circuit

This receiver is designed to operate from a battery power supply the values of which are shown in Fig. 1. All of the tubes used are of the 2 volt type. The receiver is designed to operate at a very low current drain from the batteries and still have a very satisfactory quality of output.

The circuit has a preselector stage incorporating 2 tuned circuits for image rejection. This couples into the type 32 first detector-oscillator tube through a combination of inductive coupling in T1 and capacitive coupling through C3. In Fig. 1 the two coils to the right of the 32 1st detector tube are the primary and secondary of the 1st I. F. transformer while below this tube are the oscillator coils. The oscillating circuit is tuned by the oscillator section of the gang condenser and is always resonant at a frequency of 175 K. C. above the frequency to which the R. F. circuit is tuned.

One stage of I. F. amplification is employed using a 34 tube. Fixed condensers tune the primary and secondary of the first I. F. transformer. A second I. F. unit of the impedance coupled type is provided in which the inductance L4 is tuned by a trimmer condenser C9. The volume control is of the variable antenna input and I. F. bias type. Referring to Fig 1 it will be noted that one end of the volume control strip is connected to the antenna and the other end is connected to resistor R9. Also note that the volume control strip is tapped. Bias voltage for the 34 I. F. tube is obtained from a potentiometer consisting of resistors R9, R10 and the 60,000 ohm section of the volume control R8 which resistors are connected across the 22½ volt "C" battery.

As the slider of the volume control is moved away from the antenna end, the signal input to the antenna stage is increased. The bias voltage of the I. F. tube is not affected until the tap is reached. As the slider moves from this point to the end of the strip the I. F. bias is decreased, thus increasing the sensitivity. When this happens the plate current goes up and more battery current is used.

A 34 tube is used as the 2nd detector or demodulator. Demodulation takes place in the grid circuit of this tube.

Resistance coupling is used between the 2nd detector and the 1st audio stage which uses a 30 tube. The 1st audio stage is transformer coupled to the output stage. Class "B" amplification is employed in the output stage which uses a type 19 tube. This consists of two output tubes in one envelope. A magnetic reproducer is used.

A 3 pole switch controls all three sources of battery supply.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and at the intermediate frequency, and an output meter are required for indicating the effect of adjustments.

First set the signal generator to a frequency of 175 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector thru a .05 mfd. condenser. The ground lead from the signal generator goes to the ground lead of the receiver. Adjust trimmer condenser C9 on the back panel of the chassis until maximum output is obtained. **A non-metallic screw driver should be used in making this adjustment as the I. F. trimmer is at B+ potential.**

Next set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 3 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Then set the signal generator for 1400 K. C. and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To obtain dial scale calibration tune in an 800 K. C. signal and set the dial pointer at that mark on the dial scale. When calibrated in this manner, the setting will be approximately correct at both ends of the scale.

Fig. 4—Using Voltage Regulator with 3 Volt "A" Battery
The use of the cut plate type of condenser eliminates the necessity of a 600 K. C. padder and no adjustment at this frequency, therefore, is required.

D. C. Resistance of Windings

Following are the D.C. resistances of the various windings in the chassis.

Part No.	Item	Code	D. C. Resistance in Ohms
P-5168	Double Tuned Ant. Coil Pri.....	T1	19.2
	Double Tuned Ant. Coil Sec. (Preselector)	T1	3.2
	Double Tuned Ant. Coil Sec. (1st Det.)	T1	3.2
P-5199	1st I.F. Coil Pri.....	T2	90.0
	1st I.F. Coil Sec.....	T2	116.0

VOLTAGES AT SOCKETS

Volume Control at Maximum—Antenna Shorted to Ground B+135 Volts
Voltagess to Chassis

Type of Tube	Function	Across Filament	Plate to Cath.	Screen to Cath.	Grid to Cath.	Normal Plate M. A.
32	1st Det. & Osc.	2.0	135	67.5	7.5 ⁽¹⁾⁽²⁾	2.5
34	I. F.	2.0	135	67.5	2.5 ⁽³⁾	2.8
34	2nd Det.	2.0	50	40 ⁽¹⁾	0	1.8
30	1st Audio	2.0	135		9 ⁽⁴⁾	3.0
19	Output	2.0	135		6	1.8
						Total

- (1) With 250,000 ohm meter.
- (2) Subject to variation due to oscillatory current.
- (3) With 25,000 ohm meter.
- (4) As read at "C" battery.

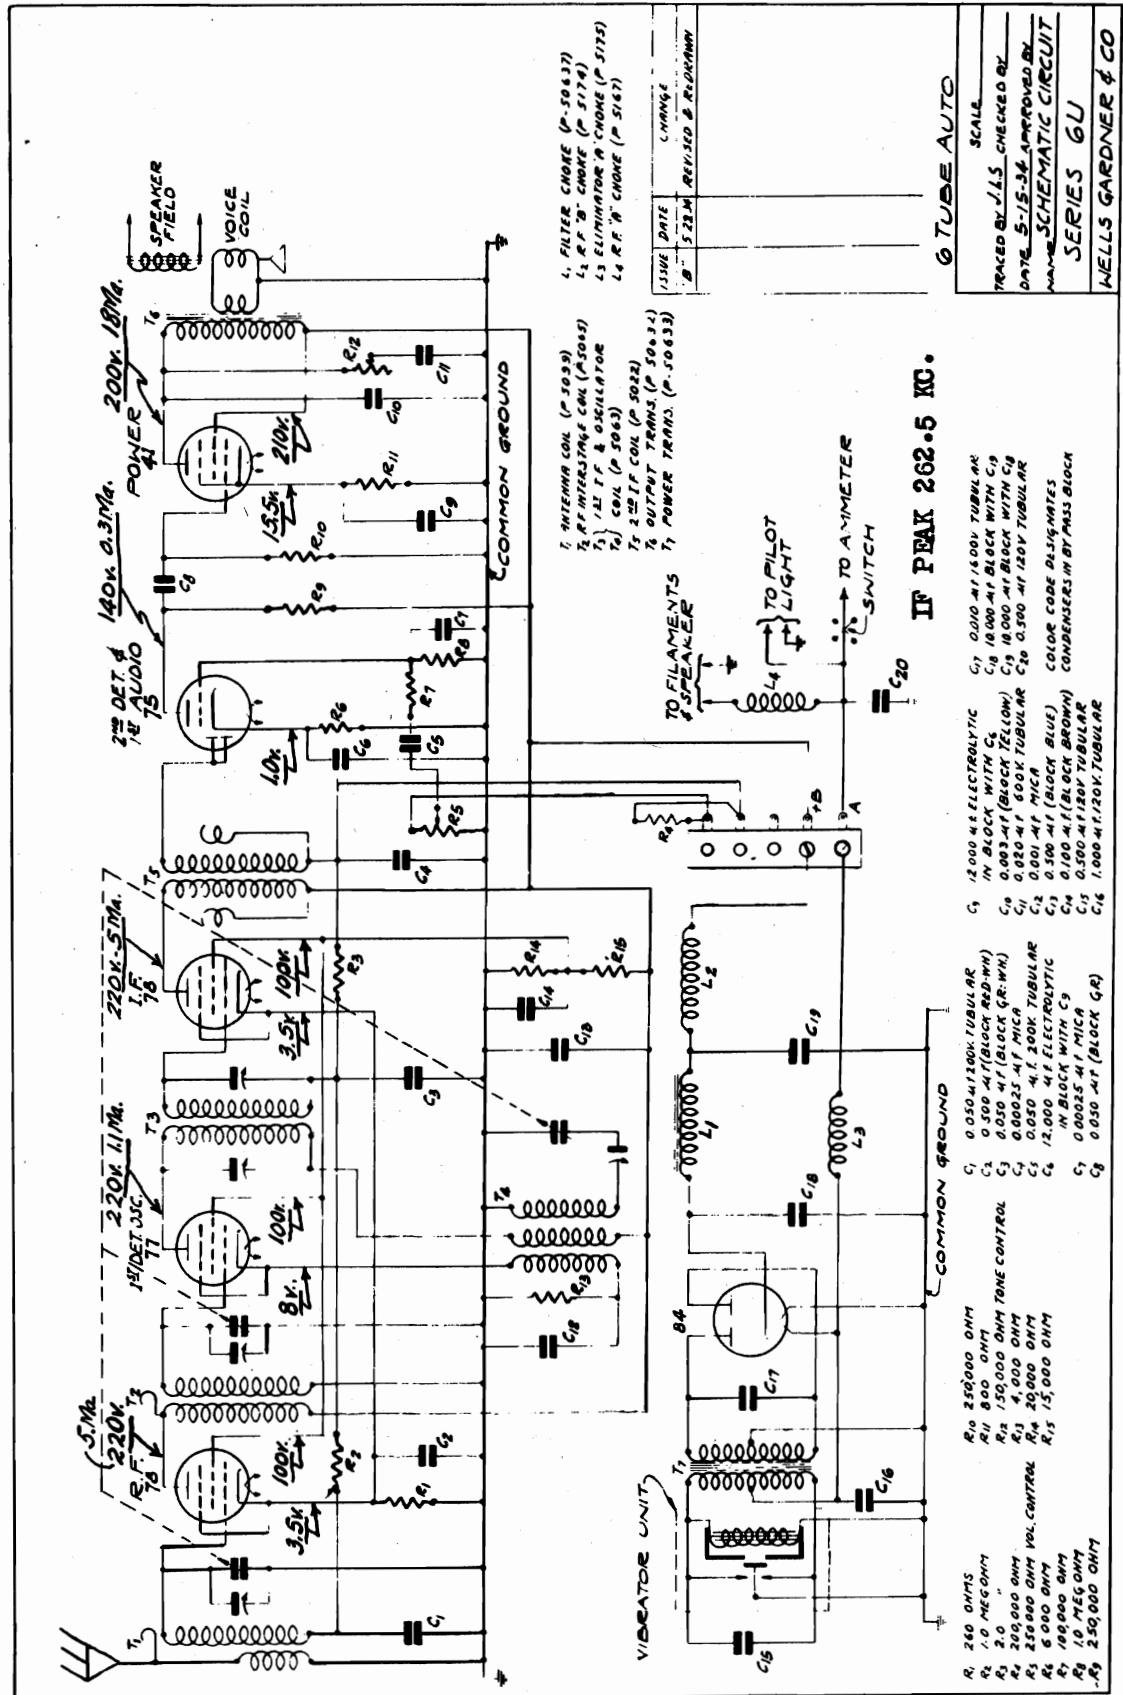

Voltagess

Check the voltagess at the sockets to see if correct values are being delivered to the tubes. The antenna and ground should be disconnected and the antenna and ground leads from the set connected together. The volume control should be turned to the right or maximum position.

The voltage chart gives the voltagess with all tubes in, the speaker connected and the set in operating condition. These voltagess are typical of the sets but will vary slightly with variations in individual receivers, tubes, test equipment used and battery voltagess.

MODEL 9-B Series
Service Notes, Parts

WELLS-GARDNER & CO., INC.

Replacing Drive Cord

Lift off the pilot light assembly.

Detach the large pointer by removing the center screw.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 6.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 6. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 6.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately 3/4" from the flange of the drum as shown in Fig. 6. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly.

Changes in Early Models

The condenser, C26 was used only on the early models of this receiver. Another change was in the tone control circuit. In the early models R8 was a 150,000 ohm resistor paralleled by a 60,000 ohm resistor. However, in the later models this arrangement was replaced by a single 45,000 ohm resistor to provide greater sensitivity in tone control.

Fig. 6—Drive Cord Replacement

Circuit

This model is a broadcast and short wave receiver with a coverage of 530 to 1730 K. C. on the broadcast band and 5.8 to 16.0 M. C. on the short wave band. Dual band coverage is accomplished by means of dual sets of R. F. and oscillator coils and a 4 section three position selector switch. The various circuits made and broken, as this switch is thrown, are indicated in the schematic circuit diagram Fig. 1.

Referring to the antenna transformer in Fig. 1, T1 is the broadcast transformer and T2 the short wave transformer. The two primaries are connected in series. With the switch in the short wave position, the short wave secondary is connected to the grid circuit of the 34 R. F. amplifier tube and the broadcast secondary is short circuited. When the switch is in the broadcast position, the short wave secondary circuit is opened up and the broadcast secondary is connected to the grid circuit of the tube. The secondary being used is tuned by the R. F. section of the three gang condenser. A separate variable trimmer condenser C2 is used for the short wave secondary.

Bias voltage for the 34 R. F. and 1st I. F. tubes is obtained from a high resistance potentiometer composed of resistors R2, R3 and R4, which are connected across the 16 1/2 volt "C" battery and the 2 volt "A" source. See Fig. 1. The grid circuit of this tube is connected between resistors R2 and R3.

The output of the R. F. 34 tube is fed through another R. F. transformer with tuned secondary into a second 34 tube which functions as the first detector. The first detector section of the three gang condenser is used for tuning this circuit. This interstage R. F. transformer consists of two portions shown as T3 and T4 on the diagram. T4 is the short wave coupling coil and T3 is the broadcast transformer.

The short wave coupling coil is connected to the plate circuit of the 34 R. F. amplifier thru an interstage plate reactor, L5, in conjunction with a by-pass condenser, C6. The standard wave transformer, T3, functions as a simple R. F. coupling the same as that of T1. A separate trimmer condenser C7 is used for the short wave coil.

A type 30 tube is employed in a separate oscillator circuit. Referring to the diagram, T8 is the broadcast oscillator coil and T9 is the short wave oscillator coil. The coil being used is tuned by the oscillator section of the three gang condenser and these circuits are always resonant at 456 K. C. above the frequency to which the R. F. amplifier is tuned. When the switch is in the broadcast position, the connections are completed to the broadcast oscillator coil and the short wave oscillator coil is opened up. When the switch is in the short wave position, the connections are completed to the short wave coil and the broadcast coil is connected between ground and the short tap in order to render it ineffective. A 600 K. C. padding condenser C15 is used in conjunction with the broadcast oscillator and a 6,000 K. C. padding C17 is used for the short wave oscillator circuit.

REPAIR PARTS LIST FOR 9 TUBE BATTERY OPERATED BROADCAST AND SHORT WAVE SUPERHETERODYNE RECEIVER

When ordering parts be sure and give the part number. Also give the series number which will be found in the License Notice label. If there is a spot of paint on the chassis, give this color.

WELLS-GARDNER & CO., INC.

**MODEL 9-B Series
Voltage
Alignment Data**

Condenser Alignment

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings of these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION—Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 3 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 3. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K. C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 3 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

*This includes filament voltage.
**250 v. Scale.

The measurement of grid bias voltages is not recommended as this causes an abnormal rise in plate current which is injurious to the tube. When the receiver does not function properly and the trouble is apparently due to incorrect grid bias on any tube or tubes, the cause of the incorrect bias may be determined by applying the proper continuity test.

CAUTION: Do not attempt to take voltage measurements or test the '33 pentode tube with a set analyzer which is not designed to test that type of tube. A special adaptor is necessary. The latest type analyzers only are designed to test pentode tubes. The UY socket in an analyzer which is used to test '24, '35, and '27 tubes cannot be used to test '33 pentode tubes. A break-in adaptor and the external binding posts of the set analyzer may be used to take voltage measurements when an adaptor is not available.

Comparison of the voltage measurements taken and those shown in the chart below will show any irregularities. The cause of any variation may be determined by applying the proper continuity test. **REMEMBER:**—Voltage measurements will vary slightly with different sets of tubes, and also with different chassis. Unless the voltages are radically different than normal, they may be considered satisfactory.

The voltages shown in the chart were taken with a 1000 ohm per volt voltmeter; voltage measurements taken with a voltmeter having a different resistance will, of course, differ from those shown.

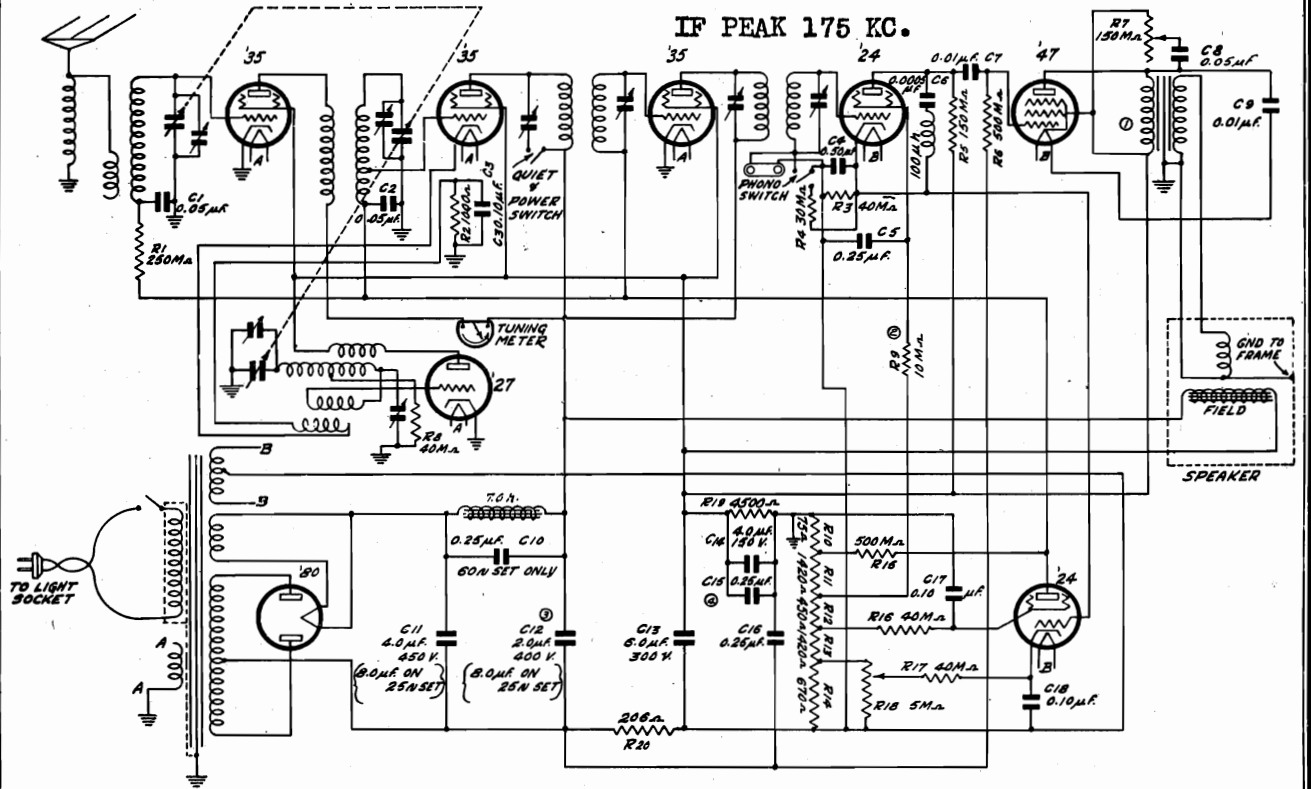

The .006 mfd. condenser connected from the plate of the pentode tube to ground is there for two reasons,—one, to prevent any I.F. or harmonic of the intermediate frequency from getting into the speaker and possibly coupling back into the antenna to cause a squeal; two, to put the proper amount of capacity across the speaker winding to produce a pleasing tone quality. This condenser may be varied to any value from .002 mfd. to .006 mfd. without losing its effectiveness in preventing the I.F. from getting into the speaker.

Voltage

Circuit

The circuit consists of an antenna stage, a 78 R.F. stage, a 77 1st detector-oscillator stage, a 78 I.F. stage, a 75 dual diode-triode tube, which functions as a diode 2nd-detector and triode 1st audio stage, and a single 41 output stage. An 84 full wave rectifier is used in the power unit. The intermediate frequency is 262 K.C. The diode current establishes a drop across a resistor which is used as additional bias voltage for the R.F. and I.F. tubes giving automatic volume control action. Noise suppression between stations is obtained by the resistor in the cathode circuit of the 75 tube, the drop across which must be overcome before rectification in this tube begins. The manual volume control varies the audio voltage applied to the grid of the 75 tube.

A vibrator interrupts the current through the primary of the power transformer in the power unit. This, together with the turns ratio in this trans-

Fig. 11—Condenser Block—Internal Wiring

Voltages at Sockets

Lower ranges will be necessary for the grid and heater voltages. It is not absolutely necessary to have a high resistance meter for the heater or "A" battery reading.

These voltages will vary with variations in receivers, tubes, test equipment used, and "B" eliminator output voltage.

In the following chart are given the voltages at the sockets with all the tubes in, all units connected, and the set in operating condition, but with no signal being received. The antenna should be grounded.

A thousand ohm-per-volt meter of 0-250 volt range is required for the plate and screen voltages.

Type of Tube	Function	Across Heater	Plate to Cathode	Screen to Cathode	Grid to Cathode	Normal Plate M.A.
78	R. F.	6.1	182	80	3. (1)	7.0
77	1st Det. and Osc.	6.1	178	77	5. (2)	1.3 (3)
78	I. F.	6.1	182	80	3. (1)	7.0
75	2nd Det. 1st Audio	6.1	70 (3)		1.4 (4)	.35
41	Output	6.1	172.5	176.5	12.5 (4)	16.0
84	Rect.	6.1	205			17.5 per plate

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself in broad tuning and leak of volume at portions or all of the broadcast band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attempted unless all other possible causes of the faulty operation have first been investigated, and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the broadcast band and accurately calibrated signals at and around 262 K.C., the intermediate frequency and an output indicating meter are desirable.

First set the signal generator at approximately 262 K.C. Connect the antenna lead from the generator to the control grid of the I.F. 78 tube, through a .05 mfd. condenser. The ground lead of the generator goes to the ground of the receiver. Turn the rotor plates of the tuning condenser completely out and keep the signal weak enough to prevent A.V.C. action. Note from Fig. 10 that the second I.F. transformer is self tuned and cannot be adjusted. Adjust the frequency of the signal generator until the output meter shows maximum output. The intermediate frequency setting of the generator is then correct, although it may be a very small percentage higher or lower than 262 K.C.

Next connect the signal lead from the signal generator to the grid of the 1st detector tube through a .05 mfd. condenser. Then adjust the two intermediate frequency condensers for maximum output. One

of the I.F. condenser screws is reached through the hole on the top of the 1st I.F. assembly can. The other I.F. condenser screw is reached from the bottom of the sub-panel through a hole at the bottom of this assembly.

Now set the signal generator for a signal of exactly 1400 K.C. The antenna lead from the generator is, in this instance, connected to the antenna lead of the receiver. Connect the flexible drive shaft to the chassis if it has been disconnected. As explained previously, the dial scale should be at the low frequency end and stop when the rotor is completely in mesh. Then turn the station selector knob until the dial scale is at 1400 K.C.

Then adjust the three trimmer condensers on the gang tuning condenser for maximum output, adjusting the oscillator section first.

Next, set the signal generator for a signal of 600 K.C. and adjust the oscillator 600 K.C. trimmer. The adjusting screw for this condenser is reached through a hole in the back wall of the sub-panel.

A non-metallic screwdriver is necessary for this adjustment. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 600 K.C. trimmer screw until the highest output is obtained.

Then set the signal generator again for a signal of 1400 K.C. and check the adjustment of the tuning condenser trimmers at this frequency for maximum output.

Rattle

If rattle is experienced when a signal is being received, it is, in practically all cases, due to mechanical vibration at some point in the chassis. Inspect the chassis and look for a loose tube shield or a loose part at some point which can rattle against another part. When the vibrating part is found, secure it in place in some manner. This can generally be done

If the Receiver Fails to Operate

"A" Fuse—Check the "A" line fuse in the cable.

"A" Line Open—See if power is being supplied to the speaker, tube heaters, and "B" eliminator.

"B" Eliminator Not Working—See if the "B" eliminator is in proper working order by checking the high voltage points at the tube plate terminals (see Fig. 10).

Antenna and Lead—See if antenna is properly connected to lead-in wire and antenna lead from set. Be sure antenna system is not grounded at any point.

All Tubes Not Inserted—See if all tubes are inserted as per Fig. 8.

Defective Tubes—Try out a new set of tested tubes.

Grid Caps Not Connected—See if all grid caps are properly connected to top of top grid connection tubes.

Variable Condenser Plates Shorted—Check condenser sections in chassis carefully for foreign particles or rotor stator rubbing.

MODEL WR-20
Schematic
Socket
Voltage

Universal Compact
Operates on either AC or DC
110-120 Volts, 25-60 Cycles
Adaptable for 220-Volt Current
with use of 220-Volt Resistor

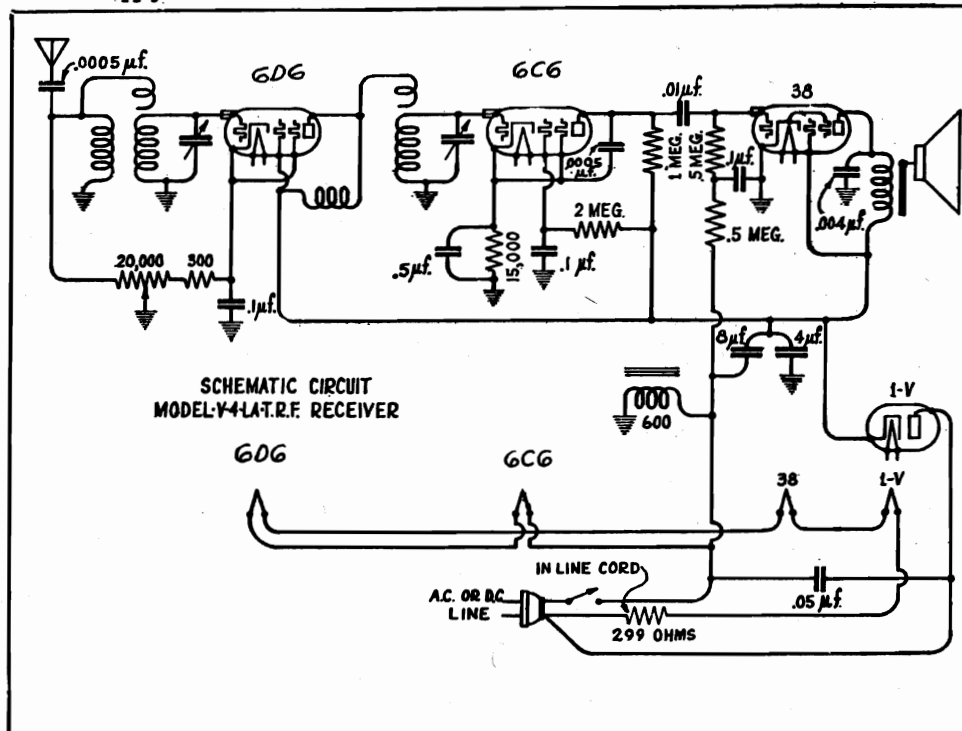

Voltage Readings:

Readings should be taken with Volume Control fully on, Tuning Control set for 550 KC., and antenna outside of set. Use a D. C. voltmeter having a resistance of 1000 ohms per volt.

Chassis	To— Plate	Screen	Cathode
77—Detector	10- 15	9- 12	1- 2
78—R.F. Amplifier	105-115	105-115	2- 3
38—Output Pentode	105-115	105-115	—

Voltage across filter choke is "C" bias for 38 Tube=10v.

Readings will not change materially regardless of type of power supply.

WESTINGHOUSE ELEC. SUPPLY CO.

ADJUSTMENTS

The receiver was carefully adjusted and tested by experts at the factory, and should reach the customer in perfect condition. Under no circumstances should these adjustments be disturbed unless it is absolutely necessary as in the repairing of a damaged set. This should be done by an experienced Auto Radio Service man only.

Intermediate Transformers

To align the intermediate frequency transformers, use a good modulated oscillator set for 172½ k.c. Set the volume control for maximum volume and turn the dial to a point where little or no signal is received; then ground the antenna.

Connect the oscillator output between the grid of the 6A7 tube and ground. Connect an output meter across the primary of the speaker transformer or across the voice coil. Using the smallest output from the test oscillator that will give a small reading on the meter, adjust the two I.F. transformers for the largest reading obtainable. Use a non-metallic screw driver if possible.

Radio Frequency and Oscillator

To align the R.F. and oscillator sections, couple the oscillator through a standard dummy antenna to the antenna lead and ground of the receiver. Set the test oscillator to some frequency between 1350-1450 k.c. Set the dial to the frequency selected. Adjust trimmers on the variable condenser beginning with the oscillator trimmer. Reduce the output of the test oscillator and repeat. In the absence of an oscillator, the R.F. sections may be aligned on broadcast.

Tune in a weak station between 1350 and 1450 k.c. and align as before. If an output meter is not available, adjust for maximum volume, then reduce the input and repeat.

Voltage Analysis:

Note: All "B" and "C" voltages should be measured on a high resistance voltmeter of 1000 ohms per volt or over.

The voltages are measured to ground from the points named. Ground the antenna to its shield when taking readings.

Battery volts—6. Volts across heaters—6 scant. Volts across speaker field—6 scant.

|---------------------------|--------------------------------|
| #1 RF Trimmer Condenser | #8 2nd Det. AVC & AF Amplifier |
| #2 1st Det. Trimmer Cond. | #9 Power Output |
| #3 Osc. Trimmer Condenser | #10 Rectifier |
| #4 1st IF Trimmer Cond. | #11 RF Amplifier |
| #5 1st IF Amplifier | #12 Det. and Osc. |
| #7 2nd IF Trimmer Cond. | #13 1st IF & Osc. Coil |

All of the adjustable condensers commonly called trimmer condensers, are very accurately adjusted at the factory and will not need any further adjustments unless a coil or I. F. transformer is changed or the adjustments have been tampered with in the field. Therefore, DO NOT attempt to change the setting of any of the trimmer condensers unless it is definitely known that adjustment is necessary, and a high-grade test oscillator and output meter is available, then proceed as follows:

1. Connect output meter across voice coil of speaker.
2. Set volume control on full.
3. Set tone control to bass position.
4. Connect dial light.

(A) I. F. Adjustment

1. Connect a .1 mfd. condenser in series with antenna lead of test oscillator.
2. Set test oscillator to 175 K. C.
3. Connect test oscillator to grid of 1st I. F. tube #6 (see Fig. #2) and adjust #7 to maximum output.

4. Connect test oscillator to grid of 1st Det. #12 and adjust condensers #4 and 5 to maximum output.
5. Repeat the above adjustments for accuracy.

(B) Oscillator Adjustment

1. Set test oscillator to 1500 K. C.
2. Connect test oscillator leads to grid of 1st Det. #12.
3. Set gang condenser to 1500 K. C. as follows:
 - (a) Open gang to fullest extent.
 - (b) Close slowly to the thickness of a thin cardboard strip or approximately .015".
4. Peak oscillator condenser #3 on end of gang.

(C) R. F. Adjustment

1. Set test oscillator to 1400 K. C.
2. Change antenna condenser in oscillator lead from .1 mfd. to .0002 mfd., and connect test oscillator to antenna lead of set.
3. Set condenser gang at 1400 K. C.
4. Peak condensers #1 and 2 on gang.
5. Do not touch oscillator trimmer #3 at 1400 K. C. setting of gang.

CIRCUIT DESCRIPTION

The Models WR-28-29 are six tube, dual wave-band receivers, designed to operate over the frequency ranges from 1570 to 540 kilocycles and 15,500 to 5,700 kilocycles. The circuits comprise an R. F. selector circuit, a combination first detector oscillator, two stages of intermediate frequency amplification (456 KC) with double tuned circuits coupling each stage, a combination second detector, A.V.C. and first audio stage, a power output stage and a rectifier tube.

The wave change switch serves to change the electrical circuits to the wave band desired and in addition operates to illuminate the particular dial scale in use.

ALIGNING THE CHASSIS

To properly align the Models WR-28-29 chassis, it is essential to use a high grade modulated oscillator and a sensitive output meter. The R. F. signal fed into the receiver must be very weak or it will cause the A. V. C. to function making correct alignment impossible. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low signal.

Before attempting to align the chassis, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

A- I. F. ADJUSTMENT

1. Set test oscillator to 456 K. C.
2. Connect A. C. voltmeter (output meter) across voice coil of speaker.

3. Connect test oscillator to grid of 2nd I.F. tube (6D6 in rear of condenser gang) and frame of chassis.

4. Adjust #1 and #2 to maximum output on output meter.

5. Connect test oscillator to grid of 1st I.F. tube (6D6 - rear right hand tube).

6. Adjust #3 and #4 to maximum output.

7. Connect test oscillator to grid of 1st detector (6A7).

8. Adjust #5 and #6 to maximum output.

This completes the I. F. adjustment.

B - R. F. ADJUSTMENT
(Broadcast Band)

1. Connect test oscillator to antenna and ground leads. Set wave change switch to broadcast band position as indicated by the dial light. Set station selector to 540 K. C.

2. With test oscillator still adjusted to 456 K. C., increase signal strength of test oscillator until signal is heard in loud speaker.

3. Adjust #7 (through small hole in right hand rear panel of chassis) until signal disappears or goes through a null. If signal disappears, increase signal output from test oscillator and readjust #7 until a definite minimum is obtained. The purpose of this adjustment is to correctly adjust a wave trap installed to block direct transmission of 456 K. C. (usually ship telegraph signals) from antenna to first detector.

4. Set test oscillator and station selector to 1400 K. C.

MODEL WR-28,WR-29

WESTINGHOUSE ELEC. SUPPLY CO.

Schematic
Alignment, Part 2

5. Adjust #8 to maximum output.
6. Adjust #9 to maximum output.
7. Set test oscillator and station selector to 600 K. C.
8. Adjust #10 to maximum output (top screw)
9. Set test oscillator and station selector to 1400 K. C. and readjust #8 and #9 for correct calibration.

2. Set test oscillator and station selector to 15,000 K. C.
3. Adjust #11 until signal is tuned in.
4. Adjust R. F. trimmer condenser (mounted underneath chassis on R. F. coil) to maximum output.

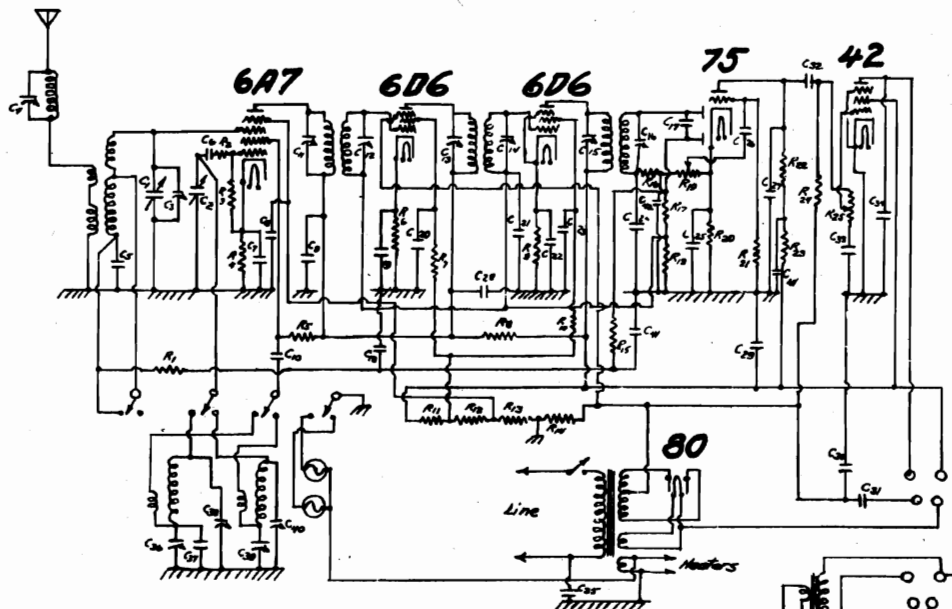

C - R. F. ADJUSTMENT
(Short Wave Band)

1. Set wave change switch to short wave band position.

5. Set test oscillator and station selector to 6000 K. C.

6. Adjust #12 to maximum output (bottom screw)

7. Set test oscillator and station selector to 15,000 K. C. and readjust #11 and R. F. trimmer underneath chassis for correct calibration. This completes the lining up process.

IF 456 KC.

Voltage, Socket
Alignment Data
Parts List

WESTINGHOUSE ELEC. SUPPLY CO.

4. Adjust trim condensers, located underneath chassis and mounted to the coil leads at the extreme right end, to maximum output.
5. Set test oscillator and station selector to 1800 KC.
6. Rotate #14 until signal is at maximum.
7. Return test oscillator and station selector to 3600 KC setting and readjust #13 for correct calibration.

D - ADJUSTMENT OF 3rd BAND

1. Set wave change switch to 3rd band position and set test oscillator and station selector to 9000 KC. On bottom of chassis fastened to the back plate is the 3rd band oscillator coil in its shield container. This coil is directly in back of the wave change switch. A Green wire twisted around a Green and White wire will be used to make adjustments to bring this band to correct calibration. If set is not on calibration, an increase or decrease of the twist will serve to readjust the calibration. This adjustment will serve for about one-half a scale division either way. If set is initially off more than this, it indicates a serious fault in the oscillator circuit, such as wrong component values, incorrect wiring, or defective oscillator tube or other major fault.

Assuming that the correction can be made, the set is now placed on its proper marking and adjustment is made of the preslector trim condensers for this wave band. These condensers are the 100,000 ohm units mounted integral with the preslector coils. The coil leads are connected to the main switch assembly and are located between the 2nd band (furtherest left on under side) and the highest frequency selector coils which are located under the isolantite trim condensers.

2. Adjust test oscillator and station selector to 5000 KC setting.
3. Adjust 3rd band lagging condenser to maximum output. This condenser is located on the back plate to the right of the 3rd band oscillator coil mentioned above.
4. Return to 9000 KC setting and check the previous setting.

E - ADJUSTMENT OF 4th BAND

1. Set wave change switch to the 4th band position and adjust test oscillator and station selector to 20,000 KC.
2. Adjust oscillator trim condenser (lower left hand unit on back of chassis) for maximum output.
3. Then adjust trim condensers for further maximum output. These condensers are two isolantite base units mounted integral with the switch assembly.
4. Set test oscillator and station selector to 12,000 KC.
5. Adjust oscillator lag condenser (upper left hand corner of rear plate) until signal is tuned in.
6. Return test oscillator and station selector to 20,000 KC and check setting.

A - ALIGNING THE I.F. (456 KC)

1. Set test oscillator to 456 KC.
2. Connect output meter across voice coil of speaker.
3. Connect test oscillator to grid of 2nd I.F. tube (#1).
4. Adjust #4 and #5 to maximum output as indicated on output meter.
5. Connect test oscillator to grid of 1st I.F. tube (#2).
6. Adjust #6 and #7 to maximum output.
7. Connect test oscillator to grid of 1st detector tube (#3).
8. Adjust #8 and #9 to maximum output.

B - ADJUSTMENT OF BROADCAST OR 1st BAND

Note: Because of set sensitivity it is difficult to make a perfect adjustment. This is easily accomplished by cutting out the amplification of an I. F. stage. To do this, remove grid clip on tube #1, and connect to this tube the grid clip previously connected to tube #2. Remove tube #2 from its socket.

1. Set test oscillator and station selector to 1400 KC.
2. Connect test oscillator to grid of 1st detector tube (#3).
3. Adjust #10 (Red color coded) until signal is tuned in.
4. Connect test oscillator to antenna and ground leads of chassis.
5. Adjust #11 and the two alignment condensers underneath the chassis located directly in front of the chassis located directly in front of the broadcast selector coils, until signal is correctly tuned in.
6. Set test oscillator and station selector to 500 KC.
7. Adjust #12 to maximum output.
8. Return to 1400 KC setting and readjust #10 for correct calibration.

C - ADJUSTMENT OF 2nd BAND

1. Adjust wave change switch to 2nd band position and set station selector to 3600 KC.
2. Set test oscillator to 3600 KC.
3. Adjust #13 (Green color coded) until signal is tuned in.

SERVICE TECHNICAL DATA

Stage	Tube	Filament	Plate	Screen	Cathode
Rectifier	83V	5.0	340		
Audio power output	6A5	6.0	305		
Audio power output	6A6	6.0	290	250	
2nd Det. I.F. C, 1st audio	42	6.0	240	100	30
I.F. amplifier	67	6.0	240	100	4.5
I.F. amplifier	78	6.0	240	100	4.5

MODEL 4B6, Road Mate
Schematic, Voltage
Alignment

The three R. F. trimming condensers are adjusted at 1400 K. C.. Proceed as follows: Procure a modulated oscillator giving a signal at 1400 K.C..

IF PEAK 175 KC.

Remove the chassis from case, couple the output of the oscillator from antenna to ground, set the dial at 1400 and the oscillator at 1400 K.C..

Place the oscillator and receiver in operation and adjust the oscillator output so that a weak signal is heard in the loudspeaker when the volume control is at its maximum position.

Then adjust the trimming condensers starting with C 3, C 2 and then C 1 until maximum output is obtained. Readjust a second time as there is a slight interlocking of adjustments.

A more accurate adjustment can be made with an output meter.

I. F. Adjustment:

The four I. F. trimming condensers are adjusted at 175 K.C.. Proceed as follows:

Procure a modulated oscillator giving a signal at 175 K.C., a non-metallic screw driver and an output meter.

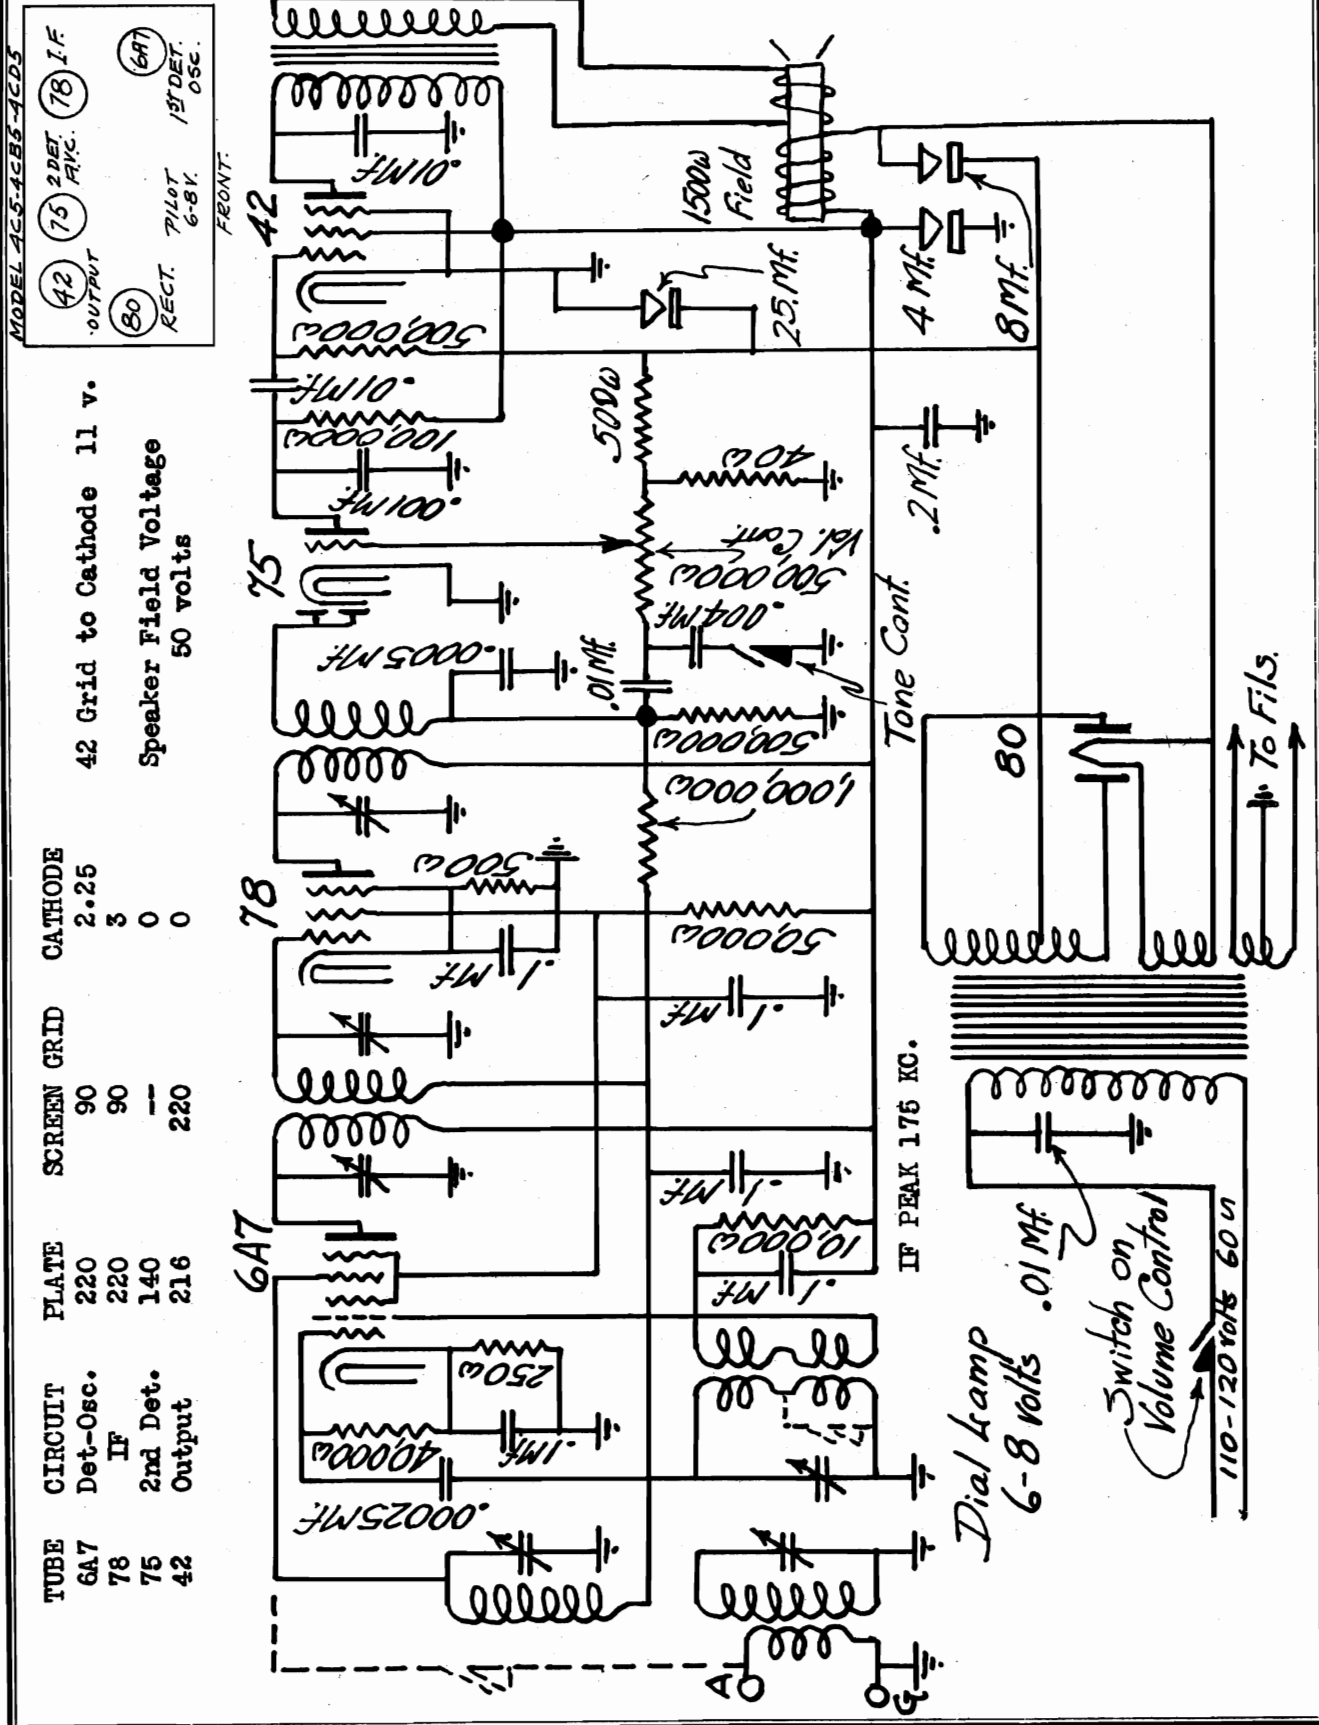

Connect the oscillator output between the first detector grid and ground. Connect output meter.

Adjust the tuning condenser so that no signal except the I. F. oscillator is heard at maximum volume. With the volume control at maximum, reduce the oscillator output until a small deflection is obtained. Unless this is done the action of the AVC will make it impossible to obtain correct adjustments.

Trim in order C 4, C 5, C 6 and C 7, repeat adjustments and then follow with the R. F. adjustments.

Parts List

THE RUDOLPH WURLITZER CO.

TO CALIBRATE THE 450

With the band switch in the broadcast position (clockwise), set the dial to the position where a station (or oscillator) of known frequency, about 1400 kc., should come in.

(a) Adjust oscillator trimmer (screw adjustment, top-rear of gang condenser) until desired signal is received. The calibration will fall within reasonable limits over the balance of the tuning range with no further adjustments.

TO ALIGN THE 450

With the band switch in the broadcast position (clockwise), set the dial to approximately 1400 kc.

(a) Attach the output meter from screen to plate of the 2A5 tube.

(b) Attach the local oscillator tuned to the set to the green antenna lead and,

(c) Adjust the R. F. trimmer (screw adjustment, top, front of gang condenser) for maximum indication on output meter.

The alignment will fall within reasonable limits over the balance of the tuning range with no further adjustments.

The Model 450 is a five tube dual band superheterodyne covering the broadcast band and an additional short-wave band of from 1440 to 3500 kc. The circuit used embodies a 58 oscillator-modulator, a 58 I. F. amplifier operating at 456 kc., a 57 plate circuit second detector, and a 2A5 output audio stage. The volume control functions to increase the bias on the I. F. 58 and decrease the signal from the antenna to effect a decrease in volume. In all ganging operations this control must be advanced to its maximum position (clockwise), and THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER must be used.

The I. F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier to be at fault. In that event:-

(a) Attach the output meter from screen to plate of the 2A5 tube.

(b) Attach the local oscillator tuned to 456 kc. to the antenna lead of the receiver and,

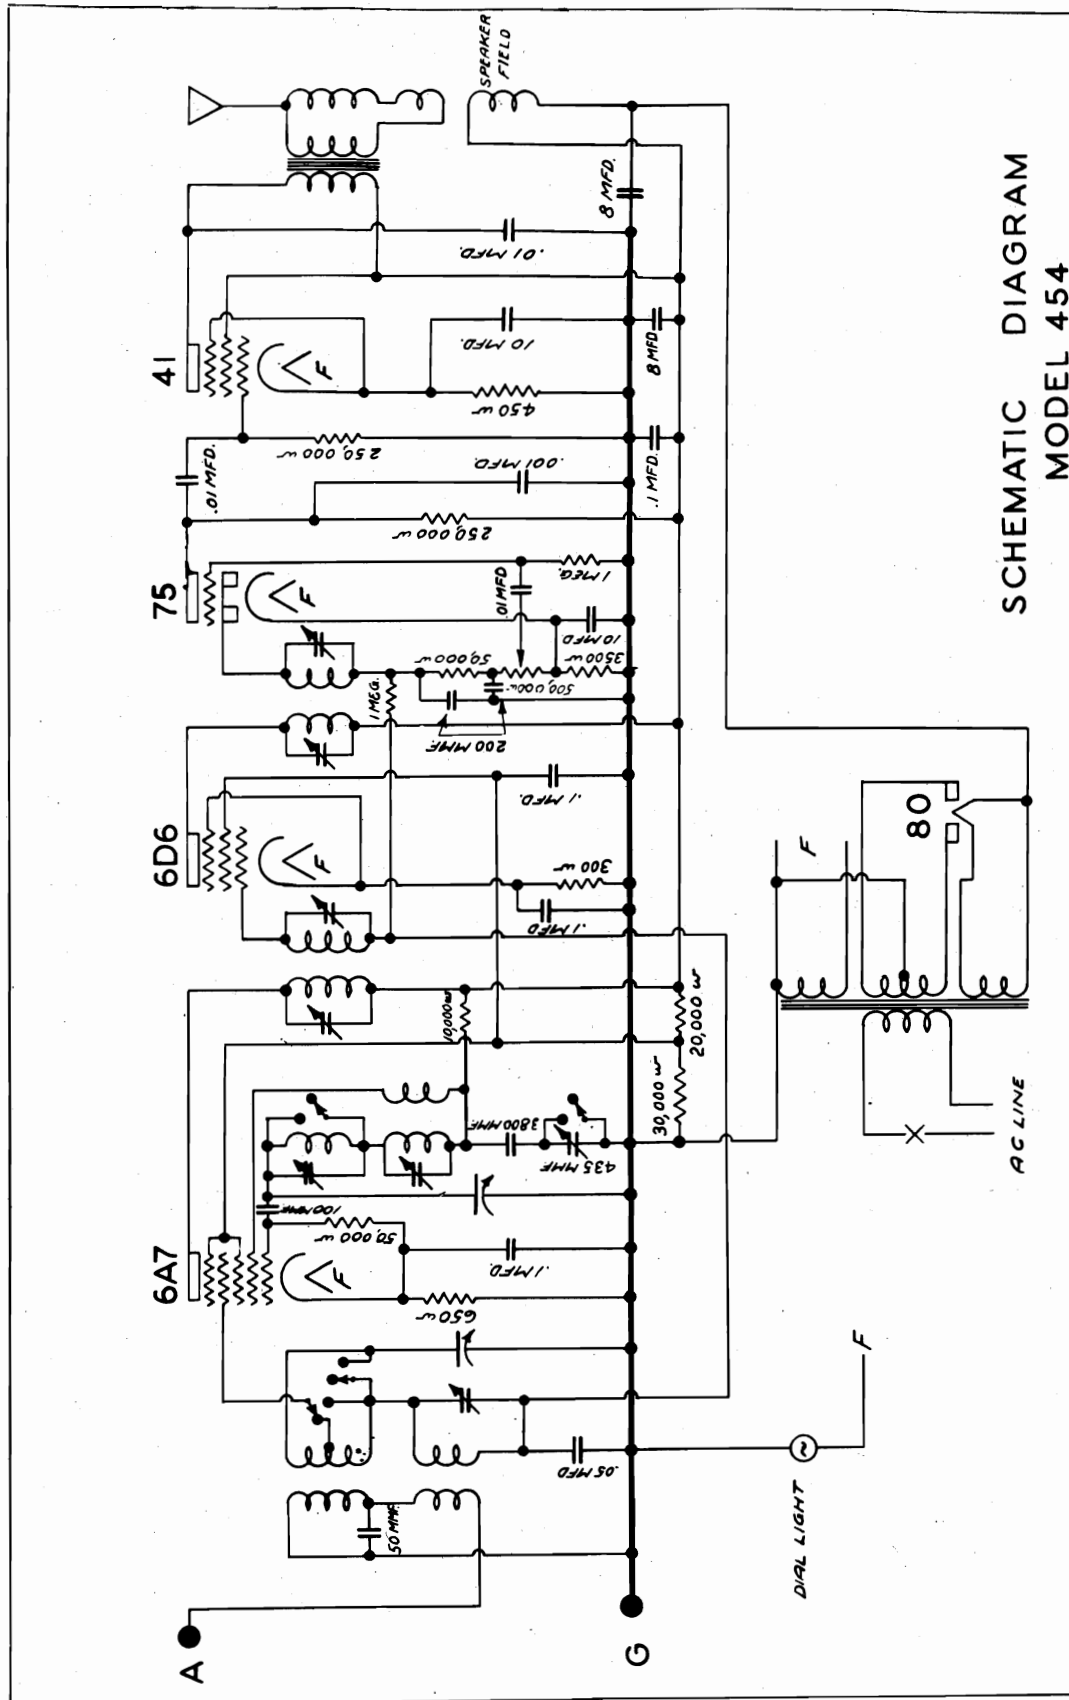

(c) Adjust the I. F. trimmers (screw adjustments, accessible when the name plate is removed) for maximum indication on the output meter.

There are no adjustments to be made on the short-wave band.

DWG. NO. 86

MODEL 460
Alignment Data

THE RUDOLPH WURLITZER CO.

The Model 460 is a 6 tube superheterodyne, completely self-contained, for operation from a 6 volt d.c. source. A cable drive remote control head is used, one cable operating the volume control and switch and the other cable operating the tuning condenser.

The circuit comprises a stage of R.F. amplification, an oscillator-modulator, and a stage of I.F. amplification at 175 kc., each using a 6D6 tube. A 6B7 is used as a diode second detector-A.V.C. and first audio stage and a 4L is used in the audio output stage. The power supply, an integral part of the chassis, uses an 85 or a 6Z4 as a full wave rectifier for the B supply. The filter choke is in the negative side of the B supply, and the voltage drop across it, after being filtered, furnished the C supply for the set.

The pentode section of the 6B7 is used as the first audio stage, resistance coupled into the 4L. One of the diode plates of the 6B7 is used for the diode second detector and the other diode plate is used in the diode A.V.C. circuit. An inspection of Drawing #86 will indicate that under normal signal conditions, the cathode of the 6B7 is considerably more positive than the A.V.C. diode plate. As a result no current will flow through the A.V.C. diode until the signal applied to this diode plate is greater than the bias on the 6B7 cathode. The advantage of the circuit is two-fold, greater volume on weak signals and more uniform volume on all signals than straight diode A.V.C. provides.

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER and turn both the volume and tone controls to their maximum positions (clock-wise).

TO ALIGN (or gang) THE I.F. CIRCUITS

- (1) Attach the output meter from screen to plate of the 4L tube.
- (2) Feed the signal from the local oscillator tuned to exactly 175 kc. into the receiver at the control grid of the oscillator-modulator 6D6.
- (3) Adjust the I.F. trimmers for maximum indication on the output meter, ALWAYS KEEPING THE SIGNAL INPUT LOW.

(a) The first I.F. trimmers are mounted in the end of the first I.F. transformer located between the gang condenser

and the chassis pan. The nut adjusts the primary trimmer. (b) The second I.F. trimmers are mounted in the end of the second I.F. transformer, located under the chassis pan directly below the speaker field. The nut adjusts the primary trimmer.

TO CALIBRATE THE OSCILLATOR

- (1) Set the dial pointer to 53 with the plates entirely enmeshed.
- (2) Set the dial pointer to the position where a station or (oscillator) of known frequency, about 1500 kc., should be received and adjust oscillator trimmer (screw adjustment, top of gang condenser, inside end) until the desired signal is heard.
- (3) Set the dial pointer to the position where a station (or oscillator) of known frequency, about 1100 kc., should be received and correct calibration (if necessary) by bending the rotor plates of the inside gang condenser section.
- (4) Repeat operation 3 at, or near, 850 kc.
- (5) Repeat operation 3 at, or near, 700 kc.
- (6) Repeat operation 3 at, or near, 580 kc.

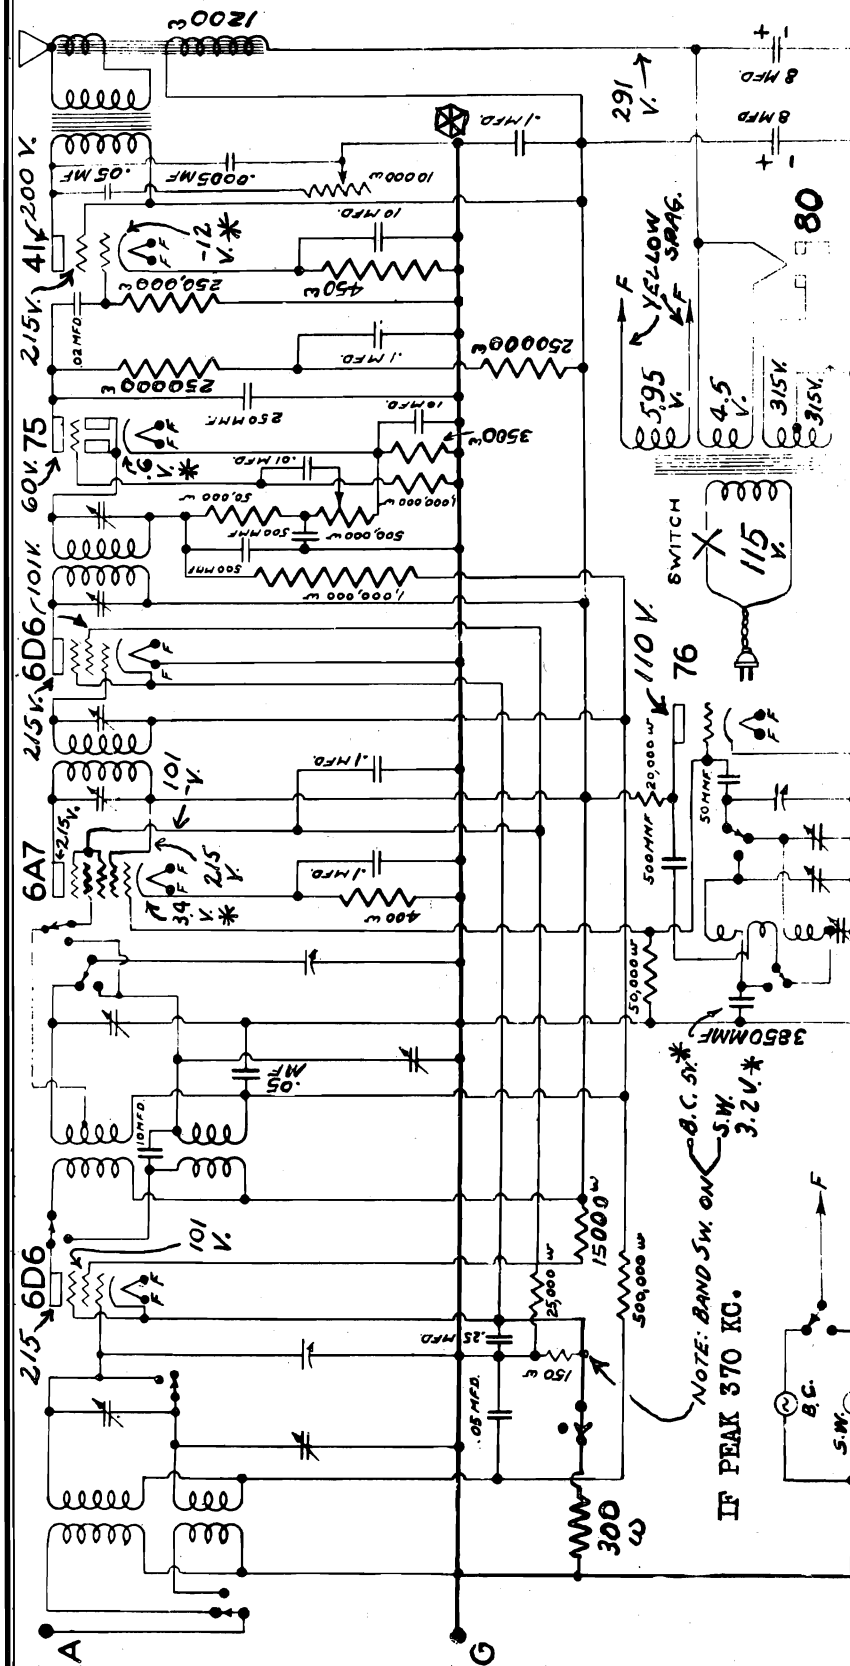

TO ALIGN (or gang) THE R.F. CIRCUITS

- (1) Attach the output meter from screen to plate of the 4L tube.
- (2) Attach the local oscillator to the antenna lead and KEEP THE SIGNAL INPUT L.W.
- (3) With the receiver and oscillator tuned to resonance at, or near, 1500 kc. adjust the antenna and R.F. trimmers (screw adjustments, top of gang condenser, outside and middle sections) until maximum output is obtained.
- (4) With the receiver and oscillator tuned to resonance at, or near, 1100 kc. bend the rotor plates of the outside and middle gang condenser sections to obtain maximum output.
- (5) Repeat operation 4 at, or near, 850 kc.
- (6) Repeat operation 4 at, or near, 700 kc.
- (7) Repeat operation 4 at, or near, 580 kc.

NOTE--RE OPERATION 2, CALIBRATION PROCEDURE: If more than one position of the oscillator trimmer enables the desired signal to be received REDUCE THE INPUT TO THE RECEIVER until one, and only one position of the oscillator trimmer will enable the desired signal to be received.

MODEL Lyric C-4, M-4
Notes, Alignment Data

THE RUDOLPH WURLITZER CO.

The only difference between the Lyric Models C-4 and M-4 is the placement of the volume control and gang condenser. On the Model C-4 the volume control is mounted on a

bracket at the left, and the gang condenser on the right.

On the Model M-4 the volume control is mounted below the

gang condenser on the right. Hereinafter these models

are referred to indiscriminately as Model C/M-4. The

early Model C/M-4 is a single (broadcast) band receiver.

The later models have an additional short wave band,

approximately 1500 to 4000 kc., which is selected by a

toggle switch at the right rear of the chassis pan.

There are no calibration or alignment adjustments to make

on this band. For short wave reception the switch must

be thrown toward the end of the chassis pan. For

Broadcast reception, toward the center of the chassis pan.

Connect the output meter (when used) from screen to

plate of 43 tube.

Advance the volume control to its maximum position

(clockwise).

In all ganging operations USE THE WEAKEST SIGNAL THAT

WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER.

Do this by reducing the input, NOT BY RETARDING THE

VOLUME CONTROL.

The C/M-4 uses the 6B7 as a reflexed I.F.--A.F. amplifier,

and the I.F. trimmer adjustments are very critical. For

this reason, and because these adjustments are carefully

made at the factory, the alignment of the I.F. trimmers

is not recommended. If, however, the I.F. amplifier is

definitely at fault--the following procedure should be

followed:-

(1) Attach the output meter from screen to plate of

43 tube.

(2) Attach antenna lead to local oscillator tuned to

456 kc.

(5) KEEPING THE INPUT FROM THE LOCAL OSCILLATOR AS LOW AS POSSIBLE, adjust the I.F. trimmers for maximum reading on the output meter.

(A) The first I.F. trimmer is located under the chassis pan, adjustable through a hole in the chassis pan, near right center, directly in front of the first I.F. transformer. The slot adjustment is the primary trimmer. The nut ($\frac{1}{4}$ " hex) adjustment is the secondary trimmer.

(B) The second I.F. trimmer is located under the chassis pan, adjustable through a hole in the chassis pan, left center, near volume control.

TO CALIBRATE THE C/M-4

(1) Throw the toggle switch (if any) to the broadcast position.

(2) Set the gang condenser to the position where a station (or oscillator) of known frequency, about 1500 kc., should be received.

(3) Adjust the oscillator trimmer (screw adjustment, top of gang condenser, front end) until desired signal is heard. The calibration of the rest of the dial will fall within reasonable limits without further adjustment.

TO ALIGN (or gang) THE C/M-4

(1) Throw the toggle switch (if any) to the broadcast position.

(2) Connect the output meter from screen to plate of the 43 tube.

(3) Turn condenser to approximately 1400 kc., connect antenna lead to local oscillator tuned to set, and check setting of volume control.

(4) Adjust R. F. trimmer (screw adjustment, rear end, top of gang condenser) until output meter indicates maximum output. KEEP SIGNAL INPUT LOW.

The alignment of the balance of the tuning range will fall within reasonable limits with no further adjustments.

ALIGNMENT PROCEDURE FOR LYRIC C-4 & M-4

THE RUDOLPH WURLITZER CO.

The Lyric Model P-5 is a five tube superheterodyne of the universal type with the heaters of the tubes connected in series. A 456 kc. I. F. amplifier is used and a series (acceptor) wave trap is shunted across the primary of the antenna coil to minimize the pick-up of stations operating at, or very near, the I. F.

The circuit used includes, a 6A7 electron coupled oscillator-first detector, and a 75 duplex diode hi-mu triode in the second detector-first A. F. circuit. Diode type A. V. C. is employed.

The first I. F. transformer is fitted with an adjustable tickler to control the sensitivity of the receiver. This tickler is mounted on a small wooden dowel protruding from the center, bottom, of the transformer and is connected between the cathode and suppressor of the 78 I. F. tube. To increase the sensitivity of this receiver, pull out on the dowel. To decrease the sensitivity of, (or to stabilize), this receiver, push the dowel in. A socket is provided at which the autotransformer may be connected, thus enabling the P-5 to be operated from a 6 volt D. C. source.

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER. DO THIS BY REDUCING THE INPUT, NOT BY RETARDING THE VOLUME CONTROL.

The I. F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier to be at fault. In that event:-

- (1) Attach the output meter from screen to plate of the 43 tube.
- (2) Attach the local oscillator, tuned to 456 kc., to the antenna lead.
- (3) Adjust the I. F. trimmers for maximum indication on the output meter.

(A) The first I. F. trimmer is a dual unit, located on the rear of the chassis pan. The nut adjustment is the secondary trimmer.

(B) The second I. F. trimmer is a dual unit located on the top of the chassis pan near the volume control. The nut adjustment is the primary trimmer.

(4) Adjust the wave trap trimmer for MINIMUM indication (dip) on the output meter.

(A) This trimmer is a single unit at the extreme left end, on the rear of the chassis pan.

TO CALIBRATE THE P-5

(1) Set the condenser to the point where a station (or oscillator) of known frequency, about 1400 kc., should be received.

(2) Adjust the oscillator trimmer (screw adjustment top, front of gang condenser) until desired signal is heard. The calibration will then fall within reasonable limits with no further adjustment.

TO ALIGN (or gang) THE R. F. CIRCUIT

(1) Attach output meter from screen to plate of the 43 tube.

(2) Turn condenser to 1400 kc.

(3) Attach antenna lead to local oscillator tuned to resonance with receiver.

(4) Adjust R. F. trimmer (screw adjustment top, rear of gang condenser) for maximum indication on the output meter. The alignment of the R. F. stage will fall within reasonable limits with no further adjustments.

ALIGNMENT PROCEDURE FOR MODEL P-5

MODEL SA-5
Alignment Data

THE RUDOLPH WURLITZER CO.

The Model SA-5 is a 5 tube superheterodyne covering the broadcast band and utilizing a band pass filter between the antenna and the first detector, a 2A7 electron coupled oscillator-first detector circuit, a 175 kc., I. F. amplifier, and a 2A6 duplex diode hi-mu triode second detector-first A. F. circuit. Diode type A.V.C. is employed.

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER. DO THIS BY REDUCING THE INPUT, NOT BY RETARDING THE VOLUME CONTROL.

The I. F. trimmers are carefully adjusted at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier to be at fault. In that event:-

- (1) Attach the output meter from screen to plate of the 2A5 tube.
- (2) Attach local oscillator tuned to exactly 175 kc. to the control grid of the 2A7, providing a D. C. from this point to ground.
- (3) Adjust the I. F. trimmers for maximum indication on the output meter. These I. F. trimmers are mounted on a strip extending from near the 2A7 socket toward the center of the chassis pan. A recheck of each trimmer adjustment, to insure perfect alignment of the I. F. stages, is recommended.

TO CALIBRATE THE SA-5

- (1) Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc, should be received. Adjust the oscillator trimmer (screw adjustment, top center of gang condenser) until desired signal is heard.
- (2) Set the dial to the point where a station (or oscillator) of known frequency, about 1000 kc., should be received and bend the rotor plates, when necessary, to correct the calibration.
- (3) Repeat operation 2 at, or near, 800 kc.
- (4) Repeat operation 2 at, or near, 600 kc.

TO ALIGN (or gang) THE R. F. CIRCUITS

- (1) Set the dial to 1400 kc.
 - (A) Attach the output meter from screen to plate of the 2A5 tube.
 - (B) Attach local oscillator and tune to resonance with receiver.
 - (C) Adjust antenna trimmer (screw adjustment top, rear of gang condenser) for maximum indication on output meter.
 - (D) Adjust R. F. trimmer (screw adjustment top, front of gang condenser) for maximum indication on output meter.
- (2) Set dial to 1000 kc.
 - (A) Adjust local oscillator to resonance with receiver.
 - (B) Bend rotor plates (front and rear gang condenser sections) for maximum indication on output meter.
 - (3) Repeat operation 2 at 800 kc.
 - (4) Repeat operation 2 at 600 kc.

THE RUDOLPH WURLITZER CO.

In all ganging operations USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER. Do this by reducing the input, NOT BY RETARDING THE VOLUME CONTROL.

The I. F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier to be at fault. In that event:-

1. Feed the signal from the local oscillator tuned to exactly 175 kc. into the set at the control grid 2A7, using some type of coupling device that will provide D. C. path from control grid to ground.

2. Attach the output meter from screen to plate of the 2A5 tube.

3. KEEPING THE SIGNAL AS LOW AS POSSIBLE, adjust the I. F. trimmers to give a maximum indication on the output meter. These I. F. trimmers will be found under the chassis pan, mounted on a strip extending from near the 2A7 socket to the center of the chassis pan. After having carefully adjusted these trimmers for maximum output, a final check should be made by going over each adjustment a second time to insure perfect alignment.

TO CALIBRATE THE SA-6

1. Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc., should come in. Adjust oscillator trimmer (screw adjustment top rear of gang condenser) until the desired signal is heard.

2. Set the dial to the point where a station (or oscillator) of known frequency, about 1000 kc. should come in. Then bend the rotor segments (about half engaged with the stator plates at this dial setting) to correct the calibration. If the dial reading is higher than the actual frequency, bend the segments away from the stator, and vice-versa,

3. Repeat operation two at, or near, 800 kc.

4. Repeat operation two at, or near, 600 kc.

This completes the calibration procedure.

TO ALIGN (or gang) THE R. F. CIRCUIT

1. Set dial to 1400 kc.

(A) Attach the output meter from screen to plate of the 2A5 tube.

(B) Attach the lead from local oscillator to the antenna post of the receiver, and adjust the oscillator to resonance with the receiver.

(C) KEEPING THE SIGNAL AS LOW AS POSSIBLE, adjust the antenna trimmer (screw adjustment, top of gang condenser, front end) for maximum indication on the output meter. Then adjust the R. F. trimmer (screw adjustment, top center of gang condenser) for maximum indication on output meter.

2. Set dial to 1000 kc.

(A) Adjust the local oscillator for resonance with the receiver.

(B) Bend the segments of the rotor plates on the front and center sections of the gang condenser to give maximum indication on the output meter.

3. Repeat operation two at 800 kc.

4. Repeat operation two at 600 kc.

This completes the alignment procedure.

MODEL SA-91-A
Alignment Data

THE RUDOLPH WURLITZER CO.

BALANCING

Caution: When balancing radio frequency or IF circuits, be sure that the volume control is turned to the full "On" position and the output of the test oscillator adjusted to give a very weak signal. This is necessary to minimize the automatic volume control action and to permit the most accurate adjustment.

INTERMEDIATE FREQUENCY CIRCUITS

The intermediate frequency amplifier of this receiver operates at 175 kc. and an accurately calibrated test oscillator generating this frequency is necessary for ganging.

Current from the test oscillator should be fed into the set by removing the control grid cap on the type 57 detector modulator tube, and connecting the oscillator output terminals between the chassis pan and the control grid cap of this tube.

The IF transformers are tuned by adjusting the screws under the removable name plate on the rear of the chassis.

To align the RF circuits the test oscillator should first be set to some known frequency between 1400 and 1500 kc. and the set tuned so that the dial pointer indicates this frequency. The trimmer condenser of the oscillator section of the variable condenser (front section) should then be tuned until the test signal is received with greatest output.

There are two possible adjustments on the trimmer condensers at which this signal may be received; the proper adjustment is that at which the trimmer is set to minimum capacity; that is, the adjustment at which the trimmer plate is farthest out. When this has been done the trimmer condensers of the second and third variable condensers are to be set to give maximum output.

The set should next be balanced at approximately 1250, 950, 700 and 550 kc. in the order mentioned as follows:

The test oscillator is set to some known frequency, approximately that recommended above, and the set adjusted for maximum output by bending the adjustable sections of the rotor end plates of the variable condensers. In doing this, the plates on the oscillator section should be bent first and those of the remaining sections bent after the oscillator is adjusted.

AUTOMATIC VOLUME CONTROL

The detector and automatic gain control functions are performed by the diode section of the type 55 tube which rectifies the energy sent to it by the intermediate frequency amplifier. The DC component of this energy passes through a net work of high resistances and by-pass condensers to the control grids of the RF and IF tubes to control the amount of amplification in these stages.

An increase in signal strength results in an opposite action decreasing the amount of RF and IF amplification. The audio component of the signal rectified by the diode, is passed through the manual volume control which also serves as a part of the diode resistance net work. The adjustment of this control sets the amount of energy passed on to the audio amplifier for further amplification.

THE RUDOLPH WURLITZER CO.

The Model SU-5 is a dual wave superheterodyne receiver covering the broadcast band (550 to 1500 kc.), and a short wave band of from 1580 to 3700 kc.

Connect the line cord lead marked with a red dot to the grounded side of the line. Connect the output meter from screen to plate of the 43 tube.

Advance the tone and volume controls to their maximum positions (clockwise).

In all ganging operations USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER, do this by reducing the input, NOT BY RETARDING THE VOLUME CONTROL.

The I. F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I. F. amplifier is at fault, in that event:-

(1) Attach the output meter to the 43 tube.
(2) Attach antenna lead to a local oscillator tuned to 456 KC.

(3) KEEPING THE SIGNAL INPUT AS LOW AS POSSIBLE, adjust the two I. F. trimmers to give maximum indication on output meter.

(A) The first I. F. trimmer is on the rear of the chassis directly under the first I. F. transformer, between the 6A7 and 78 tubes. The slot adjustment is the primary trimmer. The hex nut adjustment is the secondary trimmer.

(B) The second I. F. trimmer is located on the top of the chassis pan, left end, near the volume control. The adjustments are the same as on the first I. F. trimmer. UNDER NO CIRCUMSTANCES SHALL THE SINGLE TRIMMER AT THE EXTREME RIGHT REAR OF THE CHASSIS (usually marked with red) BE ADJUSTED.

TO CALIBRATE BROADCAST BAND:-

(1) Turn the band switch to the broadcast position (clockwise).

(2) Set the dial pointer to the position where a station (or oscillator) of known frequency, about 1400 kc., should come in.

(3) Adjust oscillator trimmer (screw adjustment, top of gang condenser, front-dial-end) until desired signal is heard.

The calibration of the rest of the dial will fall within reasonable limits with no further adjustment.

TO ALIGN (or gang) THE BROADCAST BAND:-

(1) Connect the output meter to the 43 tube.

(2) Set dial to approximately 1400 kc., connect antenna lead to local oscillator tuned to set, and check settings of volume and tone controls.

(3) Adjust R. F. trimmer (screw adjustment, top of gang condenser, rear end) until output meter indicates maximum output. KEEP SIGNAL INPUT LOW! The alignment over the balance of the tuning range will fall within reasonable limits without further adjustment.

TO CALIBRATE THE SHORT WAVE BAND:-

(1) Turn the band switch to the short wave position (counter-clockwise).

(2) Set the dial pointer to the position where a station (or oscillator) of known frequency about 3700 kc., should come in.

(3) Adjust the short wave oscillator trimmer (screw adjustment, under chassis pan-adjustable through hole in chassis pan top front, right corner near gang condenser) until desired signal is heard. The calibration of the rest of the dial will fall within reasonable limits without further adjustment.

TO ALIGN (or gang) THE SHORT WAVE BAND:-

(1) Connect the output meter to 43 tube.

(2) Set dial to approximately 3600 kc. (3.6 MC.), connect antenna lead to local oscillator tuned to set and check settings of tone and volume controls.

(3) Adjust short wave R. F. trimmer (screw adjustment, rear of antenna coil mounting bracket, between 6A7 and 78 tubes) until the output meter indicates maximum output. KEEP THE SIGNAL INPUT LOW! The alignment over the balance of the tuning range will fall within reasonable limits without further adjustment.

ALIGNMENT PROCEDURE FOR LYRIC SU-5

MODEL SW-88

Alignment Data

THE RUDOLPH WURLITZER CO.

The Model SW-88 is an eight tube superheterodyne designed to receive modulated signals whose carrier frequency is between 550 and 22,000 kc. This tuning range is divided into four bands.

1st. Scale	550	1500 kc.	546	200 m.	Broadcast.
2nd. Scale	1450	3700 kc.	207	81.1 m.	Police Calls.
3rd. Scale	3500	9000 kc.	85.7	33.5 m.	Domestic S.W.
4th. Scale	8500	22000 kc.	35.3	13.6 m.	Foreign S.W.

The desired band is selected by a four position wave change switch mounted directly below the tuning control. This switch knob also controls the sliding mask behind the dial scale, allowing only the calibration of the band in use to be illuminated.

The Model SW-88 uses a 57 first detector, a 56 oscillator whose output is inductively coupled into the cathode circuit of the first detector, two stages of I.F. amplification (at 485 kc.) using 58 tubes, a 56 diode second detector and A.V.C. tube, a 57 first audio, and a 2A5 in the audio output stage.

IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER, AND TURN THE VOLUME & TONE CONTROLS TO THEIR MAXIMUM POSITIONS (clockwise).

The I.F. trimmer adjustments are carefully made at the factory and should not be tampered with unless a thorough investigation definitely proves the I.F. amplifier to be at fault, in that event:-

- (1) Attach the output meter from plate to screen of 2A5 tube.
- (2) Feed the signal from the local oscillator tuned to exactly 485 kc. into the receiver at the control grid of the first detector, providing a D.C. path from the point to ground.
- (3) Adjust the I.F. trimmers to give maximum indication on the output meter. There are three I.F. transformers, each with two screw adjustments. On the early models these adjustments are on the bottom of the transformers, accessible from the under side of the chassis. On the later models these adjustments are on the top of the transformers.

(4) NEXT-feed the 485 kc. signal in at the antenna post, replace the first detector grid cap, and adjust the wave trap condenser for MINIMUM indication on the output meter. This adjustment is a $\frac{1}{4}$ hex nut on a two plate trimmer under the chassis, below the gang condenser, near the band switch.

CORRECTION--The 9000 kc. R.F. trimmer is erroneously shown connected to switch point 4 in the Model SW-88 Service Schematic, Drawing No. 83. This trimmer should be wired to point 3, and point 4 should be left open.

TO CALIBRATE THE SW-88

- (1) Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc., should come in.

(A) Set Band switch to band 1 (top scale).

(B) Adjust oscillator trimmer (screw adjustment, top-rear of gang condenser) until desired signal is heard. There will be two peaks in adjusting this trimmer. The peak obtained with the loosest trimmer setting is correct.

- (2) Repeat operation 1 at, or near, 550 kc., using band 1.

(A) Adjust oscillator pad (fourth adjustment from right, on rear of chassis pan) until desired signal is heard.

- (3) Repeat operation 1 at, or near, 1450 kc., using band 2.

(A) Adjust oscillator pad (third adjustment from right on rear of chassis pan) until the desired signal is heard.

- (4) Repeat operation 1 at, or near, 3500 kc., using band 3.

(A) Adjust oscillator pad (second adjustment from right on rear of chassis pan) until the desired signal is heard.

- (5) Repeat operation 1 at, or near, 8500 kc., using band 4.

(A) Adjust oscillator pad (extreme right adjustment on rear of chassis pan) until the desired signal is heard.

TO ALIGN (or gang) THE R.F. CIRCUITS

- (1) Set the dial to 1400 kc., using band 1.

(A) Attach oscillator, tuned to set, to antenna post.

(B) Attach output meter from screen to plate of 2A5 tube.

(C) Adjust R. F. trimmer (screw adjustment, top-front-of-gang condenser) for maximum output. KEEP SIGNAL INPUT LOW!

- (2) Set the dial to 3700 kc., using band 2.

(A) Tune the oscillator to the receiver and adjust R.F. trimmer (extreme left adjustment on rear of chassis pan) for maximum output. KEEP SIGNAL INPUT LOW!

- (3) Set the dial to 9000 kc., using band 3.

(A) Tune the oscillator to the receiver and adjust R.F. trimmer (second adjustment from left on rear of chassis pan)

Note 1--In case the local oscillator will not reach the higher alignment frequencies, harmonics of lower frequencies may be used.

ALIGNMENT PROCEDURE FOR MODEL SW-88

MODEL SA-133

Alignment Data

THE RUDOLPH WURLITZER CO.

TO CALIBRATE THE SA-133

- (1) Adjust the dial mechanism (if necessary) so that with the plates entirely enmeshed the dial will indicate 525 kc.
- (2) Set the dial to the point where a station (or oscillator) of known frequency, about 600 kc., should be received and adjust the oscillator pad (screw adjustment under hole in chassis pan between oscillator section on gang condenser shields) until desired signal is heard.
- (3) Set the dial to the point where a station (or oscillator) of known frequency, about 1400 kc., should be received and adjust the oscillator trimmer (screw adjustment, top of gang condenser, third from front) until desired signal is heard.
- (4) Re-check operations 2 & 3.
- (5) Check the calibration at, or near, 1200 kc. and correct (if necessary) by bending outer oscillator section rotor plates.
- (6) Repeat operation 5 at, or near, 950 kc.
- (7) Repeat operation 5 at, or near, 660 kc.
- (8) A thorough re-check of the foregoing 7 operations to insure perfect calibration is recommended. If the alignment procedure to this point has been performed correctly the calibration will be accurate to within 2kc. at all points on the dial.

TO ALIGN THE R. F. CIRCUITS OF THE SA-133

- (1) Attach the output meter from plate to plate of the 2A5 tubes.
- (2) Attach the local oscillator to the antenna and tune to set at each test frequency.
- (3) At 1400 kc., adjust the antenna, link, and R.F trimmers (screw adjustments, top of gang condenser--see Drawing #62) for maximum indication on the output meter USING THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION.
- (4) At 1200 kc. bend the plates of the antenna, link and R.F rotors to give maximum indication on the output meter.
- (5) Repeat operation 4 at 950 kc.
- (6) Repeat operation 4 at 650 kc.
- (7) Repeat operation 4 at 570 kc.
- (8) Re-check operations 3-8 inclusive to insure perfect alignment.
- (9) REMOVE RESISTORS FROM THE I.F. TRANSFORMERS.
- (10) Remove the output meter and local oscillator, attach antenna, set dial to a point where no signal is being received and turn channel control counter-clockwise just far enough to silence the static and other inter-station noises.

The Model SA-133 is now ready for operation.

The difficulty in correctly aligning the I.F. stages is a result of the design of the I. F. transformers. In order to obtain a high degree of selectivity without sacrificing tone quality these transformers have been designed to provide a very narrow resonance curve with an essentially flat top. This is accomplished by over-coupling these transformers enough to get "double-bumps" the correct distance apart. With these transformers over-coupled it is impossible to correctly align them, therefore, it is necessary to decouple each I. F. transformer while it is being aligned. This is accomplished by shunting one winding with a 20,000 ohm resistor and aligning the other winding.

In the event that the I.F. stages require realignment the following procedure should be followed.

- (1) Attach the output meter from plate to plate of the 2A5 tubes.
- (2) Remove the silencing tube of the channel control circuit
- (3) Attach the local oscillator tuned to exactly 175 kc. to the control grid of the first detector, using some type of coupling device that provides a d.c. path to ground. IN ALL GANGING OPERATIONS USE THE WEAKEST SIGNAL THAT WILL GIVE A SATISFACTORY INDICATION ON THE OUTPUT METER.
- (4) Attach a resistor across the secondary of the first I.F. transformer (by inserting the leads in holes 3 & 4--See Figure 3, Drawing #82-B) and adjust screw A for MAXIMUM indication on the output meter.
- (5) Remove the resistor from the secondary of the first I.F. transformer and place it across the primary (holes 1 & 2) and adjust screw (B) for MAXIMUM indication on the output meter. LEAVE THIS RESISTOR WHERE IT IS FOR THE BALANCE OF THE ALIGNMENT PROCEDURE.
- (6) With a second resistor repeat operation 4, (holes 7 & 8, screw (C)).
- (7) With this second resistor repeat operation 5, (holes 5 & 6, screw (D)).
- (8) With a third resistor repeat operation 4, (holes 11 & 12, screw (E)).
- (9) With this third resistor repeat operation 5, (holes 9 & 10, screw (F)).
- (10) Adjust the channel control pad (screw adjusting trimmer under chassis pan near third I.F. transformer, (adjustable through hole in chassis pan bottom cover) for MINIMUM (dip) indication on the output meter. This dip is not very pronounced, and unless extreme care is exercised it may be passed over without being noticed. Note--Be sure the resistor leads make good contact when inserted in holes in transformers.

MODEL M-601 (P51)

Parts List

ZENITH RADIO CORP.

Variable Condenser Assembly

22-101 Three gang condenser
 S-861 Dial drum assembly
 S-769 Pilot lamp bracket and socket
 100-18 2½ volt lamp
 11-2 Pulley string
 80-69 Dial string tension spring

Fixed Condensers

22-91 .03 mfd. condenser (audio coupling)
 S-392 Antenna series condenser
 22-103 Five section bypass condenser
 22-108 .002 mfd. condenser (bypass)
 22-117 .5 " " "
 22-118 6. " " (electrolytic low voltage)
 22-119 6. " " (" high ")

Resistors

63-135 25M ohm resistor (Red, Green end, Or ange Dot)
 63-137 250M " " (" " " Yellow ")
 63-151 15M " " (Brown " " Orange ")
 63-152 43M " " (Yellow Orange " ")
 63-159 4M " " (" Black end Red ")
 63-162 100 " " (Flat wire wound black ")
 63-163 320 " " (" " " Red ")
 63-164 Volume control

Coils

S-857 1st R.F.coil (antenna) (Coil Only)
 S-859 2nd " " " (intermediate) (" ")
 S-865 3rd " " " (detector) (" ")
 20-8 R.F.choke

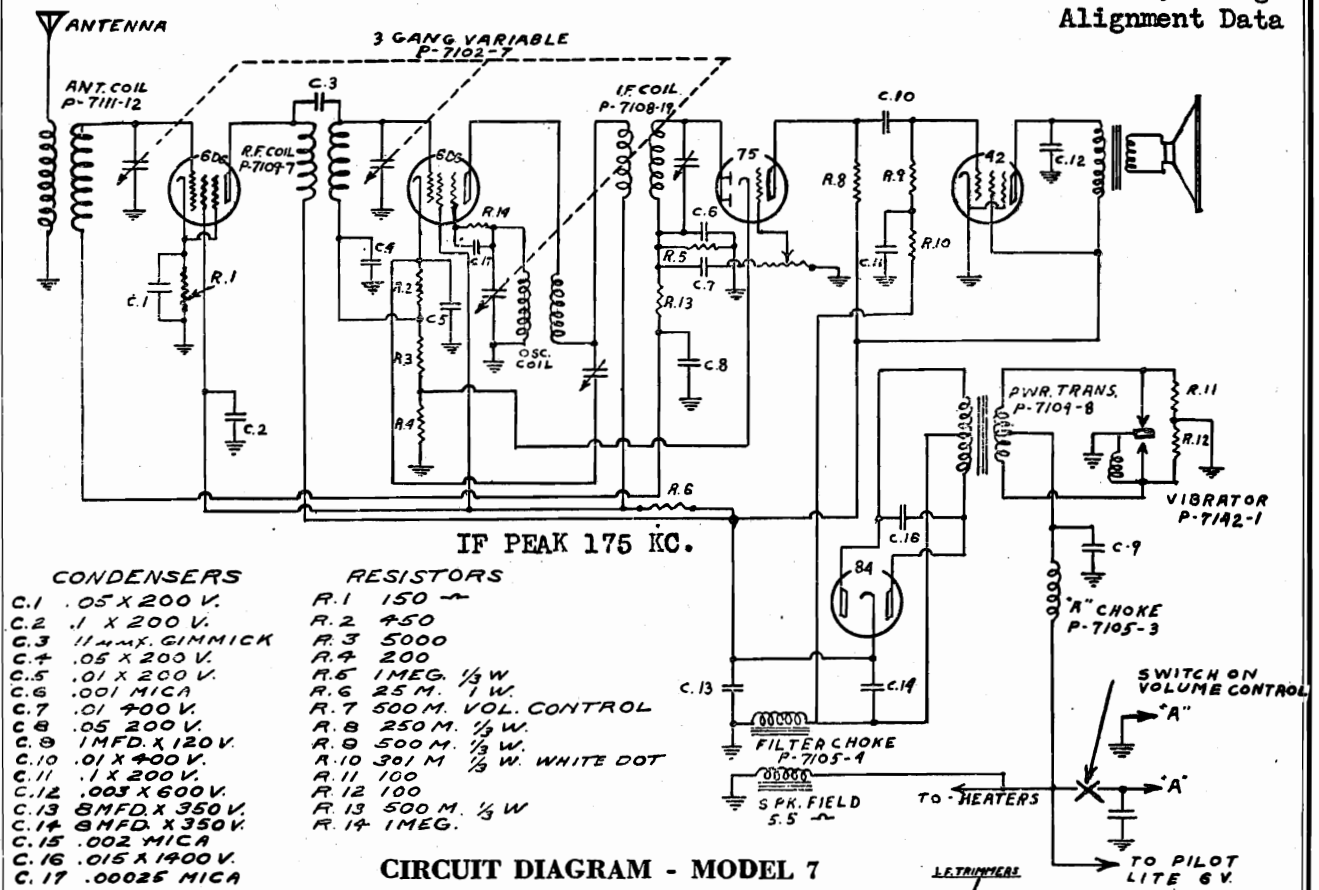

Shields

126-59 R.F. coil shield can
 126-68 Condenser shield
 MS-163 Tube shield
 S-771 Coil mounting base

Miscellaneous

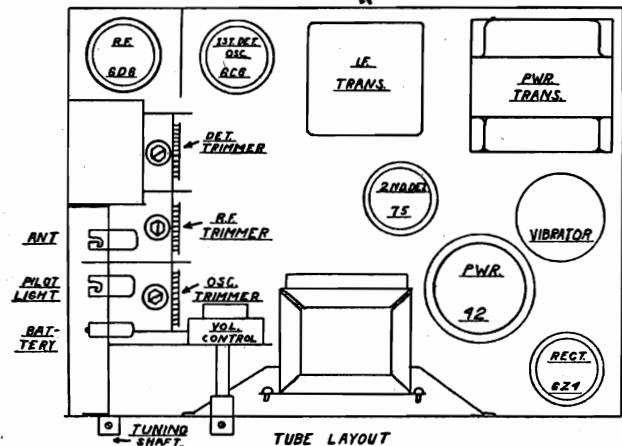

26-20 Calibrated dial strip
 46-50 Knobs for switch & volume control
 46-51 Knob for dial
 49-34 Dynamic speaker
 57-269 Escutcheon plate
 78-34 Four prong socket
 78-35 Five " "
 78-39 " " Pentode socket
 83-226 Speaker terminal strip
 85-29 Off & On switch
 95-91 Power transformer (60 cycle)
 95-92 " " (25 ")

**I. F. ALIGNMENT:**

1. With variable condenser at its maximum capacity position and with volume control full on, connect in series with a .1 mfd. condenser, an oscillator set at 175 kilocycles to the grid cap of the 6C6 tube.
2. Adjust trimming condensers I. F. transformer, part number 7108-19 (see top view of chassis) to resonance with oscillator, as indicated on an output meter connected across the primary terminals of the speaker input transformer. Maximum deflection on the meter indicates resonance.

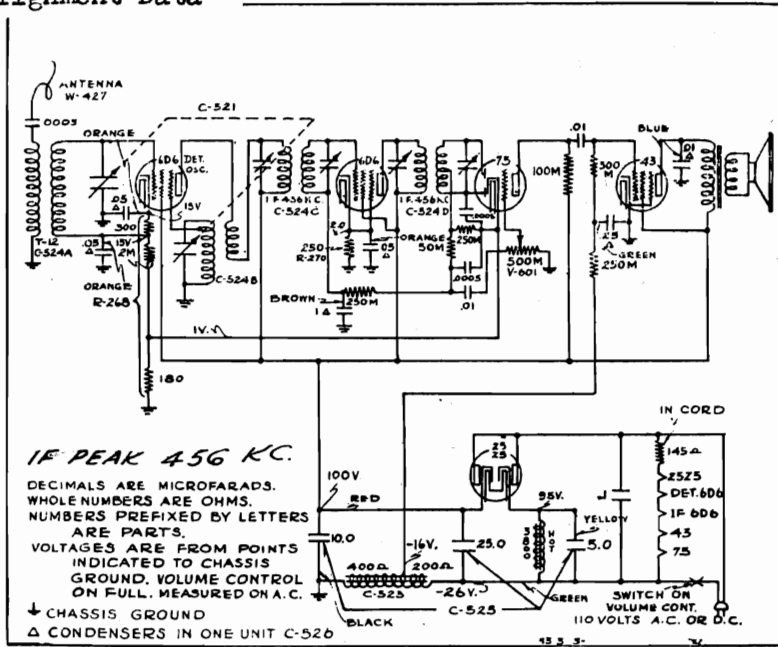

Note: The I. F. transformer has two trimmers, both of which are adjustable through the rear of the case.

FREQUENCY ALIGNMENT:

1. Attach oscillator connected in series with a 200 mmfd. condenser to the antenna lead and with the variable condenser at its minimum capacity position (extreme right of its rotation) and with an oscillator set at 1550 kilocycles, adjust condenser trimmer of oscillator section (shaft end) to resonance.
2. Re-set oscillator to 1400 kilocycles, rotate variable condenser to pick up signal, adjust antenna and R. F. trimmers to resonance.
3. Check alignment at 1200-1000-800-600-530 kilocycles by setting oscillator to these frequencies and picking up signal by rotating condenser.
4. Bend slotted plates of antenna and R. F. sections only if necessary. **UNDER NO CIRCUMSTANCES BEND PLATES OF OSCILLATOR SECTION.**

MODEL 701
MODEL 702
Schematic, Socket
Alignment Data

ZENITH RADIO CORP.

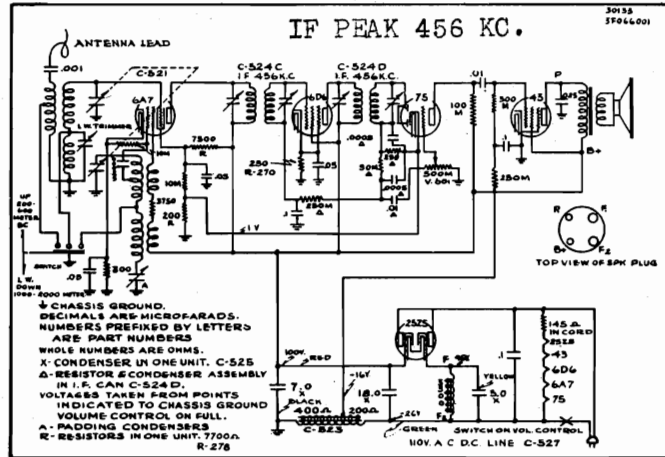

Schematic circuit diagram Model 701 AC-DC Superheterodyne, with automatic volume control

Should it be necessary, at any time, to rebalance this set the procedure is as follows: Attach a 456 kilocycle oscillator to the grid of the 6D6 tube in back of the variable condenser and adjust the trimming condensers of the I. F. transformers to maximum deflection on an output meter connected across the primary of the speaker input transformer. While adjusting these trimmers, the variable condenser should be at the maximum capacity position—at the extreme right of its rotation.

Next disconnect the antenna wire and connect an oscillator in series with a 75 mmf. condenser to the antenna coil. Rotate the condenser plates to the minimum capacity position—extreme left turn, and adjust the trimmer condenser of the rear section of the variable condenser to resonance with an oscillator set at 1725 kilocycles, then adjust the condenser of the front section of the variable condenser to resonance. Align at 1400—1200—1000—800—600—530 kilocycles, bend slotted plates of variable condenser if necessary.

MODEL 701

Schematic Circuit Diagram and Aligning Instructions Model 702 AC-DC Superheterodyne 200-600 Meters: 1000-2000 Meters

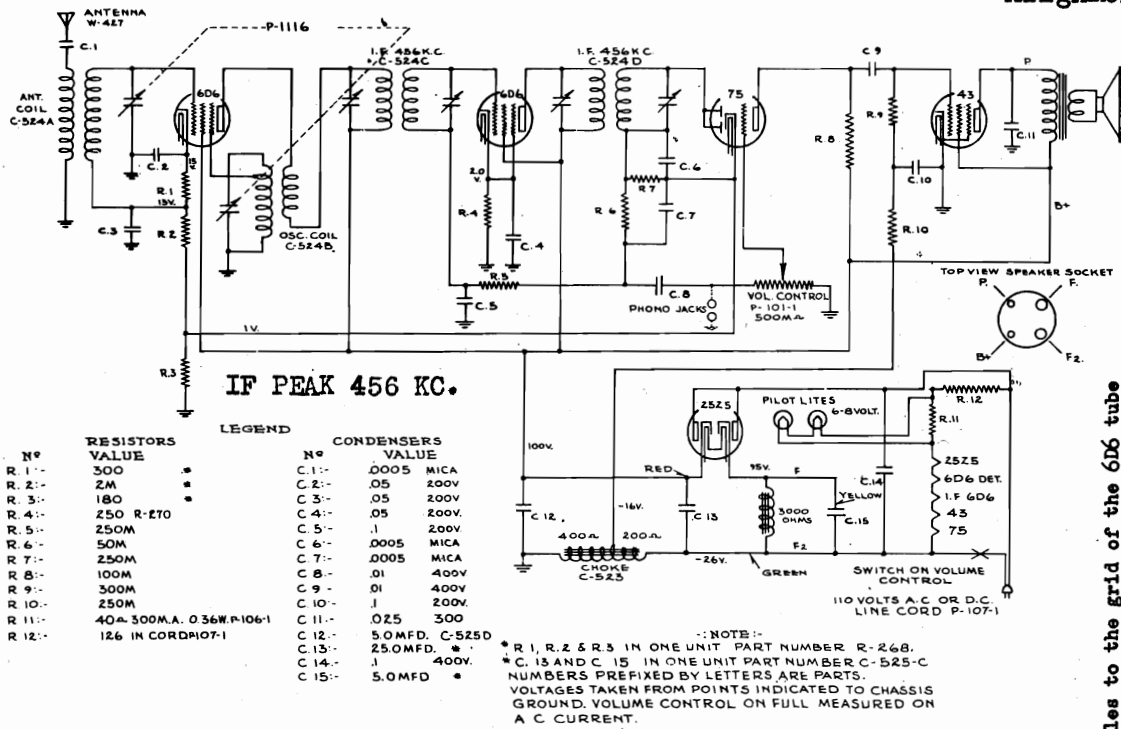

Should it be necessary, at any time, to rebalance this set the procedure is as follows: Attach a 456 kilocycle oscillator to the grid of the 6A7 tube in back of the variable condenser and adjust the trimming condensers of the I. F. transformers to maximum deflection on an output meter connected across the primary of the speaker input transformer. While adjusting these trimmers, the variable condenser should be at the maximum capacity position—at the extreme right of its rotation.

With switch lever up in 200-600 meter position, disconnect the antenna wire and connect an oscillator in series with a 250 mfd. condenser to the antenna coil, rotate the condenser plates to the minimum capacity position, extreme left turn, and adjust trimmer condenser of the oscillator netted across the primary of the speaker input transformer to resonance with the oscillator set at 200 meters, adjust the front section to resonance at 215 meters, align at 250—300—400—500 meters and bend slotted plates of variable condenser if necessary. To adjust long wave, 1000-2000 meters, with switch lever down, set variable at maximum capacity, extreme right turn, and tune generator to maximum output, then peak long wave padder (hexagon nut of L. W. Padder), at the same time tuning oscillator until maximum output is attained. Attach oscillator leads to grid of 6A7 ground, set variable condenser at minimum capacity, extreme left turn, and adjust oscillator to resonance with set. Remove oscillator lead from grid of 6A7 and attach to antenna lead, then adjust long wave R.F. trimmer to maximum output (set screw adjustment of L. W. Padder). Do not disturb either oscillator or variable condenser while making this adjustment.

MODEL 801

INTERMEDIATE FREQUENCY 456 K. C.

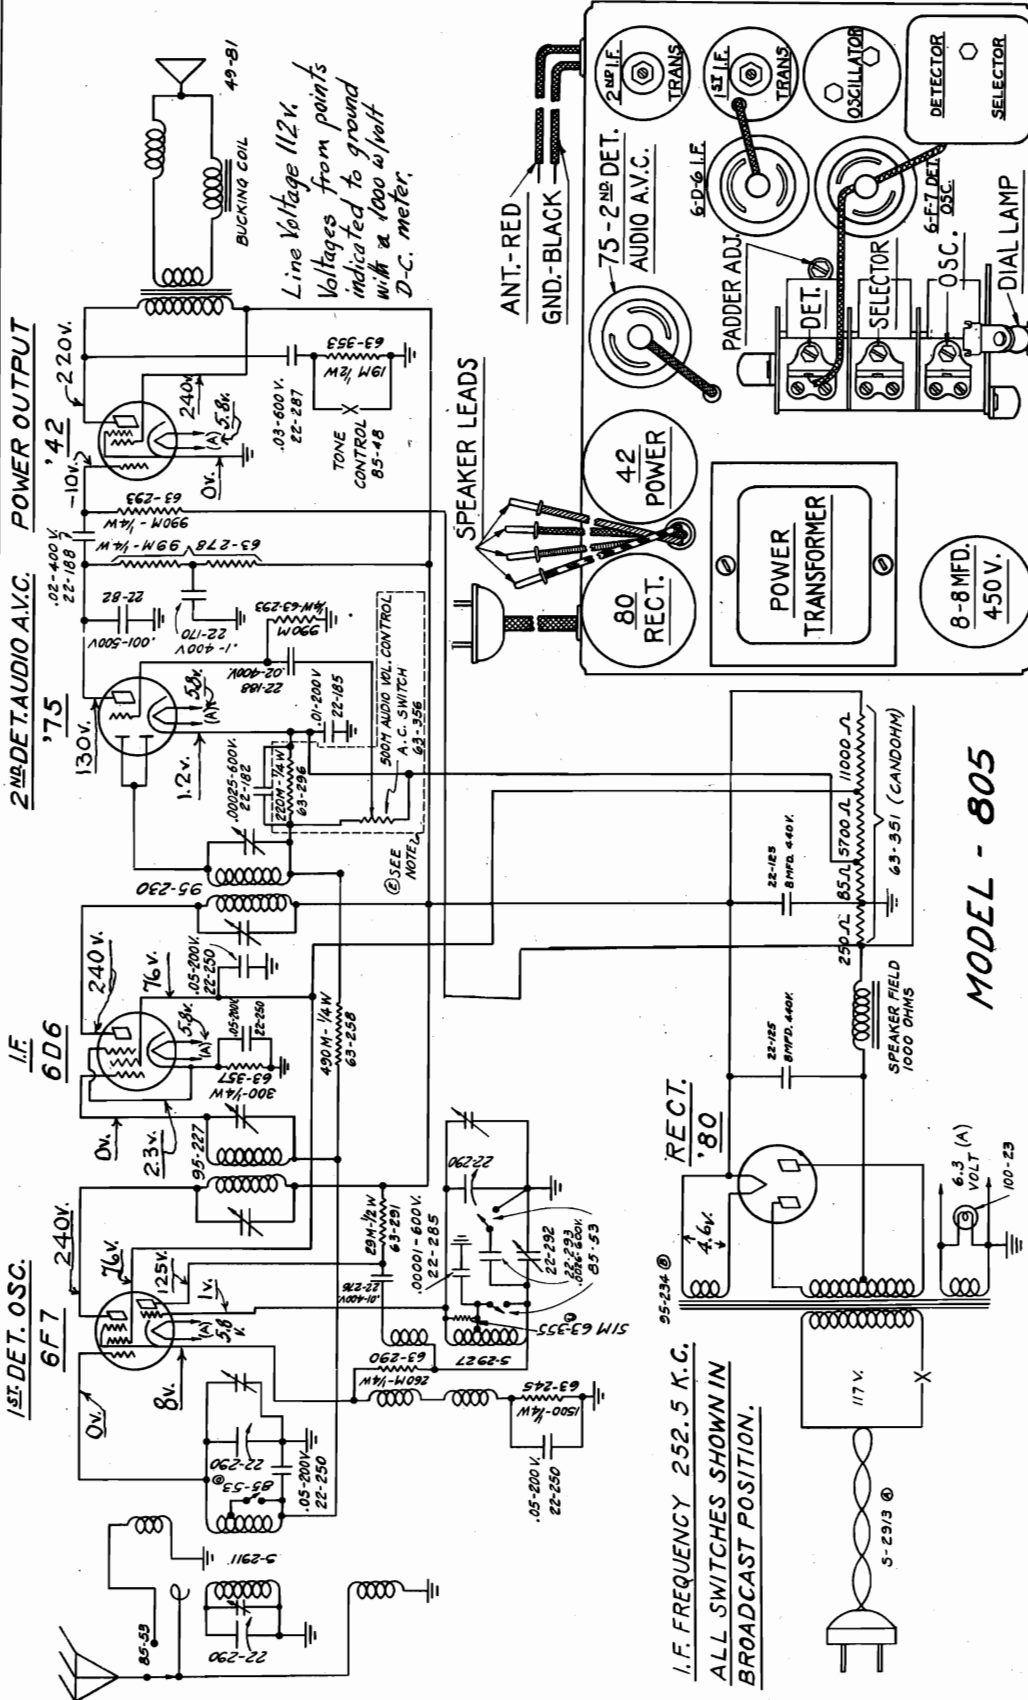

I.F. ALIGNMENT
1. To peak I.F. transformers, connect oscillator set at 456 kilocycles to the grid of the 6D6 tube directly in back of the variable condenser and adjust the trimming condensers of the I.F. transformers to resonance (Maximum deflection on an output meter connected across the primary of the speaker input transformer).
Each I.F. trimmer has two adjustments, one nut and one screw, both of which are adjustable from the top.

BROADCAST BAND ALIGNMENT

1. Disconnect antenna wire and connect oscillator in series with a 75 mmfd. condenser to the antenna coil. With the variable condenser set at its minimum capacity position, at the extreme right of its rotation, and with an oscillator output adjusted to 1720 kilocycles, adjust trimmer of oscillator section of variable condenser (rear section) to resonance (maximum deflection on an output meter connected across the primary of the speaker input transformer). Next adjust the trimmer condenser of the front section of the variable condenser to resonance.
2. Check alignment at 1400-1200-1000-800-600-530 kilocycles, bending the slotted plates of the front section of the variable condenser only if absolutely necessary.

25Z5	RECT.	24	Spkr. Fld. 80	-	-	-	-

Line Voltage 112

Antenna and Ground Disconnected

All voltages measured from B-(negative side of C18) using a 1000 ohm per volt D.C. meter (except heaters).

F - Filament; K - Cathode; g1 - Control Grid; g2 - Screen Grid; g3 - Suppressor Grid; p - Plate.

Alignment

1. Balance intermediate transformers at 125 K.C. with service oscillator connected to grid of first detector and chassis.
2. Rotate wave-band switch clockwise to the short-wave position. Connect service oscillator to antenna and ground leads and set for 18750 K.C. Balance oscillator trimmer on gang for correct dial reading at 16 meters.
3. Turn wave-band switch to center or standard broadcast position. Adjust padder condenser (located on top center of chassis next to gang) for correct dial reading at 500 meters (600 K.C.).
4. Balance oscillator trimmer (located underneath chassis at right center) for correct dial reading at 210 meters (1440 K.C.). Balance R.F. and 1st detector trimmers on gang to resonance
5. Turn switch counter-clockwise to long-wave position. Adjust oscillator padder (located underneath chassis at rear right side) for correct dial reading at 2000 meters (150 K.C.).

NOTE: If howls are encountered on short-wave band the oscillator trimmer on gang is too tight.

42	PWR.	5.4	0	4	0	230	215
80	Rect.	4.2	-	-	-	-	235

Line Voltage 112 V.

Aerial and Ground disconnected.

F - Filament

K - Cathode

G1 - Control Grid

G2 - Suppressor Grid

G3 - Screen Grid

P - Plate

All measurements taken from points indicated to ground with 1000 ohms per volt D.C. meter (except filaments).

Balance I.F. transformers at 485 K.C., trimmers on condenser gang at 1500 K.C. and oscillator padder at 600 K.C.

The screw adjustment at the right hand rear of chassis is a wave trap for the elimination of code interference at the I.F. frequency. Connect 485 K.C. oscillator on antenna and adjust for weakest signal.

Service Bulletin

MODELS 835-880

CHASSIS 1001-1001A

SERVICE NOTES

Dial Slips or Binds. Tighten lugs on planetary drive. See that both pointers are free. Make sure gang is squarely lined up with dial.

Off Calibration. Check for loose set screws on dial assembly to condenser shaft. Black pointer may be loose on shaft. Check alignment as outlined in Alignment Procedure.

Poor Tone. Defective tubes in audio. One side of push-pull circuit faulty. Check audio and output transformers. See A.V.C. blocking.

Insensitive. Out of alignment, weak tubes or defective by-pass condenser.

Shadowgraph Inoperative. weak 76 tube, burnt out shadowgraph, open resistor in 76 plate circuit.

Distortion at Medium Volume. Defective 75 tube, defective volume control. Separate green volume control-lead and speaker-lead close to grid of 42 tube.

Insensitive on Any Short Wave Band. Check alignment, make sure R.F. circuit is not aligned to image frequency. Change 6A7 tube. Change position of fixed condensers adjacent to rear section of wave change switch. Location of these condensers in relation to each other and their distance from the chassis will effect dial calibration and sensitivity, especially on the Blue Band.

Stops Oscillating Around 9 M.C. Change 6A7 tube, leakage in 50 mfd. or .0029 mfd. condenser.

A.V.C. Blocks. Shorted resistor on antenna choke. C-14 padder shorted. Grounded R.F. grid circuit.

Oscillates on Broadcast. Check alignment. Push brown wire away from 6A7 socket. Grounded cathode on 1st I.F. or grounded to 600 K.C. padder. Check for open by-pass condenser.

Noisy. Shorting plates in gang condenser. Poor contact in band switch. Loose shields or shield bases. Static shields may be touching leads under gang condenser.

Overheats. Check pilot light and heater circuits for partial short or ground.

Flutters. Rearrange leads under chassis especially around 6A7.

Oscillates on Short Wave Bands. Make sure brown R.F. grid return lead is pushed away from 6A7 socket. Check for ground on any A.V.C. lead. Open by-pass condenser.

Tone Control Inoperative. Resin joint or poor contact on tone control switch. Defective condensers in tone control circuits.

Continuous Audio Whistle. Rearrange leads in audio circuit.

Alignment

Separate coils are used for each band. Mounted on the coils are individual trimmers that align each band, independent of the other bands.

Connect 485 K.C. service oscillator to grid of 6A7 and chassis ground. Adjust I.F. trimmers on rear of I.F. transformers for strongest signal.

Connect 485 K.C. service oscillator to antenna and ground. Turn dial to 540 K.C. on broadcast band and adjust wave trap trimmer on right rear side of chassis for weakest signal.

Broadcast - Black Band

Set service oscillator at 1400 K.C., remaining attached to antenna ground posts. Turn dial to some point and adjust #1 trimmer (top one on oscillator coil) to resonance. Adjust #1 R.F. trimmer (top one on R.F. coil); #1 detector trimmer (through hole in chassis base) and band pass trimmer (top front section of gang) all to resonance.

Set service oscillator at 600 K.C. Adjust padder (located in center rear of chassis) for correct dial reading.

Recheck 1400 K.C. alignment.

Orange Band

Set service oscillator at 4 M.C., still attached to antenna and ground) and adjust trimmer #2 (2nd from top) on oscillator coil for correct dial reading. Adjust #2 R.F. trimmer (2nd from top on R.F. coil) and #2 detector trimmer (center hole through chassis) to resonance.

Brown Band

Loosen #3 detector trimmer (top one on detector coil). Set service oscillator at 10.5 M.C. Adjust #3 oscillator trimmer (third from top on oscillator coil) for correct dial reading. Adjust #3 R.F. trimmer (third from top of R.F. coil) and #3 detector trimmer (rear one through hole in top of chassis). Adjust #3 detector trimmer on coil to resonance.

Blue Band

Tighten #4 detector trimmer (bottom one on detector coil). Set service oscillator at 21 M.C. Adjust #4 oscillator trimmer (bottom one on oscillator coil) for correct dial reading. Adjust #4 R.F. trimmer (lower one on R.F. coil) and #4 detector trimmer (lower one on detector coil) to resonance.

It is very easy to mistake the image frequency for the fundamental on this band. Rotate dial and if shadowmeter narrows at any point, especially at 15 K.C., the band should be rebalanced.

Green Band

There are no adjustments to be made on this band.
