(d) **The Selectivity Control** introduces the crystal filter into the i-f circuit for single-signal reception of c-w telegraph or telephone transmission. Crystal phasing is performed by means of an air-trimmer capacitor. In its midway position marked "Max." the crystal circuit is balanced and maximum selectivity is obtained. This setting is characterized by minimum background noise. In the extreme clockwise position the crystal is short circuited by means of the crystal switch. Other positions broaden the crystal selectivity curve on one side of resonance and cause a rejection dip on the other side. They are useful for phone reception through severe interference.

NOTE—The *Tone Control* should always be turned to "Speech" when the *Crystal Selectivity Control* is in use. This reduces the "lows" which cause instability and flutter under conditions of extreme selectivity.

Four curves are given herewith which illustrate the effect of the *Crystal Selectivity Control*. (See Figure 5.)

(e) **The Automatic Volume Control Switch** eliminates automatic-volume-control action in order to obtain best reception of slow-speed code transmission and to avoid thumping.

(f) **The Tuning Control** is a double knob. The section for rapid tuning is adjacent to the receiver panel and has a speed reduction ratio of 20:1. The second section, in front of the latter and on the inside shaft, is for precise adjustment and has a speed reduction ratio of 100:1. The combination of the high ratio tuning drive and the vernier-index dial make precise and easy tuning readily attainable.

(g) **The Range Selector** selects any one of the four scales of which the frequency limits are tabulated under "Electrical Specifications-Tuning Range" (Section 3). The lettered dial scales correspond to the lettered *Range Switch* positions.

(h) **The Volume Control** is connected in the audio-frequency circuit and increases the output level with clockwise rotation as indicated. It alone is used to regulate volume when the *Automatic Volume Control* is switched "on." However, with the AVC switch "off," the *Signal Input Control* must be used as well, in order to prevent overloading of the Second Detector.

(i) **The Beat Oscillator Switch** serves to interrupt screen and plate-supply voltage to the beat-frequency oscillator tube. The beat-oscillator stage can be rendered inoperative at any time, but, since the filament remains heated continuously, is ready for instantaneous operation.

(j) **The Heterodyne Control** governs the beat-oscillator output frequency over a limited a-f range by means of an iron-core solenoid adjustment (induction tuning) within the beat-oscillator tuning coil. It is calibrated in kilocycles on either side of the normal resonant position (zero beat). In order to obtain a beat note of a desired frequency it is first necessary to tune the receiver to zero beat with the *Heterodyne Control* set at "0," and then to rotate the *Heterodyne Control* to the desired a-f setting.

NOTE—It is important that the "0" position on the *Heterodyne Control* scale correspond *exactly* with the crystal frequency. The proper method of *setting* is given under Service, Section 12, page 17.

For c-w reception this control should be set at the desired beat frequency which may be on either side of the "0" position. The human ear is most sensitive at frequencies between 500 and 1500 cycles and settings of this order should therefore be made. The *Selectivity Control* then turned to "Max." has the effect of almost completely suppressing any audio-image which may be produced by a station at a frequency a few kilocycles removed from that of the desired station, causing a beat of nearly equal pitch. The curves (Figure 5, page 8) make this apparent. With the *Crystal Selectivity Control* in an intermediate position, adjustment and tuning may be made to place in the "rejection dip" an interfering station within a few hundred cycles of the desired one. The required beat-note is then obtained by adjustment of the *Heterodyne Control*. The higher the beat-frequency used the greater is the audio image.

(k) **The Phone Jack** is on the left end of the cabinet. When a phone plug is inserted in this jack, it simultaneously connects a resistance load across the secondary of the output transformer in place of the voice coil of the electrodynamic loudspeaker. It also connects the phones across the plate circuit of the output tube, a blocking condenser being used to isolate the d-c voltage. The loudspeaker field which is employed as a filter for the rectifier stage, still forms an active part of the circuit when using headphones. By inserting the phone plug part way in the jack both headphone and loudspeaker signals may be obtained. The loudspeaker is connected to the chassis by means of a cable and plug.

7. Dial

The *Tuning Dial* is of the airplane type, semi-transparent, illuminated, and clearly marked. It incorporates a mechanical band-spread system with two vernier scales (outside and central), particularly suited to amateur or other work where precise logging is required. The four main scales are plainly marked with their respective letters—A, B, C, D—and are calibrated directly in megacycles. The amateur bands are shown by solid arcs on the B, C and D scales, together with meter markings in heavy type. The standard and short-wave broadcast bands are indicated by an additional shading line.

The two vernier scales mentioned above are known as the *vernier* and *vernier-index* scales, the former being fully circular and the latter semi-circular.

It will be observed that the *vernier* scale is graduated from "0" to "100" and traversed by the long single-ended red pointer, and that the *vernier-index* scale is graduated from "0" to "9" and traversed by the short double-ended black pointer used for the main frequency scales. The red pointer makes one complete revolution for each unit of travel of the short black pointer on the *vernier-index* scale. Thus, any station may be logged accurately with three digits; for example, if the *vernier-index* reading is between "3" and "4" and the *vernier* reading is "72," then the log number is "372." The index number is always the lower of the two numbers between which the pointer is located. (It may occasionally happen that with the *vernier-index* pointer on or just beyond a digit, the *vernier* pointer may read above 95; the next lower digit is then used as the first of the three figures in the reading.)

In logging stations by this method, the band letter also should be named. For the above example, therefore, the full log number would be "A-372," "B-372," "C-372," or "D-372" depending upon the setting of the range switch.

Band-Spread.— The *Mechanical Band-Spread* incorporated in this instrument is combined with circuit design in such a manner as to render available to the operator the following advantages:

1. Single-control tuning.
2. Precise logging.
3. Ability to reset to a definite frequency without use of reference points.

To assist in operation, a table is given of the tuning knob rotation when tuning through the

Tuning

The r-f amplifier, oscillator and first detector circuits of this superheterodyne receiver are tuned by a three-gang variable capacitor and thus controlled from a single knob. Extremely precise and rapid tuning is attained by means of the dual-ratio vernier-drive system used in conjunction with the gang capacitor as mentioned under "Controls." To tune the instrument for desired reception, proceed as follows:

(a) Turn *Power Switch* "on."

(b) Select position of *Range Switch* at which the band letter corresponds to that frequency scale which includes the desired station or channel.

(c) Set *A.V.C. Switch* "on" and *Beat Oscillator Switch* "off."

(d) Turn *Crystal Selectivity Control* fully clockwise to "Crystal off" position.

(e) Advance *Signal Input Control* fully clockwise for maximum sensitivity.

(f) Advance *Volume Control* clockwise until background noise is heard.

(g) With rear part of tuning knob, rotate black pointer to approximate frequency of desired station, then with the front part make slow adjustment to the exact center of the carrier, as indicated by the *Electron-Ray Indicator*.

(h) Decrease volume as necessary and set *Tone Control* to "Bass," "Music" or "Speech" for preferred quality of reproduction. Full tone range reproduction is obtained with the knob set to "Music."

(i) **Silent Tuning** may be obtained by reducing the volume until no signals are heard, and then tuning by means of the visual indications of the electron-ray tube.

(j) **Weak Modulated Signals.**—The beat-oscillator may be used to advantage in locating weak, modulated signals. For this purpose it should be tuned exactly to the intermediate frequency of the receiver by turning the *Heterodyne Control* to "0," so that an audio-frequency note of ascending pitch will be obtained on each side of resonance of the incoming signal when the *Beat-Oscillator Switch* is turned "on." Any other carrier will be tuned to exact resonance when the gang or tuning capacitor is adjusted for "zero beat" and weak signals will be located almost as well as those of greater strength because of the heterodyne "whistle" produced while passing through resonance. After proper adjustment has been made, turn *Beat-Oscillator Switch* "off."

(k) **C-W Signals.**—For c-w (code) reception, the tuning procedure is the same as for modulated signals except that the *Beat-Oscillator* performs a definite rather than incidental function. It is set, not at the intermediate frequency, but slightly above or below so as to provide an audio-frequency beat note when the receiver is tuned to resonance with any carrier. Adjust the pitch with the *Heterodyne Control* knob. Turn *A.V.C. Switch* "off" when receiving slow speed c-w transmission.

(l) **Selectivity.**—The value of the *Crystal Selectivity Control* is most evident on c-w reception. Its importance should not be forgotten in phone reception and for identification of distant stations which are normally lost in the background noise. The curves should be studied carefully before operating the *Selectivity Control*. The following suggestions also may be of value:

1. Tuning is extremely critical with control in the "Max." position and in consequence the movement of the slow speed *Tuning* knob should be *very slow* and deliberate.
2. First locate the desired band or station with control at "Crystal off," i. e. in its position of minimum selectivity.
3. Remember to set *Tone Control* at "Speech" for stable operation of *Crystal Selectivity Control*.

FOR SELECTIVITY CON-
TROL CURVES, SEE INDEX

Antenna

A most important factor in good reception is the antenna. Both "noise reducing" and "directional" properties as well as a definite "length" to suit the signal frequency are essential antenna requirements for good reception. A special system or one of multiple antennas of the *single-wire* or *doublet* type is therefore necessary. The RCA *Double-Doublet* antenna system consists of *two* doublet antennas having different lengths and therefore different resonance characteristics. They are inter-connected so that one will compensate for the weak points of the other throughout the intervening frequency range. A *Triple-Doublet* system of lengths cut to suit individual requirements will give still better results. Be sure to obtain the latest information on RCA Antennas. Dipole lengths, as listed in the following table, connected with the coupling transformers specified, are recommended for the respective amateur bands.

The triple- or double-doublets are most easily applied to those bands for which the same coupling transformer can be used. For example, a double-doublet with an aircraft type coupling transformer would be best for 160 and 80 meters, or with a standard transformer on 40 and 20 meters, but not with either transformer on 80 and 40 meters.

Proper cross connections must be made on all dipole systems as illustrated in Figure 4.

Standard RCA Transmission Line should be used. Lengths are not critical for the above resonant antenna conditions.

REPLACEMENT

Stock No.	Description	List Price
	RECEIVER ASSEMBLIES	
5237	Bushing—Variable tuning condensor mounting bushing assembly—Package of 3	.43
12115	Cable—6-conductor braided reproducer cable approximately 75-in. long—Complete with 6-contact female connector, Stock No. 11934	1.55
11350	Cap—Grid contact cap—Package of 5	.20
11223	Capacitor—Adjustable capacitor (C26)	.46
12077	Capacitor—5 Mmfd. (C52)	.42
11941	Capacitor—22 Mmfd. (C19)	.22
11321	Capacitor—33 Mmfd. (C9)	.26
11289	Capacitor—50 Mmfd. (C13, C28)	.26
11291	Capacitor—115 Mmfd. (C29, C30, C32)	.24
8076	Capacitor—115 Mmfd. (located in beat-oscillator coil, Stock No. 12084) (C54)	.20
11998	Capacitor—115 Mmfd. (C41, C42, C46, C47)	.28
5116	Capacitor—175 Mmfd. (C59)	.18
11500	Capacitor—175 Mmfd. (C48)	.18
11290	Capacitor—400 Mmfd. (C20, C57, C68)	.25
12086	Capacitor—400 Mmfd. Located in beat-oscillator coil Stock No. 12084 (C55)	.25
12104	Capacitor—560 Mmfd. (C33)	.24
11633	Capacitor—900 Mmfd. (C58)	.32
11939	Capacitor—1200 Mmfd. (C34, C35)	.42
12571	Capacitor—1225 Mmfd. (C24)	.20
11287	Capacitor—4500 Mmfd. (C21, C73)	.30

4839	Capacitor—0.1 Mfd. (C8, C45)	.28
11248	Capacitor—4 Mfd. (C65)	1.06
11203	Capacitor—10 Mfd. (C67)	1.18
5212	Capacitor—18 Mfd. (C66)	1.16
12092	Coil—Antenna coil—"A" and "C" bands (L1, L2, L5, L6, C1, C2, C4)	2.24
12098	Coil—Antenna coil—"B" band (L3, L4, C3)	.82
12084	Coil—Beat frequency oscillator coil (L23, C54, C55, R24)	1.70
12093	Coil—Detector coil—"A" and "C" bands (L7, L8, L11, L12, C10, C11, C15)	2.34
12099	Coil—Detector coil—"B" band (L9, L10, C12)	.88
12094	Coil—Oscillator coil—"A" and "C" bands (L14, L16, C22, C23, C27)	2.14
12100	Coil—Oscillator coil—"B" band (L15, C25)	.82
5221	Coil—Oscillator coil—"D" band (L13)	.64
11214	Condenser—3-gang variable tuning condenser (C5, C17, C31)	4.20
12089	Condenser—Crystal switch and phasing control condenser—Less extension shaft (S11, C36)	1.25
11934	Connector—6-contact female connector for reproducer cable, Stock No. 12115	.38
12006	Core—Adjustable core for I.F. transformer, Stock Nos. 12095, 12096 or 12097	.22
12085	Core—Adjustable core and stud assembly—For beat-oscillator coil, Stock No. 12084	.16
12107	Coupling—Extension shaft coupling for Stock No. 12089 phasing control	Price on application
12108	Crystal—Crystal filter and case	14.00
11246	Foot—Chassis foot and bracket—Package of 2	.76
8041	Plate—I.F. or R.F. coil shield locking plate—Package of 2	.12
11244	Resistor—Voltage divider resistor, comprising one 7,500-ohm and one 9,200-ohm section (R32, R33)	1.08
12102	Resistor—Voltage divider resistor, comprising one section of 160-ohm and one section 110-ohm (R34 R35)	.44
11937	Resistor—2.5 ohms—wire wound (R37)	1.12
12432	Resistor—45 ohms—Flexible type (R40, R41)—For use only in models with 110-220-volt power transformer—Package of 5	.60
11932	Resistor—330 ohms—carbon type, 1/10-watt (R14, R15)—Package of 5	.75
11296	Resistor—330 ohms—carbon type, ¼-watt (R2)—Package of 5	1.00
5165	Resistor—820 ohms—carbon type, ¼ watt (R6)—Package of 5	1.00
11935	Resistor—1,000 ohms—carbon type, 1/10-watt (R10)—Package of 5	.75
5112	Resistor—1,000 ohms—carbon type, ¼-watt (R3, R16)—Package of 5	1.00
3381	Resistor—10,000 ohms—carbon type, ¼-watt (R21, R26)—Package of 5	1.00
8070	Resistor—22,000 ohms—carbon type, ½-watt (R11)—Package of 5	1.00

RCA MFG. CO., INC.

Stock No.	Description	List Price
11300	Resistor—33,000 ohms—carbon type, 1/10-watt (R8)—Package of 5	.75
8067	Resistor—39,000 ohms—carbon type, ½-watt (R9)—Package of 5	1.00
11646	Resistor—47,000 ohms—carbon type, ¼-watt (R25)—Package of 5	1.00
11282	Resistor—56,000 ohms—carbon type, 1/10-watt (R7, R18)—Package of 5	.75
5029	Resistor—56,000 ohms—carbon type, ¼-watt (R30)—Package of 5	1.00
8064	Resistor—82,000 ohms—carbon type, ½-watt (R36)—Package of 5	1.00
3118	Resistor—100,000 ohms—carbon type, ¼-watt (R1, R4, R12, R13, R17)—Package of 5	1.00
11281	Resistor—100,000 ohms—carbon type, 1/10-watt (R24)—Package of 5	.75
11323	Resistor—270,000 ohms—carbon type, ¼-watt (R29)—Package of 5	1.00
11172	Resistor—470,000 ohms—carbon type, ¼-watt (R31)—Package of 5	1.00
11452	Resistor—470,000 ohms—carbon type, 1/10-watt (R19)—Package of 5	.75
12013	Resistor—1 Megohm—carbon type, 1/10-watt (R38)—Package of 5	.75
3033	Resistor—1 Megohm—carbon type, ¼-watt (R20)—Package of 5	1.00
11626	Resistor—2.2 Megohm—carbon type, ¼-watt (R22)—Package of 5	1.00
11936	Resistor—4.7 Megohm—carbon type—¼-watt (R23)—Package of 5	1.00
12090	Sensitivity Control (R5)	1.22
4669	Screw—8-32 x 5/32-in. set screw for extension shaft, Stock No. 12105—Package of 10	.25
12103	Shaft—Extension shaft for phasing control, Stock No. 12089	.15
12105	Shaft—Extension shaft for beat-oscillator coil adjustment	.15
5249	Shield—Antenna, detector or oscillator coil shield	.20
12112	Shield—First or third I.F. transformer shield	.28
12111	Shield—Second I.F. transformer shield	.28
12110	Shield—Top cap shield for Radiotron 6J7 beat-oscillator	.14
11195	Socket—5-contact 5Z4 Radiotron socket	.15
11313	Socket—5-contact 6F5 Radiotron socket	.18
11198	Socket—7-contact 6L7, 6F6, 6H6 second I.F. or R.F. 6K7 Radiotron socket	.15
12113	Socket—7-contact 6J7 beat-oscillator Radiotron socket	.16
12114	Socket—7-contact 6J7 oscillator Radiotron socket	.16
11196	Socket—8-contact first I.F. 6K7 Radiotron socket	.15
11381	Socket—Tuning tube socket and cover	.45
12106	Spring—Retaining spring for beat-oscillator shaft, Stock No. 12105—Package of 5	.15
12374	Switch—Beat-frequency oscillator switch (S14)	.55
12109	Switch—Automatic volume control switch (S10)	.30
12088	Switch—Combination power, tone and stand-by switch (S13, S15, S16)	1.00
12091	Switch—Range switch (S1, S2, S3, S4, S5, S6, S7, S8, S9)	3.55
5238	Terminal—Antenna terminal board and clip	.14
12095	Transformer—First intermediate frequency transformer (L17, L18, C33)	1.50
12101	Transformer—Power transformer, 105-125 volts, 25-60 cycle (T1)	5.20
12331	Transformer—Power transformer, 105-130, 140-160, 195-250 volts, 50-60 cycle	5.15
12096	Transformer—Second intermediate frequency transformer (L19, L20, C41, C42)	1.85
12097	Transformer—Third intermediate frequency transformer (L21, L22, C46, C47, C48, R18, R19)	2.52
11649	Trap—Wave-trap (L27, C70, R39)	1.15
12087	Volume Control (R27)	1.84

Stock No.	Description	List Price
	DRIVE ASSEMBLIES	
11952	Dial—Station selector dial scale	.78
12116	Drive—Variable tuning condenser drive assembly—Comprising reflector, bracket, drive, hub and gear assembled	1.35
11982	Fastener—Station selector dial scale fastener—Package of 25	.42
4827	Gear—Spring gear assembly for vernier pointers	1.25
11228	Gear—Vernier pointer drive gear	.42
11303	Indicator—Station selector vernier indicator pointer	.22
4520	Indicator—Station selector indicator pointer	.18
4340	Lamp—Dial lamp—Package of 5	.60
12577	Screw—8-32 x 1¼ in. slotted set screw for drive assembly—Package of 10	.15
12117	Shaft—Dual speed drive shaft for variable condenser drive assembly—Comprising shaft, drive, spool, spring and washer—assembled	.36
11222	Socket—Dial lamp socket	.18
	MISCELLANEOUS ASSEMBLIES	
11192	Clamp—Tuning tube mounting clamp	.12
12122	Escutcheon—Station selector escutcheon	.60
12130	Foot—Rubber foot assembly—Package of 4	.25
6614	Glass—Station selector dial glass	.30
12128	Jack—Telephone jack (J1)	1.02
12124	Knob—Heterodyne adjustment or selectivity control knob—Package of 5	.70
12123	Knob—Power (Tone), signal input, AVC, range, volume or beat-oscillator control knob—Package of 5	.70
12129	Knob—Station selector knob assembly—Comprising 1 main and 1 vernier tuning knob—Package of 5	2.10
4340	Lamp—Pilot lamp—Package of 5	.60
12120	Panel—Control panel	1.68
12121	Panel—Front panel assembly, complete	5.45
4678	Ring—Spring ring for station selector dial glass—Package of 5	.34
12127	Screw—Chassis mounting screw assembly—Package of 4	.18
12126	Screw—6-32 x ⅜-in. fillister head screw—Used to hold front panel—Package of 10	.42
12125	Screw—8-32 x 5/16-in. cupped point set screw for knob, Stock No. 12124—Package of 10	.20
4982	Spring—Retaining spring for main tuning knob in Stock No. 12129—Package of 10	.26
11349	Spring—Retaining spring for knob, Stock No. 12123—Package of 5	.15
11222	Socket—Pilot lamp socket	.18
	REPRODUCER ASSEMBLIES	
11954	Board—Terminal board assembly, with eyelets and lead wire clips	.14
11231	Bolt—Yoke and core assembly bolt and nut	.16
8060	Bracket—Output transformer mounting bracket	.14
11257	Clamp—Cone center suspension clamping nut and screw assembly—Package of 5	.25
11254	Coil—Field coil (L26)	2.00
11233	Coil—Neutralizing coil (L24)	.30
11235	Cone—Reproducer cone (L25)—Package of 5	3.50
11953	Connector—6-contact male connector for reproducer	.28
9658	Reproducer complete—Less baffle assembly	6.16
11253	Transformer—Output transformer (T2)	1.56
11886	Washer—Spring washer—Used to hold field coil securely—Package of 5	.20

Average Output of Pickup....... 1½-volts, at 1,000 c.p.s. across ¼ meg. load

PHONOGRAPH MOTOR SERVICE DATA

The synchronous motor used in this instrument is designed to be simple and foolproof. Among its many features are constancy of speed, low power consumption, single moving part, ease of starting, rubber damper, ease of repair, and long life. The parts that may require attention are plainly shown in figure 1. The motor is started by turning "on" the power switch and giving the turntable a clockwise spin with the hand. Smooth starting and running will be insured by keeping the bearings well cleaned and oiled.

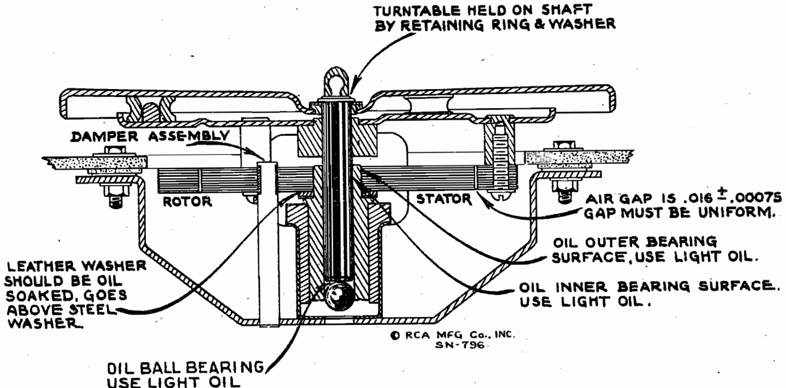
Hum and Vibration.—A small amount of hum when starting, decreasing to a negligible amount when running, is normal. If excessive vibration occurs it may be due to:

1. Insufficient lubrication, or any failure that will cause binding.
2. Leather washer not oiled. (Check to make certain that the leather washer is above the steel washer.)
3. Motor not properly supported from motor board.
4. Burrs on poles of rotor or stator. Remove with fine emery cloth.

Removing Rotor.—The rotor and turntable assembly simply rests on the ball bearing at bottom of vertical bearing. Remove by lifting up.

Rotor Adjustment.—Loosen the three screws that hold the rotor to the turntable, insert three 16-mil shims at equal distances around the gap between the rotor and stator, and then carefully tighten the three screws. The top of rotor must be flush with top of stator; add additional steel washers beneath the stator if necessary.

Lubrication.—Oiling points are indicated in figure



Service Data

Loudspeaker.—Centering of the loudspeaker is made in the usual manner with three narrow celluloid or paper feelers after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. A dust cover should be cemented in place with ambroid upon completion of adjustment.

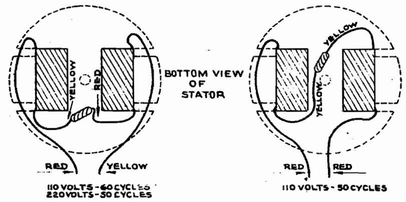


Figure 5—Motor Coil Assembly and Connections
D-C resistance of each coil (for 110 volts, 50 and 60 cycles) is approximately 82 ohms.

Precautionary Lead Dress

1. Dress power leads to phono motor switch away from the audio wiring.
2. Dress power cord and motor cable to end of chassis (free from volume control wiring).
3. Dress pilot lamp lead away from 6Q7G grid.
4. Capacitors C13 and C15 (located at volume control) must be dressed at right angles to each other and as far apart as possible.

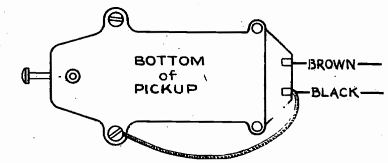

Figure 6—Pickup Connections

Alignment Procedure

Cathode-ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output meter alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-oscillator.—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

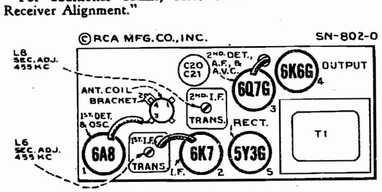

Figure 2—Radiotron and Trimmer Locations

Pre-setting dial.—With gang condenser in full mesh, move dial pointer to coincide with horizontal lines. This is a friction adjustment.

Re-sealing I.F. Adjustment Screws.—After completion of alignment, seal the I.F. magnetite-core adjustment screws with a few drops of household cement.

Steps	Connect the high side of test-oscillator to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
No. 1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	Quiet point between 550-750 kc	L7 and L8 (2nd I-F Transformer)
No. 2	6A8 1st-det. grid cap, in series with .01 mfd.	455 kc		L5 and L6 (1st I-F Transformer)
No. 3	Antenna lead, in series with 200 mmfd.	1,500 kc	1,500 kc	C18* (osc.) C3 (antenna)

* Trimmer C17 on gang condenser should be screwed clockwise for maximum capacity before adjusting C18.

REPLACEMENT PARTS

Insist on genuine factory-tested parts, which are readily identified and may be purchased from authorized dealers.

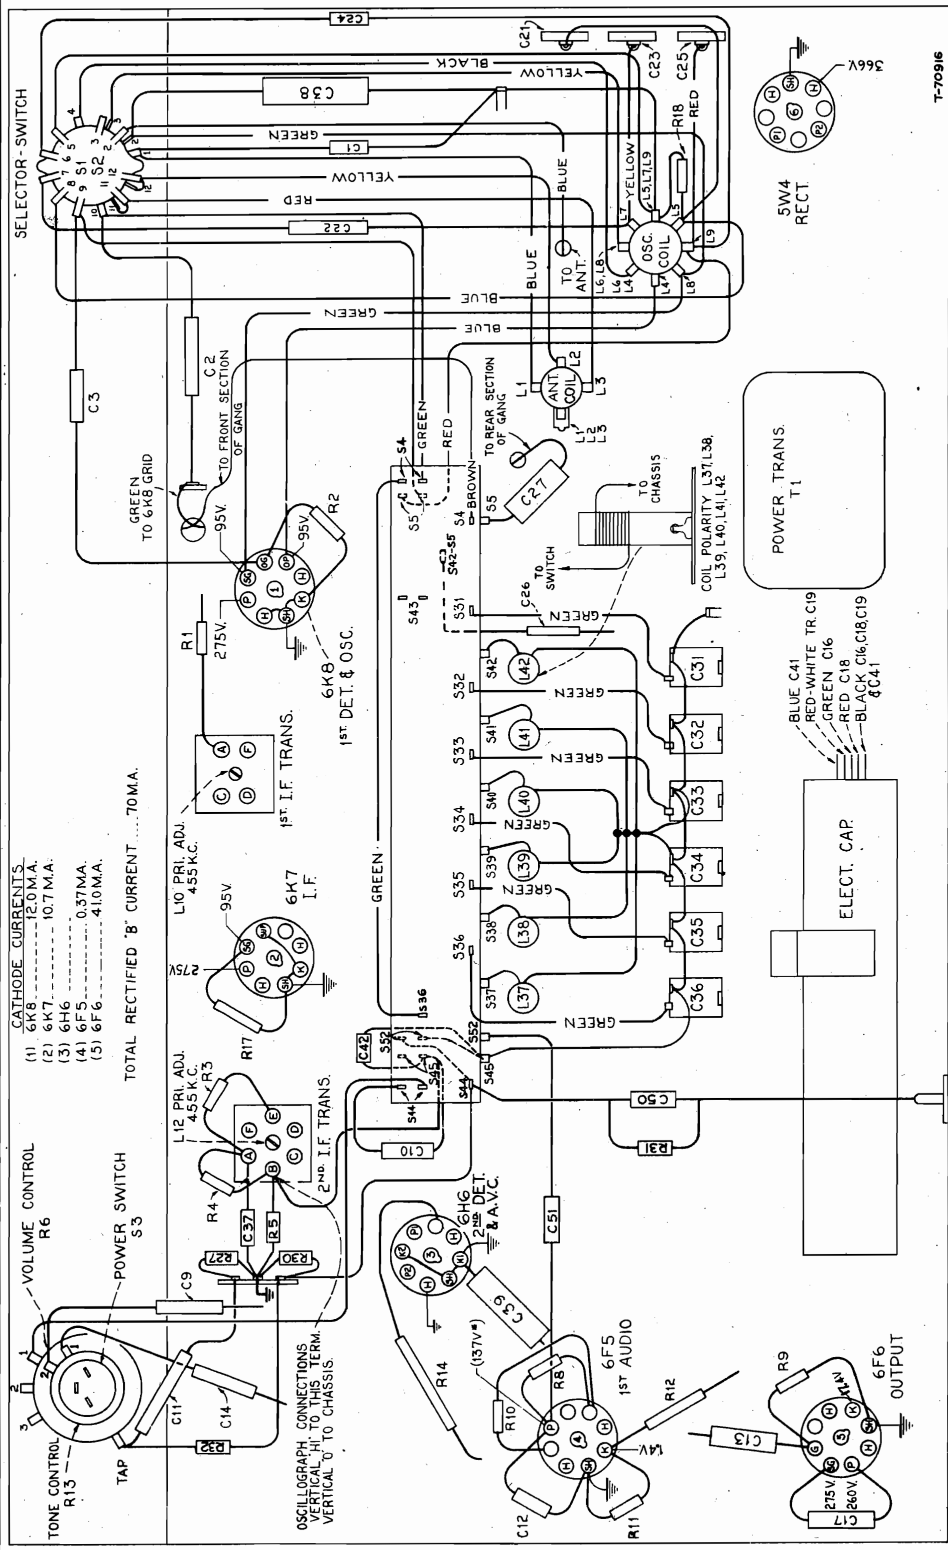
* **NOTE:** Values with star (*) are operating voltages in circuits with high series resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

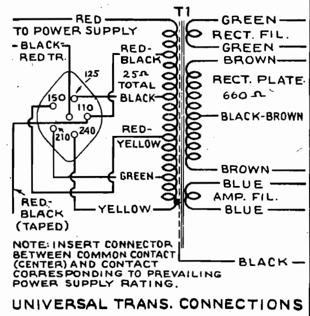
Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within ±20% with 117-volt a-c supply.



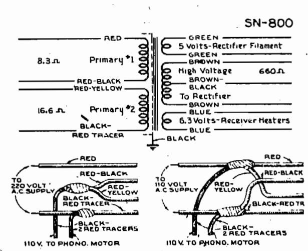
Six Electric Tuning Positions............ 550-1,500 kc
2 stations between approximately 550- 950 kc (Buttons 1 and 2)
2 stations between approximately 680-1,180 kc (Buttons 3 and 4)
2 stations between approximately 890-1,500 kc (Buttons 5 and 6)

Precautionary Lead Dress.—

1. Dress power-switch leads against left apron to prevent hum pickup.
2. Dress R1 away from front of chassis.
3. Leads across back of chassis should be dressed under electrolytic to prevent approaching Victrola jack.
4. Dress lead from L5 to range switch away from other leads.
5. Dress leads away from antenna coil.
6. Dress other parts and leads away from R14, as it becomes heated.



Above — Universal Power Transformer Connections. (110-volt supply for the Victrola motor is obtained by connecting the motor to the red and the red-black leads.)



Above—Replacement Universal Power Transformer. (Stock No. 31446.)

ADJUSTMENTS FOR ELECTRIC TUNING

These models have eight push buttons. The left-hand button is a Victrola switch. The right-hand button connects the gang condenser for manual tuning. The other six buttons are for electric tuning of six different stations in the standard-broadcast range. The station buttons connect to separate magnetite-core oscillator coils and separate antenna trimmers which must be adjusted for the desired stations. Use an insulated screwdriver or alignment tool such as RCA Stock No. 31031. Allow at least five minutes warm-up period before making adjustments.

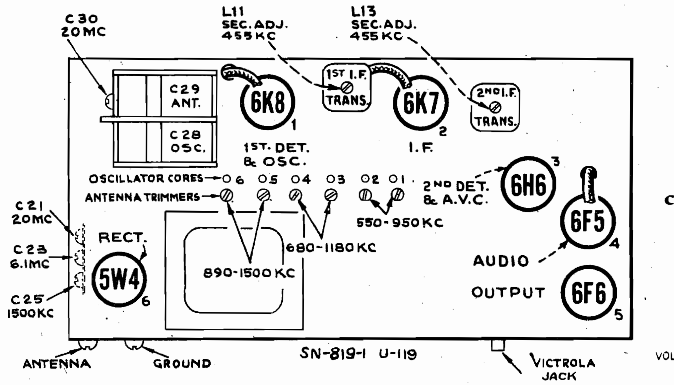
Use one or two feet of wire as an antenna to ensure sharp peaking.

The procedure is as follows:

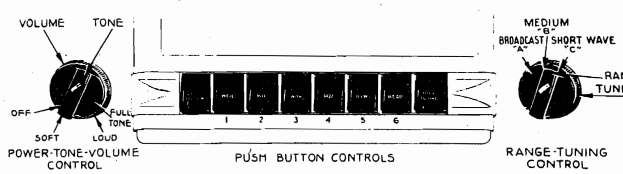
1. Make a list of the desired six stations, arranged in order from low to high frequencies.
2. Push in the dial-tuning button, and manually tune in the first station on the list.
3. Push in station button No. 1 (second from left) and adjust No. 1 oscillator core (L37) to receive this station. Screw the core all the way in, to lowest frequency, and then unscrew slowly until station is received.
4. Adjust No. 1 antenna trimmer (C36) for maximum output on this station.

Clockwise adjustment of cores and trimmers tunes the circuits to lower frequencies.

5. Adjust for each of the remaining five stations in the same manner.
6. Make a final careful adjustment of the oscillator cores and antenna trimmers.



Tube and Trimmer Locations



Location of Controls

The left-hand push-button is a Victrola switch.
The right-hand push-button is for dial tuning.

Alignment,Motor Data
Parts

RCA MFG. CO., INC.

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-Oscillator.—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

Calibration Scale on Indicator-Drive-Cord drum.—The tuning dial if fastened in the cabinet and cannot be used for reference during alignment; therefore, a calibration scale is attached to the rear of the drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The 180° mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The distance from the front of the chassis to the drum must not exceed 3/8-inch. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

Pointer for Calibration Scale.—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "180°" mark on the calibration scale when the plates are fully meshed.

Dial-Indicator Adjustment.—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

After completion of alignment, seal the i-f core-adjusting screws with household cement.

For additional details, refer to booklet "RCA Victor Receiver Alignment."

Steps	Connect the high side of test-osc. to—	Tune test-osc. to—	Turn radio dial to—	Adjust the following for max. peak output
1	6K7 I-F grid cap, in series with .01 mfd.	455 kc	"A" band, Quiet Point between 550-750 kc	L12 and L13 (2nd I-F Trans.)
2	6K8 det. grid cap, in series with .01 mfd.	455 kc		L10 and L11 (1st I-F Trans.)
3	Antenna Terminal, in series with 400 ohms	20 mc	20 mc (23°) "C" band	C21* (osc.) C30** (ant.)
4	Antenna Terminal, in series with 400 ohms	6.1 mc	6.1 mc (31°) "B" band	C23 (osc.)†
5	Antenna Terminal, in series with 200 mmf.	1,500 kc	1,500 kc (28½°) "A" band	C25 (osc.)
6	Follow "Adjustments for Electric Tuning"			

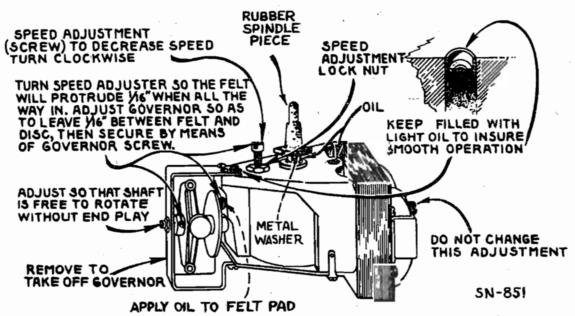
* Use minimum capacity peak if two peaks can be obtained.

** Rock gang slightly and use maximum capacity peak if two peaks can be obtained with C30. Check to determine that C21 has been adjusted to the correct peak by tuning to approximately 28° (19.09 mc), where a weaker signal should be received.

† Use minimum capacity peak if two peaks can be obtained. Check to determine that C23 has been adjusted to the correct peak by turning to approximately 49° (5.19 mc), at which point a weaker signal should be received.

Note: Oscillator tracks 455 kc above signal on all bands.

Victrola Mechanism



Motor Lubrication and Adjustments

The crystal pickup unit is thoroughly sealed in a metal casing as protection against extreme changes of climate. If failure occurs due to a defective crystal unit, no attempt should be made to repair the unit, but a new replacement crystal unit should be installed.

The turntable drive is a self-starting, variable-speed, governor-type induction motor. The motor speed-adjustment screw is located under the turntable, which must be removed for speed adjustment. The motor speed should be 78 r.p.m., and may be checked by placing a piece of paper between a record and the turntable, with the paper protruding beyond the edge of the record, and counting the number of revolutions of the turntable per minute while playing a record.

The motor spindle is tapered, and a conical rubber piece fits snugly on the spindle. The hole in the turntable bushing is tapered to fit the rubber. This provides an excellent self-centering floating mounting.

Lubrication and adjustments are described in the accompanying illustrations. Note that the switch lever should be adjusted so that the lever will snap to the "off" position when the pickup needle is 1¾ inches from the center-line of the spindle.

Operation.—*To start* turn on the radio power switch, push in the Victrola push button (left-end button) and push the turntable switch lever toward the base of the pickup arm. *To stop* move the pickup arm toward the spindle, in order to actuate the turntable switch, before returning the arm to the arm rest. Records with the standard eccentric or spiral stopping groove will automatically throw the turntable switch at the end of a record.

A metal washer is placed on the spindle under the rubber piece. The washer has ears on the under side which fit over a pin that projects through the spindle.

11703	Governor—Motor governor complete—50-60 cycle	3.05
31624	Governor—Motor governor complete—25 cycle	3.05
31724	Motor—105-125 volts, 25 cycle (M1)	22.95
31462	Motor—105-125 volts, 50-60 cycle (M1)	20.20
31461	Motor—105-125 volts, 60 cycle (M1)	17.35
31616	Screw—Motor rotor bearing screw and nut	.25
31620	Screw—Motor speed regulator screw and nut	.20
31621	Shaft—Motor turntable spindle shaft and gear—60 cycle or 50-60 cycle	1.90
31773	Shaft—Motor turntable spindle shaft and gear—25 cycle	2.95
31622	Washer—Motor spindle shaft thrust bearing washers (1 metal, 1 felt)	.10
	MOTOR BOARD ASSEMBLIES	
9848	Cup—Used needle cup and lid complete	.75
31464	Damper—One rubber spindle cap and one metal damper plate	.30
31465	Mounting—Pickup arm base mounting—one rubber washer, one lockwasher, one nut	.10
30870	Plug—2-contact male plug for motor and switch leads	.35
31158	Screw—Motor mounting screws, washers, and spacers, (sufficient for one motor)	.25
31155	Spring—Used needle cup lid spring	.04
30100	Spring—Auto. switch springs—one long spring and one short spring	.08
31466	Switch—Automatic motor switch and switch lever	3.60
31467	Switch—Switch only—for auto. switch (S50)	.35
31463	Turntable	1.50
	PICKUP AND ARM ASSEMBLIES	
31156	Crystal—Pickup crystal cartridge and needle screw and shorting switch (S51)	4.25
31468	Pickup and Arm complete	7.50
31160	Screw—Needle screw	.12
31469	Shaft—Pickup pivot arm and shaft assembly complete with base	.95
	SPEAKER ASSEMBLIES Model U-119 (Speaker No. 84308-2)	
31762	Cone—Speaker cone and voice coil (L14)	1.75
31761	Speaker Complete	5.15
31444	Transformer—Output transformer (T2)	1.95
	SPEAKER ASSEMBLIES Model U-122E (Speaker No. RL63H-5)	
14356	Board—3-contact speaker terminal board	.15
13866	Cap—Cone center dust cap	.25
12012	Coil—Field coil (L16)	2.90
11469	Coil—Hum neutralizing coil (L15)	.30
31310	Cone—Speaker cone and voice coil (L14)	1.75
31302	Plug—4-contact male plug for speaker	.25
14358	Screw—Screw, washer, and lockwasher to hold core in yoke	.04
31453	Speaker Complete	10.25
14355	Transformer—Output transformer (T2)	2.00
14357	Washer—Spring washer to hold field coil	.06
	SPEAKER ASSEMBLIES Model U-124 (Speaker No. RL70H-1)	
13866	Cap—Dust cap for cone center	.25
12012	Coil—Field coil (L16)	2.90
11469	Coil—Hum neutralizing coil (L15)	.30
31275	Cone—Speaker cone and voice coil (L14)	1.75
31302	Plug—4-contact male plug	.25
31592	Speaker—Speaker complete	9.35
14358	Screw—Screw, washer, and lockwasher to hold core in yoke	.04
14355	Transformer—Output transformer (T2)	2.00
14357	Washer—Spring washer to hold field coil	.06
	MISCELLANEOUS ASSEMBLIES	
31397	Button—Station selector push-button	.15
31456	Cover—8 protective covers for push-button markers	.08
31591	Dial—Station selector dial scale—Model U-124 only	.75
31406	Dial—Station selector dial scale—Models U-119 and U-122E only	.90
31395	Escutcheon—Tuning dial escutcheon only less push-buttons and dial scale	1.15
13085	Hinge—Cabinet lid hinge—Model U-119 only	.22
30698	Hinge—Cabinet lid hinge—Model U-124 only	.95
31103	Hinge—Cabinet lid hinge—Model U-122E only	.50
31392	Indicator—Indicator pointer, carriage, and clip	.30
31355	Knob—Range switch knob	.12
14359	Knob—Station selector knob	.20
31391	Knob—Tone control knob	.15
30773	Knob—Volume control knob	.15
31458	Marker—"Dial Tuning" marker for push-button—Models U-119 and U-122E only	.01
31460	Marker—"Dial Tuning" marker for push-button—Model U-124 only	.04
31457	Marker—"Record Player" marker for push-button—Models U-119 and U-122E only	.01
31459	Marker—"Record Player" marker for push-button—Model U-124 only	.04
31589	Marker—Station call letter markers—Models U-119 and U-122E	.35
31590	Marker—Station call letter markers—Model U-124	.40
31393	Screen—Dial color screen	.40
11210	Screw—Chassis mounting screws, washers, and lockwashers—Model U-124 only	.05
31390	Screw—Chassis mounting screws, washers, and lockwashers—Model U-119 only	.10
31471	Screw—Chassis mounting screws, washers, and lockwashers—Model U-122E only	.15
31470	Springs—Motorboard suspension stop spring, bottom spring, screw, and lockwasher (4 reqd.)	.10
4982	Spring—Retaining spring for knob Stock No. 14359	.05
14270	Spring—Retaining spring for knob Stock Nos. 30773 and 31355	.05
30330	Spring—Retaining spring for knob Stock No. 31391	.03
31164	Support—Cabinet lid support—Model U-119 only	.45
30946	Support—Cabinet lid support—Model U-122E only	.60
11831	Support—Cabinet lid support—Model U-124 only	1.85

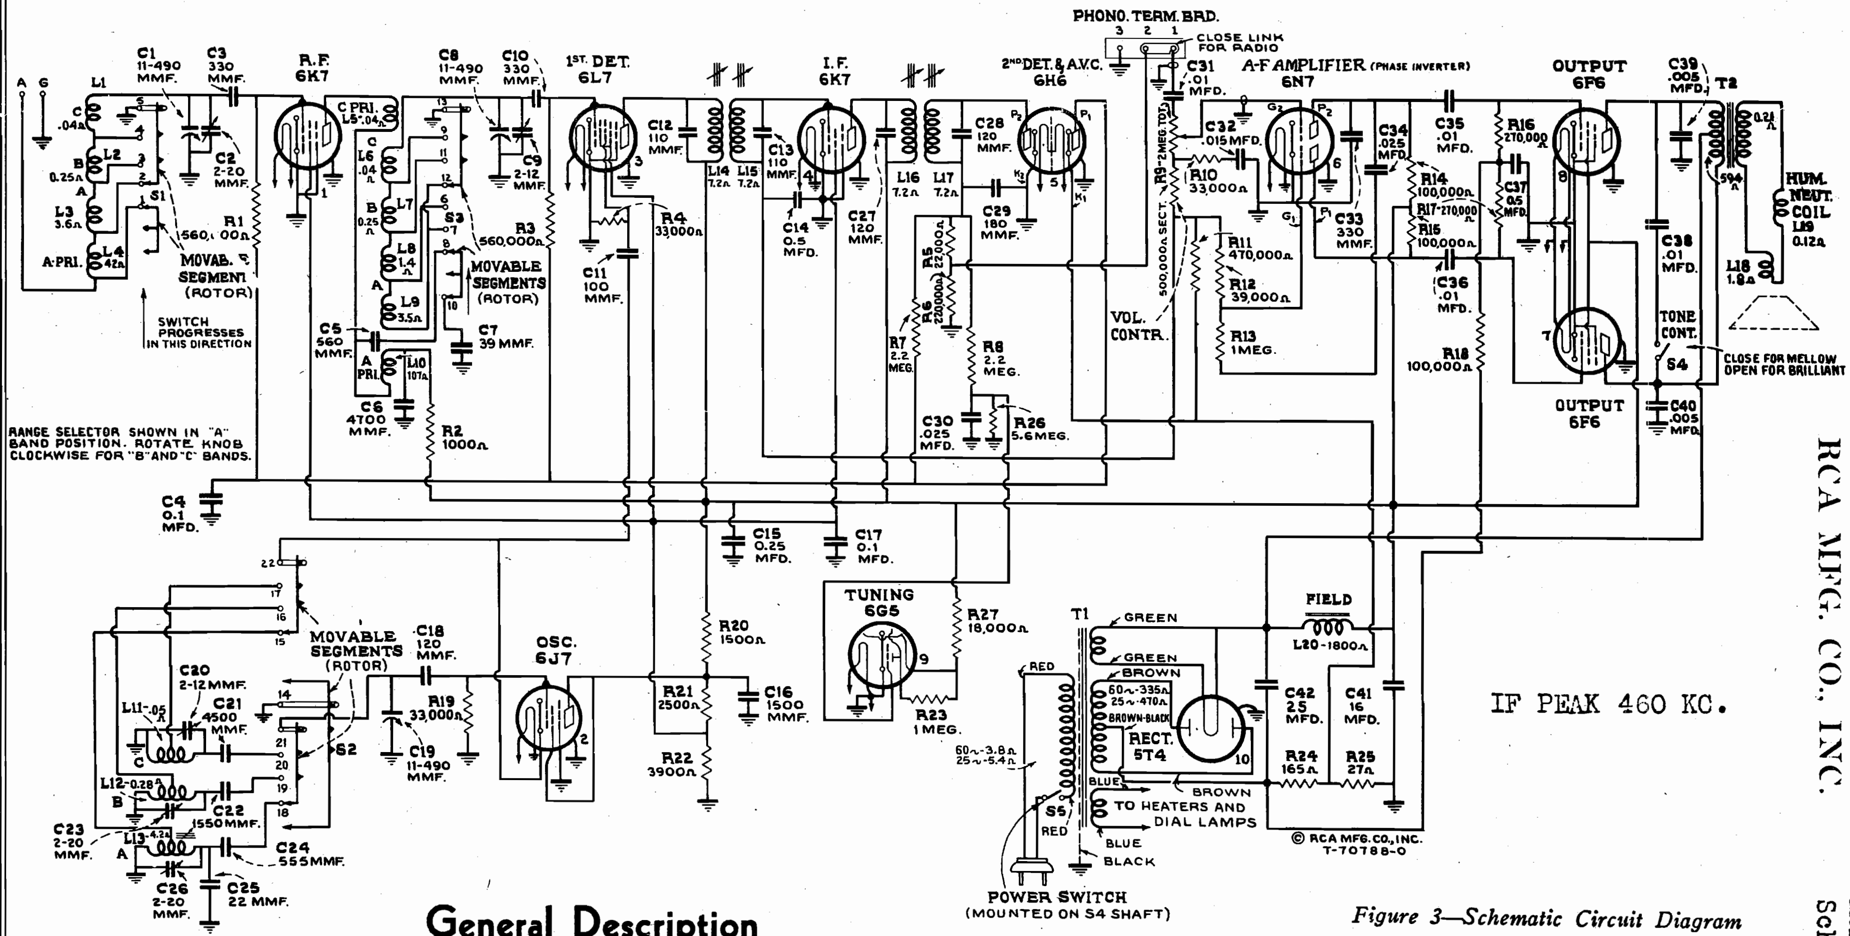
Schematic, Notes

RCA MFG. CO., INC.



IF PEAK 460 KC.

Figure 3—Schematic Circuit Diagram

General Description

These receivers employ a ten-tube, three-band, "Magic Brain," superheterodyne circuit, the arrangement of which is shown by the Schematic Circuit Diagram. Models 810K and 810K1 are console models, each employing a 12-inch electrodynamic loudspeaker. Model 810T is a table model employing an 8-inch electrodynamic loudspeaker. Features of design include an r-f amplifier stage, "qumulative-wound" antenna and r-f transformers for high signal-to-noise ratio; magnetite-core, i-f transformers and low-frequency oscillator tracking; automatic volume control; phonograph terminal board; "Magic Eye" tuning tube; plunger-type, air-dielectric trimming capacitors; aural-compensated, audio-volume control; "Mellow-Brilliant" tone control; audio phase-inverter voltage amplifier; push-pull, power-output stage; improved dust-proof electrodynamic loudspeaker; and a new sunburst dial with short-wave stations listed by name and illuminated band and tone indicators. In addition, Model 810K1 has a cabinet incorporating the "Sonic-Arc" Magic Voice.

Electrical Specifications

Frequency Ranges

"Broadcast" (A) .... 530-1,720 kc
"Medium Wave" (B) .... 2,100-6,800 kc
"Short Wave" (C) .... 6,800-22,000 kc

R-F Alignment Frequencies

"Short Wave" (C) .... 20,000 kc (osc., det., ant.)
"Medium Wave" (B) .... 6,000 kc (osc.)
"Broadcast" (A) .... 600 kc (osc.), 1,500 kc (osc.)

Intermediate Frequency .... 460 kc

Radiotron Complement

(1) RCA-6K7 .... R-F Amplifier
(2) RCA-6J7 .... Heterodyne Oscillator
(3) RCA-6L7 .... First Detector
(4) RCA-6K7 .... Intermediate Amplifier
(5) RCA-6H6 .... Second Detector and A.V.C.
(6) RCA-6N7 .... Phase Inverter A-F Amplifier
(7) RCA-6F6 .... Power Output
(8) RCA-6F6 .... Power Output
(9) RCA-6G5 .... "Magic Eye" Tuning Tube
(10) RCA-5T4 .... Full-Wave Rectifier

Pilot Lamps (4) .... Mazda No. 46, 6.3 volts, 0.25 amp.

Power Supply Ratings

Rating A .... 105-125 volts, 50-60 cycles, 135 watts
Rating B .... 105-125 volts, 25-60 cycles, 135 watts
Rating C .... 100-130/140-160/195-250 volts, 40-60 cycles, 135 watts

Power Output

Undistorted .... 10 watts
Maximum .... 12.5 watts

Loudspeaker

Type .... Electrodynamic
Impedance (v.c.) .... 2.2 ohms at 400 cycles

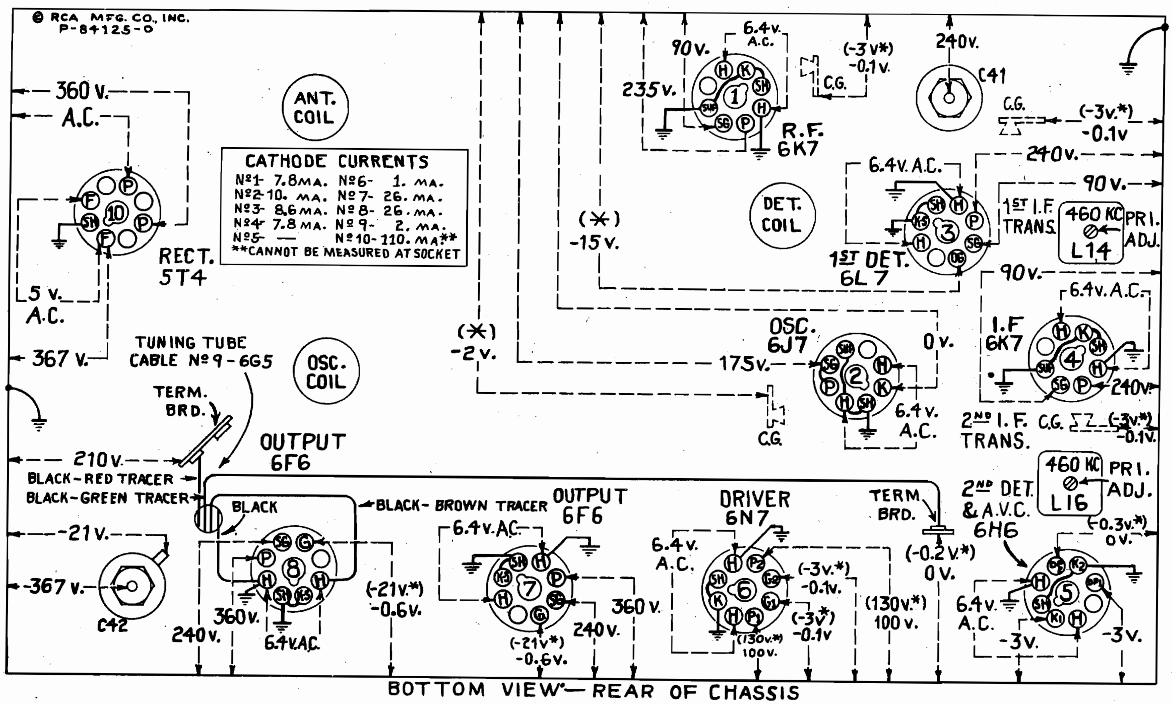

Figure 2—Radiotron Socket Voltages, Coil, and Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc ("Standard Broadcast")—No signal being received—Volume control minimum

***Note:** Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter through the high series circuit resistance.*

Voltage values as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250, and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

Service Data

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R1, L1, C1, etc., provide reference between the illustrations and Replacement Parts List. The coils, transformer windings, and reactors are rated in terms of d-c resistance to permit continuity checks.

Loudspeaker.—Centering of the loudspeaker is made in the usual manner with three narrow paper feelers after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

Phonograph Attachment.—A terminal board is provided for connecting a phonograph into the audio amplifying circuit. RCA Victor Models R-93, R-93-A, R-93-2, or R-94 Record Players should be connected as follows: Remove link between terminals 1 and 2 on terminal board. Connect green wire in Radio-Record switch cable to terminal 1, yellow to terminal 2, and shield extension to terminal 3. Tape unused red and blue leads separately. Connect a 2-conductor twisted cable between the Record Player binding posts and the screw terminals on Radio-Record switch. If additional volume is desired, connect an RCA Stock No. 9632 transformer between the two conductor twisted cable and the screw-terminals on Radio-Record switch as follows: yellow and brown transformer leads and one side of twisted cable to ground screw-terminal on switch; black transformer lead to other side of twisted cable; and blue transformer lead to other screw-terminal on switch.

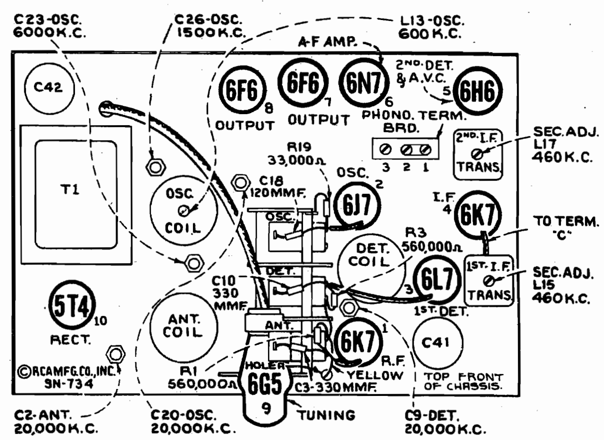

Figure 1—Radiotron, Coil, and Trimmer Locations

Alignment Procedure

Calibrate the tuning dial by adjusting main dial pointer to the low-frequency (end) calibration mark on dial with the gang tuning-condenser plates in full-mesh position; then adjust the small (vernier) pointer to "O." These are friction adjustments.

Perform alignment in proper order, tabulated below, starting with No. 1 and following all operations across, then No. 2, etc. Adjustment locations are shown on figures 1 and 2.

Cathode-ray alignment is highly preferable; the connections to the chassis are shown on figure 4. If an output indicator is used, connect it across the loudspeaker voice-coil and advance the receiver volume control to full-volume position.

Connect the "low" output terminal of the test oscillator to the receiver "G" (ground) terminal for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc" means that the receiver should be tuned to a point between 550 and 750 kc where no signal or interference is received from a station or local (heterodyne) oscillator.

Order of Align-ment	Test Oscillator			Range Selector	Receiver Dial Setting	Circuit to Adjust	Adjustment Symbols	Adjust to Obtain
	Connection to Receiver	Dummy Antenna	Frequency Setting					
1	6K7 I-F Grid Cap	.001 Mfd.	460 kc	"A" Left	No Signal 550-750 kc	2nd I-F Trans.	L16 and L17	Max. (peak)
2	6L7 Det. Grid Cap	.001 Mfd.	460 kc	"A"	No Signal 550-750 kc	1st I-F Trans.	L14 and L15	Max. (peak)
3	Ant. Term.	300 Ohms	20,000 kc	"C" Right	20,000 kc	"C" Osc.	C20	Max. (peak) *
4	Ant. Term.	300 Ohms	20,000 kc	"C"	20,000 kc	"C" Det.	C9	Max. (peak) †
5	Ant. Term.	300 Ohms	20,000 kc	"C"	20,000 kc	"C" Ant.	C2	Max. (peak) ‡
6	Ant. Term.	300 Ohms	6,000 kc	"B" Center	6,000 kc	"B" Osc.	C23	Max. (peak) *
7	Ant. Term.	200 Mmfd.	600 kc	"A" Left	600 kc	"A" L-F Osc.	L13	Max. (peak)
8	Ant. Term.	200 Mmfd.	1,500 kc	"A"	1,500 kc	"A" H-F Osc.	C26	Max. (peak)
9	Ant. Term.	200 Mmfd.	600 kc	"A"	600 kc	"A" L-F Osc.	L13	Max. (peak)
10	Ant. Term.	200 Mmfd.	1,500 kc	"A"	1,500 kc	"A" H-F Osc.	C26	Max. (peak)

* Use minimum capacity peak if two peaks can be obtained.
† Use maximum capacity peak if two peaks can be obtained.
‡ After this adjustment, check for image signal by shifting receiver dial to 19,080 kc.

RCA MFG. CO., INC.

MODELS 810K, 810K1, 810T
Lead Dress, Parts

Precautionary Lead Dress.—(1) Keep leads to a-c switch dressed away from antenna coil and trimmer C2. (2) Keep all filament leads twisted. (3) Keep yellow lead from term. E of 2nd i-f trans. to phono. term. board as short as possible. (4) Keep leads of C21 as short as possible. (5) Dress shielded lead from volume control to phono. term. board against side of chassis and away from 6L7 socket. (6) Yellow lead from 6J7 oscillator cathode to dummy terminal on 6L7 socket must be dressed away from chassis base and from brown filament lead. (7) All molded capacitors should be dressed so that flat side is perpendicular to chassis base. (8) Yellow lead from cathode of 6J7 socket to term. 22 of S2 must be dressed under spaghetti on 6J7 socket jumper and pulled tight away from chassis. The following bus leads should be kept as short as possible and, when necessary, replaced only with wire having same diameter as original: (9) Lead from L11-L12-L13 to ground lance; (10) Lead from term. 13 of S3 to ground lance; (11) Lead from term. 9 of S3 to L6-L7; (12) Lead from L6 to C8; (13) Lead from C9 to C8; (14) Lead from term. 5 of S1 to ground lance; (15) Lead from L1-L2 to term. 4 of S1; (16) Lead from L1 to C1; (17) Lead from term. 21 of S2 to C19. (18) Keep filament leads dressed away from grid prongs of 6N7. (19) Keep blue and green leads from plate prongs of output tubes twisted their entire length.

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers.

STOCK No.	DESCRIPTION
	RECEIVER ASSEMBLIES
12038	Band—Rubber band for tuning tube
14384	Belt—Variable condenser drive belt
14517	Board—Antenna and ground terminal board
12717	Board—Phonograph terminal board
14338	Bushing—Variable condenser mounting bushing assembly
14524	Cable—Band indicator cable approx. 6½ in. long
14523	Cable—Tone control indicator cable approx. 3 in. long
14394	Cable—Tuning tube cable and socket
11350	Cap—Grid contact cap
12607	Cap—First I.F. transformer shield top
12581	Cap—Second I.F. transformer shield top
12884	Capacitor—Adjustable trimmer (long) (C2, C23, C26)
12714	Capacitor—Adjustable trimmer (Medium) (C9, C20)
14021	Capacitor—22 Mmfd. (C25)
13545	Capacitor—39 Mmfd. (C7)
12720	Capacitor—100 Mmfd. (C11)
14262	Capacitor—110 Mmfd. (C12, C13)
12404	Capacitor—120 Mmfd. (C27, C28)
12724	Capacitor—120 Mmfd. (C18)
12406	Capacitor—180 Mmfd. (C29)
12952	Capacitor—330 Mmfd. (C3, C10, C33)
12727	Capacitor—555 Mmfd. (C24)
12537	Capacitor—560 Mmfd. (C5)
13762	Capacitor—1500 Mmfd. (C16)
12729	Capacitor—1550 Mmfd. (C22)
12728	Capacitor—4500 Mmfd. (C21)
12897	Capacitor—4700 Mmfd. (C6)
4838	Capacitor—.005 Mfd. (C39, C40)
13138	Capacitor—.01 Mfd. (C31, C35, C36)
4937	Capacitor—.01 Mfd. (C38)
11315	Capacitor—.015 Mfd. (C32)
4870	Capacitor—.025 Mfd (C30, C34)
4839	Capacitor—0.1 Mfd. (C4, C17)
12484	Capacitor—0.25 Mfd. (C15)
12741	Capacitor—0.5 Mfd. (C14, C37)
5212	Capacitor—16 Mfd. (C41)
14531	Capacitor—25 Mfd. (C42)
14372	Coil—Antenna coil and shield (L1, L2, L3, L4)
14516	Coil—Oscillator coil and shield (L11, L12, L13)
14414	Coil—R.F. coil and shield (L5, L6, L7, L8, L9, L10)
14513	Condenser—3 gang variable tuning condenser (C1, C8, C19)
5040	Connector—4 contact female connector for reproducer cable
12006	Core—Adjustable core and stud for transformer Stock No. 14376 and Stock No. 14283
12800	Core—Adjustable core and stud for coil Stock No. 14516
14518	Dial—Station selector dial scale complete with tuning tube escutcheon
14514	Drive—Variable condenser vernier drive pinion gear and shaft
14345	Drum—Variable condenser drive belt drum complete with set screws
14387	Escutcheon—Tuning tube escutcheon
11982	Fastener—Dial scale fastener
30085	Gear—Indicator drive gear and hub, and pointer stem and gear
14341	Idler—Station selector drive belt idler
14519	Indicator—Station selector indicator pointer
14520	Indicator—Vernier indicator pointer
5226	Lamp—Dial lamp
14028	Nut—Jamb nut for adjustable trimmer capacitor Stock No. 12714 and No. 12884
12471	Plate—6J7 Radiotron socket mounting plate and rubber cushions—less socket
14340	Pulley—Station selector drive belt pulley and knob shaft
14522	Reflector—Dial reflector and bracket complete with dial lamp bracket, tuning tube bracket and tone and band indicators
14720	Resistor—1000 Ohms, Carbon type, ¼ watt (R2)
14078	Resistor—18,000 Ohms, Carbon type, 1 watt (R27)
14284	Resistor—22,000 Ohms, Carbon type, 1/10 watt (R5)
11300	Resistor—33,000 Ohms, Carbon type, 1/10 watt (R19)
13735	Resistor—33,000 Ohms, Carbon type, ¼ watt (R4, R10)
11322	Resistor—39,000 Ohms, Carbon type, ¼ watt (R12)
5145	Resistor—100,000 Ohms, Carbon type, ¼ watt (R14), R15, R18)
11398	Resistor—220,000 Ohms, Carbon type, 1/10 watt (R6)
11453	Resistor—270,000 Ohms, Carbon type, 1/10 watt (R16, R17)
11172	Resistor—470,000 Ohms, Carbon type, ¼ watt (R11)
11397	Resistor—560,000 Ohms, Carbon type, 1/10 watt (R1, R3)
12013	Resistor—1 Megohm, Carbon type, 1/10 watt (R23)
13730	Resistor—1 Megohm, Carbon type, ¼ watt (R13)
11626	Resistor—2.2 Megohm, Carbon type, ¼ watt (R7, R8)
11668	Resistor—5.6 Megohm, Carbon type, ¼ watt (R26)
14532	Resistor—Voltage divider comprising one 1500 Ohm, one 2500 Ohm, one 3900 Ohm, one 27 Ohm and one 165 Ohm sections (R20, R21, R22, R24, R25)
14343	Retainer—Station selector knob shaft and pulley retainer
14350	Screw—No. 8-32 x 3/16 square head set screw for drum Stock No. 14345 gear Stock No. 30085 and hub and arm on band indicator cable
14374	Shield—Antenna or R.F. coil shield
12008	Shield—First or Second I.F. transformer shield
14375	Shield—Oscillator coil shield
14114	Socket—Dial lamp socket
11195	Socket—5 contact 5T4 Radiotron socket
11196	Socket—8 contact 6F6, 6H6, 6K7, 6L7, 6N7, or 6J7 Radiotron socket
12907	Spring—Tension spring for indicator drum gear Stock No. 30085
14342	Spring—Tension spring for idler Stock No. 14341
12007	Spring—Retaining spring for core Stock No. 12006 and No. 12800
14371	Switch—Low frequency tone and power switch (S4, S5)
14515	Switch—Range switch (S1, S2, S3)
14376	Transformer—First I.F. transformer (L14, L15, C12, C13)
14283	Transformer—Second I.F. transformer (L16, L17, C27, C28, C29, R5, R6)
11211	Transformer—Power transformer 105-125 volts, 50-60 cycle (T1)
11212	Transformer—Power transformer 105-125 volts, 25-60 cycle (T1)
11213	Transformer—Power transformer 105-125/140-160/200-250 volts, 50-60 cycle (T1)
14335	Volume Control—(R9)
14379	Washer—Felt washer for indicator pointer
	REPRODUCER ASSEMBLIES MODEL 810T (RL-63-F2)
14356	Board—3 contact reproducer terminal board
13866	Cap—Cone center dust cap
11234	Coil—Field coil (L20)
11469	Coil—Hum neutralizing coil (L-19)
12642	Cone—Reproducer cone and dust cap (L18)
5039	Plug—4 contact male plug for reproducer
14533	Reproducer—Reproducer complete
14358	Screw—Screw, washer, and lockwasher to hold core in yoke
14534	Transformer—Output transformer (T2)
14357	Washer—Spring washer to hold field coil
	REPRODUCER ASSEMBLIES MODELS 810K and 810K1 (RL-70-E2)
13866	Cap—Dust cap for cone center
11234	Coil—Field coil (L20)
11469	Coil—Hum neutralizing coil (L19)
12667	Cone—Reproducer cone and dust cap (L18)
5039	Plug—4 contact male plug for reproducer
14535	Reproducer—Reproducer complete
14358	Screw—Screw, washer and lockwasher to hold core in yoke
14534	Transformer—Output transformer (T2)
14357	Washer—Spring washer to hold field coil
	MISCELLANEOUS ASSEMBLIES
14527	Escutcheon—Station selector escutcheon and crystal complete with tone and band indicating strips
14528	Index—Tone control indicating strip—mounts in station selector escutcheon
14529	Index—Band indicating strip—mounts in station selector escutcheon
14359	Knob—Station selector knob
14269	Knob—Volume control, tone control or range switch knob
11210	Screw—Chassis mounting screw and washer assembly for console model
11377	Screw—Chassis mounting screw and washer assembly for the table model
4982	Spring—Retaining spring for knob Stock No. 14359
14270	Spring—Retaining spring for knob Stock No. 14269

MODEL 810T4
Parts List

RCA MFG. CO., INC.

RADIOTRON COMPLEMENT

(1) RCA-6K7 .... R-F Amplifier
(2) RCA-6J7.................... Heterodyne Oscillator
(3) RCA-6L7.......................... First Detector
(4) RCA-6K7................... Intermediate Amplifier
(5) RCA-6H6............. Second Detector and A.V.C.
(6) RCA-6N7........... Phase Inverter A-F Amplifier
(7) RCA-6F6......................... Power Output
(8) RCA-6F6......................... Power Output
(9) RCA-6G5............. "Magic Eye" Tuning Tube
(10) RCA-5U4G.................. Full-Wave Rectifier

REPLACEMENT PARTS

Insist on genuine factory tested parts, which are readily identified and may be purchased from authorized dealers.

STOCK No.	DESCRIPTION
	RECEIVER ASSEMBLIES
12038	Band—Rubber band for tuning tube
14384	Belt—Variable condenser drive belt
14517	Board—Antenna and ground terminal board
12717	Board—Phonograph terminal board
14338	Bushing—Variable condenser mounting bushing assembly
14524	Cable—Band indicator cable, approximately 6½ inches long
14523	Cable—Tone control indicator cable, approximately 3 inches long
14394	Cable—Tuning tube cable and socket
11350	Cap—Grid contact cap
12607	Cap—First I-F transformer shield top
12581	Cap—Second I-F transformer shield top
12884	Capacitor—Adjustable trimmer (long) (C2, C9, C23, C26, C46, C54, C56)
12714	Capacitor—Adjustable trimmer (medium) (C55)
12896	Capacitor—15 Mmfd. (C25)
13545	Capacitor—39 Mmfd. (C48)
12723	Capacitor—56 Mmfd. (C47)
30233	Capacitor—68 Mmfd. (C44)
12720	Capacitor—100 Mmfd. (C11)
14262	Capacitor—110 Mmfd. (C12, C13)
12404	Capacitor—120 Mmfd. (C27, C28)
12724	Capacitor—120 Mmfd. (C18)
12406	Capacitor—180 Mmfd. (C29)
30232	Capacitor—200 Mmfd. (C45)
14546	Capacitor—220 Mmfd. (C5)
12952	Capacitor—330 Mmfd. (C3, C10, C33)
30231	Capacitor—510 Mmfd. (C24)
13762	Capacitor—1,500 Mmfd. (C16)
12729	Capacitor—1,550 Mmfd. (C22)
12728	Capacitor—4,500 Mmfd. (C21)
12897	Capacitor—4,700 Mmfd. (C6)
4838	Capacitor—.005 Mfd. (C39, C40, C52, C53)
13138	Capacitor—.01 Mfd. (C31, C35, C36, C50)
11315	Capacitor—.015 Mfd. (C32)
4870	Capacitor—.025 Mfd. (C30, C34)
4839	Capacitor—0.1 Mfd. (C4, C17, C49)
12484	Capacitor—0.25 Mfd. (C15)
12741	Capacitor—0.5 Mfd. (C37, C51)
5212	Capacitor—16 Mfd. (C41)
14531	Capacitor—25 Mfd. (C42)
30228	Coil—Antenna coil and shield—A, B, C, and X bands (L1, L2, L3, L4, L21)
14516	Coil—Oscillator coil and shield—A, B, and C bands (L11, L12, L13)
12881	Coil—Oscillator coil and shield—X band only (L23)
30229	Coil—R-F coil and shield—A, B, C, and X bands (L5, L6, L7, L8, L9, L10, L22)
14513	Condenser—3-gang variable tuning condenser (C1, C8, C19)
5040	Connector—4-contact female connector for reproducer cable
30567	Connector—4-contact female connector with metal shell for reproducer cable in later production
12006	Core—Adjustable core and stud for transformer, Stock Nos. 14376 and 14308
12800	Core—Adjustable core and stud for coil, Stock No. 14516
30230	Dial—Station selector dial scale, complete with tuning tube escutcheon
14514	Drive—Variable condenser vernier drive pinion gear and shaft
14345	Drum—Variable condenser drive belt drum, complete with set screws
14387	Escutcheon—Tuning tube escutcheon
11982	Fastener—Dial scale fastener
30085	Gear—Indicator drive gear and hub, and pointer stem and gear
14341	Idler—Station selector drive belt idler
14519	Indicator—Station selector indicator pointer
14382	Indicator—Vernier indicator pointer
5226	Lamp—Dial lamp
14028	Nut—Jamb nut for adjustable trimmer capacitor, Stock Nos. 12714 and 12884
12471	Plate—6J7 Radiotron socket mounting plate and rubber cushions—less socket
14340	Pulley—Station selector drive belt pulley and knob shaft
30227	Reflector—Dial reflector and bracket, complete with dial lamp bracket, tuning tube bracket and tone and band indicators
13250	Resistor—330 ohms, carbon type, ¼ watt (R26)

STOCK No.	DESCRIPTION
14720	Resistor—1,000 ohms, carbon type, ¼ watt (R2)
14078	Resistor—18,000 ohms, carbon type, 1 watt (R29)
14284	Resistor—22,000 ohms, carbon type, 1/10 watt (R5)
11300	Resistor—33,000 ohms, carbon type, 1/10 watt (R19)
13735	Resistor—33,000 ohms, carbon type, ¼ watt (R4, R10)
11646	Resistor—47,000 ohms, carbon type, ¼ watt (R12)
12333	Resistor—68,000 ohms, carbon type, ¼ watt (R6)
8064	Resistor—82,000 ohms, carbon type, ½ watt (R27)
11281	Resistor—100,000 ohms, carbon type, 1/10 watt (R18)
5145	Resistor—100,000 ohms, carbon type, ¼ watt (R14, R15)
5027	Resistor—150,000 ohms, carbon type, ¼ watt (R28)
11453	Resistor—270,000 ohms, carbon type, 1/10 watt (R16, R17)
11172	Resistor—470,000 ohms, carbon type, ¼ watt (R11)
11397	Resistor—560,000 ohms, carbon type, 1/10 watt (R1, R3)
12013	Resistor—1 megohm, carbon type, 1/10 watt (R23)
13730	Resistor—1 megohm, carbon type, ¼ watt (R13)
11626	Resistor—2.2 megohms, carbon type, ¼ watt (R7, R8)
14532	Resistor—Voltage divider — comprising one 1,500 ohm, one 2,500 ohm, one 3,900 ohm, one 27 ohm, and one 165 ohm sections (R20, R21, R22, R24, R25)
14343	Retainer—Station selector knob shaft and pulley retainer
14350	Screw—No. 8-32 x 3/16 square-head set-screw for drum, Stock No. 14345, gear, Stock No. 30085, and hub and arm on band indicator cable
12799	Shield—Antenna or R-F coil shield
12008	Shield—First or second I-F transformer shield
14375	Shield—Oscillator coil shield for Stock No. 14516
12883	Shield—Oscillator coil shield for Stock No. 12881
14114	Socket—Dial lamp socket
11195	Socket—5-contact 5U4G Radiotron socket
11196	Socket—8-contact 6F6, 6H6, 6K7, 6L7, 6J7, or 6N7 Radiotron socket
12907	Spring—Tension spring for indicator drum gear, Stock No. 30085
14342	Spring—Tension spring for idler, Stock No. 14341
12007	Spring—Retaining spring for core, Stock Nos. 12006 and 12800
30084	Switch—High-frequency tone and power switch (S4, S5)
30226	Switch—Range switch (S1, S2, S3)
12654	Trap—Wave trap (L24)
14376	Transformer—First I-F transformer (L14, L15, C12, C13)
14308	Transformer—Second I-F transformer (L16, L17, C27, C28, C29, R5)
11212	Transformer—Power transformer, 105-125 volts, 25-60 cycles (T1)
11213	Transformer—Power transformer, 105-250 volts, 50-60 cycles (T1)
14335	Volume Control (R9)
14379	Washer—Felt washer for indicator pointer
	REPRODUCER ASSEMBLIES (RL-63F-2)
14356	Board—3-contact reproducer terminal board
13866	Cap—Cone center dust cap
11234	Coil—Field coil (L20)
11469	Coil—Hum neutralizing coil (L19)
12642	Cone—Reproducer cone and dust cap (L18)
5039	Plug—4-contact male plug for reproducer
14533	Reproducer, complete
14358	Screw—Screw, washer, and lockwasher to hold core in yoke
14534	Transformer—Output transformer (T2)
14357	Washer—Spring washer to hold field coil
	MISCELLANEOUS ASSEMBLIES
5040	Connector—4-contact female connector for reproducer interconnecting cable in later production
30568	Connector—4-contact male connector for reproducer interconnecting cable in later production
30234	Escutcheon—Station selector escutcheon and crystal, complete with tone and band indicating strips
14611	Index—Tone control indicating strip—mounts in station selector escutcheon
30235	Index—Band indicating strip—mounts in station selector escutcheon
14359	Knob—Station selector knob
14269	Knob—Volume control, tone control, or range switch knob
11377	Screw—Chassis mounting screw and washer assembly
4982	Spring—Retaining spring for knob, Stock No. 14359
14270	Spring—Retaining spring for knob, Stock No. 14269

Height .... 20¼ inches
Width .... 17¼ inches
Depth .... 11¹¹⁄₁₆ inches
Weight (net)................................. 33 pounds
Weight (shipping)............................ 43 pounds
Chassis Base Dimensions. 14⅞ inches x 9¾ inches x 3¼ inches
Over-all Chassis Height........................ 9¾ inches

Electrical Specifications

Frequency Ranges

"Long Wave" (X)........ 2,000-850 meters (150-353 kc)
"Medium Wave" (A)..... 565-180 meters (531-1,666 kc)
"Short Wave 1" (B)........ 2.1-6.8 mc (143-44.1 meters)
"Short Wave 2" (C) ...... 6.8-22 mc (44.1-13.64 meters)
Intermediate Frequency........................ 460 kc

R-F Alignment Frequencies

"Short Wave 2" (C).......... 20,000 kc (osc., det., ant.)
"Short Wave 1" (B).................... 6,000 kc (osc.)
"Medium Wave" (A)...... 600 kc (osc.), 1,500 kc (osc.)
"Long Wave" (X). 166.7 kc (osc.), 353 kc (osc., det., ant.)

Pilot Lamps (5).............. Mazda No. 46, 6.3 volts, 0.25 amp.

Power Supply Ratings

Rating A................... 105-125 volts, 50-60 cycles, 135 watts
Rating B................... 105-125 volts, 25-60 cycles, 135 watts
Rating C..... 100-130/140-160/195-250 volts, 40-60 cycles, 135 watts

Power Output

Undistorted .... 10 watts
Maximum.............. 12.5 watts

Loudspeaker

Type.......... 8-inch Electrodynamic
Impedance (v.c.) 2.2 ohms at 400 cycles

Operating Controls. (1) Power Switch—Tone; (2) Tuning (large inner knob), Range Selector (small outer knob, left to right "X," "A," "B," "C"); (3) Volume

Tuning Drive Ratio .... 20 to 1

MODEL 810T4
Lead Dress, Voltage
Notes, Trimmers

General Description

This receiver employs a ten-tube, four-band, "Magic Brain," superheterodyne circuit, the arrangement of which is shown by the Schematic Circuit Diagram. Features of design include an r-f amplifier stage; "qumulative-wound" "A" antenna and r-f transformers for high signal-to-noise ratio; magnetite-core, i-f transformers and low-frequency "X" and "A" oscillator tracking; automatic volume control; phonograph terminal board; "Magic Eye" tuning tube; plunger-type, air-dielectric trimming capacitors; aural-compensated, audio-volume control; "Bass-Mellow-Brilliant" tone control; audio phase-inverter voltage amplifier; push-pull, power-output stage; improved dust-proof electrodynamic loudspeaker; a new sunburst dial with short-wave stations listed by name and illuminated band and tone indicators; and the improved "Magic Voice."

Service Data

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R1, L1, C1, etc., provide reference between the illustrations and Replacement Parts List. The coils, transformer windings, and reactors are rated in terms of d-c resistance to permit continuity checks.

Loudspeaker.—Centering of the loudspeaker is made in the usual manner with three narrow celluloid or paper feelers after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

Phonograph Attachment.—A terminal board is provided for connecting a phonograph into the audio amplifying circuit. RCA Victor Models R-93, R-93-A, R-93-2, or R-94 Record Players should be connected as follows: Remove link between terminals 1 and 2 on terminal board. Connect green wire in Radio-Record switch cable to terminal 1, yellow to terminal 2, and shield extension to terminal 3. Tape unused red and blue leads separately. Connect a 2-conductor twisted cable between the Record Player binding posts and the screw terminals on Radio-Record switch. If additional volume is desired, connect an RCA Stock No. 9632 transformer between the two-conductor twisted cable and the screw-terminals on Radio-Record switch as follows: yellow and brown transformer leads and one side of twisted cable to ground screw-terminal on switch; black transformer lead to other side of twisted cable; and blue transformer lead to other screw-terminal on switch.

Precautionary Lead Dress.—(1) Twist yellow, blue, and green leads from oscillator coil to S2. (2) Dress C45 and C21 away from C55. (3) Dress black lead from S2 to ground lance away from C55. (4) Dress yellow lead from 6J7 socket to S2 under bus on 6J7 socket. (5) Make lead from S3 to ground 2½ inches long and dress away from chassis. (6) Twist filament leads. (7) Dress shielded lead from C31 to phono. term. board away from 6L7 socket. (8) Dress yellow lead from term. "K" of 6J7 to C11 away from chassis and from brown filament lead. (9) Dress all molded capacitors perpendicular to chassis. (10) Dress filament leads away from terms. "G1" and "G2" of 6N7. (11) Twist blue leads from terms. "P" of 6F6's. Make the following as short as possible: (12) Lead from oscillator coils to ground. (13) Lead from S2 to C19. (14) Lead from detector coil to S3. (15) Lead from detector coil to C8. (16) Lead from S1 to chassis ground lance. (17) Lead from antenna coil, to S1. (18) Lead from antenna coil to C1. (19) Yellow lead from 2nd i-f transformer to phono. term. board. When necessary to replace bus leads, use only wire having same diameter as original.

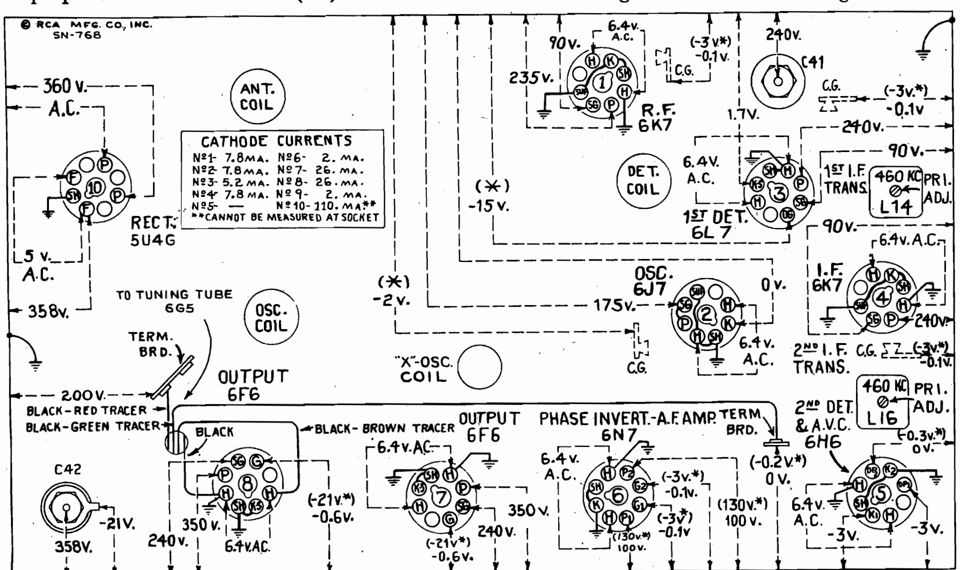

Figure 2—Radiotron Socket Voltages, Coil, and Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc or 300 meters, "A" band ("Medium Wave")—No signal being received—Volume control minimum

***Note:** Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter through the high series circuit resistance.*

Voltage values as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250 and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

RCA MFG. CO., INC.

Alignment Procedure

Calibrate the tuning dial by adjusting main dial pointer to the low-frequency (end) calibration mark on dial with the gang tuning-condenser plates in full-mesh position; then adjust the small (vernier) pointer to "0." These are friction adjustments.

Perform alignment in proper order, tabulated below, starting with No. 1 and following all operations across, then No. 2, etc. Adjustment locations are shown on figures 1 and 2.

Cathode-ray alignment is highly preferable; the connections to the chassis are shown on figure 4. If an output indicator is used, connect it across the loudspeaker voice-coil and advance the receiver volume control to full-volume position.

Connect the "low" output terminal of the test oscillator to the receiver "G" (ground) terminal for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the rec er to obtain an observable output indication. This will avo a-v-c action.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 545-400 meters" means that the receiver should be tuned to a point between 545 and 400 meters where no signal or interference is received from a station or local (heterodyne) oscillator. In extreme noisy locations, one end of C10 (top of gang) should be unsoldered during i-f alignment.

Conversion of kilocycles (kc) to meters for alignment frequencies is as follows: 20,000 kc (20 mc) = 15 meters; 6,000 kc (6 mc) = 50 meters; 1,500 kc = 200 meters; 600 kc = 500 meters; 460 kc = 652 meters; 353 kc = 850 meters; and 166.7 kc = 1,800 meters.

For further details on alignment, refer to booklet "RCA Victor Receiver Alignment."

Order of Alignment	Test Oscillator			Range Selector	Receiver Dial Setting	Circuit to Adjust	Adjustment Symbols	Adjust to Obtain
	Connection to Receiver	Dummy Antenna	Frequency Setting					
1	6K7 I-F Grid Cap	.001 Mfd.	460 kc	"Medium Wave"	No Signal 545-400 meters	2nd I-F Trans.	L16 and L17	Max. (peak)
2	6L7 Det. Grid Cap	.001 Mfd.	460 kc	"Medium Wave"	No Signal 545-400 meters	1st I-F Trans.	L14 and L15	Max. (peak)

Thirteen-Tube, Five-Band, A-C, Superheterodyne Receiver

General Description

This receiver employs a thirteen-tube, five-band, "Magic Brain" superheterodyne circuit. Features of design include "Electric Tuning" with push-button operation; automatic frequency control; spread-band, "Overseas" dial; "qumulative-wound" antenna and detector "A" band coils; tuned r-f amplifier; magnetite-core adjusted i-f transformers and low-frequency "A" oscillator tracking; two-stage i-f amplifier; phonograph terminal board; "Magic Eye" tuning tube; twelve-inch electrodynamic loudspeaker; plunger-type, air-dielectric trimming capacitors; temperature-stabilized capacitors; two-point aural-compensated volume control; "Fidelity" control; "Music-Speech" control; and a driven push-pull power-output stage. In addition, this model has a cabinet incorporating the "Sonic Arc" Magic Voice.

Radiotron Cathode Current Readings

(13)	RCA-5T4—Rectifier	128 ma.**

(**Cannot be measured at socket)

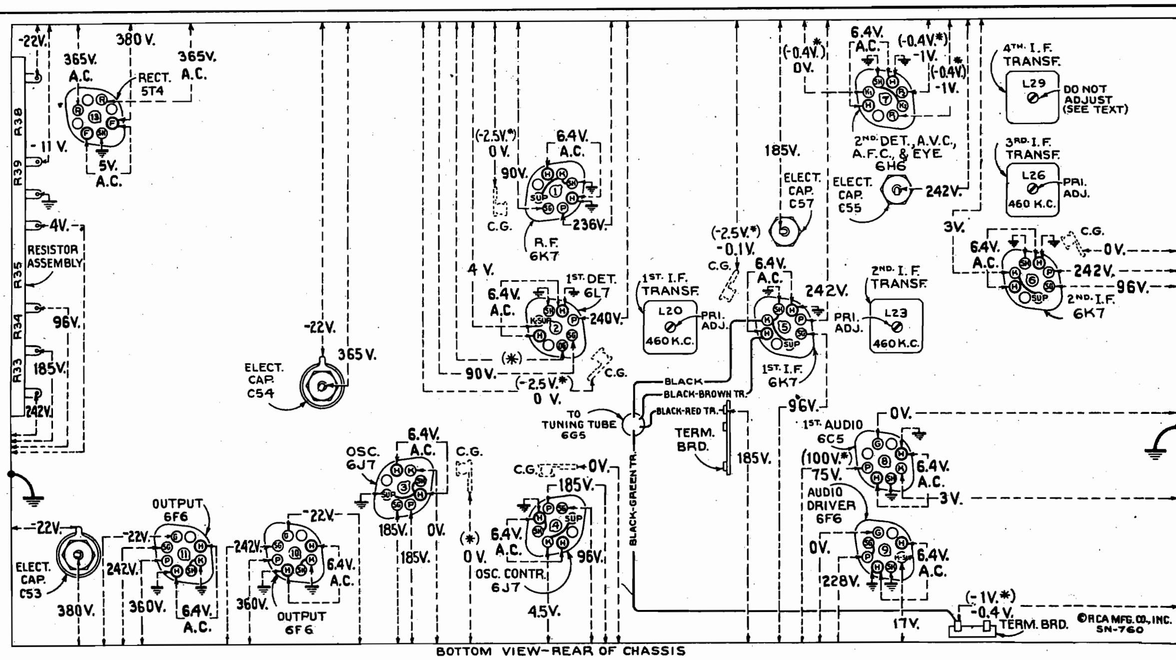

Figure 6—Radiotron Socket Voltages, Coil, and Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc ("Standard Broadcast")—"Manual" control—No signal being received—Volume control minimum—Fidelity control optional

***Note:** Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter.*

Voltage values as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250 and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

MODEL 813K
Socket, Trimmers
Tuner Wiring

RCA MFG. CO., INC.

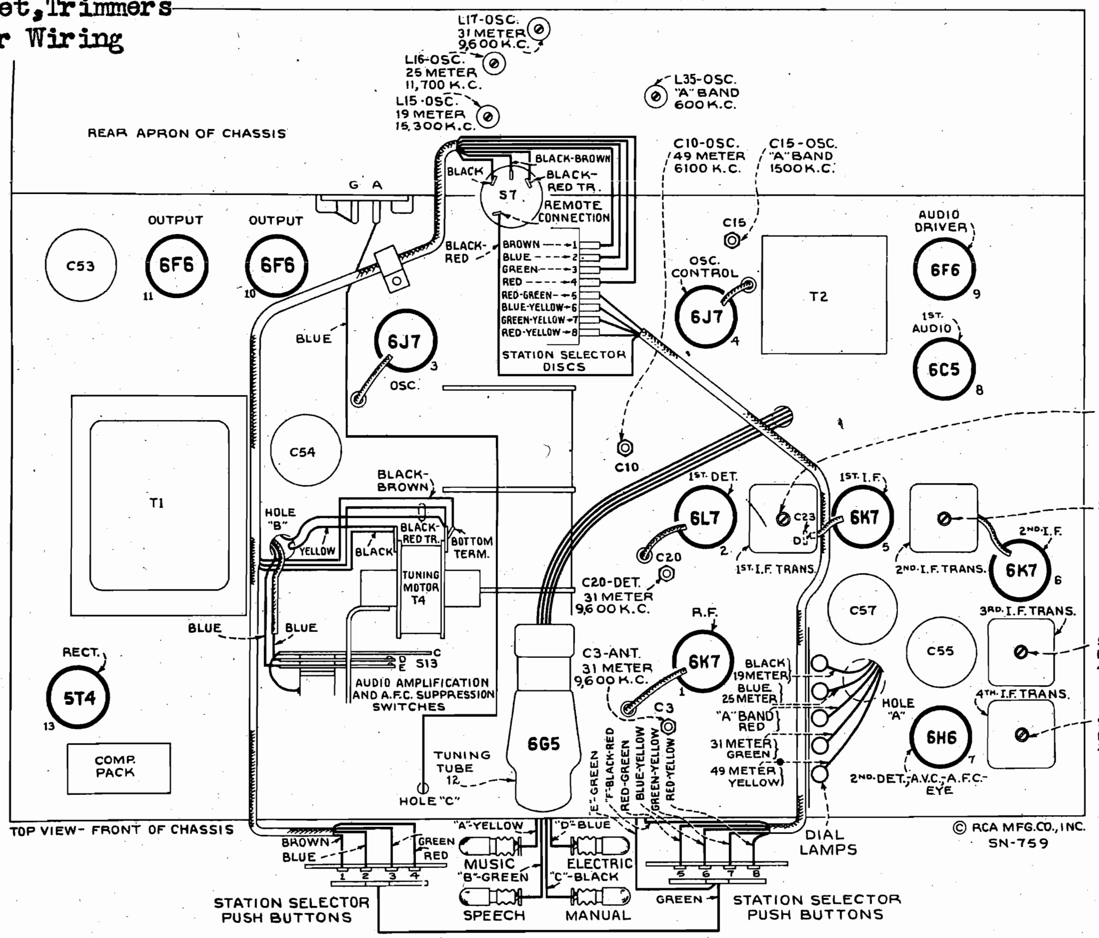

Figure 3—Radiotron, Coil, and Trimmer Locations

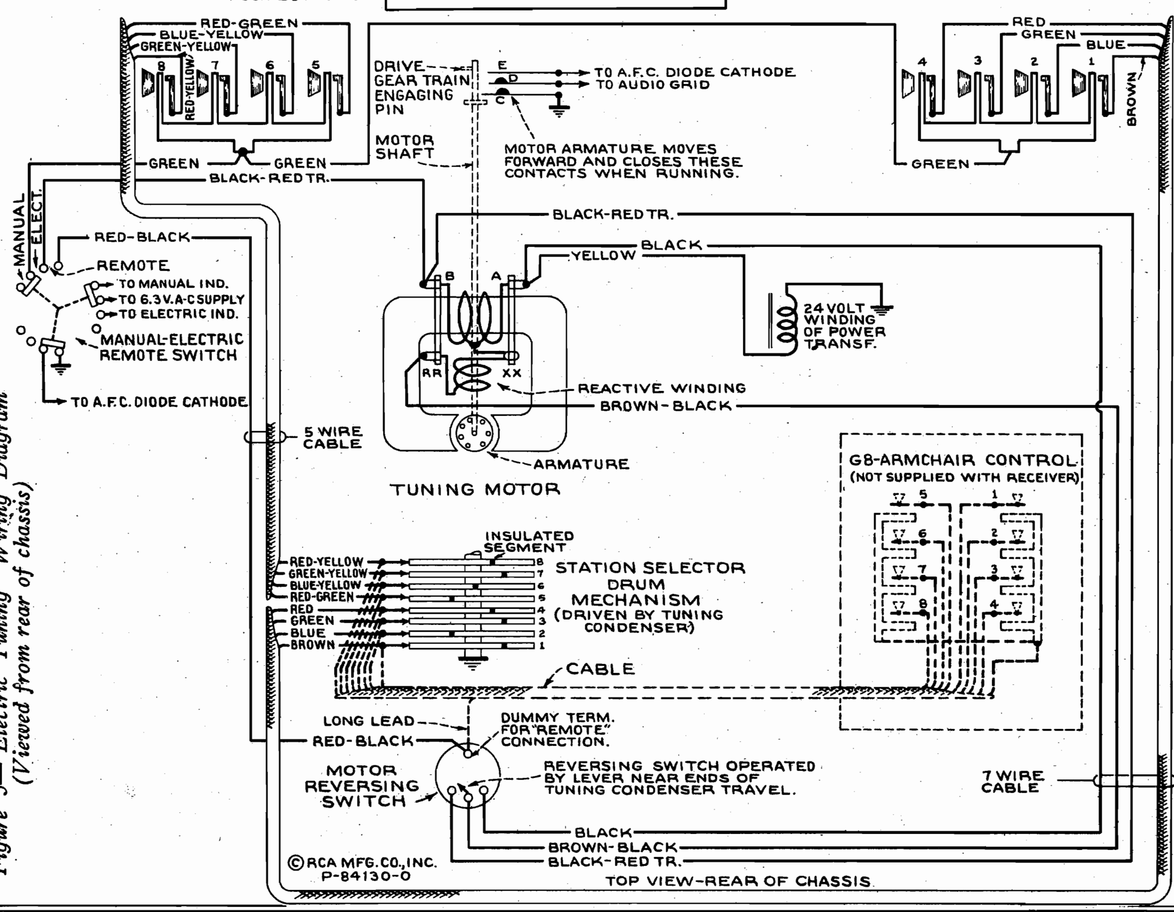

Figure 5—"Electric Tuning" Wiring Diagram (Viewed from rear of chassis)

RCA MFG. CO., INC.

Calibrate the tuning dial by adjusting dial pointer to the left ends of horizontal calibration lines with the gang tuning-condenser plates in full-mesh position. This is a screw-driver adjustment.

The "Fidelity" control should be turned counter-clockwise during all alignment operations. The "Manual-Electric-Remote" switch should be turned to "Manual" (clockwise) during alignment unless otherwise specified. The bottom shield-pan must be in place during spread-band alignment. Permit the set to operate at least five minutes before attempting alignment.

CAUTION.—The magnetite core screw L29 on the bottom of the 4th i-f transformer has been accurately adjusted, for an exact electrical balance of coil L29 to center tap, during manufacture and **should not be disturbed.** However, if for any reason the adjustment has been moved from its original position, it will be necessary to mechanically adjust this screw until the end of the stud protrudes exactly ⅛ of an inch (four threads exposed) above the brass bushing prior to any alignment operations.

Perform alignment in proper order, tabulated below, starting with No. 1 and following all operations across, then No. 2, etc. A-f-c discriminator adjustments should follow r-f and i-f adjustments tabulated below. Adjustment locations are shown on figures 3 and 6.

Cathode-ray alignment is preferable for adjustments 2, 3, and 4 due to the flat-top i-f characteristics; the connections to the chassis are shown on figure 2. If an output indicator is used, connect it across the loudspeaker voice-coil and advance the receiver volume control to full-volume position. The Magic Eye may be used as an output indicator for all other adjustments. It is preferable to replace the 6G5 tuning tube with a 6E5 during alignment.

Connect the "low" output terminal of the test oscillator to the receiver chassis for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action and reduce possibility of error in spread-band adjustments.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc" means that the receiver should be tuned to a point between 550 and 750 kc where no signal or interference is received from a station or local (heterodyne) oscillator. "Min. Eye" means minimum width of dark sector of Magic Eye.

For further details on alignment, refer to booklet "RCA Victor Receiver Alignment."

Order of Alignment	Test Oscillator			Range Selector	Receiver Dial Setting	Circuit to Adjust	Adjustment Symbols	Adjust to Obtain
	Connection to Receiver	Dummy Antenna	Frequency Setting					
1	———	———	———	———	———	4th I-F Trans.	L28	Turn Extreme Counter-clockwise

16	Proceed to A-F-C Discriminator Adjustments Outlined Below							

a—Refer to "Spread-band Adjustments" below for Test Oscillator setting for adjustments 5, 6, 7, 8, and 9.

b—Use minimum inductance peak (plunger out) if two peaks can be obtained. To check for correct harmonic, carefully set Test Oscillator to 1,200 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "31M." band near 9.6 mc.

c—Use minimum inductance peak (plunger out) if two peaks can be obtained. To check for correct harmonic, carefully set Test Oscillator to 900 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "25M." band near 11.7 mc.

d—Use minimum inductance peak (plunger out) if two peaks can be obtained. To check for correct harmonic, carefully set Test Oscillator to 900 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "19M." band near 15.3 mc.

e—Refer to "Spread-band Adjustments" below for method of using the RCA Stock No. 9572 Crystal Calibrator for adjustments 10 and 11.

f—Use minimum capacity peak if two peaks can be obtained from 1,000 kc harmonics.

MODEL 813K

Adjustments, Lead Dress

RCA MFG. CO., INC.

Spread-band Adjustments.—Bottom shield-pan must be in place before attempting spread-band alignment. Alignment of the spread ("Overseas") bands requires special procedure since test oscillators used alone are not ordinarily sufficiently accurate for this purpose. The RCA Stock No. 9572 Crystal Calibrator affords a convenient and accurate alignment standard. Wrap a few turns of wire around the crystal calibrator and connect one free end to the antenna terminal of the receiver. Using the crystal calibrator to obtain the necessary accuracy, follow the tabulated alignment procedure for the "31M.", "25M.", and "19M." bands.

The "31M." band alignment, for example, is done as follows: Tune the receiver ("Standard broadcast" band) to the 1,000 kc crystal calibrator output with the crystal calibrator "Hi-Lo" switch in "Hi" position. Snap "Hi-Lo" switch to "Lo" and carefully tune receiver to 1,600 kc (the sixth 100 kc harmonic above 1,000 kc) for minimum "Magic Eye" opening (Min. Eye). Move crystal calibrator away from antenna wire, connect test oscillator, and carefully adjust test oscillator for minimum "Magic Eye" opening at a setting of approximately 1,600 kc. (If Stock No. 150 Test Oscillator is used, refer to second paragraph below.) Raise test-oscillator output to give sufficient harmonic output and use 6th harmonic (9,600 kc) for aligning in "31M." band at 9.6 mc. Align in the "25M." band at 11.7 mc (11,700 kc), the 9th harmonic of the test-oscillator 1,300 kc output. Align in the "19M." band at 15.3 mc (15,300 kc), the 9th harmonic of the test-oscillaton 1,700 kc output. In each case select the peak giving minimum "Magic Eye" opening.

For the "49M." band, snap crystal calibrator "Hi-Lo" switch to "Hi", turn the range selector to "49M." band, and set receiver dial pointer to 6.0 mc. Adjust oscillator trimming capacitor C10 for minimum "Magic Eye" opening. Use the peak indicated by the alignment table. Snap "Hi-Lo" switch to "Lo" and locate 6,100 kc (the first 100 kc harmonic above 6,000 kc) by slightly readjusting C10 with the dial pointer set at 6.1 mc. This method insures selection of correct crystal-calibrator harmonic.

When aligning with the RCA Stock No. 150 Test Oscillator use the variable (unmodulated) oscillator† and "Magic Eye" indication of receiver output. Set test-oscillator dial 800 kc lower than the desired signal for the four lower frequency ranges and 800 kc higher than the desired signal for the two high ranges and use in same manner as TMV-97-C. Insert an open-circuit telephone plug in the test oscillator "Ext. Mod." jack, so the modulated fixed-frequency oscillator will be cut off, and align on the unmodulated variable oscillator signal, which will close the "Magic Eye" and evidence itself by a rushing noise in the speaker.

If the crystal calibrator signals are weak, disconnect test oscillator while using the crystal calibrator.

More accurate alignment in the spread-bands can be accomplished by making final slight adjustments using American, English, or German short-wave broadcasting stations of known frequency for frequency standards.

A-F-C Discriminator Adjustments.—These adjustments are rather critical and should be performed with extreme care. Improper adjustment may result in complete failure of the oscillator control tube to function or else may cause it to detune the oscillator instead of tuning it to the signal. It is assumed that the magnetite core adjusting screw L28 (top of 4th i-f transformer) has been turned all the way out (extreme counter-clockwise) during the preceding tabulated adjustments. Adjustments are as follows: Remove spring "N" on link and arm assembly which connects the "Manual-Electric-Remote" switch shaft to the throw-out gear bracket. Turn "Fidelity" control counter-clockwise. Connect antenna to receiver antenna terminal. With the "Manual-Electric-Remote" switch in "Manual" (right) position, tune in a strong local station near 600 kc or the low-frequency end of the "A" band as accurately as possible by means of the tuning tube "Magic Eye." The most accurate adjustment will be obtained by adjusting the "vernier" tuning knob mid-way between the two points where the eye just appears to start to open. This will place the generated i-f carrier signal frequency exactly in the center of the i-f amplifier response curve (should be 460 kc if i-f amplifier was properly aligned) and is the frequency to which the a-f-c discriminator (4th i-f transformer) should be tuned to resonance. Without disturbing any of the receiver adjustments, place the "high" test-oscillator lead about ¾ of an inch from the grid cap lead of the RCA-6K7, 1st i-f amplifier tube, adjust the test-oscillator output to maximum, turn test-oscillator "Modulation" off, and carefully zero-beat the test-oscillator frequency (approximately 460 kc) with the i-f carrier signal. Avoid placing the test-oscillator lead nearer to the grid-cap lead than specified above, as doing so will tend to detune the i-f amplifier. It may be necessary to reduce the local station signal, during this operation, by shortening antenna lead or grounding antenna "A" terminal to chassis in order to increase the loudness of the beat note sufficiently for accurate zero-beat adjustment.

Throw "Manual-Electric-Remote" switch to "Electric" (center) position. A high whistle or beat note will now be heard. Turn the magnetite core screw L28 (top of 4th i-f transformer) slowly clockwise. As this screw is turned, the beat note will first increase to a high audio frequency and will then decrease to a **zero-beat** and then increase in frequency again. The point of exact **zero-beat** is the position for correct adjustment of the discriminator. Zero-beat should also still exist when the "Manual-Electric-Remote" switch is thrown back to "Manual" position. The adjustment is now complete and may be checked by slightly detuning the receiver above and below the local station frequency with the "Manual-Electric-Remote" in "Manual" position, switching to "Electric" position, and noting the oscillator pull-in. Replace spring "N."

† The No. 150 Test Oscillator employs a fixed-frequency (800 kc), modulated oscillator and a variable, unmodulated oscillator. The scale is calibrated to the sum frequency for the two higher frequency ranges and to the difference frequency for the four lower frequency ranges.

Circuit Arrangement

The circuit consists of an r-f amplifier stage; first-detector (converter) stage; separate heterodyne-oscillator stage; oscillator-control stage; two i-f amplifier stages; diode detector, automatic-frequency and volume-control stage; audio voltage-amplifier stage; audio-driver stage; push-pull power-amplifier stage; tuning indicator "Magic Eye"; and a full-wave rectifier.

The antenna and first-detector coils are constructed with a special type of winding ("qumulative") to provide increased sensitivity and selectivity on the "Standard Broadcast" band. Special capacitors shunting the spread-band oscillator coils change in capacity with temperature variations to reduce oscillator frequency drift.

Spread-band tuning is accomplished electrically by shunting the low-capacity section of the oscillator variable capacitor with relatively large temperature-stabilized fixed capacitors for tuning the oscillator coil on the "19M," "25M," "31M," and "49M" bands. Antenna and first-detector coils are designed to be sufficiently broad-tuned to require no variable tuning over the narrow frequency range of the spread-bands.

The spread-band oscillator coils and the "Standard Broadcast" band oscillator, first-detector, and antenna coils are all wound on separate forms. The antenna and first-detector spread-band coils are tapped. Undesirable interaction between coils is avoided by shorting proper unused sections by means of the range selector.

The intermediate-frequency amplifier consists of two RCA-6K7 tubes in a two-stage transformer-coupled circuit. The windings of all i-f transformers are resonated by fixed capacitors and are adjusted by molded magnetite cores to tune to 460 kc. A third winding, L22, in the first i-f transformer, closely coupled to the primary, L20, is placed in series with the main secondary, L21, when the fidelity control switch S11 is thrown to "broad" position (see figure 1), thereby increasing the coupling between the primary and secondary circuits with a consequent broadening of the band width of the i-f amplifier, permitting higher fidelity reception.

The function of the automatic-frequency-control circuit is to automatically change the frequency of the heterodyne oscillator so that the correct i-f frequency is formed for the i-f amplifier. The circuit consists essentially of an i-f discriminator which, as the name implies, discriminates or furnishes control voltage of the correct polarity to an oscillator frequency-control tube for generated i-f carrier frequencies slightly above and below 460 kc, or the frequency to which the i-f amplifier is tuned.

The plate circuit of the RCA-6J7 oscillator-control tube is caused to act as an apparent variable inductance in parallel with the "A" band oscillator tuned circuit of which coil L35 is a part. The series combination of resistor R5 and the capacitor C16 is also in parallel with the oscillator tuned circuit. Since the resistance of R5 is many times greater than the reactance of C16, at the oscillator frequency, the r-f current through the combination will be practically in phase with the r-f voltage across the oscillator tuned circuit. However, the r-f voltage impressed across the C16 capacitance section of the combination, or from grid to cathode, will lag the r-f voltage across the combination, or the tuned circuit, approximately 90 degrees. The grid-cathode r-f voltage will be amplified by the control tube but will be shifted an additional 180 degrees (grid and plate voltages of all tubes are always opposite in phase) so that the amplified r-f voltage appearing across the plate circuit will now lead the voltage across the combination or the tuned circuit by 90 degrees, or, in other words, the control tube is acting as an equivalent shunt inductance. The amount of this action is determined by the amplification of the tube which, in turn, is governed by the grid-cathode bias voltage. In operation, a residual bias is developed across the cathode resistor R6. The d-c control-grid voltage is fed to the control grid from the discriminator circuit through resistor R7. If this voltage is negative with respect to ground, the amplification of the control tube will be decreased, the apparent plate-circuit inductance of the tube increased, which will lower the frequency of the oscillator tube. The converse will occur when the grid voltage is positive with respect to ground.

The action of the discriminator circuit depends upon the fact that a 90-degree phase difference exists between the primary and secondary potentials of a double-tuned loosely-coupled transformer when the resonant frequency is applied, and that this phase difference varies as the applied frequency varies, i.e., the maximum resultant response voltage across the primary and secondary windings connected in series will occur at a frequency either lower or higher in frequency than the frequency to which the individual windings are resonated, respectively, depending on whether the windings are connected series aiding or opposing.

The discriminator, or fourth i-f transformer, consists of the primary winding, L30, which is a part of the third i-f transformer secondary tuned circuit (tuned to 460 kc) and the center-tapped secondary, L29. The upper and lower halves of L29 may be considered as two secondary coils, the upper series aiding and the lower series opposing the primary, L30. The magnetite core in L29 is inserted to inductively balance the two halves. The function of coil L28 (magnetite core adjusted), in parallel with L29, is to tune the secondary to 460 kc. Therefore, the maximum voltage will be applied to diode circuit P_1K_1 and R18 when the i-f signal frequency is below 460 kc and to the diode circuit P_2K_2 and R17 when the i-f signal frequency is above 460 kc. Resistors R17 and R18 are connected in series between ground and a point leading to the oscillator control-tube grid.

D-c voltages, resulting from diode rectification, across R17 and R18 are always in opposition, consequently the oscillator control-tube grid-bias voltage is a differential amount, depending upon the i-f signal strength and its frequency deviation from the nominal value of 460 kc. The polarity of this differential oscillator control-tube grid-bias, with respect to ground, depends on whether the i-f signal frequency is above or below 460 kc, but is always in the direction which will bring the generated i-f frequency nearer to 460 kc. A-f-c action is automatically eliminated for "manual" tuning by grounding diode cathode K_1 through switch S9.

Service Data

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R1, L1, C1, etc., provide reference between the illustrations and Replacement Parts List. The coils, transformer windings, and reactors are rated in terms of d-c resistance to permit continuity checks.

Precautionary Lead Dress.—(1) Green bus leads from C1 to S1 and from C59 to S2 should be dressed away from nearby parts. (2) Green bus lead from C13 to S3 should be 2¾-inches long and dressed away from nearby parts. (3) Bus leads from C12 to L18 and from L18 to S3 should be as short as possible. (4) Red and blue leads from tube No. 3 to 19M. oscillator coil should be dressed away from coil. (5) Tube No. 3 grid lead should be 6-inches long and dressed away from grounded metal parts. (6) All leads behind oscillator coils should be dressed close to chassis. (7) "Magic Eye" cable should be clamped to dial bracket. (8) Filament leads should all be twisted. (9) Leads from C44 and C48 should be dressed close to chassis. (10) A-c leads near R22 should be dressed away from R22. (11) Leads from S11 to the first i-f transformer should be twisted and dressed away from chassis. (12) Capacitors C7, C8, and C9 should be dressed perpendicular to chassis and away from each other and grounded metal parts. (13) Motor-cable leads should be dressed away from pinion gear. (14) Blue bus lead from "A" detector coil to "P" of tube No. 1 should be dressed centrally between band-switch shield and air trimmer C20. The following should be dressed away from the chassis: (15) Yellow bus lead from "K" of tube No. 3 to S3. (16) Yellow bus lead from "OG" of tube No. 2. (17) Blue bus lead from C47 to R26.

Phonograph Attachment.—A terminal board is provided for connecting a phonograph into the audio-amplifying circuit. RCA Victor Models R-93, R-93-A, R-93-2, or R-94 Record Players should be connected as follows: Remove the link from the phonograph terminal board. Connect green wire in Radio-Record switch cable to terminal 1; yellow to terminal 2; shield to terminal 3; and tape up the red and blue. Connect a 2-conductor twisted cable between the Record Player binding posts and the screw-terminals on Radio-Record switch. If additional volume is desired, connect an RCA Stock No. 9632 transformer between the 2-conductor twisted cable and the screw-terminals on Radio-Record switch as follows: Yellow and brown transformer leads and one side of twisted cable to ground screw-terminal on switch; black transformer lead to other side of twisted cable; and blue transformer lead to other screw-terminal on switch.

Loudspeaker.—Two types of loudspeakers are used which will be referred to as types 1 and 2. In type 1 the cone centering diaphragm is cemented to a fixed ring, while in type 2 the centering diaphragm is cemented to an adjustable ring. Replacement of cone for either type is identical. Centering of cone for type 1 loudspeaker is made with three narrow celluloid or paper feelers after first removing the front dust cover and cutting free the cone centering diaphragm. The dust cover may be removed by a light application of acetone, using care not to allow the acetone to flow into the air gap. The centering diaphragm should be cemented in place after placement of feelers. Sufficient time should be allowed for the ambroid to set before removing feelers. Use ambroid to replace dust cover. Centering of cone for type 2 loudspeaker differs only in that it is not necessary to cut free the centering-diaphragm, adjustment being made in the usual manner by means of screws on the adjustable cone centering ring.

RCA MFG. CO., INC.

ELECTRIC TUNING

Principle of Operation

The electric tuning mechanism consists essentially of a quick engaging and dis-engaging reversible electric motor, tuning condenser driving gear train, and eight mechanically interlocked (pushing one button releases all others) station selector push buttons respectively wired to eight adjustable station selector contactor discs (each with a motor stopping insulated segment) mounted on a drum which is direct-coupled to the gang tuning condenser shaft. The arrangement permits any one of eight pre-determined stations to be electrically tuned in by merely touching the correct push button. If all eight buttons are inadvertently locked in, firmly pushing the right-hand button will release them.

The operation may be more readily understood by reference to figures 1, 4, and 5. When the motor is not energized, the armature is pushed to the rear or slightly out of the magnetic center by tension of contact spring "C" and the motor shaft is dis-engaged from the driving gear train. Pressing in any one of the eight push buttons will complete the motor circuit through a station selector contactor disc, assuming that the "Manual-Electric-Remote" switch is in "Electric" position and that the insulated segment in the contactor disc is not opposite its contactor. As the motor starts, the armature will be drawn forward, due to solenoid action, and the pin "F" on the end of its shaft will engage the arm "G" on the small main pinion gear, thereby driving the tuning mechanism. At the same time contact springs "E" and "D" will be grounded, causing suppression of audio amplification and automatic frequency control during the tuning cycle. The motor will continue to operate until the insulated segment in the selector disc breaks the motor circuit, whereupon spring "C" will instantly dis-engage the motor pin "F" from the arm "G" on the small pinion driving gear and open contacts "E" and "D." Pushing another button will cause the above mentioned cycle to be repeated except that the motor will be interrupted by the insulated segment on a corresponding disc. The discs are individually adjustable on a drum mechanism, providing a choice of eight "Electric Tuned" "Broadcast" stations. The arrangement of the motor is such that its rotation will continue in the same direction regardless of the number of "Electric" tuning cycles until the tuning condenser approaches either full-out or full-in of mesh, whereupon lever "H" trips switch S7 which reverses the direction of rotation. A throw-out idler gear is link-coupled to the "Manual-Electric-Remote" control to disconnect the motor drive gear train when the control is thrown to "Manual" position.

Mechanism Adjustments

The electric tuning mechanism is designed to be as simple in construction and as fool proof in operation as is possible. In order to maintain the accurate results possible with this device care must be taken in effecting any repairs or adjustments. Reference should be made to figure 4 and the following:

A-F-C and A-F Amplification Suppression Switches.—This switch assembly is located on the motor bracket and closes due to solenoid action of motor armature. The tension of the long contact spring "C" is important in bringing about quick dis-engagement of the motor and in permitting the motor to pull into mesh with the drive mechanism. Normal adjustment is attained when the short springs "D" and "E" are aligned exactly straight with contact points separated approximately 1/32 of an inch and with the spring "C" spaced approximately 7/32 of an inch from spring "D" at the point of contact. If necessary, in order to obtain positive pull-in and quick dis-engagement of the motor, the tension of spring "C" should be increased or decreased by bending. This action should be checked with the front apron of the chassis raised two inches higher than the rear. Contacts of the switch must be kept clean. Crocus cloth or a relay burnisher may be used for this purpose.

Motor Reversing Switch.—It is necessary to automatically stop and reverse the drive motor before the tuning condenser reaches the ends of its travel. Approximately 175 degrees of sweep is required, and the reversal must take place above 1,700 kc and below 540 kc but not too near the limits of the scale. The coupling between the station selector drum and the tuning condenser shaft should be attached so that the reversing switch trip lever "H" is exactly vertical when the condenser is full-out of mesh. There should be 1/32 of an inch clearance between the end of the condenser shaft and the selector drum shaft. While the trip lever is in this position the reversing switch bracket should be adjusted by means of its elongated mounting holes until the switch pin "I" just lightly touches trip lever "H."

Main Pinion Gear.—Clearance between the small high-speed pinion gear "E" and the intermediate gear "K" determines the amount of mechanical noise produced. Correct adjustment will give approximately 1/32 of an inch movement of back lash at the end of pinion arm "G" when gear "K" is held stationary. Arm "G" must also be adjusted for correct mesh with motor shaft drive pin "F." With the motor shaft completely forward and pinion "E" tight against its front bearing, the pinion mounting stud "J" should be adjusted so that pin "F" meshes full thickness with the rotating arm "G." An increase of this mesh will increase over travel on tuning while a decrease of mesh will decrease the over travel. The elongated hole in the front bracket allows sufficient movement of the mounting stud "J" to permit above mentioned gear mesh adjustment.

"Manual-Electric-Remote" Changeover. — (1) Link and arm adjustment—To properly line up the mechanical link between the switch shaft and throw-out gear bracket "MM," the set screws holding the link arm on the switch shaft must be loosened, the switch turned to the "Manual" position (extreme right) and the link lever revolved until the distance between the link-connecting pin (extends through chassis apron) and the right-hand (viewed from front) side of the slot, in front apron of chassis, is exactly 5/16 of an inch. If this adjustment is not properly made, correct operation of "Electric" or "Remote" tuning will not result. (2) Throw-out Gear Adjustment—To obtain smooth operation on "Electric" or "Remote" positions it is important that the proper clearance is maintained between the throw-out gear "M" and the intermediate gear "L." With the "Manual-Electric-Remote" control thrown to "Remote" position (extreme left) adjust the mesh between these gears by means of the eccentric screw "O" and lock nut "P," contacting the throw-out gear bracket "MM," until there is approximately 1/64 of an inch backlash of gear "L" when gear "M" is held stationary.

Vernier Tuning.—In case it becomes necessary to remove tuning condenser drive shaft "T," it should be replaced by sliding anti-backlash gear "R" on condenser shaft apart so that compression amounting to one tooth on the gear is obtained in the springs. Adjust mesh of gear "R" with pinion gear "U" on vernier shaft before tightening screws "S" so that smooth tuning is obtained throughout the range.

Motor Alignment. — The motor shaft must be exactly aligned with the axis of the pinion gear with which it engages. This may be adjusted by loosening the mounting screws "V" of the motor and aligning shaft by sight. Correct alignment may be tested by slowly rotating motor and observing the relation between the pin "F" of the motor shaft and the arm "G" on the pinion. The relation of the two should remain the same throughout the revolution. Additional movement for adjustment may be obtained by the motor bracket screws "W" if necessary.

Station Selector Drum.—(1) Bearing Adjustment—The selector drum may be removed by unscrewing the two bearing adjusting screws "X" on the front and rear bearings and sliding shaft out of slots on frame. To replace drum, the reverse procedure should be followed holding bearing adjusting plates "Y" firmly against the shaft and tightening adjusting screws. (2) Contact adjustment—Two types of contact strips are used. They are designated on figure 4, as types 1 and 2, on which the individual contacts are respectively adjustable and fixed. On type 1, the individual contacts should be adjusted by setting the end contact springs near the mid-position of their travel and aligning the remaining springs to them by means of a straight edge. Either type of contact strip should be adjusted to the selector drum by firmly placing two selector adjusting keys in the station adjustment strip, positions 1 and 8 (locking respective discs), loosening contact strip adjusting nuts "Z" and shifting the contact strip until the end contacts are exactly centered on the respective disc insulating segments. More accurate adjustment may be made by silhouetting the point of contact with a piece of white paper held behind the contact. Adjustment will be facilitated by removing complete assembly from rear of tuning condenser by unscrewing the three mounting screws. Contacts and discs must be kept free of dirt, filings, and other extraneous matter.

Lubrication. — The dial pointer slide should be greased with petrolatum. This same lubrication should be applied lightly to all gear faces of the drive mechanism and sparingly with a cloth to the station selector discs. Any good household oil, such as "3-IN-ONE," is suitable for the motor shaft bearings. A light grade of engine oil should be used for all gear bearings. Medium viscosity engine oil, similar to "PYROIL" (B), should be applied between the thrust washers on the motor shaft. "CASTORDAG," a mixture of graphite and castor oil, is recommended for use at the selector drum end-bearing slots and at the bearings of cable pulleys.

Station Adjustment

Any eight stations may be chosen for "Electric" tuning. Remove the two escutcheon plates from the side of the dial, place proper call letter labels in the celluloid windows, and replace escutcheons. Turn the power on and proceed to set up the "Electric" tuning as follows:

1. Set Range Selector to "Standard Broadcast."
2. Turn "Manual-Electric-Remote" control to "Electric."
3. Turn Fidelity control counter-clockwise.
4. Press push button No. 1 (left) and wait until station pointer comes to rest.
5. Turn the "Manual - Electric - Remote" control to "Manual."
6. Remove adjusting key from receptacle on top of station selector drum mechanism.
7. Insert key in position marked "1" in station adjustment strip and push the key all the way down to properly fit in slot in disc.
8. Tune the receiver very carefully by means of the manual tuning knob and the "Magic Eye," to station chosen for No. 1.
9. Remove key.
10. Turn the "Manual-Electric-Remote" control to "Electric."

Button No. 1 is now properly set for "Electric" tuning. Proceed similarly for the other seven push buttons, matching each station on the dial with the same number on the station adjustment strip. Repeat the above steps but place the key respectively in positions 2, 3, 4, etc., and in each case tune to the proper station. Pressing the proper button will now cause the desired station to be tuned in electrically.

Armchair Control

When a Model G-8 armchair control is attached to the receiver as shown in figure 5 it duplicates the action of the push buttons on the front panel when the "Manual-Electric-Remote" control is turned to "Remote" position.

Service Hints

a. Capacitor C18 should be carefully checked for leakage or short circuit in cases of intermittent operation or no operation. R9 should be shorted out and C18 replaced by Stock No. 4839, as shown by the Schematic Circuit Diagram figure 1, in the event of trouble in this circuit.

b. Capacitor C5 should be checked for leakage or short circuit.

c. Resistor R5 was 33,000 ohms in some instruments. Replace with Stock No. 12333.

d. Capacitor C16 was 82 mmfd. in some instruments. Replace with Stock No. 14021.

e. Capacitor C38 was two 0.5 mfd. in parallel on some instruments. Replace with Stock No. 30623.

Radiotron Complement

(1) RCA-6K7 .... R-F Amplifier
(2) RCA-6L7 .... First Detector
(3) RCA-6J7 .... Heterodyne Oscillator
(4) RCA-6J7 .... Oscillator Control
(5) RCA-6K7 .... First I-F Amplifier
(6) RCA-6K7 .... Second I-F Amplifier
(7) RCA-6H6 .... Second Detector, A.V.C., and A.F.C.
(8) RCA-6C5 .... First Audio Amplifier
(9) RCA-6F6 .... Audio Driver
(10) RCA-6F6 .... Power Output
(11) RCA-6F6 .... Power Output
(12) RCA-6G5 .... "Magic Eye" Tuning Tube
(13) RCA-5T4 .... Full-Wave Rectifier

Pilot Lamps (9) .... Mazda No. 46, 6.3 volts, 0.25 amp.

Power Supply Ratings

Rating A .... 105-125 volts, 50-60 cycles, 150 watts
Rating B .... 105-125 volts, 25 cycles, 150 watts
Rating C .... 100-130/140-160/195-250 volts, 50-60 cycles, 150 watts

Power Output

Undistorted .... 15 watts
Maximum .... 20 watts

Loudspeaker

Type .... 12-inch Electrodynamic
Impedance (v.c.) .... 11.5 ohms at 400 cycles

Mechanical Specifications

Height .... 43 inches
Width .... 28⅝ inches
Depth .... 16 15/16 inches
Weight (net) .... 108 pounds
Weight (shipping) .... 153 pounds
Chassis Base Dimensions .... 22⅛ inches x 12⅜ inches x 4⅛ inches
Over-all Chassis Height .... 12⅞ inches
Operating Controls .... (1) Power Switch—Low Tone, (2) Volume, (3) Tuning, (4) Range Selector, (5) Manual-Electric-Remote, (6) Fidelity
Tuning Drive Ratios (manual) .... 10 to 1 and 50 to 1

Parts List

RCA MFG. CO., INC.

STOCK No.	DESCRIPTION
14911	Capacitor—580 Mmfd. (C11)
12897	Capacitor—4700 Mmfd. (C5)
13033	Capacitor—.007 Mfd. (C49, C51)
4937	Capacitor—.01 Mfd. (C50)
13138	Capacitor—.01 Mfd. (C17, C24, C27, C39, C46)
11315	Capacitor—.015 Mfd. (C47)
4870	Capacitor—.025 Mfd. (C42)
4886	Capacitor—.05 Mfd. (C30, C61)
4839	Capacitor—0.1 Mfd. (C4, C18, C26, C37, C60)
5170	Capacitor—0.25 Mfd. (C25)
30623	Capacitor—1 Mfd. (C38)
5212	Capacitor—16 Mfd. (C55)
14377	Capacitor—16 Mfd. (C57)
13611	Capacitor—20 Mfd. (C56)
14531	Capacitor—25 Mfd. (C53, C54)
30017	Capacitor Pack—Compensating capacitor pack comprising one .025 Mfd. and one .015 Mfd. capacitor, one 22,000 ohm and one 27,000 ohm resistor (C41, C43, R21, R23)
14902	Capacitor Pack—Comprising two sections 10 mfd. each (C44, C48)
14865	Coil—"A" band antenna coil (L6, L7)
14866	Coil—Special band spread antenna coil (L1, L2, L3, L4, L5)
14867	Coil—"A" band detector coil (L12, L13)
14868	Coil—Special band spread detector coil (L8, L9, L10, L11)
14869	Coil—"A" band oscillator coil (L19, L35)
14873	Coil—19 meter band oscillator coil (L14, L15)
14872	Coil—25 meter band oscillator coil (L16)
14871	Coil—31 meter band oscillator coil (L17)
14870	Coil—49 meter band oscillator coil (L18)
14858	Condenser—3 gang variable tuning condenser complete with gear train (C1, C12, C13, C59)
5040	Connector—4 contact female connector for reproducer cable
30567	Connector—4 contact female connector with metal shell for reproducer cable in later production
14733	Contact—Spring contact for engaging discs in station selector drum for type 1 contact assembly
30365	Contact—Comprising 8 spring contacts assembled on insulating strip for engaging discs in station selector drum (type 2 contact assembly)
14857	Cord—Indicator drive cord
12006	Core—Adjustable core and stud for I-F transformers
14890	Cushion—Black rubber dial cushion
14888	Dial—Dial assembly, ready to mount on support brackets. Includes 7 glass dial strips and indicator slider assembled on metal frame
14862	Drive—Tuning condenser vernier drive shaft and pinion gear
14856	Drum—Drive cord drum complete with set screws
14731	Drum—Station selector drum rotor—comprising 8 station selector contactor discs assembled on shaft
14738	Gear—Drive pinion gear and arm
14739	Gear—Drive gear and set screws—located on tuning condenser knob shaft
14734	Gear—Intermediate gear assembly—comprising one .749-in. O.D., 34 tooth gear and one .291-in. O.D., 12 tooth pinion assembled
14735	Gear — Intermediate gear assembly — comprising one 1.541-in. O.D., 72 tooth gear and one .291-in. O.D., 12 tooth pinion assembled
14860	Gear — Intermediate gear assembly — comprising one 1.541-in. O.D., 72 tooth gear and hub assembled
14861	Gear—Throwout gear and bracket
14900	Indicator—Station selector indicator pointer
5226	Lamp—Dial Lamp
14729	Motor—Tuning drive motor for 60 cycle models only (M-1)
14730	Motor—Tuning drive motor for 25 cycle models only (M-1)
14859	Plate—Tuning condenser front plate and studs assembled for mounting drive gears
12471	Plate—6J7 socket mounting plate assembly for cushion socket—less socket
14886	Pulley—Indicator drive cord pulley—located on right or left hand dial bracket
14854	Reactor—Filter reactor (L33)
30647	Resistor—1.8 ohms, Resisto-fuse, 1 amp. (R42)
13250	Resistor—330 ohms, carbon type, ¼ watt (R15)
30158	Resistor—820 ohms, carbon type, ¼ watt (R30)

STOCK No.	DESCRIPTION
5112	Resistor—1000 ohms, carbon type, ¼ watt (R10)
13030	Resistor—1000 ohms, carbon type 1/10 watt (R2, R13)
11283	Resistor—1200 ohms, carbon type, ¼ watt (R41)
13031	Resistor—3300 ohms, carbon type, 1/10 watt (R29)
5114	Resistor—15,000 ohms, carbon type, 1 watt (R31)
14078	Resistor—18,000 ohms, carbon type, 1 watt (R24)
14284	Resistor—22,000 ohms, carbon type, 1/10 watt (R36)
12454	Resistor—33,000 ohms, insulated, ¼ watt (R4, R12)
12333	Resistor—68,000 ohms, carbon type, ¼ watt (R5)
5145	Resistor—100,000 ohms, carbon type, ¼ watt (R14, R28)
11452	Resistor—470,000 ohms, carbon type, 1/10 watt (R17, R18)
11172	Resistor—470,000 ohms, carbon type, ¼ watt (R8)
11397	Resistor—560,000 ohms, carbon type, 1/10 watt (R1, R11, R27)
12013	Resistor—1 Megohm, carbon type, 1/10 watt (R25)
3033	Resistor—1 Megohm, carbon type, ¼ watt (R7)
11151	Resistor—2.2 Megohm, carbon type, ¼ watt (R20)
5131	Resistor—2.2 Megohm, carbon type, 1/10 watt (R19)
13673	Resistor—10 Megohm, carbon type, ¼ watt (R40)
14875	Resistor—Voltage divider comprising one 1600 ohm, one 4500 ohm, one 7,000 ohm, one 300 ohm and two 85 ohm sections (R6, R33, R34, R35, R38, R39)
14887	Retainer—Indicator drive cord pulley retainer
14897	Scale—19 meter glass dial strip
14896	Scale—25 meter glass dial strip
14894	Scale—31 meter glass dial strip
14893	Scale—49 meter glass dial strip
30012	Scale—"A" band glass dial strip
4669	Screw—No. 8-32x5/32 square head set screw for drum Stock No. 14856, arm Stock No. 14726 and Stock No. 14883
12418	Screw—No. 8-32x3/16 milled head screw for gear Stock No. 14739
14848	Selector—Station selector drum mechanism—comprising selector contactor discs, spring contacts, and motor reversing switch assembled in metal frame
14882	Shield—Chassis bottom shield
12735	Shield—Dial lamp shield
12008	Shield—I-F transformer shield can
14901	Shield—Rubber shield for tuning tube
14892	Slide—Indicator pointer slider and spring assembly
11195	Socket—5 contact 5T4 Radiotron socket
11196	Socket—8 contact 6K7, 6J7, 6F6, 6H6, or 6C5, Radiotron socket
14877	Socket—8 contact 6J7 Radiotron impregnated socket for socket mounting plate Stock No. 12471 and 6K7 or 6L7 Radiotron
14114	Socket—Dial lamp socket
13638	Spring—Drive cord tension spring
12007	Spring—Retaining spring for core Stock No. 12006
3676	Spring—Tension spring for link and arm Stock No. 14883
14694	Spring—Tension spring for station selector push-button switch latch bar
14889	Strap—Strap and bolt assembly used to hold glass dial strips in position
14899	Strip—Bottom glass dial strip
14891	Strip—Finish strip used between glass dial strips
14898	Strip—Top glass dial strip
14742	Stud—Mounting stud for gear and arm Stock No. 14738
14874	Switch—"Manual-Electric-Remote" switch (S5, S9, S12)
14863	Switch—"Power-Tone" (Music-Speech) switch (S4, S8, S10)
14732	Switch—Motor reversing switch and mounting plate for station selector (S7)
14864	Switch—Range switch (S1, S2, S3)
14728	Switch—A-F-C and A-F amplification suppression switch (S13)
14904	Switch—Station selector switch parts comprising one 4 point contact board, one 4 point conductor plate, insulator and lockplate
14703	Tone control—"Fidelity" control (R26, S11)
14706	Transformer—First I-F transformer (L20, L21, L22, C22, C23)
14707	Transformer—Second I-F transformer (L23, L24, L25, C28, C29)
14708	Transformer—Third I-F transformer (L26, L27, C31, C32)
14709	Transformer—Fourth I-F transformer (L28, L29, L30, C35)

STOCK No.	DESCRIPTION
14855	Transformer—Driver transformer (T2)
14879	Transformer—Power transformer 105-125 volts, 50-60 cycle (T1)
14880	Transformer—Power transformer 105-125 volts, 25-60 cycle (T1)
14881	Transformer—Power transformer 100-130/140-160/195-250 volts, 50-60 cycle (T1)
12861	Volume Control (R22)
	REPRODUCER ASSEMBLIES (RL76-2)
14606	Cap—Dust cap for cone center
14922	Coil—Reproducer field coil (L34)
14602	Cone—Reproducer cone, voice coil, center suspension and dust cap (L32)
5039	Plug—4 contact male plug for reproducer
14920	Reproducer—Complete
14921	Transformer—Output transformer (T3, C52)
14357	Washer—Spring washer to hold field coil securely
	MISCELLANEOUS ASSEMBLIES
14745	Button—Station selector switch button
30361	Card—Call letter cards for station selector
5040	Connector—4-contact female connector for reproducer inter-connecting cable in later production
30568	Connector—4-contact male connector for reproducer inter-connecting cable in later production
14925	Crystal—Dial escutcheon crystal only
14923	Escutcheon—Dial and tuning tube escutcheon only—less crystal and buttons
14924	Escutcheon—Dial and tuning tube escutcheon and crystal complete
14926	Indicator—"Electric-Manual" indicating screen
14927	Indicator—"Music-Speech" indicating screen
14751	Key—Key for use in adjusting "Electric Tuning"
14359	Knob—"Tuning" (large) control knob
14688	Knob—"Range Selector" knob
14269	Knob—"Power-Tone" (Music-Speech), "Volume", "Tuning" (small), "Manual-Electric-Remote", and "Fidelity" control knobs
5210	Screw—Chassis mounting screw and washer assembly
14746	Shield—Celluloid shield for station markers
4982	Spring—Retaining spring for knob Stock No. 14359
14270	Spring—Retaining spring for knob Stock Nos. 14269 and 14688
	RECEIVER ASSEMBLIES
14726	Arm—Hub and arm complete with set screws—Connects station selector drum to rear of tuning condenser shaft
14883	Arm—Arm and hub assembly located on "Manual-Electric-Remote" switch shaft
14517	Board—Antenna and ground terminal board
12717	Board—Phonograph terminal board
14885	Bracket—Left hand dial bracket and pulley assembly
14884	Bracket—Right hand dial bracket and pulley assembly
14878	Bracket — Tuning tube mounting bracket and clamp assembly
5237	Bushing—Variable condenser rubber mounting bushing assembly
14919	Cable—5 conductor push-button selector cable
14918	Cable—7 conductor tuning drive motor and push-button selector cable
12607	Cap—First or second I-F transformer shield cap
12581	Cap—Third or fourth I-F transformer shield cap
11350	Cap—Grid contact cap
12884	Capacitor—Adjustable trimmer (long) (C3, C10, C15, C20)
14392	Capacitor—4.7 Mmfd. (C62)
14021	Capacitor—22 Mmfd. (C16)
12723	Capacitor—56 Mmfd. (C40)
12813	Capacitor—82 Mmfd. (C58)
14910	Capacitor—90 Mmfd. (C21)
14908	Capacitor—96.5 Mmfd. (C9)
14906	Capacitor—100 Mmfd. (C7)
12720	Capacitor—100 Mmfd. (C36)
14907	Capacitor—103.5 Mmfd. (C8)
14909	Capacitor—110 Mmfd. (C6)
12404	Capacitor—120 Mmfd. (C35)
14712	Capacitor—180 Mmfd. (C31, C32)
14711	Capacitor—220 Mmfd. (C28, C29)
12952	Capacitor—330 Mmfd. (C2, C19, C45)
14710	Capacitor—430 Mmfd. (C22, C23)
13052	Capacitor—470 Mmfd. (C14)
14724	Capacitor—560 Mmfd. (C63)

MODEL 816K
Parts List

RCA MFG. CO., INC.

STOCK No.	DESCRIPTION
	RECEIVER ASSEMBLIES
14726	Arm—Hub and arm complete with set screws—Connects station selector drum to rear of tuning condenser shaft
14883	Arm—Arm and hub assembly located on "Manual-Electric-Remote" switch shaft
14517	Board—Antenna and ground terminal board
12717	Board—Phonograph terminal board
14885	Bracket—Left hand dial bracket and pulley assembly
14884	Bracket—Right hand dial bracket and pulley assembly
14878	Bracket — Tuning tube mounting bracket and clamp assembly
5237	Bushing—Variable condenser rubber mounting bushing assembly
14919	Cable—5 conductor push-button selector cable
14918	Cable—7 conductor tuning drive motor and push-button selector cable
12607	Cap—First or second I-F transformer shield cap
12581	Cap—Third, fourth or fifth I-F transformer shield cap
11350	Cap—Grid contact cap
12884	Capacitor—Adjustable trimmer (long) (C3, C10, C15, C20, C65, C68)
14392	Capacitor—4.7 Mmfd. (C62)
13002	Capacitor—12 Mmfd. (C67)
30016	Capacitor—12 Mmfd. (C34)
12896	Capacitor—15 Mmfd. (C64)
30015	Capacitor—15 Mmfd. (C33)
14021	Capacitor—22 Mmfd. (C16)
12948	Capacitor—33 Mmfd. (C40)
14910	Capacitor—90 Mmfd. (C21)
14908	Capacitor—96.5 Mmfd. (C9)
14906	Capacitor—100 Mmfd. (C7)
12720	Capacitor—100 Mmfd. (C36, C58)
14960	Capacitor—100 Mmfd. (C73)
14907	Capacitor—103.5 Mmfd. (C8)
14909	Capacitor—110 Mmfd. (C6)
12404	Capacitor—120 Mmfd. (C35, C71, C72, C75)
14712	Capacitor—180 Mmfd. (C31, C32)
14711	Capacitor—220 Mmfd. (C28, C29)
12952	Capacitor—330 Mmfd. (C2, C19, C45)
14710	Capacitor—430 Mmfd. (C22, C23)
13052	Capacitor—470 Mmfd. (C14)
14911	Capacitor—580 Mmfd. (C11)
13140	Capacitor—1500 Mmfd. (C63)
30160	Capacitor—2700 Mmfd. (C66)
12897	Capacitor—4700 Mmfd. (C5)
4838	Capacitor—.005 Mfd. (C49, C51)
4937	Capacitor—.01 Mfd. (C50)
13138	Capacitor—.01 Mfd. (C17, C24, C27, C30, C39, C46, C69, C70)
11315	Capacitor—.015 Mfd. (C47)
4870	Capacitor—.025 Mfd. (C42)
4886	Capacitor—.05 Mfd. (C61)
4839	Capacitor—0.1 Mfd. (C4, C18, C25, C26, C37, C60)
12741	Capacitor—0.5 Mfd. (2 in parallel) (C38)
5212	Capacitor—16 Mfd. (C55)
14377	Capacitor—16 Mfd. (C57)
13611	Capacitor—20 Mfd. (C56)
14531	Capacitor—25 Mfd. (C53, C54)
30053	Capacitor Pack—Compensating capacitor pack comprising two .015 mfd. capacitors, one 27,000 ohm and one 33,000 ohm resistors (C41, C43, R21, R23)
14902	Capacitor Pack—Comprising two sections 10 mfd. each (C44, C48)
14948	Coil—"A" band antenna coil (L7, L8)
14949	Coil—"B" band antenna coil (L5, L6)
14950	Coil—"C" band antenna coil (L3, L4)
14951	Coil—Special band spread antenna coil (L1, L2)
14867	Coil—"A" band detector coil (L21, L22)
14952	Coil—"B" band detector coil (L20)
14953	Coil—"C" band detector coil (L19)
14954	Coil—Special band spread detector coil (L18)
14869	Coil—"A" band oscillator coil (L16, L17)
14955	Coil—"B" band oscillator coil (L15)
14956	Coil—"C" band oscillator coil (L14)
14873	Coil—19 meter band oscillator coil (L9, L10)
14872	Coil—25 meter band oscillator coil (L11)
14871	Coil—31 meter band oscillator coil (L12)
14957	Coil—49 meter band oscillator coil (L13)
14858	Condenser—3 gang variable tuning condenser complete with gear train (C1, C12, C13, C59)
5040	Connector—4 contact female connector for reproducer cable
14733	Contact—Spring contact for engaging discs in station selector drum for type 1 contact assembly
30365	Contact—Comprising 8 spring contacts assembled on insulating strip for engaging discs in station selector drum (type 2 contact assembly)
14857	Cord—Indicator drive cord
12006	Core—Adjustable core and stud for I-F transformers
14890	Cushion—Black rubber dial cushion
14862	Drive—Tuning condenser vernier drive shaft and pinion gear
14856	Drum—Drive cord drum complete with set screws
14731	Drum—Station selector drum rotor—comprising 8 station selector contactor discs assembled on shaft
10907	Fuse—3 Amp. (F1)
14738	Gear—Drive pinion gear and arm
14739	Gear—Drive gear and set screws—located on tuning condenser knob shaft
14734	Gear—Intermediate gear assembly—comprising one .749-in. O.D., 34 tooth gear and one .291-in. O.D., 12 tooth pinion assembled.
14735	Gear — Intermediate gear assembly — comprising one 1.541-in. O.D., 72 tooth gear and one .291-in. O.D., 12 tooth pinion assembled.
14860	Gear — Intermediate gear assembly — comprising one 1.541-in. O.D., 72 tooth gear and hub assembled
14861	Gear—Throwout gear and bracket
14900	Indicator—Station selector indicator pointer
5226	Lamp—Dial lamp
14729	Motor—Tuning drive motor for 60 cycle models only (M-1)
14730	Motor—Tuning drive motor for 25 cycle models only (M-1)
14859	Plate—Tuning condenser front plate and studs assembled for mounting drive gears
12471	Plate—6J7 socket mounting plate assembly for cushion socket—less socket
30557	Plug—Power cord plug less fuses Stock No. 10907
14886	Pulley—Indicator drive cord pulley—located on right or left hand dial bracket
14946	Reactor—Filter reactor (L37)
13250	Resistor—330 ohms, carbon type, ¼ watt (R15)
11355	Resistor—390 ohms, carbon type, ¼ watt (R6)
30158	Resistor—820 ohms, carbon type, ¼ watt (R30)
11935	Resistor—1000 ohms, carbon type, 1/10 watt (R2, R13)
14720	Resistor—1000 ohms, carbon type, ¼ watt (R10, R36)
14993	Resistor—1200 ohms, carbon type, 1/10 watt (R41)
13031	Resistor—3300 ohms, carbon type, 1/10 watt (R29)
5114	Resistor—15,000 ohms, carbon type, 1 watt (R31)
14078	Resistor—18,000 ohms, carbon type, 1 watt (R24)
14284	Resistor—22,000 ohms, carbon type, 1/10 watt (R37)
12454	Resistor—33,000 ohm, insulated, ¼ watt (R4, R12)
12333	Resistor—68,000 ohms, carbon type, ¼ watt (R5)
11365	Resistor—82,000 ohms, carbon type, ¼ watt (R32)
5145	Resistor—100,000 ohms, carbon type, ¼ watt (R14, R28)

12007	Spring—Retaining spring for core Stock No. 12006
3676	Spring—Tension spring for link and arm Stock No. 14883
14694	Spring—Tension spring for station selector push-button switch latch bar
14889	Strap—Strap and bolt assembly used to hold glass dial strips in position
14891	Strip—Finish strip used between glass dial strips
14742	Stud—Mounting stud for gear and arm Stock No. 14738
14874	Switch — "Manual-Electric-Remote" switch (S6, S10, S13)
14863	Switch—L-F tone and power switch (S7, S9, S11)
14732	Switch—Motor reversing switch and mounting plate for station selector (S12)
14947	Switch—Range switch (S2, S3, S4)
14728	Switch—A-F-C and A-F amplification suppression switch (S8)
14904	Switch—Station selector switch parts comprising one 4 point contact board, one 4 point conductor plate, insulator and lockplate
14703	Tone control—H-F tone control (R26, S5)
14706	Transformer—First I-F transformer (L23, L24, L25, C22, C23)
14958	Transformer—Second I-F transformer (L26, L27, L28, C28, C29, C75, R16)
14708	Transformer—Third I-F transformer (L29, L30, C31, C32)
14709	Transformer—Fourth I-F transformer (L31, L32, L33, C35)
14959	Transformer—Fifth I-F transformer (L35, L36, C71, C72, C73, R37, R40)
14855	Transformer—Driver transformer (T2)
14944	Transformer—Power transformer 105-125 volts, 50-60 cycle (T1)
14945	Transformer—Power transformer 105-125 volts, 25-60 cycle (T1)
30156	Transformer—Power transformer 100-130/140-160/195-250 volts, 50-60 cycle (T1)
12861	Volume Control (R22)
	REPRODUCER ASSEMBLIES (RL76-3)
14606	Cap—Dust cap for cone center
14922	Coil—Reproducer field coil (L38)
14602	Cone—Reproducer cone, voice coil, center suspension and dust cap (L34)
5039	Plug—4 contact male plug for reproducer
30131	Reproducer—Complete
14992	Transformer—Output transformer (T3, C52)
14357	Washer—Spring washer to hold field coil securely
	MISCELLANEOUS ASSEMBLIES
14745	Button—Station selector switch button
30361	Card—Call letter cards for station selector
14925	Crystal—Dial escutcheon crystal only
14923	Escutcheon—Dial and tuning tube escutcheon only—less crystal and buttons
14924	Escutcheon—Dial and tuning tube escutcheon and crystal complete
14926	Indicator—"Electric-Manual" indicating screen
14927	Indicator—"Music-Speech" indicating screen
14751	Key—Key for use in adjusting "Electric Tuning"
14359	Knob—Large station selector knob
14688	Knob—Range switch knob
14269	Knob—Volume control, "Manual-Electric-Remote" switch, H-F tone control, L-F tone control or small station selector knob
5210	Screw—Chassis mounting screw and washer assembly
14746	Shield—Celluloid shield for station markers
4982	Spring—Retaining spring for knob Stock No. 14359
14270	Spring—Retaining spring for knob Stock Nos. 14269 and 14688

MODEL 816K
Schematic

RCA MFG. CO., INC.

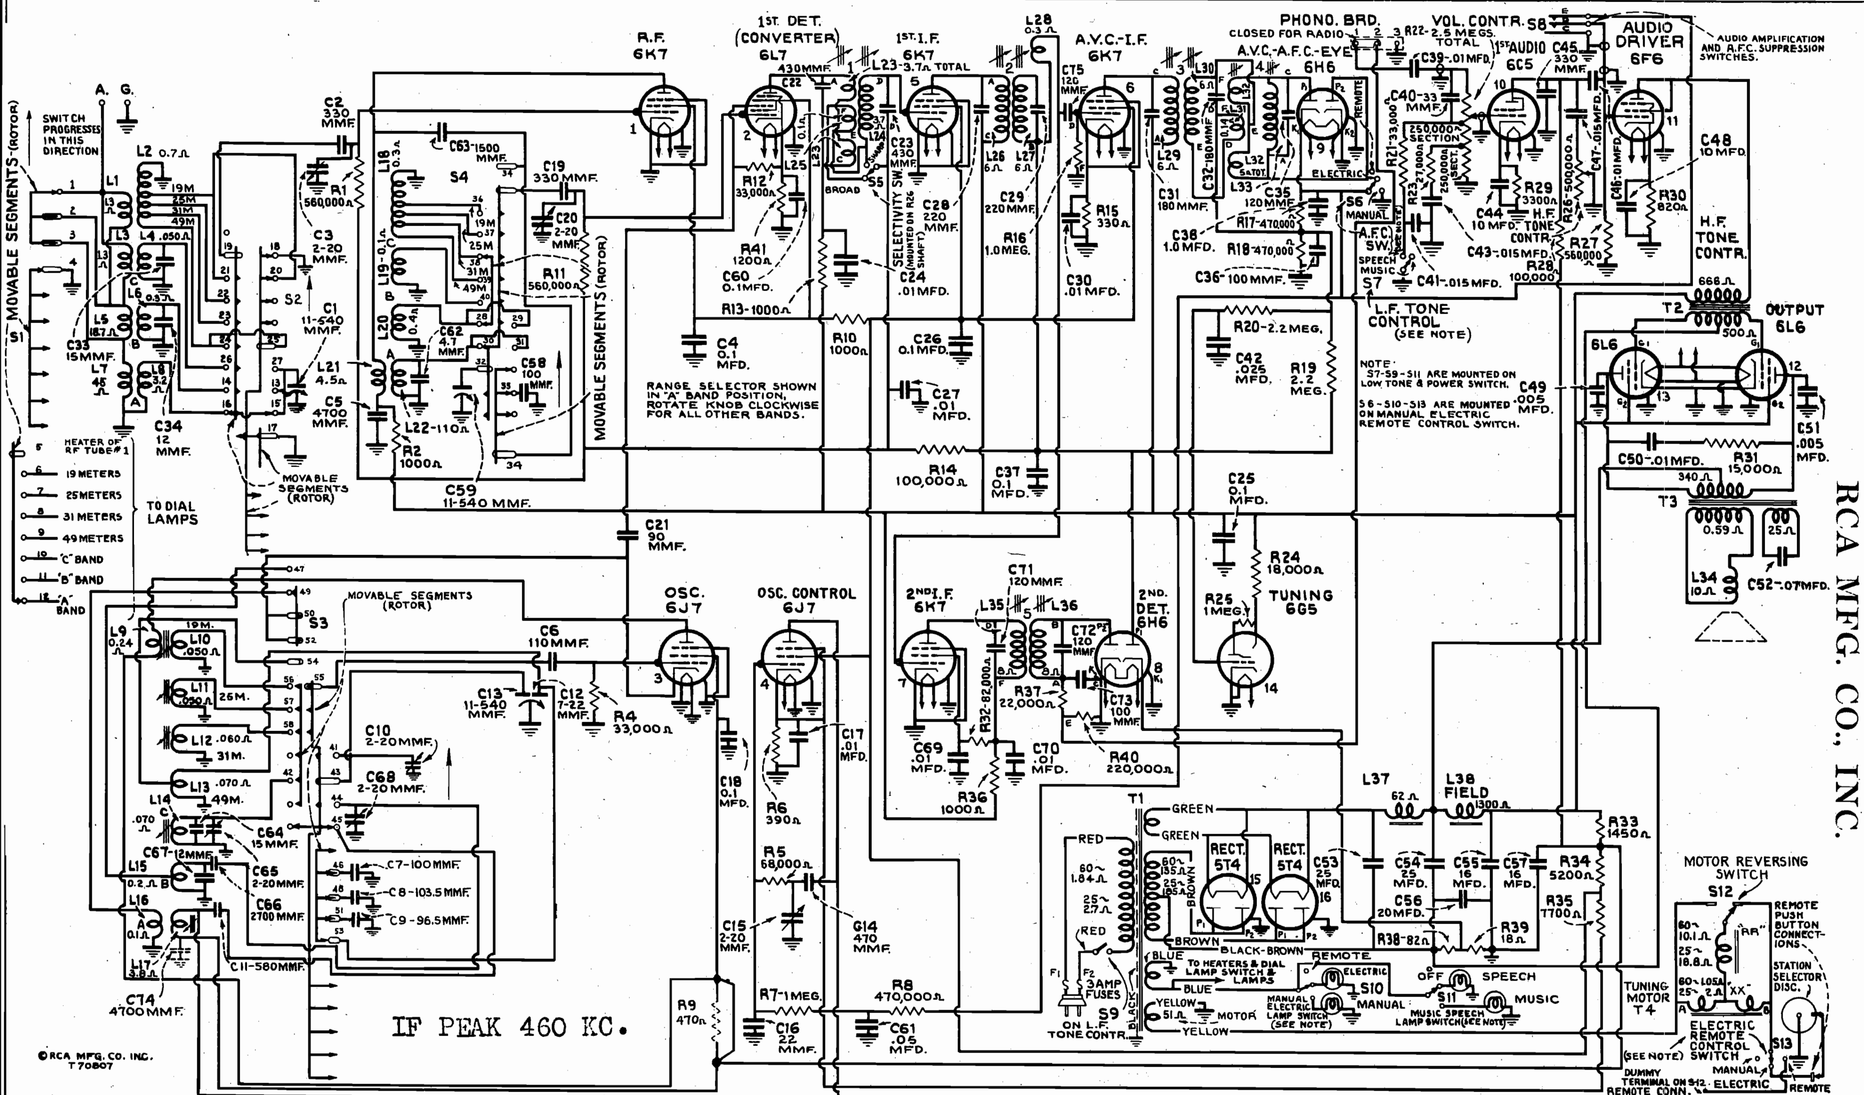

Figure 1—Schematic Circuit Diagram

This receiver employs a sixteen-tube, seven-band, "Magic Brain" superheterodyne circuit. Features of design include "Electric Tuning" with push-button operation; automatic frequency control; spread-band "Overseas" dial; "qumulative-wound" antenna and detector "A" band coils; tuned r-f amplifier; magnetite-core adjusted i-f transformers and low-frequency "A" and "C" oscillator tracking; two-stage signal i-f amplifier; parallel a-v-c., a-f-c., and "Magic Eye" i-f amplifier; phonograph terminal board; "Magic Eye" tuning tube; twelve-inch electrodynamic loudspeaker; plunger-type, air-dielectric trimming capacitors; temperature-stabilized capacitors; two-point aural-compensated volume control; "Fidelity" control; "Music-Speech" control; and a driven push-pull power output stage. In addition, this model has a cabinet incorporating the "Sonic Arc" Magic Voice.

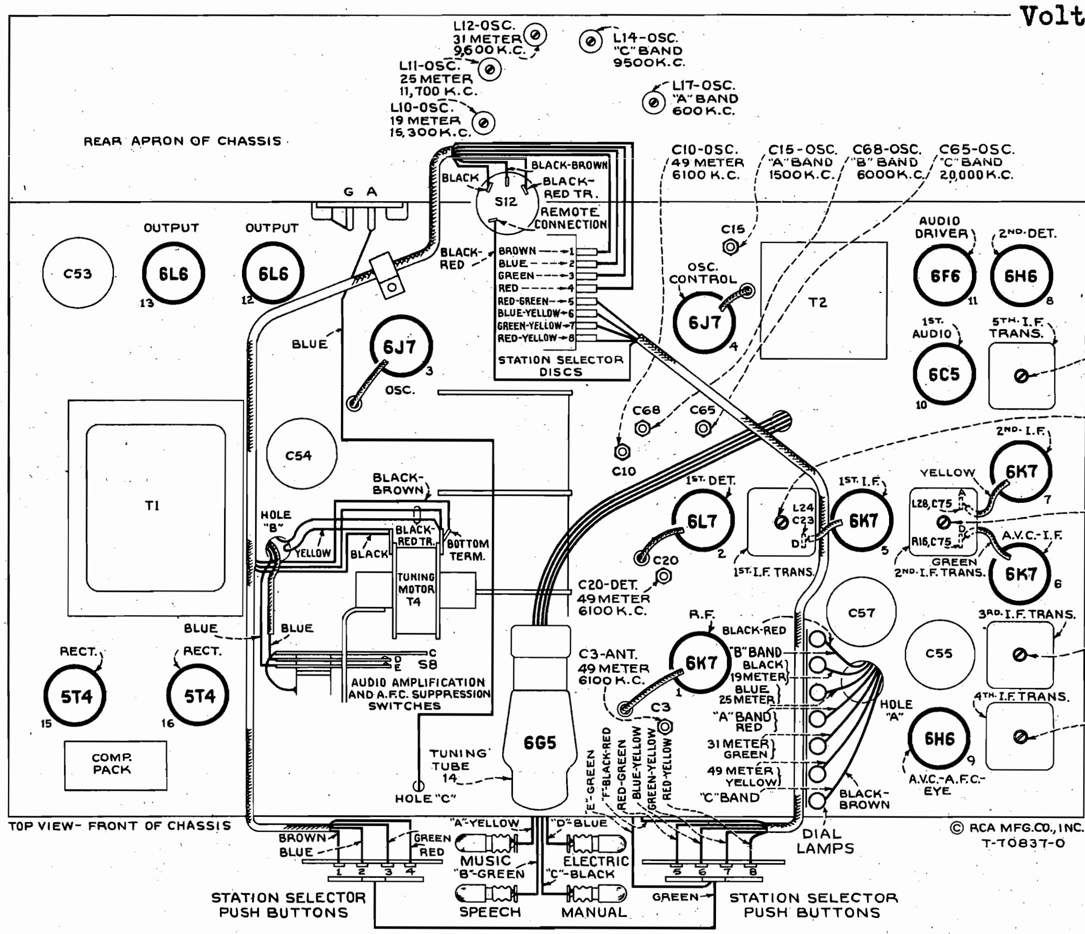

Figure 3—Radiotron, Coil, and Trimmer Locations

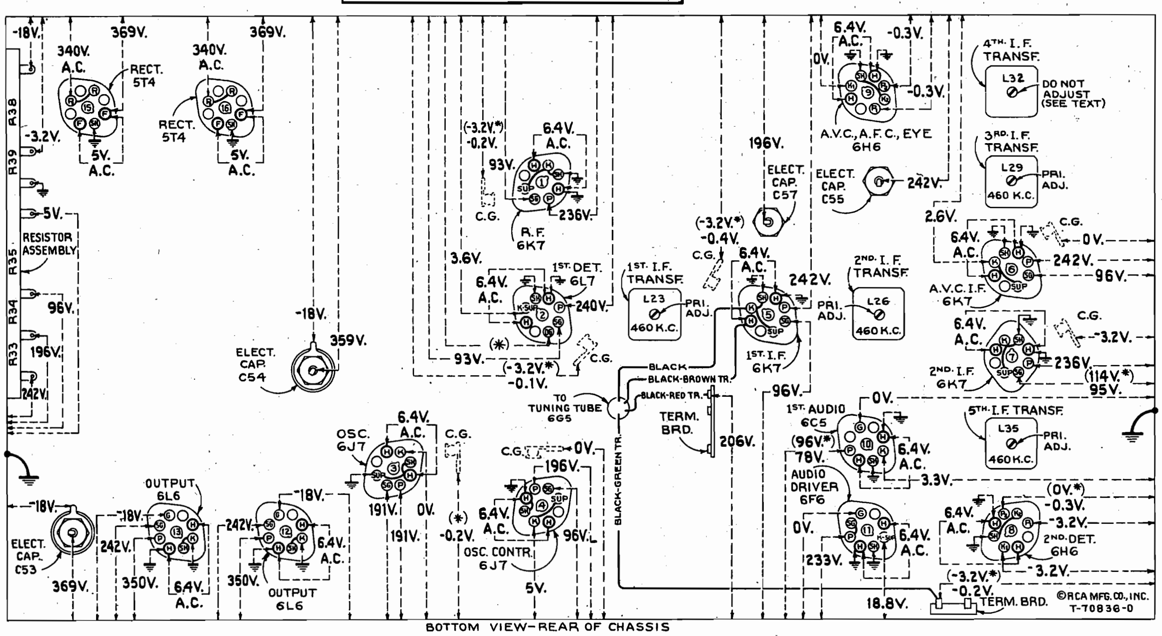

Figure 6—Radiotron Socket Voltages, Coil, and Trimmer Locations

Measured at 115 volts, 60-cycle supply—Tuned to approximately 1,000 kc ("Standard Broadcast")—"Manual" control—No signal being received—Volume control minimum—Fidelity control optional

***Note:** Two voltage values are shown for some readings. The value shown in parentheses with asterisk (*) indicates operating conditions without voltmeter loading. The other value (generally lower) is the actual measured voltage and differs from the value shown in parentheses because of the additional loading of the voltmeter.*

Voltage values as specified should hold within ±20% when the receiver is normally operative at its rated line voltage. To duplicate the conditions under which the voltages were measured requires a 1,000-ohm-per-volt d-c meter, having ranges of 10, 50, 250 and 500 volts. Use the nearest range above the specified measured voltage. A-c voltages were measured with a corresponding a-c meter.

Alignment Procedure

Calibrate the tuning dial by adjusting dial pointer to the left ends of horizontal calibration lines with the gang tuning-condenser plates in full-mesh position. This is a screw-driver adjustment.

The "Fidelity" control should be turned counter-clockwise during all alignment operations. The "Manual-Electric-Remote" switch should be turned to "Manual" (clockwise) during alignment unless otherwise specified. The bottom shield pan must be in place during spread-band alignment. Permit the set to operate at least five minutes before attempting alignment.

CAUTION.—The magnetite core screw L32 on the bottom of the 4th i-f transformer has been accurately adjusted, for an exact electrical balance of coil L32 to center tap, during manufacture and should not be disturbed. However, if for any reason the adjustment has been moved from its original position, it will be necessary to mechanically adjust this screw until the end of the stud protrudes exactly ⅛ of an inch (four threads exposed) above the brass bushing prior to any alignment operations.

Perform alignment in proper order, tabulated below, starting with No. 1 and following all operations across, then No. 2, etc. A-f-c discriminator adjustments should follow r-f and i-f adjustments tabulated below. Adjustment locations are shown on figures 3 and 6.

Cathode-ray alignment is preferable; the connections to the chassis are shown on figure 2. Cathode-ray connection "A" is used for adjustment of i-f transformers Nos. 1, 2, and 3 and connection "B" for adjustment of i-f transformer No. 5. If an output indicator is used, connect it across the loud-speaker voice-coil and advance the receiver volume control to full-volume position. The Magic Eye may be used as an output indicator for all adjustments except L35 and L36. It is preferable to replace the 6G5 tuning tube with a 6E5 during alignment.

Connect the "low" output terminal of the test oscillator to the receiver chassis for all alignment operations. Regulate the output of the test oscillator so that minimum signal is applied to the receiver to obtain an observable output indication. This will avoid a-v-c action and reduce possibility of error in spread-band adjustments.

The term "Dummy antenna" means the device which must be connected between the "high" test-oscillator output and the point of connection to the receiver in order to obtain ideal alignment. "No signal, 550-750 kc" means that the receiver should be tuned to a point between 550 and 750 kc where no signal or interference is received from a station or local (heterodyne) oscillator. "Min. Eye" means minimum width of dark sector of Magic Eye.

For further details on alignment, refer to booklet "RCA Victor Receiver Alignment."

Spread-band Adjustments.—Alignment of the spread ("Overseas") bands requires special procedure since test oscillators used alone are not ordinarily sufficiently accurate for this purpose. The RCA Stock No. 9572 Crystal Calibrator affords a convenient and accurate alignment standard. Wrap a few turns of wire around the crystal calibrator and connect one free end to the antenna terminal of the receiver. Snap crystal calibrator "Hi-Lo" switch to "Hi" (1,000 kc), turn the range selector to "49M." band, and set receiver dial pointer to 6.0 mc. Adjust oscillator trimming capacitor C10 for minimum "Magic Eye" opening (Min. Eye). Use the peak indicated by the alignment table. Snap "Hi-Lo" switch to "Lo" (100 kc) and locate 6,100 kc (the first 100 kc harmonic above 6,000 kc) by slightly readjusting C10 with the dial pointer set at 6.1 mc. This method insures selection of correct crystal calibrator harmonic. Adjust 1st detector and antenna trimming capacitors, C20 and C3, for maximum output.

Follow the tabulated alignment procedure for the "31M.", "25M.", and "19M." bands. Use the crystal calibrator to obtain the necessary accuracy. For example, tune the receiver to the 1,000 kc crystal calibrator output with the crystal calibrator "Hi-Lo" switch in "Hi" position. Snap "Hi-Lo" switch to "Lo" and carefully tune receiver to 1,200 kc (the second 100 kc harmonic above 1,000 kc) for minimum "Magic Eye" opening. Move crystal calibrator away from antenna wire, connect test oscillator, and carefully adjust test oscillator for minimum "Magic Eye" opening at a setting of approximately 1,200 kc. Raise test-oscillator output to give sufficient harmonic output and use 8th harmonic (9,600 kc) for aligning in "31M." band at 9.6 mc. Align in the "25M." band at 11.7 mc, (11,700 kc), the 9th harmonic of the test-oscillator 1,300 kc output. Align in the "19M." band at 15.3 mc (15,300 kc), the 9th harmonic of the test-oscillator 1,700 kc output. In each case select the peak giving minimum "Magic Eye" opening.

When aligning with the RCA Stock No. 150 Test Oscillator use the variable (unmodulated) oscillator† and "Magic Eye" indication of receiver output. Set test-oscillator dial 800 kc lower than the desired signal for the four lower frequency ranges and 800 kc higher than the desired signal for the two high ranges and use in same manner as TMV97-C. Insert an open-circuit telephone plug in the test oscillator "Ext. Mod." jack, so the modulated fixed-frequency oscillator will be cut off, and align on the unmodulated variable oscillator signal, which will close the "Magic Eye" and evidence itself by a rushing noise in the speaker.

† The No. 150 Test Oscillator employs a fixed-frequency (800 kc), modulated oscillator and a variable, unmodulated oscillator. The scale is calibrated to the sum frequency for the two higher frequency ranges and to the difference frequency for the four lower frequency ranges.

If the crystal calibrator signals are weak, disconnect test oscillator while using the crystal calibrator.

More accurate alignment in the spread-bands can be accomplished by making final slight adjustments using American, English, or German short-wave broadcasting stations of known frequency for frequency standards.

A-F-C Discriminator Adjustments.—These adjustments are rather critical and should be performed with extreme care. Improper adjustment may result in complete failure of the oscillator control tube to function or else may cause it to detune the oscillator instead of tuning it to the signal. It is assumed that the magnetite core adjusting screw L33 (top of 4th i-f transformer) has been turned all the way out (extreme counter-clockwise) during the preceding tabulated adjustments. Adjustments are as follows: Remove spring "N" on link and arm assembly which connects the "Manual-Electric-Remote" switch shaft to the throw-out gear bracket. Turn "Fidelity" control counter-clockwise. Connect antenna to receiver antenna terminal. With the "Manual-Electric-Remote" switch in "Manual" (right) position, tune in a strong local station near 600 kc or the low-frequency end of the "A" band as accurately as possible by means of the tuning tube "Magic Eye." The most accurate adjustment will be obtained by adjusting the "vernier" tuning knob mid-way between the two points where the eye just appears to start to open. This will place the generated i-f carrier signal frequency exactly in the center of the i-f amplifier response curve (should be 460 kc if i-f amplifier was properly aligned) and is the frequency to which the a-f-c discriminator (4th i-f transformer) should be tuned to resonance. Without disturbing any of the receiver adjustments, place the "high" test-oscillator lead about ¾ of an inch from the grid cap lead of the RCA-6K7, 1st i-f amplifier tube, adjust the test-oscillator output to maximum, turn test-oscillator "Modulation" off, and carefully zero-beat the test-oscillator frequency (approximately 460 kc) with the i-f carrier signal. Avoid placing the test-oscillator lead nearer to the grid cap lead than specified above, as doing so will tend to detune the i-f amplifier. It may be necessary to reduce the local station signal, during this operation, by shortening antenna lead or grounding antenna "A" terminal to chassis in order to increase the loudness of the beat note sufficiently for accurate zero-beat adjustment.

Throw "Manual-Electric-Remote" switch to "Electric" (center) position. A high whistle or beat note will now be heard. Turn the magnetite core screw L33 (top of 4th i-f transformer) slowly clockwise. As this screw is turned, the beat note will first increase to a high audio frequency and will then decrease to a zero-beat and then increase in frequency again. The point of exact zero-beat is the position for correct adjustment of the discriminator. Zero-beat should also still exist when the "Manual-Electric-Remote" switch is thrown back to "Manual" position. The adjustment is now complete and may be checked by slightly detuning the receiver above and below the local station frequency with the "Manual-Electric-Remote" in "Manual" position, switching to "Electric" position, and noting the oscillator pull-in. Replace spring "N"

20	Proceed to A-F-C Discriminator Adjustments Outlined Below							

a—Refer to "Spread-band Adjustments" below for method of using the RCA Stock No. 9572 Crystal Calibrator for adjustments 6, 7, 8, and 9.
b—Use minimum capacity peak if two peaks can be obtained from 1,000 kc harmonics.
c—Refer to "Spread-band Adjustments" below for Test Oscillator setting for adjustments 10, 11 and 12.
d—To check for correct harmonic carefully set Test Oscillator to 1,600 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "31M." band near 9.6 mc.
e—To check for correct harmonic carefully set Test Oscillator to 900 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "25M." band near 11.7 mc.
f—To check for correct harmonic carefully set Test Oscillator to 900 kc using Crystal Calibrator. Signal should be indicated by "Magic Eye" in "19M." band near 15.3 mc.
g—After this adjustment, check for image signal by shifting receiver dial to 19.08 mc. (19,080 kc).
h—Check for image at 8.58 mc. (8,580 kc).

MODEL 816K
Tuner Notes
Lead Dress, Phono.

RCA MFG. CO., INC.

ELECTRIC TUNING

Principle of Operation

The electric tuning mechanism consists essentially of a quick engaging and dis-engaging reversible electric motor, tuning condenser driving gear train, and eight mechanically interlocked (pushing one button releases all others) station selector push buttons respectively wired to eight adjustable station selector contactor discs (each with a motor stopping insulated segment) mounted on a drum which is direct-coupled to the gang tuning condenser shaft. The arrangement permits any one of eight pre-determined stations to be electrically tuned in by merely touching the correct push button. If all eight buttons are inadvertently locked in, firmly pushing the right-hand button will release them.

The operation may be more readily understood by reference to figures 1, 4, and 5. When the motor is not energized, the armature is pushed to the rear or slightly out of the magnetic center by tension of contact spring "C" and the motor shaft is dis-engaged from the driving gear train. Pressing in any one of the eight push buttons will complete the motor circuit through a station selector contactor disc, assuming that the "Manual-Electric-Remote" switch is in "Electric" position and that the insulated segment in the contactor disc is not opposite its contactor. As the motor starts, the armature will be drawn forward, due to solenoid action, and the pin "F" on the end of its shaft will engage the arm "G" on the small main pinion gear, thereby driving the tuning mechanism. At the same time contact springs "E" and "D" will be grounded, causing suppression of audio amplification and automatic frequency control during the tuning cycle. The motor will continue to operate until the insulated segment in the selector disc breaks the motor circuit, whereupon spring "C" will instantly dis-engage the motor pin "F" from the arm "G" on the small pinion driving gear and open contacts "E" and "D." Pushing another button will cause the above mentioned cycle to be repeated except that the motor will be interrupted by the insulated segment on a corresponding disc. The discs are individually adjustable on a drum mechanism, providing a choice of eight "Electric Tuned" "Broadcast" stations. The arrangement of the motor is such that its rotation will continue in the same direction regardless of the number of "Electric" tuning cycles until the tuning condenser approaches either full-out or full-in of mesh, whereupon lever "H" trips switch S12 which reverses the direction of rotation. A throw-out idler gear is link-coupled to the "Manual-Electric-Remote" control to disconnect the motor drive gear train when the control is thrown to "Manual" position.

FOR FIG.4, SEE FIG. 4 OF MODEL 813K

Mechanism Adjustments

The electric tuning mechanism is designed to be as simple in construction and as fool proof in operation as is possible. In order to maintain the accurate results possible with this device care must be taken in effecting any repairs or adjustments. Reference should be made to figure 4 and the following:

A-F-C and A-F Amplification Suppression Switches.—This switch assembly is located on the motor bracket and closes due to solenoid action of motor armature. The tension of the long contact spring "C" is important in bringing about quick dis-engagement of the motor and in permitting the motor to pull into mesh with the drive mechanism. Normal adjustment is attained when the short springs "D" and "E" are aligned exactly straight with contact points separated approximately 1/32 of an inch and with the spring "C" spaced approximately 7/32 of an inch from spring "D" at the point of contact. If necessary, in order to obtain positive pull-in and quick dis-engagement of the motor, the tension of spring "C" should be increased or decreased by bending. This action should be checked with the front apron of the chassis raised two inches higher than the rear. Contacts of the switch must be kept clean. Crocus cloth or a relay burnisher may be used for this purpose.

Motor Reversing Switch.—It is necessary to automatically stop and reverse the drive motor before the tuning condenser reaches the ends of its travel. Approximately 175 degrees of sweep is required, and the reversal must take place above 1,700 kc and below 540 kc but not too near the limits of the scale. The coupling between the station selector drum and the tuning condenser shaft should be attached so that the reversing switch trip lever "H" is exactly vertical when the condenser is full-out of mesh. There should be 1/32 of an inch clearance between the end of the condenser shaft and the selector drum shaft. While the trip lever is in this position the reversing switch bracket should be adjusted by means of its elongated mounting holes until the switch pin "I" just lightly touches trip lever "H."

Main Pinion Gear.—Clearance between the small high-speed pinion gear "E" and the intermediate gear "K" determines the amount of mechanical noise produced. Correct adjustment will give approximately 1/32 of an inch movement of back lash at the end of pinion arm "G" when gear "K" is held stationary. Arm "G" must also be adjusted for correct mesh with motor shaft drive pin "F." With the motor shaft completely forward and pinion "E" tight against its front bearing, the pinion mounting stud "J" should be adjusted so that pin "F" meshes full thickness with the rotating arm "G." An increase of this mesh will increase over travel on tuning while a decrease of mesh will decrease the over travel. The elongated hole in the front bracket allows sufficient movement of the mounting stud "J" to permit above mentioned gear mesh adjustment.

"Manual-Electric-Remote" Changeover.—(1) Link and arm adjustment—To properly line up the mechanical link between the switch shaft and throw-out gear bracket "MM," the set screws holding the link arm on the switch shaft must be loosened, the switch turned to the "Manual" position (extreme right) and the link lever revolved until the distance between the link-connecting pin (extends through chassis apron) and the right-hand (viewed from front) side of the slot, in front apron of chassis, is exactly 5/16 of an inch. If this adjustment is not properly made, correct operation of "Electric" or "Remote" tuning will not result. (2) Throw-out Gear Adjustment—To obtain smooth operation on "Electric" or "Remote" positions it is important that the proper clearance is maintained between the throw-out gear "M" and the intermediate gear "L." With the "Manual-Electric-Remote" control thrown to "Remote" position (extreme left) adjust the mesh between these gears by means of the eccentric screw "O" and lock nut "P," contacting the throw-out gear bracket "MM," until there is approximately 1/64 of an inch backlash of gear "L" when gear "M" is held stationary.

Vernier Tuning.—In case it becomes necessary to remove tuning condenser drive shaft "T," it should be replaced by sliding anti-backlash gear "R" on condenser shaft apart so that compression amounting to one tooth on the gear is obtained in the springs. Adjust mesh of gear "R" with pinion gear "U" on vernier shaft before tightening screws "S" so that smooth tuning is obtained throughout the range.

Motor Alignment.—The motor shaft must be exactly aligned with the axis of the pinion gear with which it engages. This may be adjusted by loosening the mounting screws "V" of the motor and aligning shaft by sight. Correct alignment may be tested by slowly rotating motor and observing the relation between the pin "F" of the motor shaft and the arm "G" on the pinion. The relation of the two should remain the same throughout the revolution. Additional movement for adjustment may be obtained by the motor bracket screws "W" if necessary.

Station Selector Drum.—(1) Bearing Adjustment—The selector drum may be removed by unscrewing the two bearing adjusting screws "X" on the front and rear bearings and sliding shaft out of slots on frame. To replace drum, the reverse procedure should be followed holding bearing adjusting plates "Y" firmly against the shaft and tightening adjusting screws. (2) Contact adjustment—Two types of contact strips are used. They are designated on figure 4, as types 1 and 2, on which the individual contacts are respectively adjustable and fixed. On type 1, the individual contacts should be adjusted by setting the end contact springs near the mid-position of their travel and aligning the remaining springs to them by means of a straight edge. Either type of contact strip should be adjusted to the selector drum by firmly placing two selector adjusting keys in the station adjustment strip, positions 1 and 8 (locking respective discs), loosening contact strip adjusting nuts "Z" and shifting the contact strip until the end contacts are exactly centered on the respective disc insulating segments. More accurate adjustment may be made by silhouetting the point of contact with a piece of white paper held behind the contact. Adjustment will be facilitated by removing complete assembly from rear of tuning condenser by unscrewing the three mounting screws. Contacts and discs must be kept free of dirt, filings, and other extraneous matter.

Lubrication.—The dial pointer slide should be greased with petrolatum. This same lubrication should be applied lightly to all gear faces of the drive mechanism and sparingly with a cloth to the station selector discs. Any good household oil, such as "3-IN-ONE," is suitable for the motor shaft bearings. A light grade of engine oil should be used for all gear bearings. Medium viscosity engine oil, similar to "PYROIL" (B), should be applied between the thrust washers on the motor shaft. "CASTORDAG," a mixture of graphite and castor oil, is recommended for use at the selector drum end-bearing slots and at the bearings of cable pulleys.

Station Adjustment

Any eight stations may be chosen for "Electric" tuning. Remove the two escutcheon plates from the side of the dial, place proper call letter labels in the celluloid windows, and replace escutcheons. Turn the power on and proceed to set up the "Electric" tuning as follows:

1. Set Range Selector to "Standard Broadcast."
2. Turn "Manual-Electric-Remote" control to "Electric."
3. Turn Fidelity control counter-clockwise.
4. Press push button No. 1 (left) and wait until station pointer comes to rest.
5. Turn the "Manual-Electric-Remote" control to "Manual."
6. Remove adjusting key from receptacle on top of station selector drum mechanism.
7. Insert key in position marked "1" in station adjustment strip and push the key all the way down to properly fit in slot in disc.
8. Tune the receiver very carefully by means of the manual tuning knob and the "Magic Eye," to station chosen for No. 1.
9. Remove key.
10. Turn the "Manual-Electric-Remote" control to "Electric."

Button No. 1 is now properly set for "Electric" tuning. Proceed similarly for the other seven push buttons, matching each station on the dial with the same number on the station adjustment strip. Repeat the above steps but place the key respectively in positions 2, 3, 4, etc., and in each case tune to the proper station. Pressing the proper button will now cause the desired station to be tuned in electrically.

Armchair Control

When a Model G-8 armchair control is attached to the receiver as shown in figure 5 it duplicates the action of the push buttons on the front panel when the "Manual-Electric-Remote" control is turned to "Remote" position.

Service Hints

a. Capacitors C18 and C74 should be carefully checked for leakage or short circuit in cases of intermittent operation or no operation. C74 should be eliminated from the circuit, R9 should be shorted out, and C18 replaced by Stock No. 4839, as shown by the Schematic Circuit Diagram figure 1, in the event of trouble in this circuit.

b. Capacitor C5 should be checked for leakage or short circuit.

c. Resistor R5 was 33,000 ohms in some instruments. Replace with Stock No. 12333.

d. Capacitor C16 was 82 mmfd. in some instruments. Replace with Stock No. 14021.

Service Data

The various diagrams of this booklet contain such information as will be needed to isolate causes for defective operation if such develops. The ratings of the resistors, capacitors, coils, etc., are indicated adjacent to the symbols signifying these parts on the diagrams. Identification titles such as R1, L1, C1, etc., provide reference between the illustrations and Replacement Parts List. The coils, transformer windings, and reactors are rated in terms of d-c resistance to permit continuity checks.

Precautionary Lead Dress.—(1) Green bus lead from C1 to S2 should be 2¾ inches long, (2) green bus lead from C59 to S4 should be 2½ inches long, (3) green bus lead from C13 to S3 should be 2¾ inches long, (4) bare bus lead from C12 to S3 should be 1⅛ inches long, (5) blue and red leads from tube No. 3 to L9 should be dressed away from the coil, (6) tube No. 3 grid lead should be 6 inches long, (7) all leads to rear of oscillator coils should be dressed close to the chassis, (8) clamp "Magic Eye" cable to the dial bracket, (9) filament leads should all be twisted, (10) leads from C44 and C48 should be replaced dressed away from other leads, (11) twisted a-c leads near R22 should be dressed away from R22, (12) leads from S5 to the first i-f transformer should be twisted, (13) temperature-stabilizing capacitors marked 1A, 2A, and 3A should be dressed perpendicular to chassis, (14) blue bus lead from L21 to tube No. 1 plate should be dressed away from shield plate on range selector assembly, (15) C36, C38, and K_2 of tube No. 9 should be grounded to the ground lances near corner of chassis. The following should be dressed away from chassis: (16) Yellow bus lead from cathode of tube No. 3 to S3, (17) yellow bus lead to OG of tube No. 2, (18) yellow bus lead from the 5th i-f transformer to phonograph terminal board, (19) blue bus lead from C47 to R26. When necessary to replace bus leads, use only wire having same diameter as original.

Phonograph Attachment.—A terminal board is provided for connecting a phonograph into the audio-amplifying circuit. RCA Victor Models R-93, R-93-A, R-93-2, or R-94 Record Players should be connected as follows: Remove the link from the phonograph terminal board. Connect green wire in Radio-Record switch cable to terminal 1; yellow to terminal 2; shield terminal 3; and tape up the red and blue. Connect a 2-conductor twisted cable between the Record Player binding posts and the screw-terminals on Radio-Record switch. If additional volume is desired, connect an RCA Stock No. 9632 transformer between the 2-conductor twisted cable and the screw-terminals on Radio-Record switch as follows: Yellow and brown transformer leads and one side of twisted cable to ground screw-terminal on switch; black transformer lead to other side of twisted cable; and blue transformer lead to other screw-terminal on switch.

Loudspeaker.—Two types of loudspeakers are used which will be referred to as types 1 and 2. In type 1 the cone centering diaphragm is cemented to a fixed ring, while in type 2 the centering diaphragm is cemented to an adjustable ring. Replacement of cone for either type is identical. Centering of cone for type 1 loudspeaker is made with three narrow celluloid or paper feelers after first removing the front dust cover and cutting free the cone centering diaphragm. The dust cover may be removed by a light application of acetone, using care not to allow the acetone to flow into the air gap. The centering diaphragm should be cemented in place after placement of feelers. Sufficient time should be allowed for the ambroid to set before removing feelers. Use ambroid to replace dust cover. Centering of cone for type 2 loudspeaker differs only in that it is not necessary to cut free the centering diaphragm, adjustment being made in the usual manner by means of screws on the adjustable cone centering ring.

General Description

The RCA Victor Model 910KG Receiver employs a ten-tube, three-band, "Magic Brain" superheterodyne circuit, the arrangement of which is shown in the schematic circuit diagram. Features of design include: "Electric Tuning" for eight broadcast stations; a link-coupled antenna circuit; magnetite-core i-f transformers and "A"-band oscillator coil; full automatic volume control; Victrola jack and switch; "Magic Eye" tuning tube; improved 12-inch dust-proof electrodynamic loudspeaker; aurally compensated audio volume control; continuously variable high-frequency tone control; provision for armchair control attachment; illuminated band indicator; noise-reducing antenna adjustment on "A" band; temperature-stabilized capacitors; phase inverter audio amplifier; and push-pull power output stage.

The Model U-126 combination instrument consists of a radio receiver similar to the Model 910KG, and in addition, a phonograph turntable with a self-starting electric motor, and crystal pickup. The phonograph will play ten- or twelve-inch records; and automatically shuts "off" at the end of record play. The output of the pickup is "shorted" out when the pickup is on the pickup rest.

The Model U-128 combination instrument consists of a radio receiver similar to the Model 910KG, with an automatic phonograph mechanism. The phonograph has a self-starting motor, crystal pickup, and may be set to play ten-inch and twelve-inch records singly, or automatically. In the automatic position, seven twelve-inch; eight ten-inch; or a mixed group of seven, ten- and twelve-inch records, may be played in succession. The output of the pickup is "shorted" out when the pickup is on the pickup rest.

Service Data

Victrola Attachment. — A jack located near the "Magic Eye" tube is provided for connecting a Victrola Attachment into the audio-amplifying circuit on Model 910KG. The cable running from the Victrola attachment should be terminated in a Stock No. 31048 plug to fit the jack.

Loudspeaker.—Centering of the loudspeaker is made in the usual manner with three narrow celluloid or paper feelers after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. A dust cover should be cemented in place upon completion of adjustment.

Precautionary Lead Dress. — (1) The lead from the left pilot light should be kept behind the bulb and toward the "Magic Eye," to keep it away from the 6F5 grid cap, (2) leads from mica trimmers to coil should be kept away from the coil and other parts, (3) leads on oscillator coil which are an extended part of the coil winding should be as short as possible, (4) "C" band series capacitor C31 must have leads as short as possible, (5) all leads from antenna board to antenna coils should be dressed toward back apron, (6) the one lead of the line cord and the primary lead of the power transformer which run to the power switch should be twisted together, (7) shielding on leads to Victrola switch should be kept away from the switch terminals and jack.

Antenna Connections

RCA Victor Master Antenna Kit.—Connect the twisted-pair transmission line to terminals A1 and A2 on the terminal board at rear of chassis. Connect the counter-poise to A3. Terminal G may be connected to ground, but this connection is not necessary for correct operation.

Noise-Reducing Adjustment.—After the RCA Victor Master Antenna Kit is connected to the receiver, tune the receiver to a point near 900 kc where no station is heard. Turn volume control clockwise until noise is heard. If no noise of a regular character is audible, start any brush-type motor-driven appliance, such as a vacuum cleaner, electric razor, refrigerator, etc., but do not bring it too near the receiver. This will generate noise as a continuous crackling, or buzz. Adjust C5, which is mounted behind the antenna terminal board, to a point where this noise is reduced to a minimum.

Adjustment of the noise reducing trimmer C5 should be made in the customer's home, with the RCA Victor Master Antenna connected to the receiver.

This adjustment is effective only when the RCA Victor Master Antenna is used. For all other types of antenna, the noise-adjustment trimmer C5 should be screwed all the way down.

Other Antennas.—Use terminals A1 and A3 on the receiver terminal board as antenna and ground connecting points respectively. Terminal A3 may be connected to terminal G, unless this causes interference, in which case this connection should be omitted.

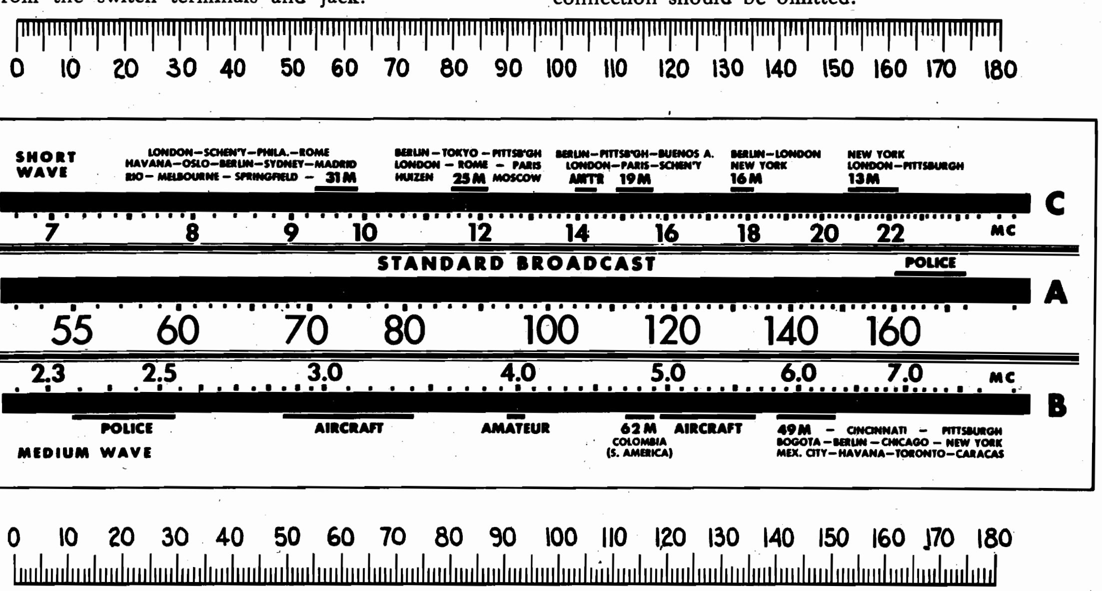

Figure 1—Tuning Dial, and Corresponding 0-180° Calibration Scale

The corresponding dial setting for any reading of the calibration scale can be determined by drawing a line straight up from this point; for example, 151.5° on the calibration scale corresponds to a dial reading of 1,500 kc on "A" band. Read instructions under "Alignment Procedure."

* Use **minimum** capacity peak if two peaks can be obtained. Check to determine that the correct peak has been used by turning to 141.5° (19,090 kc), at which point a weaker signal should be received.

** Use **minimum** capacity peak if two peaks can be obtained. Check to determine that the correct peak has been used by turning to 124° (5,190 kc), at which point a weaker signal should be received.

† Rock gang condenser and use maximum capacity peak if two peaks can be obtained with C8.

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-Oscillator.—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

Calibration Scale on Indicator-Drive-Cord Drum.—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment, therefore a calibration scale is attached to the rear of the indicator-drive-cord drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

Turntable Mechanism Model U-126

The crystal unit of the pickup is sealed in a metal case against extremes of climate. The offset mounting of the crystal unit in the pickup arm insures ideal tracking between needle and record grooves. If failure should occur due to a defective crystal, no attempt should be made to repair the crystal, but a new replacement crystal unit should be installed.

The turntable drive is a self-starting, variable-speed, governor-type, induction motor. The motor speed adjusting screw is located under the turntable, and may be adjusted by inserting a screwdriver thru one of the holes in the turntable, after the hole has been lined up with the screw. The flexible motor drive arrangement is similar to the U-128. The motor speed should be 78 r.p.m., and may be checked by placing a piece of paper between a record and the turntable, with the paper protruding beyond the edge of the record, and then counting the number of revolutions of the turntable per minute. The motor is designed to be simple and foolproof in operation. Occasionally, however, certain adjustments and lubrication may be required. These are illustrated and explained in figure 12. In addition, an application of oil to the felt pad, which rubs against the governor disc, will insure smooth operation.

The turntable is started by pushing to the rear the motor starting lever, which appears to the right of the turntable. The adjustment on the automatic motor stopping switch should be made so that the switch will snap to the "off" position when the needle in the pickup head is 1¾ inches away from the center of the turntable. The locking screw and details of the switch mechanism are shown in figure 14. The locking screw and nut may be reached, from underneath the motor board, or, by an open end wrench, under the turntable.

As the first step in r-f alignment, check the position of the drum. The "0" mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

Pointer for Calibration Scale.—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "0" mark on the calibration scale when the plates are fully meshed.

Dial-Indicator Adjustment.—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

MODELS 910KG, U126, U128
Tuner Mechanism, Data

Electric Tuning Mechanism

The circuit of the electric tuning mechanism is shown in the schematic diagram, and the mechanical details are illustrated below.

The action can be understood by following a cycle of operation:

When a station button is pushed in, it completes the 24-volt circuit through the corresponding station-setting contact and one-half of the brass selector disc, which is connected to one side of the motor field coil. This energizes the motor, and the rotor is pulled forward, engaging with the gear train that drives the tuning condenser and selector disc. The condenser and disc rotate until the insulation line comes under the particular station-setting contact, and the motor circuit is broken. Inertia carries the insulation line past the station-setting contact which then makes contact to the other half of the disc: This completes the circuit to the other side of the motor field coil, causing the motor to reverse. The floating flywheel is still turning in the original direction and therefore slows down the reversal movement of the motor; as a result the selector disc is moved slowly back until the insulation line is under the station-setting contact; when the circuit is broken and the mechanism stops.

Adjustment of Flywheel Friction

In normal operation, the motor drives the tuning condenser and selector disc until the insulation line just passes the particular station-setting contact: The motor then reverses and moves the disc slowly in the opposite direction until the insulation line is under the contact, and the mechanism stops.

In some cases, particularly with high line-voltage, the disc may make two or three reversals before stopping.

The flywheel friction adjustment screw should be set to give the least number of reversals with the chassis in normal horizontal position.

Adjustment of Selector Disc

The brass selector disc is fastened to the rear shaft of the tuning condenser by means of two set-screws. When the condenser is at maximum (plates fully meshed) the insulation line should be horizontal, with the operating-end at the left (viewed from rear). The operating-end has dark insulating material and the brass is beveled at this end.

The selector disc should be set so that the contact-tip plungers in the station-setting contacts project not more than 1/16-in. from the body of the contacts.

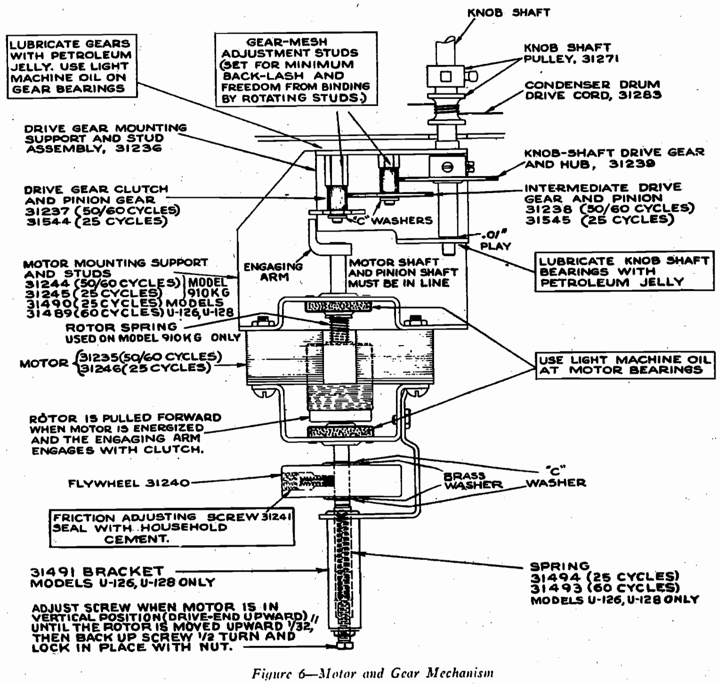

Figure 6—Motor and Gear Mechanism

There must be 1/32-inch clearance between the end of the engaging arm and the face of the intermediate gear when the motor is in its full forward position.

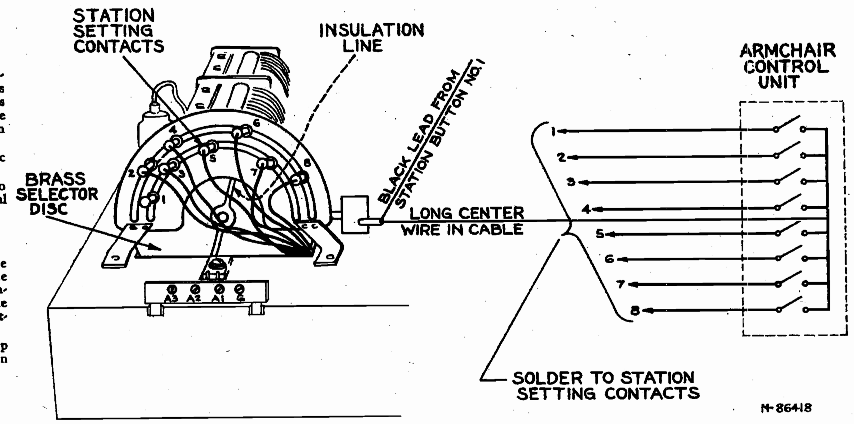

Figure 7—Station-Setting Contacts and Selector Disc

This illustration shows connections for a G8A Armchair Control Unit. This unit is not supplied with the receiver but may be added as an accessory.

Colors of Leads from Push Buttons to Station-Setting Contacts

Station Button	Color of Lead To Station-Setting Contact	Station Button	Color of Lead To Station-Setting Contact
No. 1	Black	No. 5	Red
No. 2	Brown	No. 6	Red-black
No. 3	Blue	No. 7	Brown-black
No. 4	Green	No. 8	Red-yellow

Muting Circuit

When the electric tuning mechanism is in action, the motor-supply voltage is fed into a diode rectifier circuit which applies a high bias to the first-audio amplifier. This prevents audio amplification and makes the set quiet or "mute" while the mechanism is operating.

Lubrication

Motor bearings and **gear bearings**; use light machine oil. **Gear faces**; use "Pure Oil No. 611" or petroleum jelly. **Dial-indicator pulleys and rails**; use "Castordag" or petroleum jelly.

Selector disc; apply *thin* film of petroleum jelly.

Friction leather on flywheel; apply "neats-foot" oil. When replacing leather, soak it for at least 24 hours in neats-foot oil, and insert in flywheel while dripping.

Armchair Control Unit

When a Model G8A Armchair Control is connected to the receiver as shown in figure 7 it duplicates the action of the push-buttons on the front panel when No. 1 button is pressed down. The black lead from push-button No. 1 is unsoldered from No. 1 station-setting contact and soldered to a terminal board which is to be mounted on the frame of selector mechanism. In some cases one of the other seven station buttons on the set may be used in place of No. 1 button for the operation of the Armchair Control.

This arrangement allows the use of only seven of the eight buttons when tuning in stations at the set, but allows the use of the entire eight buttons on the Model G8A Armchair Control. In operating the G8A Armchair Control the push-button must be held down until the station has been tuned in. Care must be taken not to hold two of the station-buttons down at one time as both windings of the motor may be engaged instantaneously causing the motor to be inoperative and overheated.

ADJUSTMENTS FOR ELECTRIC TUNING

1. Make a list of the desired eight stations, arranged in order from low to high frequencies.

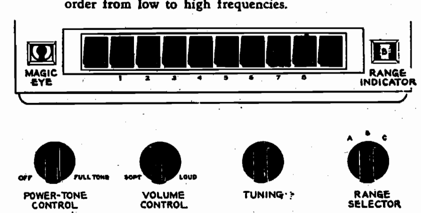

Figure 3—Location of Controls

The left-hand push-button is a Victrola-Attachment switch. The right-hand push-button is for dial tuning.

2. Turn range selector to "A" band, turn power on, and allow a few minutes for warming up.
3. Press down the "dial-tuning" (right-hand) button.
4. Manually tune in the first station on the list, using the "Magic Eye" for accurate tuning.
5. Hold down the "dial-tuning" button, and press down station button No. 1 (second from left). Both buttons will stay down. Move adjusting pin No. 1 to the insulating line on the disc at rear of gang. When the pin is correctly centered on the insulating line, the central dial lamp will go out.
6. Press down any other button in order to release the dial-tuning button and station button No. 1. Then press down station button No. 1 again. The electric tuning mechanism will function to tune in the station, and the central dial lamp will stay on.
7. Repeat this process for the remaining stations.

STOCK No.	DESCRIPTION	Unit List Price
	RECEIVER ASSEMBLIES	
31492	Bearing—Variable condenser motor rotor adjustment bearing—less bracket and cup assembly (Models U-126 and U-128)	.10
31253	Board—Antenna and ground terminal board (Model 910KG)	.25
31531	Board—Antenna and ground terminal board (Models U-126 and U-128)	.25
31229	Body—Station-setting contact body, less contact tip and tip spring	.18
31276	Bracket—Band indicator mounting bracket complete—less indicator strip, cord, and tension spring	.40
31491	Bracket—Bracket and bearing cup for variable condenser motor rotor adjustment (Models U-126 and U-128)	.45
31282	Bracket—Magic Eye mounting bracket and holder	.22
12714	Capacitor—Adjustable trimmer 2-12 mmfd. (C29)	1.50
31292	Capacitor—Dual adjustable trimmer 3-30 mmfd. each section (C24, C25)	.40
31252	Capacitor—Adjustable trimmer 5-80 mmfd. (C5)	.25
12896	Capacitor—15 mmfd. (C2, C54)	.35
12948	Capacitor—33 mmfd. (C1)	.35
31432	Capacitor—20 mmfd. (C27)	.40
13057	Capacitor—68 mmfd. (C57) (Models U-126 and U-128)	.35
12720	Capacitor—100 mmfd. (C20)	.35
31270	Capacitor—100 mmfd. (C11, C12, C13, C14)	.35
12724	Capacitor—120 mmfd. (C37, C38)	.35
12725	Capacitor—150 mmfd. (C15)	.35
31433	Capacitor—560 mmfd. (C28)	.35
31033	Capacitor—1,500 mmfd. (C26)	.35
31405	Capacitor—6,000 mmfd. (C31)	.75
5107	Capacitor—.0025 mfd. (C53) (Models U-126, U-128)	.20
30303	Capacitor—.0035 mfd. (C46)	.40
4838	Capacitor—.005 mfd. (C17, C22, C49, C50)	.25
4858	Capacitor—.01 mfd. (C21, C48) (Models U-126 and U-128)	.25
14393	Capacitor—.01 mfd. (C6, C18, C21, C39, C48, C52, C53, C55) (C21, C48, C53, in Model 910KG only) (C55 in Models U-126 and U-128 only)	.30
11315	Capacitor—.015 mfd. (C36)	.20
30882	Capacitor—.05 mfd. (C9)	.20
4839	Capacitor—0.1 mfd. (C10, C16)	.30
12484	Capacitor—0.25 mfd. (C33)	.30
30965	Capacitor—0.25 mfd. (C40)	.30
30867	Capacitor—0.5 mfd. (C19)	.30
5212	Capacitor—16 mfd. (C35) (Model 910KG)	1.35
31496	Capacitor—16 mfd. (C35) (Models U-126 and U-128)	1.25
31495	Capacitor—20 mfd. (C34) (Models U-126 and U-128)	1.75
5040	Plug—4-contact female plug for speaker cable (Model 910KG)	.30
12493	Plug—5-contact female plug for speaker cable (Models U-126 and U-128)	.30
31280	Pulley—Indicator pointer drive cord pulley	.10
31271	Pulley—Motor pulley	.25
31272	Pulley—Range switch pulley	.20
31250	Resistor—Voltage divider comprising one 1,500 ohm, one 2,950 ohm, one 3,400 ohm, one 12 ohm, and one 180 ohm sections (R19, R28, R31, R32, R33)	.90
14284	Resistor—22,000 ohms, 1/10 watt (R24)	.15
13998	Resistor—22,000 ohms, ¼ watt (R4)	.20
11300	Resistor—33,000 ohms, 1/10 watt (R27, R30)	.15
12454	Resistor—33,000 ohms, ¼ watt (R6)	.20
14560	Resistor—100,000 ohms, ¼ watt (R35)	.20
12264	Resistor—220,000 ohms, ¼ watt (R5, R36, R42) (R42 Models U-126 and U-128 only)	.20
11398	Resistor—220,000 ohms, 1/10 watt (R14)	.15
11453	Resistor—270,000 ohms, 1/10 watt (R16, R29)	.15
11452	Resistor—470,000 ohms, 1/10 watt (R1)	.15
12285	Resistor—470,000 ohms, ¼ watt (R8)	.20
12013	Resisor—1 meg., 1/10 watt (R7, R26)	.15
30208	Resistor—1.2 meg., ¼ watt (R22, R41) (R41 Models U-126 and U-128 only)	.20
11981	Resistor—1.5 meg., 1/10 watt (R40) (Models U-126 and U-128 only)	.15
5131	Resistor—2.2 meg., 1/10 watt (R3)	.15
14887	Retainer—Indicator pointer drive cord pulley retainer	.01
31233	Rotor—Selector rotor disc—mounts on rear of variable condenser shaft	1.16
31241	Screw—¼ x 20 headless, cone point set screw for flywheel	.02
4119	Screw—No. 8-32 headless set screw for gear Stock No. 31239	.02
14350	Screw—No. 8-32 square head set screw for selector rotor disc	.03
4669	Screw—No. 8-32 square head set screw for pulley Stock Nos. 31271 and 31272, and drum Stock No. 31273	.03
31364	Socket—Dial lamp socket	.20
13871	Socket—Magic Eye socket	.45
31347	Socket—Pickup socket and bracket	.30
31251	Socket—Tube socket	.25
31365	Socket—Tuning indicator lamp insulated socket	.30
31279	Spring—Band indicator tension spring	.03
31232	Spring—Contact tip spring for station-setting contact	.01
13638	Spring—Indicator pointer drive cord tension spring	.08
31418	Spring—Variable condenser drive cord tension spring	.05
12007	Spring—Retaining spring for core Stock No. 31269	.02
31230	Spring—Station-setting contact body spring	.01
31262	Spring—Tension spring for core Stock No. 31260	.01
31242	Spring—Tension spring for flywheel	.01
31313	Spring—Tension spring for push button switch latch bar	.06
31494	Spring—Variable condenser motor rotor adjustment bearing spring for 25 cycle models only (Models U-126 and U-128 only)	.02
31493	Spring—Variable condenser motor rotor adjustment bearing spring for 50-60 cycle models only (Models U-126 and U-128 only)	.02
31236	Support—Variable condenser drive gear mounting support and studs assembly	.65
31245	Support—Variable condenser motor mounting support and studs for 25 cycle models only (Model 910KG only)	.70
31490	Support—Variable condenser motor mounting support and studs for 25 cycle models only (Models U-126 and U-128 only)	.60
31244	Support—Variable condenser motor mounting support and studs for 50-60 cycle models only (Model 910KG only)	.45
31489	Support—Variable condenser motor mounting support and studs for 50-60 cycle models only (Models U-126 and U-128 only)	.35
31360	Switch—Pickup switch for mounting on push button switch assembly (S3)	2.70
31291	Switch—Range switch (S1, S2)	.95
31312	Switch—Station selector push button switch and bracket complete	4.25
31248	Tone Control—H.f. tone control and power switch (R12, S4)	1.50
31267	Transformer—First i-f transformer (L8, L9, C11, C12)	2.20
31268	Transformer—Second i-f transformer (L10, L11, C13, C14)	2.05
31308	Transformer—Power transformer 105/130-140/160-200/250 volts, 50-60 cycle (T1)	13.85
31226	Transformer—Power transformer 110 volts, 25-60 cycle (T1)	13.00
31225	Transformer—Power transformer 110 volts, 50-60 cycle (T1)	8.50
31450	Volume Control (R9) (Model 910KG only)	1.50
31249	Volume Control (R9) (Models U-126 and U-128 only)	1.50
14531	Capacitor—25 mfd. (C34) (Model 910KG)	1.55
31237	Clutch—Variable condenser drive gear clutch and pinion gear—engages pin on motor shaft—50-60 cycle models only	.35
31544	Clutch—Variable condenser drive gear clutch and pinion gear—engages pin on motor shaft—25 cycle models only	.45
31293	Coil—"A" band antenna coil (L5, L6, L7)	1.30
31296	Coil—"A" band oscillator coil (L17)	1.05
31294	Coil—"B" band antenna coil (L3, L4)	.80
31295	Coil—"B" and "C" band oscillator coil (L15, L16)	.85
31297	Coil—"C" band antenna coil (L1, L2)	.90
31290	Condenser—3-gang variable condenser (C3, C4, C7, C8, C32)	6.50
31231	Contact—Contact tip for station-setting contact.	.06
31345	Contact—Push button switch contacts—comprising 10 contacts riveted on insulating strip	.70
31344	Contact—Push button switch contacts—comprising 13 contacts riveted on insulating strip	1.20
31278	Cord—Band indicator drive cord	.12
31281	Cord—Indicator pointer drive cord	.50
31283	Cord—Variable condenser drum drive cord	.20
31269	Core—Adjustable core and stud for i-f transformers	.15
31260	Core—Adjustable core and stud for "A" band oscillator coil	.35
31273	Drum—Indicator drive cord drum	.80
31240	Flywheel—Variable condenser drive motor flywheel	.25
31239	Gear—Variable condenser knob shaft drive gear and hub	.65
31545	Gear—Variable condenser intermediate drive gear and pinion gear—25 cycle models only	.40
31238	Gear—Variable condenser intermediate drive gear and pinion gear—50-60 cycle models only	.50
31304	Indicator—Band indicator strip (Model 910KG)	.15
31532	Indicator—Band indicator strip (Models U-126 and U-128)	.15
11891	Lamp—Dial, pilot, or compartment lamp, 6.3 V, 0.25 amp	.17
31480	Lamp—Electric tuning adjustment indicator lamp, 6.3 V, 0.15 amp	.20
31243	Leather—Friction leather for flywheel	.04
31346	Lock—Push button switch lock plate—comprising 10 contact locks in one strip	.80
31246	Motor—Variable condenser drive motor (M1)—25 cycle models only	6.50
31235	Motor—Variable condenser drive motor (M1)—50-60 cycle models only	4.85
31228	Plate—Selector contact plate—less contacts	.45
31227	Plate—Selector mounting plate—mounts on rear of variable condenser	.50
30868	Plug—2-contact female plug for phono. motor cable (Models U-126 and U-128)	.35
	MOTORBOARD ASSEMBLIES Model U-126	
31536	Coupling—Flexible motor coupling complete	2.10
9848	Cup—Used needle cup and lid complete	.75
31465	Mounting—Pickup arm base rubber mounting	.10
31535	Pin—Drive pin to fasten flexible coupling to turntable shaft	.03
30870	Plug—2-contact male plug for automatic switch leads	.35
14195	Screw—Set screw for flexible coupling	.05
30100	Springs—1 set of springs for automatic switch	.08
31155	Spring—Used needle cup cover tension spring	.04
31147	Strip—Complete set of rubber strips for flexible couplings	.40
31534	Switch—Automatic switch and lever complete	2.75
31467	Switch—Switch only for automatic switch (S7)	.35
31533	Turntable—Turntable with spindle shaft and nose complete	4.95
31537	Washers—Turntable bearing and shim washers.	.06
	MOTORBOARD ASSEMBLIES Model U-128	
31149	Base—Tone arm mounting base	.35
31152	Board—Record changer base complete with all welded and riveted posts and bearings—less all operating parts	7.90
14209	Bumper—Main lever rubber bumper (1)	.08
9848	Cup—Used needle cup, rest, and lid complete	.75
31148	Escutcheon—Index escutcheon	.40
31151	Guide—Pickup lift cable guide (coil spring, 80T 2-in. large) (2)	.10
31150	Mounting—Pickup arm base rubber mounting complete	.45
31155	Spring—Needle cup lid tension spring	.04
	OPERATING MECHANISM Model U-128	
31134	Bracket—Pickup locating lever mounting bracket (3)	.30
31144	Cam—Cam and gear assembly (4)	2.80
6808	Clutch—Trip lever friction clutch assembly (5)	.35
31146	Coupling—Motor coupling complete with turntable drive gear, rubber strips, motor coupling, and drive arm (6)	1.80
31129	Cover—Cap for top of record post	.45
31116	Finger—Trip lever friction finger assembly (7)	.45
31119	Gear—Long arm and rack gear for front left-hand record post (8)	.60
31120	Gear—Short arm and rack gear for rear right-hand record post (9)	.55
31121	Gear—Record post gear (10)	.90
31123	Guide—Main lever spring guide (11)	.40
31114	Lever—Index lever assembly (12)	.75
31137	Lever—Index lever tension spring lever (13)	.30
31138	Lever—Locating lever and pawl assembly (14)	.70
31113	Lever—Main lever assembly (15)	1.35
31140	Lever—Pickup lift cable lever and spring assembly (16)	.55
31135	Lever—Pickup locating lever assembl. (17)	.85
31130	Lever—Record separator elevating lever complete with adjustment screws (18)	.80
31132	Lever—Trip detaining lever (19)	.30
31115	Lever—Trip lever assembly (20)	1.85
31131	Lever—Trip regulator lever (21)	.25
31133	Pawl—Trip pawl assembly (22)	.80
31124	Pin—Record post drive pin (23)	.04
14207	Roller—Pickup lift cable roller and bracket assembly (24)	.55
31118	Screw—Cone pointed set screw for trip lever hub or record post shelf	.06
4563	Screw—Pickup lift cable screw and nuts	.04
14195	Screw—Set screw for flexible coupling	.05
31117	Screw—Special screw to adjust friction clutch tension	.03
31126	Separator—Record separator knife (25)	.75
31122	Shaft—Record separator post shaft (26)	.40
31125	Shelf—Record post shelf assembly (27)	1.25
31141	Spindle—Turntable spindle shaft and spring	1.40
3676	Spring—Cam pawl tension spring on main gear (12 turns, .190-in. O.D., 43/64-in. lg.)	.04
14190	Spring—Pickup locating lever short spring or locating lever pawl tension spring (28) (16 turns, .180-in. O.D., 19/32-in. lg.)	.08
31145	Spring—Main lever tension spring (29) (18 turns, 9/16-in. O.D., 3-in. lg.)	.05
31136	Spring—Pickup locating lever long spring or index lever tension spring (30) (25 turns, .190-in. O.D., 15/16-in. lg.)	.05
3666	Spring—Pickup lift cable tension spring (31) (20 turns, .195-in. O.D., 1-in. lg.)	.04
31127	Spring—Record separator pressure spring (32) (8 turns, ⅜-in. O.D., ¾-in. lg.)	.02
14191	Spring—Trip detaining lever or locating lever tension spring (33) (15 turns, .190-in. O.D., ¾-in. lg.)	.04
31142	Spring—Turntable spindle spring	.03
31147	Strip—Complete set of rubber strips for flexible coupling	.40
31139	Turntable Assembly—less spindle	3.35
31128	Washer—"C" washer for top of record post	.04
31143	Washers—Turntable thrust washers (1 steel, 1 bronze, 1 felt)	.15
	MOTOR ASSEMBLIES Models U-126, U-128	
11703	Governor—Motor speed governor	3.05
31448	Motor—105-125 volts, 25 cycle (M2)	23.70
31163	Motor—105-125 volts, 50-60 cycle (M2)	20.50
31157	Motor—105-125 volts, 60 cycle (M2)	17.75
30868	Plug—2-contact female plug for motor leads (Model U-126 only)	.35
30870	Plug—2-contact male plug for motor power cable	.35
31447	Screw—Complete set of motor mounting screws, washers, and spacers—for 25 cycle models only	.40
31158	Screw—Complete set of motor mounting screws, washers, and spacers—for 50-60 cycle models only	.25
14206	Switch—Motor toggle switch (S7) (Model U-128 only)	.90
	PICKUP AND ARM ASSEMBLIES Model U-126	
31469	Base—Pickup arm base and pivot shaft	.95
31156	Crystal—Pickup crystal cartridge and needle screw	4.25
31468	Pickup and arm complete	7.50
31160	Screw—Pickup needle screw	.12
31161	Shaft—Pickup pivot arm and shaft assembly	.45
	PICKUP AND ARM ASSEMBLIES Model U-128	
31162	Cable—Pickup arm lift cable and clips	.15
31156	Crystal—Pickup crystal cartridge and needle screw	4.25
31159	Pickup and arm complete	7.45
31160	Screw—Pickup needle screw	.12
31161	Shaft—Pickup pivot arm and shaft assembly	.45
	SPEAKER ASSEMBLIES	
13866	Cap—Dust cap for cone center	.03
11234	Coil—Field coil (L12)	3.85
11469	Coil—Neutralizing coil (L14)	.30
31275	Cone—Speaker cone and voice coil (L13)	1.75
5039	Plug—4-contact male plug for speaker (Model 910KG only)	.30
31539	Plug—5-contact male plug for speaker (Models U-126 and U-128 only)	.25
31530	Speaker complete (RL70H-2) (Model 910KG only)	12.35
31538	Speaker complete (RL70H-4) (Models U-126 and U-128 only)	10.65
14534	Transformer—Output transformer (T2)	3.65
14357	Washer—Spring washer to hold field coil securely	.06
	MISCELLANEOUS ASSEMBLIES	
31358	Button—Station selector push buttons	.15
13103	Cap—Pilot lamp cap (Bulls Eye) (Models U-126 and U-128 only)	.15
31456	Cover—8-protective covers for push button markers	.08
31540	Cushion—Chassis mounting cushion and screw assemblies—sufficient for one chassis (Models U-126 and U-128 only)	.50
31541	Cushion—Motor plate mounting cushion and clamp assembly—sufficient for one instrument (Models U-126 and U-128 only)	.50
31451	Dial—Station selector dial scale and crystal	.95
31356	Escutcheon—Tuning dial escutcheon—less dial and buttons (Model 910KG only)	2.65
31361	Escutcheon—Tuning dial escutcheon—less dial and buttons (Models U-126 and U-128 only)	2.20
30698	Hinge—Cabinet lid hinge (Models U-126 and U-128 only)	.95
31305	Indicator—Station selector indicator pointer (Model 910KG only)	.40
31542	Indicator—Station selector indicator pointer (Models U-126 and U-128 only)	.35
31355	Knob—Station selector, volume control, tone control, or range switch knob	.12
31458	Marker—"Dial Tuning" push button marker	.01
31457	Marker—"Record Player" push button marker	.01
31589	Marker—Station call letter push button markers	.35
31760	Screen—Compartment lamp screen (Models U-126 and U-128 only)	.20
31306	Screen—Dial color screen	.45
11210	Screw—Chassis mounting screws and washers—(4 required) (Model 910KG only)	.05
14270	Spring—Retaining spring for knob Stock No. 31355	.05
31470	Suspension—Motor board suspension springs, screw, and lockwasher (4 required) (Models U-126 and U-128 only)	.10
11831	Support—Cabinet lid support (Models U-126 and U-128 only)	1.85
	ANTENNA ASSEMBLIES	
31426	Counterpoise Line—Additional length 60 ft. long	1.35
12426	Insulator—Strain and counterpoise insulator	.05
9816	Transmission Line—Additional length 60 ft. long	1.50

ALL PRICES ARE SUBJECT TO CHANGE OR WITHDRAWAL WITHOUT NOTICE.

MODEL 911K
Schematic
Lead Dress

RCA MFG. CO., INC.

RCA Victor Master Antenna Kit.—Connect the twisted-pair transmission line to terminals A1 and A2 on the terminal board at rear of chassis. Connect the counter-poise to A3. Terminal G may be connected to ground, but this connection is not necessary for correct operation.

Noise-Reducing Adjustment.—After the RCA Victor Master Antenna Kit is connected to the receiver, tune the receiver to a point near 900 kc where no station is heard. Turn volume control clockwise until noise is heard. If no noise of a regular character is audible, start any brush-type motor-driven appliance, such as a vacuum cleaner, electric razor, refrigerator, etc., but do not bring it too near the receiver. This will generate noise as a continuous crackling, or buzz. Adjust C1 to a point where this noise is reduced to a minimum.

IF PEAK 455 KC

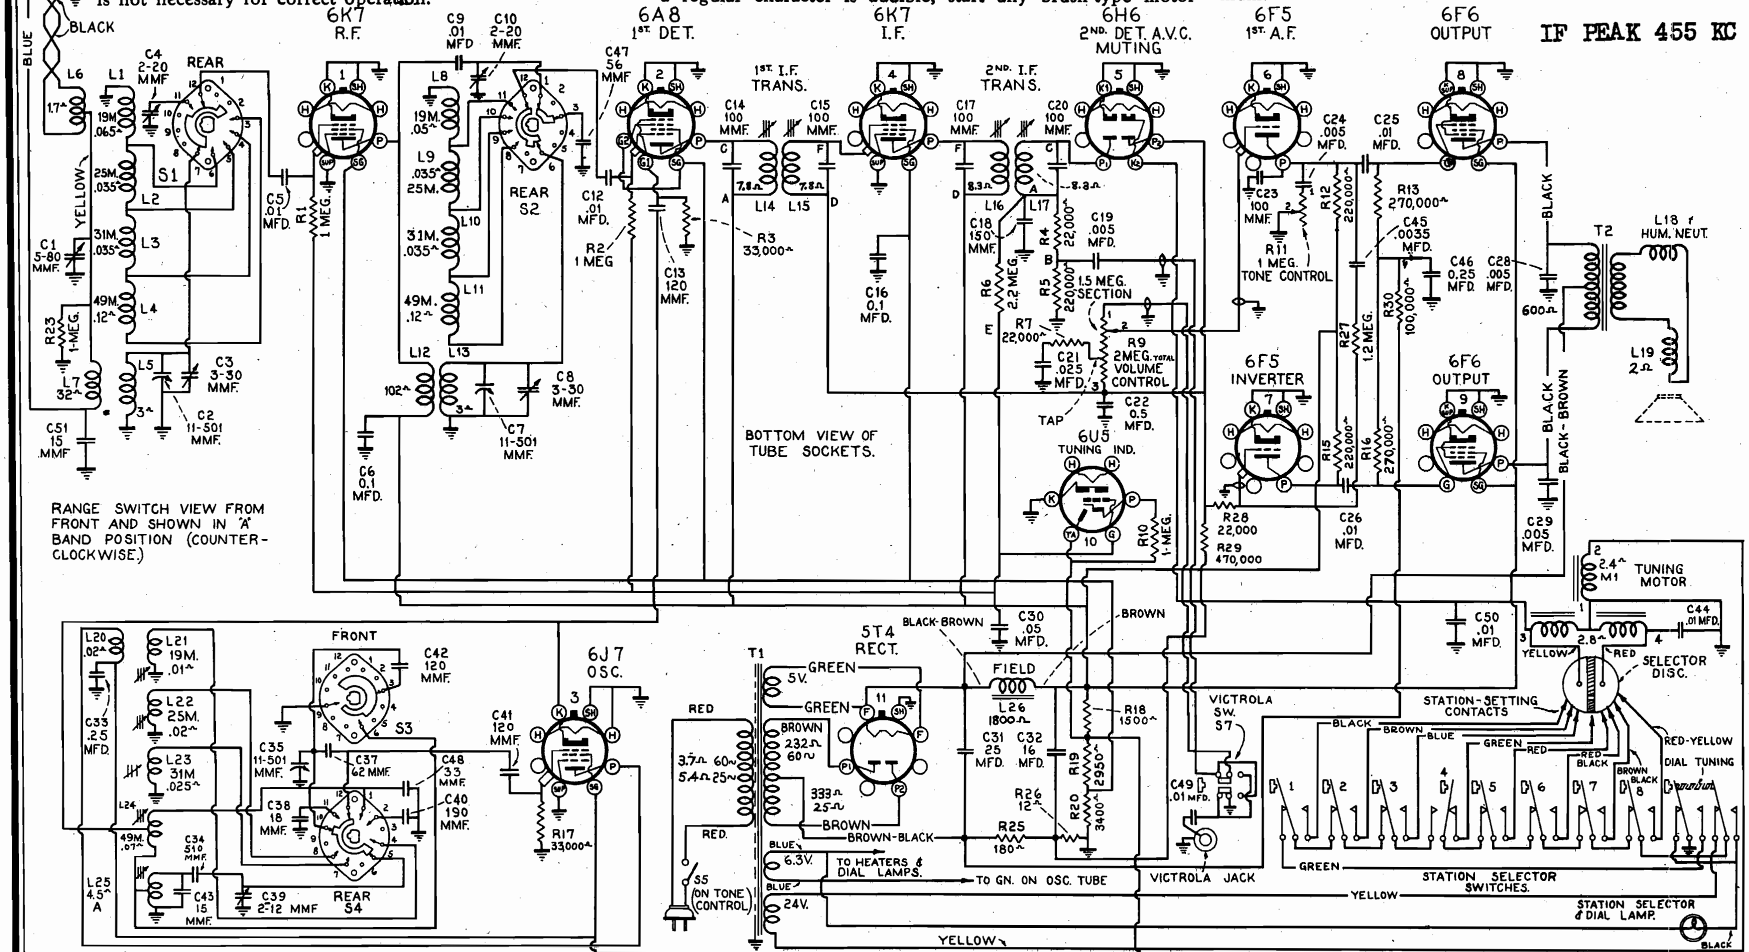

Figure 4—Schematic Circuit Diagram

Precautionary Lead Dress.—

(1) Keep tuning tube cable and the lead from the left pilot light away from the 6F5 grid cap.

(2) Leads on spread-band antenna and r-f coils should be kept short as possible.

(3) Keep black lead from L25 away from C38 and L24.

(4) Keep black lead from L25 to cathode lug on 6J7 away from R17.

(5) The power cord lead and the primary lead of the power transformer which connect to the power switch should be twisted together.

(6) Keep C13 away from the 6A8 control grid lead and from the chassis.

(7) Shielded leads to Victrola jack must be dressed away from switch terminals and jack.

(8) Blue and black leads from antenna board to coils must be twisted.

(9) Black lead and condenser which connect to 6F6 plate should be kept away from inverter grid lead and resistors which connect to it.

MODEL 911K
Chassis Wiring, Transformer
Voltage, Specs.

RCA MFG. CO., INC.

This receiver employs an eleven-tube, three-band "Magic Brain" superheterodyne circuit, the arrangement of which is shown in the Schematic Circuit Diagram. Features of design include electric tuning for eight broadcast stations; push-pull power output stage; magnetite-core i-f transformers; magnetite-core "A" band oscillator tracking adjustment; temperature-stabilized capacitors; four spread-bands; automatic volume control; jack and switch for Victrola attachment; "Magic Eye" tuning tube; 12-inch, dust-proof electrodynamic loudspeaker; aural-compensated audio volume control; continuously variable high-frequency tone control; provision for armchair control attachment; new straight-line dial; illuminated band indicator; noise-reducing adjustment on "A" band and noise reduction on "C" band with RCA Victor Master Antenna; air-core trimmer condensers.

Pilot Lamps .... One Mazda 47, 6-8 volts, .15 amp; Two Mazda 44, 6.3 volts, .25 amp.

Power Supply Ratings

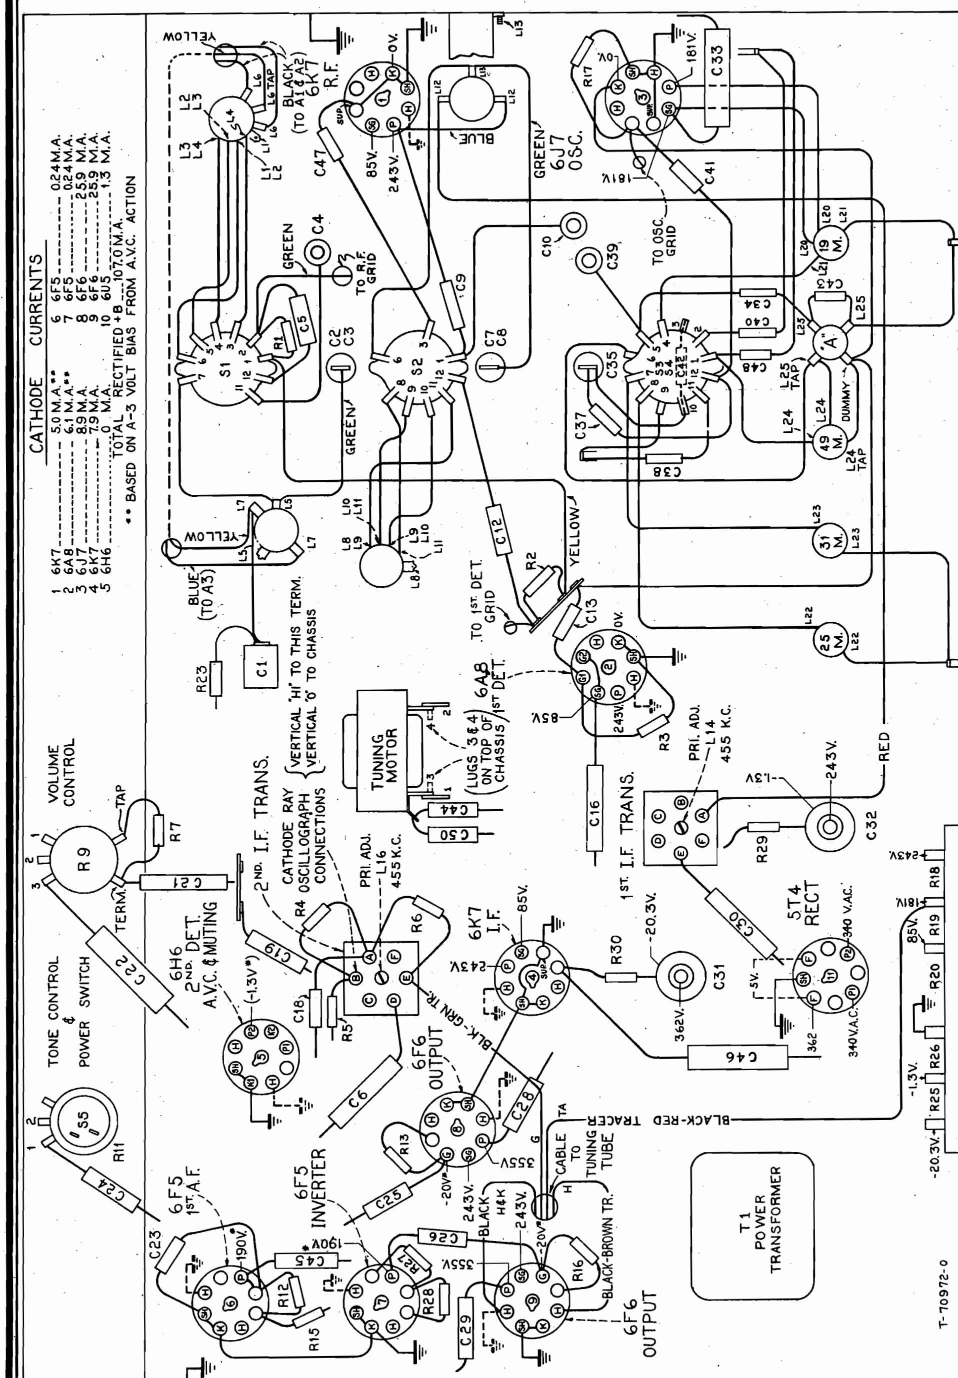
Rating A .... 105-125 volts, 50-60 cycles, 120 watts
Rating B .... 105-125 volts, 25-30 cycles, 120 watts
Rating C .... 105-125/140-160/195-250 volts, 50-60 cycles, 120 watts

Power Output

Undistorted .... 10 watts
Maximum .... 12 watts

Loudspeaker

Type .... 12-inch Electrodynamic
Voice Coil Impedance .... 2.2 ohms at 400 cycles



Measurements made to chassis unless otherwise indicated, with set tuned to quiet point and volume control at minimum. Values should hold within approximately ±20% with 117-volt a-c supply.

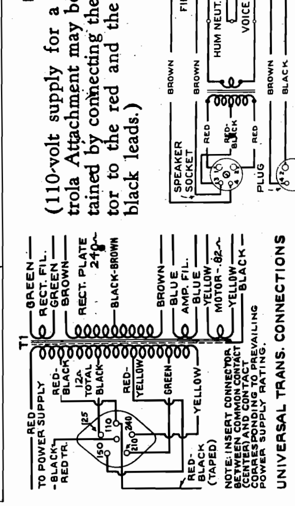
*NOTE: Values with star (*) are operating voltages in circuits with high series-resistance. The actual measured voltages will be lower, depending on the voltmeter loading.

R-F Alignment Frequencies

"Standard Broadcast" (A) ..... 1,500 kc (osc., det., ant.), 600 kc (osc.)
"49 Meter Band" .... 6,100 kc (osc.)
"31 Meter Band" .... 9,600 kc (osc., det., ant.)
"25 Meter Band" .... 11,800 kc (osc.)
"19 Meter Band" .... 15,200 kc (osc.)

Frequency Ranges

"Standard Broadcast" (A) .... 540-1,720 kc
"49 Meter Band" .... 5,920-6,230 kc
"31 Meter Band" .... 9,480-9,690 kc
"25 Meter Band" .... 11,680-11,940 kc
"19 Meter Band" .... 15,080-15,390 kc
Intermediate Frequency .... 455 kc



(110-volt supply for a Victrola Attachment may be obtained by connecting the motor to the red and red-black leads.)

Above — Universal Power Transformer Connections.

RCA MFG. CO., INC.

Electric Tuning Mechanism

The circuit of the electric tuning mechanism is shown in the schematic diagram, and the mechanical details are illustrated below.

The action can be understood by following a cycle of operation:

When a station button is pushed in, it completes the 24-volt circuit through the corresponding station-setting contact and one-half of the brass selector disc, which is connected to one side of the motor field coil. This energizes the motor, and the rotor is pulled forward, engaging with the gear train that drives the tuning condenser and selector disc. The condenser and disc rotate until the insulation line comes under the particular station-setting contact, and the motor circuit is broken. Inertia carries the insulation line past the station-setting contact which then makes contact to the other half of the disc. This completes the circuit to the other side of the motor field coil, causing the motor to reverse. The floating flywheel is still turning in the original direction and therefore slows down the reversal movement of the motor; as a result the selector disc is moved slowly back until the insulation line is under the station-setting contact, when the circuit is broken and the mechanism stops.

Adjustment of Flywheel Friction

In normal operation, the motor drives the tuning condenser and selector disc until the insulation line just passes the particular station-setting contact: The motor then reverses and moves the disc slowly in the opposite direction until the insulation line is under the contact, and the mechanism stops.

In some cases, particularly with high line-voltage, the disc may make two or three reversals before stopping.

The flywheel friction adjustment screw should be set to give the least number of reversals with the chassis in normal horizontal position.

Adjustment of Selector Disc

The brass selector disc is fastened to the rear shaft of the tuning condenser by means of two set-screws. When the condenser is at maximum (plates fully meshed) the insulation line should be horizontal, with the operating-end at the left (viewed from rear). The operating-end has dark insulating material and the brass is beveled at this end.

The selector disc should be set so that the contact-tip plungers in the station-setting contacts project not more than 1/16-in. from the body of the contacts.

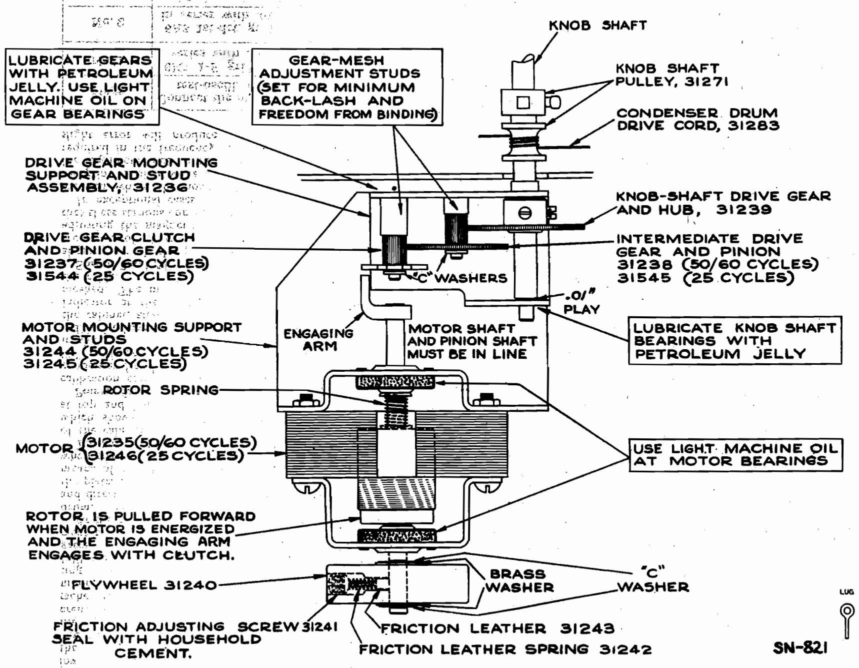


Figure 5—Motor and Gear Mechanism

There must be 1/32-inch clearance between the end of the engaging arm and the face of the intermediate gear when the motor is in its full forward position.

SN-821

Muting Circuit

When the electric tuning mechanism is in action, the motor-supply voltage is fed into a diode rectifier circuit which applies a high bias to the I-F and first-audio tubes. This prevents audio amplification and makes the set quiet or "mute" while the mechanism is operating.

Lubrication

Motor bearings and **gear bearings**; use light machine oil.
Gear faces; use "Pure-Oil No. 611" or petroleum jelly.
Dial-indicator pulleys and **rails**; use "Castordag" or petroleum jelly.
Selector disc; apply *thin* film of petroleum jelly.
Friction leather on flywheel; apply "neats-foot" oil. When replacing leather, soak it for at least 24 hours in neats-foot oil, and insert in flywheel while dripping.

Armchair Control Unit

When a Model G8A Armchair Control is connected to the receiver as shown in figure 7 it duplicates the action of the push-buttons on the front panel when No. 1 button is pressed down. The black lead from push-button No. 1 is unsoldered from No. 1 station-setting contact and soldered to a terminal board which is to be mounted on the frame of selector mechanism. In some cases one of the other seven station buttons on the set may be used in place of No. 1 button for the operation of the Armchair Control.

This arrangement allows the use of only seven of the eight buttons when tuning in stations at the set, but allows the use of the entire eight buttons on the Model G8A Armchair Control. In operating the G8A Armchair Control the push-button must be held down until the station has been tuned in. Care must be taken not to hold two of the station-buttons down at one time as both windings of the motor may be engaged simultaneously causing the motor to be inoperative and overheated.

ADJUSTMENTS FOR ELECTRIC TUNING

1. Make a list of the desired eight stations, arranged in order from low to high frequencies.

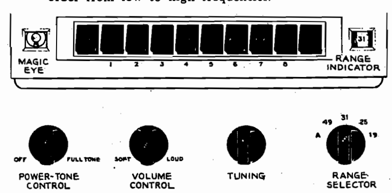

Figure 6—Location of Controls

The left-hand push-button is a Victrola-Attachment switch. The right-hand push-button is for dial tuning.

2. Turn range selector to "A" band, turn power on, and allow a few minutes for warming up.
3. Press down the "dial-tuning" (right-hand) button.
4. Manually tune in the first station on the list, using the "Magic Eye" for accurate tuning.
5. Hold down the "dial-tuning" button, and press down station button No. 1 (second from left). Both buttons will stay down. Move station-setting contact No. 1 to the insulating line on the disc at rear of gang. When the contact is correctly centered on the insulating line, the central dial lamp will go out.
6. Press down any other button in order to release the dial-tuning button and station button No. 1. Then press down station button No. 1 again. The electric tuning mechanism will function to tune in the station, and the central dial lamp will stay on.
7. Repeat this process for the remaining stations.

Figure 7—Station-Setting Contacts and Selector Disc

This illustration shows connections for a G8A Armchair Control Unit. This unit is not supplied with the receiver but may be added as an accessory.

MODEL 911K
Alignment, Socket
Trimmers, Parts

RCA MFG. CO., INC.

ALIGNMENT PROCEDURE

Cathode-Ray Alignment is the preferable method. Connections for the oscillograph are shown in the chassis drawing.

Output Meter Alignment.—If this method is used, connect the meter across the voice coil, and turn the receiver volume control to maximum.

Test-Oscillator.—For all alignment operations, connect the low side of the test-oscillator to the receiver chassis, and keep the output as low as possible to avoid a-v-c action.

Calibration Scale on Indicator-Drive-Cord Drum.—The tuning dial is fastened in the cabinet and cannot be used for reference during alignment, therefore a calibration scale is attached to the rear of the indicator-drive-cord drum which is mounted on the front shaft of the gang condenser. The setting of the gang condenser is read on this scale, which is calibrated in degrees. The correct setting of the gang in degrees, for each alignment frequency, is given in the alignment table.

As the first step in r-f alignment, check the position of the drum. The "0" mark on the drum scale must be vertical, and directly over the center of the gang-condenser shaft when the plates are fully meshed. The drum is held to the shaft by means of two set screws, which must be tightened securely when the drum is in the correct position.

To determine the corresponding frequency for any setting of the calibration scales, refer to the accompanying drawing which shows the dial with 0-180° calibration scales drawn at top and bottom.

Pointer for Calibration Scale.—Improvise a pointer for the calibration scale by fastening a piece of wire to the gang-condenser frame, and bend the wire so that it points to the "0" mark on the calibration scale when the plates are fully meshed.

Dial-Indicator Adjustment.—After fastening the chassis in the cabinet, attach the dial indicator to the drive cable with indicator at the 530 kc mark, and gang condenser fully meshed. The indicator has a spring clip for attachment to the cable.

Spread-Band Alignment.—The most satisfactory method of aligning or checking the spread-band ranges is on actual reception of short-wave stations of known frequency, by adjusting the magnetite-core oscillator coil for each band so that these stations come in at the correct points on the dial.

In exceptional cases, when the set is being serviced in a location where the noise level is high enough to prevent reception of short-wave stations, a test-oscillator may be used for alignment, but an extremely high degree of accuracy is required in the frequency settings of the test-oscillator, as a slight error will produce considerable inaccuracy on the spread-band dials. The frequency settings of the test-oscillator may be checked by one or both of the following methods:

1. Determine the exact dial settings of the test-oscillator (for frequencies at or close to the specified alignment frequencies) by zero-beating the test-oscillator against short-wave stations of known frequency.
2. Use harmonics of the standard-broadcast range of a test-oscillator, first checking the frequency settings on this range by means of a crystal calibrator (RCA Stock No. 9572), or by zero-beating against standard broadcast stations.

When a test oscillator is employed for spread-band alignment, a final check should be made on actual reception of short-wave stations of known frequency, and the magnetite-core oscillator coil for each band should be re-adjusted so that the stations come in at the correct points on the dial.

For additional information, refer to booklet "RCA Victor Receiver Alignment."

Using RCA Stock No. 150 Test Oscillator.—When using this oscillator for spread-band alignment, insert an open-circuit plug in the "EXT. MOD." jack, and set the test-oscillator dial 800 kc lower than the desired frequency for the four lower frequency ranges, and 800 kc higher than the desired frequency for the two high ranges. This provides an unmodulated signal of the desired frequency and the magic eye may be used as an output indicator for this unmodulated signal.

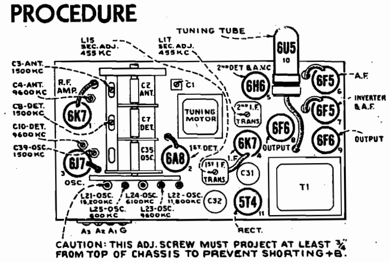

Figure 2—Tube and Trimmer Locations

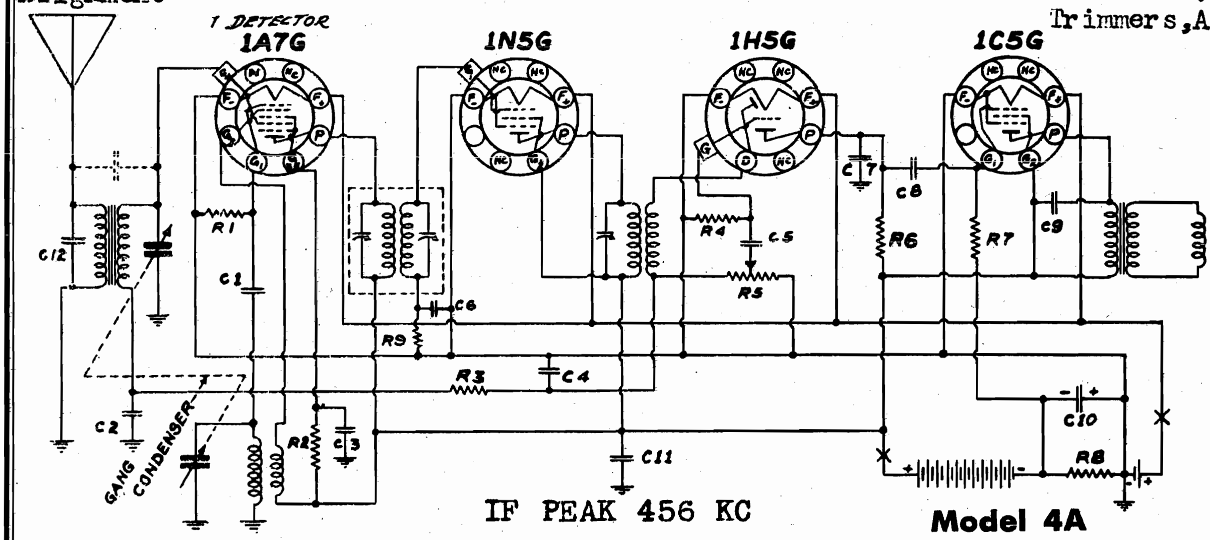
MODEL 4A
Schematic, Socket
Trimmers, Alignment



IF PEAK 456 KC

Model 4A

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band alignment should be the next procedure.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all three I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1730 KC and connect the output to the antenna lead (Blue) through a*.0002 mfd. mica condenser. Set the gang condenser to minimum capacity and adjust the gang condenser trimmer (oscillator) to receive this signal. After this has been carefully done, the next step is to set the generator to 1400 KC and after tuning in the signal adjust the antenna trimmer to peak. This is all that is necessary for the alignment unless the plates of the gang condenser have been bent out of shape. In case of bent plates, set the test oscillator and the receiver to 600 KC and bend the plates into the position for maximum sensitivity over the tuning range.*50 MMF. (MODEL 55)

4 TUBE 1½ VOLT "AB" BATTERY SUPERHETERODYNE
RANGE 535 - 1730 KILOCYCLES

IT IS ABSOLUTELY NECESSARY THAT A GOOD GROUND BE EMPLOYED WITH THIS TYPE OF RECEIVER.

POWER SUPPLY This receiver is designed to operate on a single unit "Ray-o-vac" No. AB82 Dry "AB" Battery or equivalent. No other batteries are required as this battery is a combination 90 volt "B" battery and 1½ volt "A" battery.

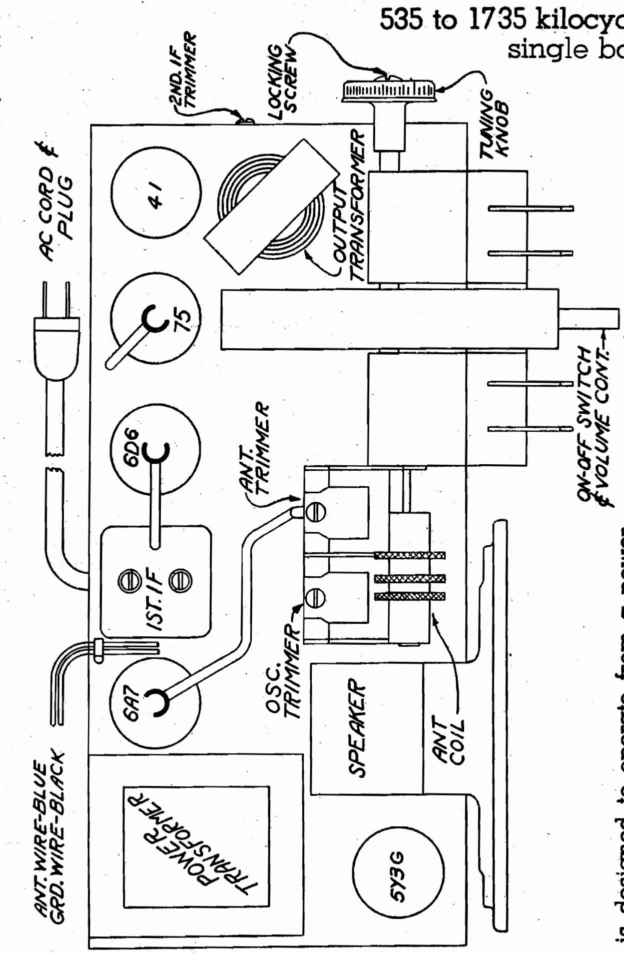
Wherever possible, a good ground should be employed. Water pipes and steam or hot water radiators make a very desirable ground connection. The ground wire should be connected to the "Black" lead.

Five Tube A.C. Superheterodyne

535 to 1735 kilocycles single band.

5A Chassis



This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band alignment should be the next procedure.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all three I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1730 KC and connect the output to the antenna lead (Blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum capacity and adjust the gang condenser trimmer (oscillator) to receive this signal. After this has been carefully done, the next step is to set the generator to 1400 KC and after tuning in the signal adjust the antenna trimmer to peak. This is all that is necessary for the alignment unless the plates of the gang condenser have been bent out of shape. In case of bent plates, set the test oscillator and the receiver to 600 KC and bend the plates into the position for maximum output.

PROCEDURE FOR SETTING UP AND OPERATING AUTOMATIC PUSH BUTTONS

Select four strong local stations tuned in regularly. Now loosen **Locking Screw** (see chassis layout) several turns with a coin or a screw driver and press in any one of the four push buttons. Holding the button down, tune in any one of four selected stations by rotating the tuning knob (side knob) slowly back and forth until the signal is cleared.

Release the push button and press in another button and hold down, tuning in another favorite station with tuning knob. Follow the same procedure for the remaining stations. Now hold tuning knob (side knob) securely and with coin or screw driver, tighten locking screw. This screw holds all stations in adjustment.

In order to change any station already set up, to another, hold tuning knob securely, loosen locking screw and select the new station as explained above. Tear the correct station call letter tabs from the set of sheets supplied and push them into rectangular windows above each push button.

The automatic push button dial is now set up for quick tuning.

6D Chassis

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; **after which, the Short Wave Band may be aligned.**

I.F. ALIGNMENT

With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test oscillator to 456 KC and connect the output of test oscillator or signal generator to the grid of the first detector tube (6A8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the Broadcast "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the Broadcast "antenna" trimmer to a maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver.

Note: Approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the antenna. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 16,000 KC and tuning in the signal. Adjust the "short wave antenna" to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

SCHEMATIC DIAGRAM
MODEL 7G

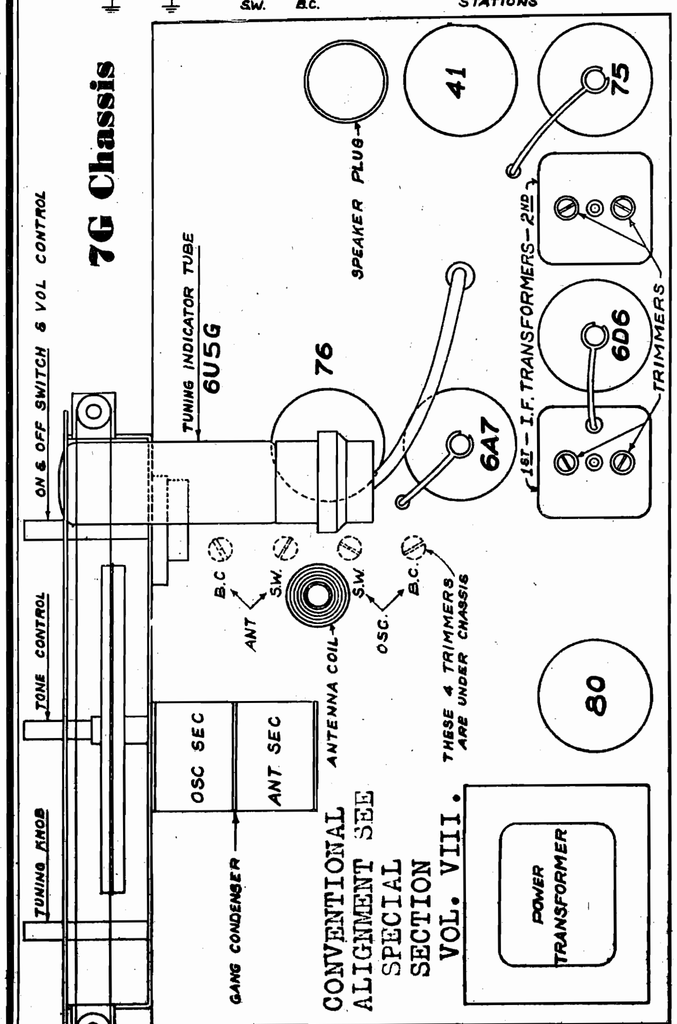
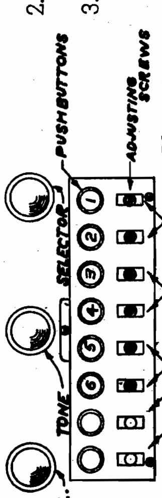
This receiver is designed to operate over two tuning ranges: from 545 to 1720 kc and from 5800 to 18,100 kc



PROCEDURE FOR SETTING UP AUTOMATIC PUSH BUTTONS



A glance at Fig. 1 will show that there are eight (8) push buttons, six (6) of which are for automatic use; the adjusting screws are located directly below these push buttons. Fig. 1 also shows the tuning range or frequencies covered by each button.

The remaining two (2) push buttons, located at the extreme left hand end of the push button plate are for short wave and manual tuning. Short wave tuning is accomplished by pressing "short wave" button and tuning with the selector knob. By pressing "manual tuning" button, the automatic disconnects and the selector knob becomes active for the broadcast band.

1. Choose a station having a frequency within the range of button No. 1 (540 to 980 kc).
2. Press "Manual Tuning" button and tune this station conventionally by using the selector knob.
3. Now press button No. 1 and turn adjusting screw in either direction until the previously selected station is heard. Adjust the screw until the dark area of the "electric eye" is smallest. This setting will give the best tonal response with maximum sensitivity.
4. Remove the call letters of the station from the call letter sheet furnished and insert in the window of the adjusting screw.
5. Repeat the above procedure for the remaining five (5) stations.

NOTE: It is advisable to retain the call letter sheet in case of station change later on.

POWER SUPPLY

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (A.C.). **NEVER PLUG INTO A D.C. OUTLET.**

3. **SETTING UP STATIONS ON PUSH BUTTONS.** Select five (5) favorite powerful local stations. With the dial pointer at the extreme left hand end, loosen knurled locking screw, (see Figures 5 and 6) two (2) full turns. *Now carefully tune in any one of five chosen stations using station selector knob; press in the first button all the way then release.* (There is no sequence of buttons—that is, any station may be set up on any particular button desired.
Note: Should there be any noticable pointer movement while pressing any push button, it is an indication that the knurled locking screw has not been loosened quite sufficiently. Now tune in the second station and press in the second button all the way then release. Repeat the same procedure for the remaining three buttons. After the stations have been set up, tighten the knurled locking screw securely. This screw will lock in place all the stations that have been set up. If you desire to change any station already set up, loosen knurled locking screw two (2) full turns and set up as explained above. Be sure to tighten knurled nut securely when resetting has been completed. Tear the correct station call letter tabs from the set of sheets supplied and insert them into the rectangular openings provided on the front of the push button knob.

SERVICE DATA

The antenna-mixer coil is located adjacent to the variable condenser and is trimmed by the trimmer on the near section of the variable condenser. The oscillator coil is mounted under the chassis and is trimmed by the port trimmer section. The I.F. transformers and trimmers are mounted under the chassis and are adjusted to 450 KC. The antenna filter is located adjacent to the antenna-mixer coil and is tuned to 450 KC to minimize interference from code stations.

AUTOMATIC PUSH-BUTTON TUNING

The receiver is adjusted for selecting five stations by means of the push-buttons. Call letters of these stations are indicated on the buttons. To receive these stations, turn on the set as described in the above paragraph and depress the button corresponding to the desired station. Adjust volume to intensity required.

The knob on the right is the tone control. When turned to the left, the higher audio frequencies are suppressed.

Directions for changing the push-button station set-up are attached to the bottom of the cabinet. A sheet of push-button call letters is furnished with the set. The call letter discs may be removed from the buttons with a pen knife, and other discs pressed in.

SERVICE DATA

The mixer coil is located next to the variable condenser on the top of the chassis. The oscillator coil is on the inside of the chassis. Parallel trimmer condensers are mounted on the variable condenser. The oscillator trimmer is nearest the front of the set.

Trimmers for the I.F. circuit are adjustable through holes in the I.F. shields. The I.F. frequency is 450 KC.

Trimmers for the push-button circuits are accessible through a slot in the bottom of the cabinet. These trimmers have the following approximate tuning ranges.

#1 group	520-850 KC	#4 group 680-1075 KC

SERVICE DATA

The Mixer coil is located next to the variable condenser on the top of the chassis. The oscillator coil is on the inside of the chassis. A trimmer condenser strip is mounted under the chassis. The trimmer nearest the center of the chassis is the broadcast mixer, next to it is the broadcast oscillator and nearest the end of the chassis is the short-wave oscillator trimmer. A trimmer for the short-wave mixer coil is mounted on the short-wave switch.

An antenna filter is mounted on the top of the chassis. The trimmer should be adjusted for minimum signal for 450 K.C. input to the antenna.

Trimmers for the I.F. transformers are adjustable thru holes in the I.F. transformer shield cans. The I.F. frequency is 450 K.C.

SERVICE DATA

The following tubes are used in this receiver:

1 6K7 R.F. Amplifier
1 6L7 Mixer
1 6J5 Oscillator
1 6K7 I.F. Amplifier
1 6H6 Diode Detector
1 6N7 A.F. Amplifier
2 6F6 Power Amplifiers
1 6G5 Tuning Indicator
1 5Z4 Full-wave Rectifier

The R.F. Mixer and Oscillator coils are located in the square shields on the right end of the chassis. Trimmers for these circuits are mounted along the end of the chassis in the following order from front to rear:- R.F. short-wave, Mixer short-wave, Oscillator broadcast, Oscillator medium wave, Oscillator short-wave. The R.F. broadcast and the Mixer broadcast trimmers are mounted on the band switch assembly.

Oscillator pads are located at the rear of the chassis. The broadcast pad is nearest the end of the chassis and the medium wave next.

Trimmers for the I.F. transformers are adjustable thru holes in the I.F. transformer shield cans. The I.F. frequency is 450 K.C.

IF PEAK 450 KC.

MODEL 72

This is a ten tube all-wave receiver with metal tubes. It is designed to operate from a 110 to 125 volt, 50 or 60 cycle power supply.

TUNING RANGES

The lower scale of figures on the dial is the calibration for the broadcast range which extends from 540 to 1715 kilocycles. The medium wave range is indicated by the middle scale of figures which are colored green. This range covers from 1.7 megacycles to 5.7 megacycles and includes the amateur, police and aircraft bands. The upper red scale is the short-wave range and extends from 5.7 to 18 megacycles. The various foreign and American short-wave broadcast bands are included on this range and are denoted by the inscriptions on the scale.

INSTALLATION

When a standard antenna is used, the length should be from 25 to 100 feet. Connect to the blue wire extending from the back of the receiver. The antenna lead-in should be kept clear of all metal objects, such as pipes and wires, an should be run in as straight a line as possible. An indoor antenna may be used for local reception or when the receiver is used in an isolated wooden building. Superior performance on short wave will result from the use of a well constructed doublet antenna, or short wave antenna system. Such antennas are available on the market in kit form with complete instructions for their installation.

A good ground is essential for clearest reception. Connect the black wire to a steam or water pipe. The pipe should be scraped clean before attaching the wire.

OPERATION

With the line cord connected, turn the volume control to the right. the dial should light up brightly. Allow about half a minute for the tubes to warm up and turn the selector knob until the desired program is heard. If too loud reduce the volume by turning the volume control to the left. For best quality the selector should be adjusted for minimum shadow in the tuning indicator which is located in the center of the dial.

MODELS 89,89C

OPERATION - PHONOGRAPH

Switch the receiver to the PHONO position on the change-over switch. Turn the volume control to the right and allow about one half minute for the tubes to warm up.

Grasp, Seven 12-inch or Eight 10-inch Records, line them up with center holes and slip them onto center pin of the turntable.

See that needle is securely fastened by means of the small thumb screw on the front of the pickup. We recommend standard length needles. On an automatic you should use a needle which will play many records without replacing. Your dealer can give you detailed information on this.

All that is necessary to start the phonograph after placing the records on the turn-table and securing the needle in pick-up, is to turn the motor switch, at the right of the turntable, to the ON position.

To play 10-inch records push the thumb stop,on right of tone arm, to the back as far as it will go, and place the lever, on the left of the turntable, in the 10-inch position. Place needle in starting position on top record.

To play 12-inch records pull the thumb stop, on the right of tone arm, as far out as it will go, and place the lever, on the left of turntable in the 12-inch position. Place needle in starting position on top record.

The last record on the turntable automatically repeats.

To reject a record, pull the lever at the base of the tone arm.

Adjust volume and tone by means of the controls on the front of the cabinet.

ALIGNMENT PROCEDURE

I.F.Alignment. Connect a signal generator set at 480kc to the 6A7 input and connect an output meter to the speaker output. Using a weak signal tune the two I.F. condensers on the composite coil and the single I.F. condenser on the output I.F. coil for maximum response.

Connect the signal generator set at 1400kc to the antenna lead using a dummy antenna of 150 mmf. Tune the set by means of the dial to 1400kc position. Adjust oscillator trimmer for this frequency. Then trim antenna stage for maximum response. Repeating the alignment may result in improved sensitivity.

* Readings are comparative voltages only. Voltage readings taken at these points in series with very high resistances.

IF ALIGNMENT: - Conn. test osc. op. to control grid of Osc.Mod (36)- Leave cap off. Set osc. for 265 KC, align IF for max. response.

RF ALIGNMENT: - Set dial and test osc. at 1720 KC, adjust Osc. and Ant. trimmers for max. response. Set dial and test osc. to 600 Kc, Adjust padder at 600 Kc. Repeat adjustments.

SEARS-ROEBUCK & CO.

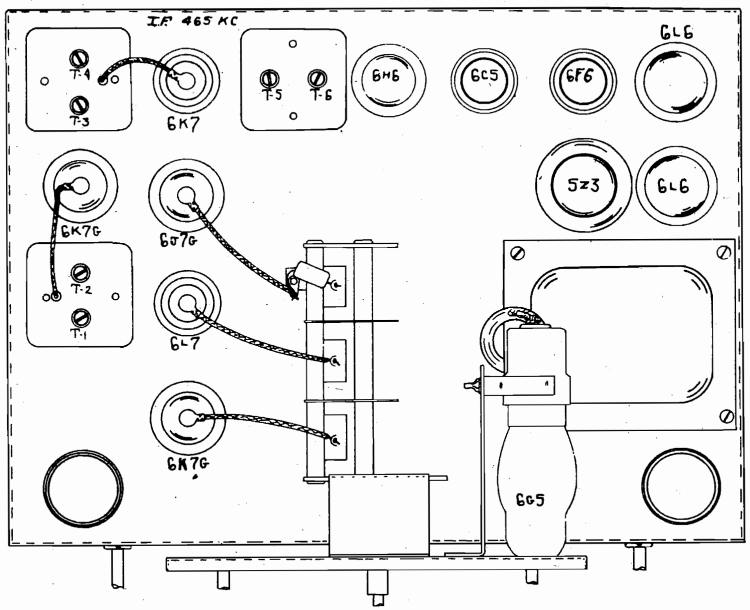

FIG. 4

NOTES ON ALIGNMENT

It is assumed that if an alignment procedure becomes necessary that the service man has an oscillator capable of accurately covering the range of the receiver and that a meter output indicator is used.

The I. F. Stages are aligned in the usual manner by feeding 465 KC into the grid of the 6L7 tube. NOTE: If oscillation is present when aligning the I. F.'s with the sensitivity control full on, reduce the sensitivity slightly until the oscillation stops.

IMPORTANT: ALIGN THE SET WITH THE SELECTIVITY CONTROL ALL THE WAY TO THE RIGHT, IN THE SHARP TUNING POSITION.

Follow Figure 4 and Figure 5 showing trimmer locations and alignment frequency.

Always adjust the oscillator first in any particular band.

Use as low an output as possible from the test oscillator in making the various adjustments.

After trimming at the high frequency end of the dial and adjusting the padding condenser at the other end, always recheck the settings of the trimmer at the high frequency end of the dial.

BE SURE THAT THE ALIGNMENT SIGNAL IS THE TRUE FUNDAMENTAL AND NOT A HARMONIC.

Check for image frequency in the usual manner.

BEFORE STARTING ALIGNMENT CHECK POSITION OF TUNING HAND AND MAKE CERTAIN THAT IT IS EXACTLY STRAIGHT ACROSS ON THE FIRST CALIBRATION LINE WHEN THE CONDENSERS ARE AT MAXIMUM CAPACITY ROTATION.

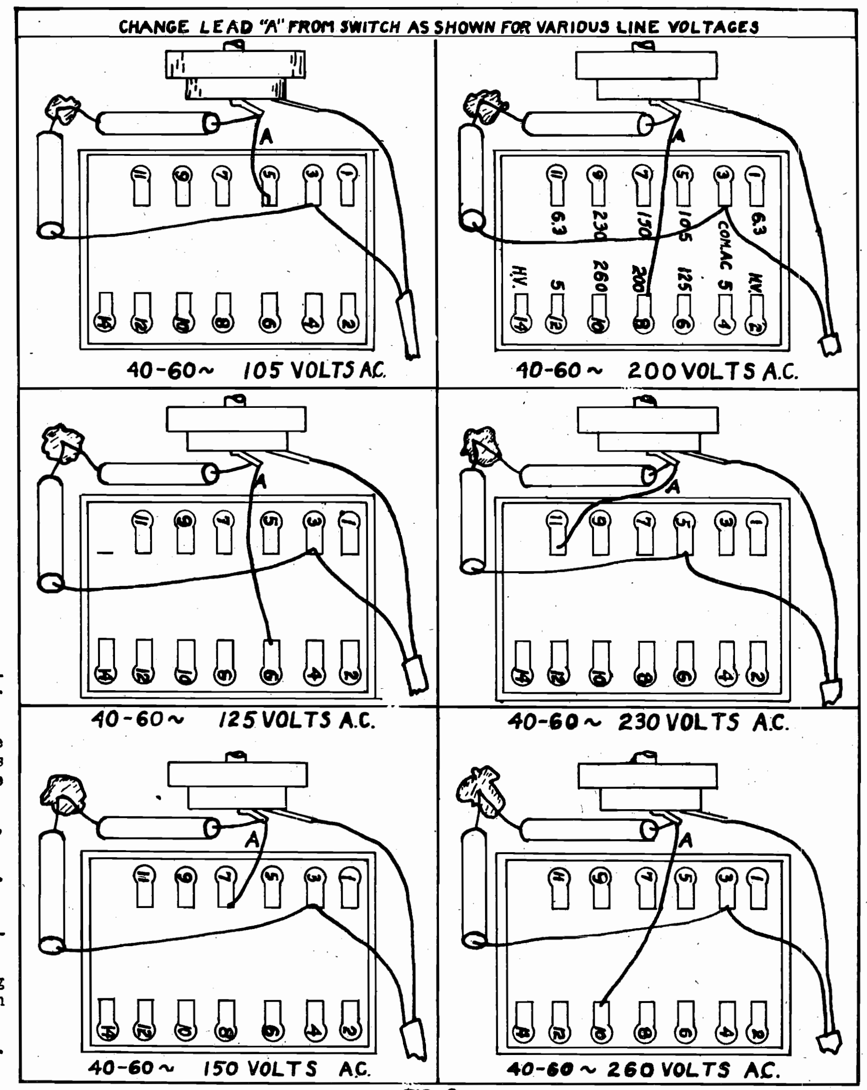

FIG. 3

SEARS-ROEBUCK & CO.

The Phono terminal at the back of the chassis may be used for phanograph connection.

NOTE: WHEN THE PHONOGRAPH IS NOT BEING USED BE SURE AND REMOVE CONNECTION FROM THE TERMINALS OTHERWISE THE RADIO WILL NOT WORK PROPERLY.

With some models a phono-radio switch is used by extending wires from the chassis. This circuit is shown on the schematic diagram.

SOCKET READINGS FOR MODEL A-12 SERIES

All Voltages taken from ground with line voltage 115 volts.
No load in antenna.
Sensitivity control variation changes kathode voltage.

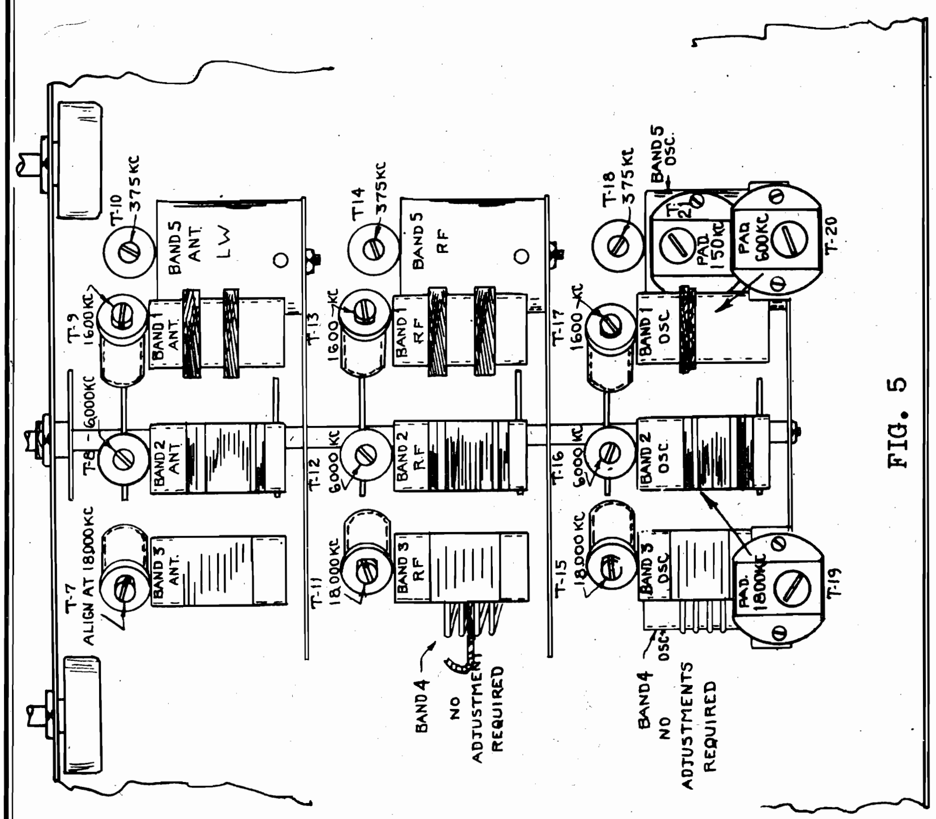

FIG. 5

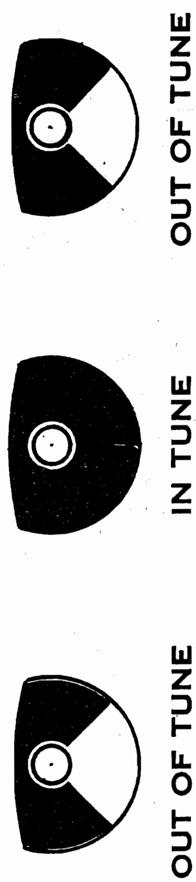

THE ELECTRIC EYE

The movement of the Electric Eye or resonance indicator is easily understood, as the station is tuned in, the green sections of the eye will draw together or tend to draw together depending upon the strength of the station. Rotate the tuning knob back and forth until the exact resonance point is found.

Turning right: power on; bass to treble

GENERAL INFORMATION

THE AVC CIRCUIT:

The grid of the 1H4G AVC tube is used as a diode plate. A portion of the IF signal at the plate of the 6S7G IF tube is fed to the 1H4G through the .0001 mfd. condenser, C22. The resulting diode current creates a voltage drop across the one megohm resistor, R10. This voltage is applied to the control grids of the 6S7G and 6D8G tubes to provide AVC. On bands "F" and "W" residual bias is furnished by the drop across the 1H4G tube filament. On band "A" residual bias is furnished by the drops across the resistors R17 and R15 which, in series with R22, are across the six volt supply.

REMOVING THE ESCUTCHEON:

The escutcheon is held in place with two "speed-nuts", behind the front panel. These "speed-nuts" can be loosened and removed by grasping one end of them with a pair of long-nose pliers and bending it away from the front panel of the set.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

ALIGNMENT PROCEDURE

"F"	6 mc	6 mc	400 ohms	Antenna Lead	-	75

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

Alignment must be made in the sequence indicated.

All of the adjustment should be repeated in their original order for greater accuracy. In particular, the band "W" adjustments should be gone over two or three times since one adjustment affects the others.

Always keep the output from the signal generator at its lowest possible value in order to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a signal at about 900 kc and, if necessary, shift the dial pointer to the station's indicated frequency on the dial.

ALIGNMENT PROCEDURE

The receiver need not be taken out of the cabinet for alignment.

Either a broadcast signal of about 1400 kc or a test oscillator signal may be used. If a broadcast signal is used, the antenna of the receiver should be extended as in a normal installation. If a test oscillator signal is used, a wire should be connected to the test oscillator output and run parallel to but insulated from the receiver's antenna wire. The generator ground connection should be connected to ground.

Tune in the 1400 kc signal and adjust the trimmer for maximum loud speaker response. This can be done most accurately if the Volume Control setting is reduced to give a low volume level. The variable should be rocked a degree or two during the adjustment. The location of this trimmer is shown in the Location of Parts diagram. It is accessible, when the chassis is in the cabinet, through the hole in the bottom of the cabinet. An insulated screw driver should be used since the chassis may be above ground potential, as explained previously.

An auto-transformer is used, instead of the usual power transformer having separate primary and secondary windings. For this reason, under certain conditions the chassis may be 115 volts above ground potential.

POWER SUPPLY:

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a broadcast station at about 900 kc and, if necessary, shift the dial pointer to the station's frequency marking on the dial.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc)of the 465 kc IF,and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

CHANGE TO REDUCE MINIMUM VOLUME:

If the minimum volume is not low enough, examine the Volume Control, R11. If one side of the control is connected to ground, disconnect it from the ground and run the connection to the cathode of the 75 tube. It is shown wired this way in the Schematic Wiring Diagram.

WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114256 wave-trap is designed to eliminate such interference.

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Splice the green lead of the wave-trap to the green antenna lead of the receiver. Cut off any excess length of wire from the trap and from the chassis antenna lead so that the green lead from the wave-trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the receiver between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%. The customer should be forewarned of this to avoid complaints of reduced sensitivity.

THE NOISE SUPPRESSION EQUIPMENT:

Two condensers and a suppressor are supplied for eliminating the electrical interference created by the gasoline engine that drives the 32 volt lighting plant generator.

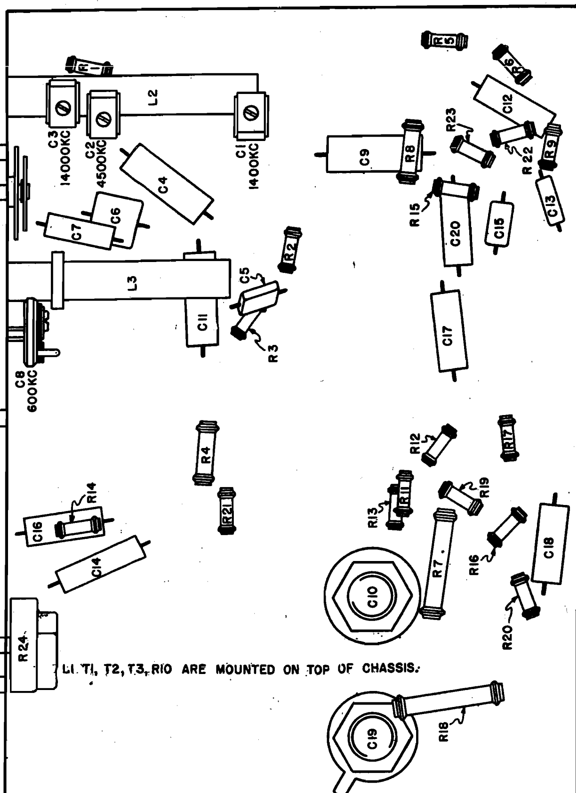
In single cylinder installations, cut the high tension wire going to the spark plug and screw the suppressor onto the two ends of the wire. In multi-cylinder installations, cut the high tension wire going to the center terminal of the distributor cap and screw the suppressor onto the two ends of the wire.

Connect one of the condensers between the two generator brushes. Ground the generator frame. Connect the other condenser from the battery side of the ignition coil to ground.

MODELS 1942,1972,1994
Chassis 391Y

SEARS-ROEBUCK & CO.

Chassis,Alignment
Sensitivity



LOCATIONS OF PARTS - MODELS 1942-1972-1994

ALIGNMENT PROCEDURE

IF ALIGNMENT

1. Connections:

Connect the ground lead of the test oscillator to the receiver chassis. Connect the output lead of the test oscillator, in series with a .1 mfd condenser, to the various points mentioned below for alignment. Connect the low scale of an output meter across the loud speaker voice coil. A reading of one volt or less will be obtained during most of the alignment. Connect a jumper between the "D" and "G" terminals of the antenna terminal block at the rear of the chassis.

2. Receiver Settings:

Turn the Wave Band switch to the BROADCAST position and the Station Selector to about 550 kc. Turn the receiver Volume Control all the way on, the Tone Control to its brilliant position (clockwise), and the Selectivity Control to its #1 position (sharp).

3. Alignment:

(a) Set the test oscillator to 175 kc. Connect the output lead of the test oscillator (in series with a .1 mfd condenser) to the control grid of the 6K7MG IF tube. Peak the IF output transformer, T2. This transformer is the square can unit mounted at the extreme left rear corner of the chassis, as one faces the rear of the chassis.

(b) Change the test oscillator output lead connection to the control grid of the 6A8MG oscillator-translator tube. Peak the IF input transformer, T1. This transformer is the square can unit with a grid lead coming out of its top.

(c) Repeat the adjustments in their original order for greater accuracy. (Change the test oscillator output lead back to the 6K7MG tube for T2 adjustment and then connect it to the 6A8MG tube again for T1 adjustment.) Always keep the test oscillator output at its lowest possible value.

RF ALIGNMENT

Important:

Alignment of band "B" or "C" affects the alignment of the other lower frequency bands. Therefore, band "C" must be aligned first, then band "B", then band "A".

SHORT WAVE BAND "C" ALIGNMENT

1. Connections:

Connections for band "C" alignment are the same as for IF alignment except that the .1 mfd condenser is disconnected from the output lead of the test oscillator. In its stead a 400 ohm carbon resistor is to be connected from the test oscillator output lead to the "A" terminal on the antenna terminal block at the rear of the chassis.

2. Receiver Settings:

Turn the Volume Control all the way on, the Tone Control all the way to the right, the Wave Switch to the "C" position, and the Variable Selectivity Control to its #1 position.

3. Alignment:

(a) Set the test oscillator to 14,000 kc and tune in its signal. Then adjust the short wave translator trimmer, C3, for maximum output meter reading. Locations of all of the trimmers are shown in the Location of Parts Illustration. The variable should be rocked a degree or two while making the adjustment. If two peaks are found at two different settings of C3, use the adjustment in which the trimmer is screwed further in (greater capacity).

SHORT WAVE BAND "B" ALIGNMENT

1. Connections:

Connections remain the same as for band "C" alignment.

2. Receiver Settings:

Turn the Wave Band switch to the "B" position. Other settings remain the same as for band "C" alignment.

3. Alignment:

(a) Set the test oscillator to 4500 kc and tune in its signal. Then peak the translator trimmer, C2. The variable should be rocked a degree or two during the adjustment. If two peaks can be obtained at two different settings of the trimmer, use the adjustment in which the trimmer is screwed further in (greater capacity).

BROADCAST BAND "A" ALIGNMENT

1. Connections:

Connections remain the same as for band "B" alignment except that the 400 ohm resistor is removed from the test oscillator output lead and a .0002 mfd mica condenser connected in its place.

2. Receiver Settings:

Turn the Wave Band switch to the BROADCAST ("A") position. All other settings remain the same as for band "B" alignment.

3. Alignment:

(a) Set the test oscillator to 1400 kc and tune in its signal. Then peak the broadcast antenna and translator trimmers. The antenna trimmer is the one on the middle section of the variable condenser. The broadcast translator trimmer, C1, is mounted on the translator coil as shown in the Location of Parts Illustration.

(b) Set the test oscillator to 600 kc and tune in its signal. Peak the broadcast oscillator padding condenser, C8. The variable should be rocked a degree or two during the adjustment.

(c) Repeat the 1400 kc adjustments and then the 600 kc adjustment for greater accuracy. Always keep the test oscillator output at its lowest possible value.

(d) Recheck the setting of band "C" translator trimmer, C3, at 14,000 kc.

Dial Calibration:

Set the test oscillator to 900 kc and tune in its signal, or tune in a 900 kc station. Then set the dial pointer to 900 kc without changing the setting of the variable condenser.

Adjustment To Minimize Image Response:

1. Set the test oscillator to 1000 kc and tune in its signal. If the test oscillator output is calibrated it should be set to .1 volts. Leaving the receiver tuned to 1000 kc, change the test oscillator frequency until the image is heard. This will occur when the test oscillator is tuned to 1350 kc.

2. There is a yellow lead running from the Wave Switch to one side of the translator trimmer condenser, C3. The image response can be minimized by placement of this yellow lead.

SENSITIVITIES

The following are approximate sensitivities but they will serve as a guide in trouble shooting. In order to make the measurements a test oscillator having a calibrated attenuator must be used. The figures given are those required to obtain an output meter reading of 1.1 volts. Readings for the IF stage are to be made with a .1 mfd condenser, in series with the test oscillator output lead. Readings for the Broadcast band are with a .0002 mfd mica condenser, and for the Short Wave bands with a 400 ohm carbon resistor in series with the test oscillator output lead, as used during the alignment procedure. The receiver Volume Control must be turned all the way to the right, the Tone Control all the way to the right and the Selectivity switch to its #1 position.

	Test Oscillator Connected To:	Frequency	Microvolts To Secure 1.1 Volts Output Meter Reading
Stage Gains	6K7MG - Grid	175 kc	5000
	6A8MG - Grid	175 kc	70

Generator modulation - 30%, 400 cycles

Position of Volume Control - Fully on

POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
Closed	465 kc	.1 mfd.	1C7G Transl. Grid	T2,T1	IF	150
Fully Open	1750 kc	.0002 mfd.	Antenna Lead	C3	Osc. Trim.	150
1400 kc.	1400 kc	.0002 mfd.	Antenna Lead	C1	Transl. Trimmer	90
600 kc (rock)	600 kc	.0002 mfd.	Antenna Lead	C4	Osc. Pad.	45

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

After the alignment has been completed, check the calibration by tuning in a broadcast station at about 900 kc. Adjust the dial pointer to the station's frequency, if necessary.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

THE AVC CIRCUIT:

The diode current of the 1F7G tube, flowing through the 500M ohm resistor, R3, creates a voltage drop across it. This voltage is applied to the control grid of the 1C7G tube to provide AVC.

BATTERY REPLACEMENT:

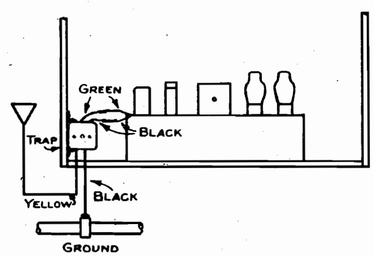
The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. The "B" batteries should be replaced when the total voltage has dropped to 68 volts, under load.

WAVE TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114256 wave-trap is designed to eliminate such interference.

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Splice the green lead of the wave-trap to the green antenna lead of the receiver. Cut off any excess length of wire from the trap and from the chassis antenna lead so that the green lead from the wave trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the receiver between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%.



CHASSIS FEATURES:
- Number RF stages -------- None
- Number IF stages --------- One
- Number condensers in gang ---- Two
- Antenna --------- Conventional
- Dial calibrated in kilocycles and meters

OPERATING FEATURES:
- Fidelity Range ---- 35-2500 cycles
- Automatic Volume Control

LOUD SPEAKER:
- Type . . . . PM Dynamic
- Size . . . . 6" and 8"

CHASSIS FEATURES:
- Number IF stages . . . . One
- Antenna . . . . . . Marconi

THE FILAMENT CIRCUIT:

Since the tubes have two volt filaments and the "A" supply is 4 volts, a series parallel arrangement is used for the filament circuit. The 1C7G, 1H6G, and 1H4G tubes are connected as one parallel group. The 1D5GP and the 1E7G form another parallel group. These two groups are then connected in series. In addition, a 120 ohm resistor, R9, is in parallel with the group of four tubes so that the group of two tubes will have the proper current. If any one tube burns out, it will affect the filament voltage and current of all of the other tubes. A simplified diagram of the filament circuit is shown below.

"F"	16 mc (rock)	16 mc	400 ohms	Ant. Lead	C2	Translator	10
"F"	7 mc	7 mc	400 ohms	Ant. Lead	-	-	70

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a broadcast station at about 900 kc and, if necessary, shift the dial pointer to the station's frequency marking on the dial.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114256 wave-trap is designed to eliminate such interference.

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Splice the green lead of the wave-trap to the green antenna lead of the receiver. Cut off any excess length of wire from the trap and from the chassis antenna lead so that the green lead from the wave-trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the receiver between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%. The customer should be forewarned of this to avoid complaints of reduced sensitivity.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. Approximately 600 hours of service can be expected before the battery voltage drops to this value. The "B" batteries should be replaced when the voltage of the 90 block has dropped to 68 volts, under load. Approximately 300 hours of service can be expected before this point is reached. For longer uninterrupted service heavy duty "B" batteries should be recommended.

These models may be used with either a 4½ volt dry "A" battery or a 4 volt storage "A" battery, without requiring any changes in connections.

Band F	16000 KC.	16000 KC.	400 Ohm.	Ant. Lead	*** C7,C5,C3	30

IMPORTANT ALIGNMENT NOTES

* Before attempting to align the receiver check to see that the dial pointer coincides with the horizontal dividing line of the scale when the gang condenser is in full mesh.

After adjusting the I.F. trimmers C21, C22, C23 and C24, go back and repeat the adjustment, since the setting of each trimmer will have some effect on others. When adjusting C1, antenna trap trimmer, increase generator output to obtain clearly defined trimmer setting for a minimum.

** When aligning the broadcast band at 600 KC. it is necessary to adjust trimmer C15 while slowly rocking the gang condenser through a small distance. Rocking the gang is essential if maximum sensitivity is to be obtained.

*** When aligning the short wave bands, care should be taken in adjusting trimmers C7 and C10, since two possible adjustments of these trimmers will result in signal peaks. The proper peak is that which occurs with the trimmer screw farthest out.

Align Short Wave Before Broadcast band as indicated in chart.

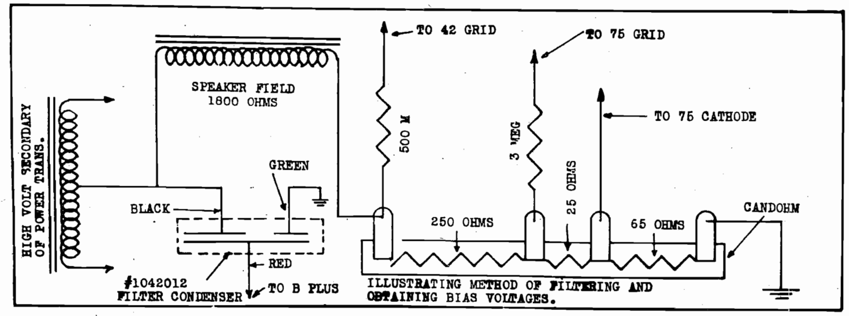
IMPORTANT ALIGNMENT NOTES

Before attempting to align the receiver, check to see that the dial pointer coincides with the horizontal dividing line of the scale when the gang condenser is in full mesh.

After adjusting the I.F. trimmers, go back and repeat the adjustment, since the setting of each trimmer will have some effect on the others.

When aligning the broadcast band at 600 KC. it is necessary to adjust trimmer C 2 while slowly rocking the gang condenser through a small distance. Rocking the gang is essential if max. sensitivity is to be obtained.

It would be advisable that after the set is aligned to go over the balancing procedure for a second time as it may be possible to derive additional sensitivity and selectivity by doubly checking the alignment.



ILLUSTRATING METHOD OF FILTERING AND OBTAINING BIAS VOLTAGES.

STEP BY STEP ALIGNMENT PROCEDURE

(1) - Peak I.F. transformers carefully at 456 Kc.
(2) - Set band switch to short wave position.
(3) - Set dial pointer at 6 Mc.
(4) - Adjust trimmer on center section of variable condenser to bring in proper peak of 6 Mc signal.
(5) - Adjust trimmer on coil L2.
(6) - Change band switch position to broadcast.
(7) - Turn dial pointer to approximately 600 Kc.
(8) - While 600 Kc signal is being fed into antenna lead, adjust padder C-2 for maximum gain, while variable gang is being rocked.
(9) - Set variable to 1400 Kc and adjust two trimmers on variable, the front and rear sections.
(10) - If variable center section (osc) has been set correctly, 1720 Kc will automatically fall broadcast scale. A very slight adjustment of the center trimmer on the gang will correct this if no police calls are heard.

ALIGNMENT PROCEDURE

The receiver need not be taken out of the cabinet for alignment.

Either a broadcast signal of about 1400 kc or a test oscillator signal may be used. If a broadcast signal is used, the antenna of the receiver should be extended as in a normal installation. If a test oscillator signal is used, a wire should be connected to the test oscillator output and run parallel to but insulated from the receiver's antenna wire. The generator ground connection should be connected to ground.

Tune in the 1400 kc signal and adjust the trimmer for maximum loud speaker response. This can be done most accurately if the Volume Control setting is reduced to give a low volume level. The variable should be rocked a degree or two during the adjustment. The location of this trimmer is shown in the Location of Parts Diagram. It is accessible, when the chassis is in the cabinet, through the hole in the plate at the bottom of the cabinet. An insulated screw-driver should be used since the chassis may be above ground potential, as explained previously.

Alignment,Sensitivity
Notes,Parts

SEARS-ROEBUCK & CO.

THE BIAS CELL:

The bias cell is filled with thick liquid. When the receiver is in its normal position the bias cell will be mounted on its side, which is the correct position, so that the liquid will come into contact with the carbon block and the inside of the metal container. However, the receiver may be stood on its end when working on it on the service bench. In this position the bias cell may be upright and the liquid may not touch the carbon block. If this happens, it will cause severe distortion. Accordingly, the necessary precaution should be observed when working on the receiver on the service bench.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

THE AVC CIRCUIT:

The diode current of the 1F7G tube, flowing through the 500M ohm resistor, R3, creates a voltage drop across it. This voltage is applied to the control grid of the 1C7G tube to provide AVC.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. The "B" batteries should be replaced when the total voltage has dropped to 68 volts, under load.

WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

In locations near ship transmitters or airports or air beacon stations, code interference may be experienced. Part #1013114256 wave-trap is designed to eliminate such interference.

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Splice the green lead of the wave-trap to the green antenna lead of the receiver. Cut off any excess length of wire from the trap and from the chassis antenna lead so that the green lead from the wave-trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Splice one of the black leads from the wave-trap to the black ground lead of the receiver. Connect the other wave-trap black lead to the ground used for the installation.

The trap is pre-tuned to the IF frequency so that normally no further adjustment is necessary. However, should interference still be experienced, tune the receiver between approximately 550 and 600 kc. Then adjust the wave-trap, by means of the trimmer screw at the bottom of the container, until the interference is eliminated. Addition of the trap will reduce the sensitivity of the receiver around 600 kc by approximately 50%. The customer should be forewarned of this to avoid complaints of reduced sensitivity.

ALIGNMENT PROCEDURE

PRELIMINARY:

Output meter connections . . . . 4000 ohm meter, in series with a .5 mfd. condenser, across speaker terminals.

Output meter reading to indicate 50 milliwatts . . . . 8.5 volts

Average sensitivity in microvolts for 50 milliwatts output . . . . See chart below

Generator ground lead connection . . . . Receiver chassis

Dummy antenna value to be in series with generator output . . . . See chart below

Connection of generator output lead . . . . See chart below

Generator modulation . . . . 30%, 400 cycles

Position of Volume Control . . . . Fully on

POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN)	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
Closed	465 kc	.1 mfd.	1C7G Transl. Grid	T2,T1	IF	150
Fully Open	1750 kc	.0002 mfd.	Antenna Lead	C3	Osc. Trim.	150
1400 kc	1400 kc	.0002 mfd.	Antenna Lead	C1	Translator Trimmer	90
600 kc (rock)	600 kc	.0002 mfd.	Antenna Lead	C4	Osc. Pad.	45

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

After the alignment has been completed, check the calibration by tuning in a broadcast station at about 900 kc. Adjust the dial pointer to the station's frequency, if necessary.

MODEL 4587
Changes

SEARS-ROEBUCK & CO.

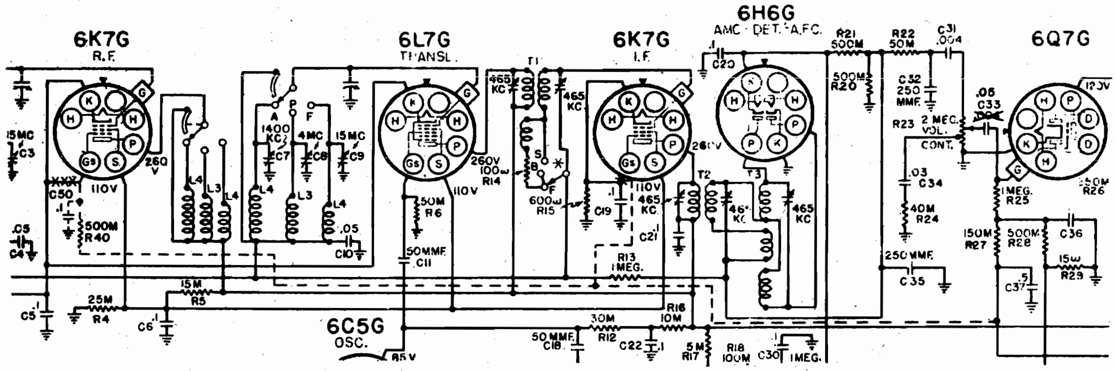

FIG. 3 - Schematic otherwise the same as Model 4587

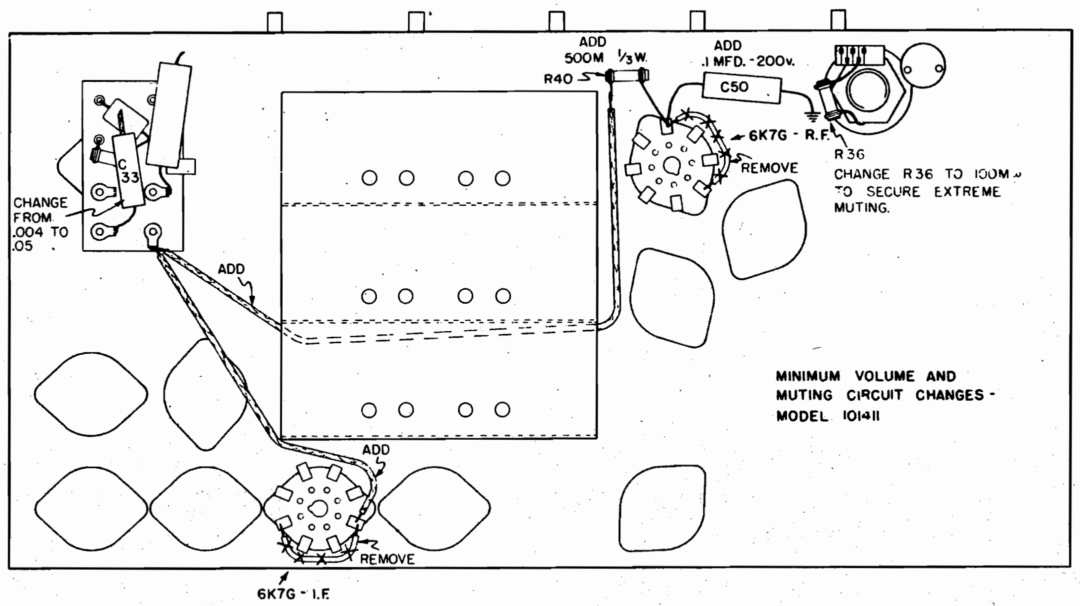

FIG. 3A

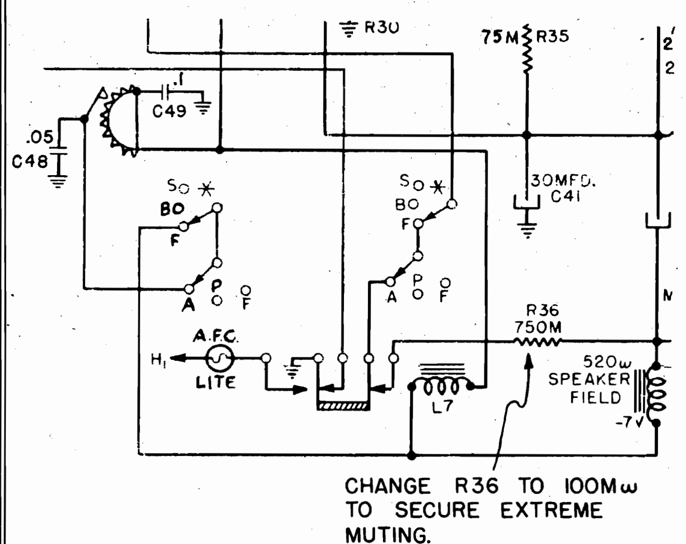

FIG. 1

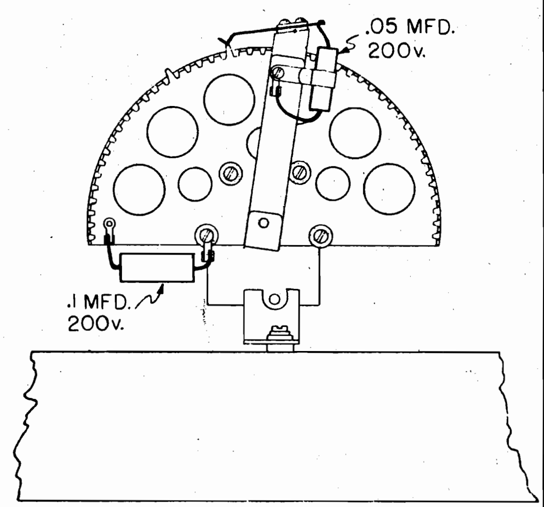

FIG. 2

SEARS-ROEBUCK & CO.

CHASSIS DESIGNATION IF THE CHANGES MENTIONED IN THIS SUPPLEMENT HAVE ALREADY BEEN MADE:

Chassis in which all the changes mentioned in this Supplement have been made at the factory will be indicated by the letter, "F", or a subsequent letter rubber stamped on the Chassis Identification Sticker at the rear of the chassis. Accordingly, do not attempt to make any of these changes on chassis marked with the letter, "F", or subsequent letter.

CORRECTING RELAY TROUBLE:

Relay trouble usually is indicated by one or more of the following symptoms:

1. Flash Tuning light stays on at all times.
2. Receiver does not operate in "Flash" position.
3. Flash Tuning light does not light (although this may be due to a burnt out bulb).
4. Radio remains muted even though not in Flash position.

To Correct Relay Trouble	(1 - type #3 relay (1 - .05 mfd. 200 volt condenser (1 - .1 mfd. 200 volt condenser
To Correct Faulty A.F.C. Muting	(1 - 500M ohm, 1/3 watt resistor (1 - .1 mfd. 200 volt condenser
To Correct Too High Minimum Volume	1 - .05 mfd. 200 volt condenser

The Service Instructions, 57RL 22, (MODEL 4587) for this Model describe two types of relay and mention that the second type should be used to correct these difficulties. The method of identifying these two types of relay by the color of their coil leads, as described in the manual, has been discontinued. A third type of relay, part #1013815562, has been developed and will be the one supplied for replacement purposes even though the original one was type #1 or type #2. The tabulation below shows how the three types of relay can be identified.

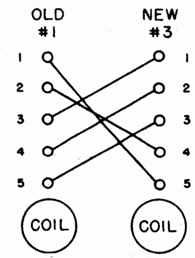
Relay Type Number	Identification
#1	No shield cover. Shield cover but no paint spot on shield cover. Yellow paint spot on shield cover.
#2	Red paint spot on cover. Red and green paint spot on cover.
#3	Blue paint spot on cover.

Relay type #1 was the first one used and most of the relay trouble probably will be experienced with this type. Relay type #2 is considerably improved and should give very much less trouble than type #1. It has the same coil construction as type #1 but has a different contact arrangement. Relay type #3 has the same contact arrangement as type #2 but has considerably stiffer springs and heavier contact pressure. It also has a higher resistance coil requiring 85 milliamperes to actuate the relay instead of the 60 milliamperes minimum required for type #1 and #2.

THE TYPE #3 RELAY SHOULD BE INSTALLED IN THE EVENT OF ANY RELAY TROUBLE WITH EITHER TYPE #1 OR TYPE #2 RELAY.

Replacing Relay Types #1 Or #2 With Type #3:

The connections to the terminals of the type #2 relay remain the same for the new type #3. The changes in connections from type #1 to #3 are: Consider the terminal to be numbered from 1 to 5 with terminal 5 the one nearest the coil. The lead that originally connected to terminal 1 of the type #1 relay is to be connected to terminal 5 of the type #3 relay. The original terminal 2 connection is to be changed to terminal 4. The original terminal 3 connection, to terminal 1. The original terminal 4 connection, to terminal 2. The original terminal 5 connection to terminal 3.



CHANGING TERMINAL CONNECTIONS FROM TYPE #1 RELAY TO TYPE #3 RELAY:

Certain circuit changes are required when relay type #3 is installed. The resistor, R37, across the relay coil is removed from the circuit. A .05 mfd. 200 volt condenser is connected from the spring arm that contacts the teeth of the semi circular toothed disc to the movable arm. A .1 mfd. 200 volt condenser is to be connected from the semi circular toothed disc to ground. These condensers are C48 and C49 in the Schematic Section, Fig. 1. Fig. 2 shows how the condensers should be mounted.

CORRECTING TOO HIGH MINIMUM VOLUME:

Sometimes, with the Volume Control set to its lowest position, the volume still is too high. This will occur in either the Flash Tuning positions or the conventional "Broad" and "Sharp" positions. To correct this, change the value of the condenser, C33, connected to the movable arm of the Volume Control, from .004 mfd. to .05 mfd.

If the center tap lug of the Volume Control is grounding to the chassis, it will prevent the volume from going to a low value. Examine this lug to be sure that it is not grounding to the chassis.

There have been instances of defective Volume Controls caused by arcing of the switch, burning the resistance element. Controls have been improved, eliminating this condition and it will not occur in replacement controls.

CORRECTING DIAL DRIVE SLIPPAGE:

Dial drive slippage may be due to the movable arm being set too close to the toothed disc. The arm will then press unnecessarily hard against the bent up teeth, making the condenser too hard to turn. If this appears to be the case, the adjusting screw on the movable arm should be loosened and the arm re-set so that it does not press too hard against the teeth.

ELIMINATING RECEPTION OF STATION OTHER THAN CHOSEN A.F.C. STATION:

The following condition sometimes occurs. Normally, a station that has been set up on the toothed disc will be heard whenever the dial pointer is turned to its call letters. It sometimes happens though that the station will only be heard if it is approached from one end of the dial but an adjacent station will be heard if approached from the other end of the dial. This is due to the fact that the proper tooth was not selected carefully enough for the station, and an adjacent tooth was bent up instead. The remedy is to put the receiver in the "SHARP" position, tune in the desired station very carefully, and to be sure to bend up the tooth that is under the projection of the contacting arm.

CORRECTING FAULTY A.F.C. MUTING:

Normally, when the receiver is in the Flash Tuning position, a station will not be heard until the Flash Tuning light operates. If the muting is faulty, the station may be heard before its call letters become illuminated and may continue to be heard after the pointer has been turned past the station's position and the Flash Tuning light has gone out. If this type of trouble is encountered, it can be corrected by making the circuit changes shown in Fig. 3. The dotted lines indicate the new connections. "X"'s indicate old connections to be broken. As will be seen, the original suppressor to cathode connections of both 6K7G tubes are to be broken. The cathode connections of the tubes remain as they were. The suppressors of the two tubes are to be connected together by a 500M ohm resistor, R40. A .1 mfd. 200 volt condenser, C50, is to be connected directly from the suppressor terminal of the 6K7G RF tube socket to ground. The suppressor of the 6K7G IF tube is to be connected to the junction of R27 and C37, as shown in Fig. 3. These changes increase the muting action by putting a negative biasing voltage on the suppressors of the RF and IF tubes.

NOTE: In extreme cases, that is if the receiver is located near a very powerful station, muting may be still unsatisfactory on that station even after the changes mentioned in the preceding paragraph have been made. If desired, in such extreme cases, the muting can be further improved by changing the value of R36 from 750M ohms to 100M ohms. However, doing so will increase the amount of "thump" or "click" that occurs when tuning stations in or out. Since this change is only for extreme cases the 100M ohm resistor is not included in the kits.

IMAGE ADJUSTMENT

Set the generator to 1524 kc and tune in the signal image at about 1000 kc on the receiver. The generator should be adjusted for high output (.1 volts). There is a lead running from L1 through a hole in the chassis to the wave switch. Adjust the position of this lead under the chassis for minimum image response.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

After the alignment procedure has been completed, tune in a broadcast signal at about 1000 kc. If necessary, shift the dial pointer so that it indicates this frequency.

Values shown under, "Microvolts", are only approximate.

WAVE-TRAP TO ELIMINATE INTERFERENCE FROM SHIP OR AIRPORT TRANSMITTERS:

Mount the trap, by means of two wood screws, at any convenient place on the chassis shelf or cabinet where it will be near the antenna terminal of the receiver. Connect the yellow lead of the wave-trap to the antenna downlead. Connect the green lead of the wave-trap to the antenna terminal of the receiver. Cut off any excess length of wire so that the green lead from the wave-trap to the chassis is as short as possible. The yellow lead from the wave-trap should be run so that it is as far as possible from the green lead. Connect the black lead from the wave-trap to the ground terminal on the chassis.

The traps are pre-tuned to the IF frequency so that ordinarily no further adjustment will be necessary. However, if interference still is experienced, tune the trap by means of the trimmer screw at the bottom of the container, until the interfering signal is eliminated.

In LATE PRODUCTION of this trap only two leads were used, black and green. The green lead is to be connected to the green antenna lead of the receiver or connected to the ant. term. if the rec. has a term. Bd. The black lead of the trap is to be connected to ground.

IMAGE ADJUSTMENT

Set the generator to 1524 kc and tune in the signal image at about 1000 kc on the receiver. The generator should be adjusted for high output (.1 volts). There is a lead running from L1 through a hole in the chassis to the wave switch. Adjust the position of this lead under the chassis for minimum image response.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

After the alignment procedure has been completed, tune in a broadcast signal at about 1000 kc. If necessary, shift the dial pointer so that it indicates this frequency.

Values shown under, "Microvolts", are only approximate.

THE AVC CIRCUIT:

The diode current of one of the diode plates of the 6B6G tube, flowing through the one megohm resistor, R18, creates a voltage drop across this resistor. This voltage is applied to the control grids of the 6A8G and 6K7G tubes to provide AVC.

DIFFERENCES BETWEEN 25 CYCLE AND 60 CYCLE POWER SUPPLY:

The 6X5G rectifier tube is used as a half wave rectifier for 60 cycle supply. Full wave rectification is used for 25 cycle supply.

PRELIMINARY:

ALIGNMENT PROCEDURE

Output meter connections . . . . Across loud speaker voice coil

Output meter reading to indicate 1 watt . . . . 1.34 volts

Average sensitivity in microvolts for 1 watt output . . . . See chart below

Generator ground lead connection . . . . Receiver chassis

Dummy antenna value to be in series with generator output . . . . See chart below

Connection of generator output lead . . . . See chart below

Generator modulation . . . . 30%, 400 cycles

Position of Volume Control . . . . Fully on

Position of Tone Control . . . . Fully clockwise (treble)

Position of Antenna Tap . . . . #1 hole

The Chassis must be in its case although the covers may be removed during the alignment procedure.

POSITION OF VARIABLE	GENERATOR FREQUENCY	DUMMY ANTENNA	GENERATOR CONNECTION	TRIMMER ADJUSTMENTS (IN ORDER SHOWN	TRIMMER FUNCTION	APPROXIMATE MICROVOLTS
Closed	262 kc	.1 mfd.	6A8G Grid	T3,T2	IF	600
Fully Open	1540 kc	.0002 mfd.	Antenna Conn.	C22	Osc. Trim.	1
1400 kc	1400 kc	.0002 mfd.	Antenna Conn.	C1,C21	Ant. Transl.	1
600 kc (rock)	600 kc	.0002 mfd.	Antenna Conn.	C8	Padder	2

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the 600 kc adjustment.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

Antenna Matching:

Two separate adjustments are provided for matching the receiver to the particular car antenna. One adjustment consists of two taps on the antenna coil. The second adjustment is a trimmer, C1, on the variable condenser. It is accessible through a hole in the bottom cover of the receiver case. These adjustments are to be made as follows:

The Tapped Antenna Coil:

The adjustment of the tapped antenna coil should be made before installing the receiver on the car. Removal of the bottom cover of the receiver will reveal a terminal board mounted in the antenna coil shield can. The variable condenser plates must be closed for it to be seen. This terminal board has four jack holes, only two of which are used. These two are marked with the numerals "1", "2". In some sets these marked holes are the first two holes. In other sets they are the two end holes. In either case they are marked. The sets are shipped with the plug in hole #1. This adjustment is correct for factory built-in aerials in cars having a fabric top. It is also correct for SILVERTONE Catalog #57E5559 Standard "V" Type Under-car Aerial; Catalog #57E5556 Deluxe Auto Aerial; Catalog #57E5570 Aerod Auto Aerial.

The plug must be removed from hole #1 in the terminal board and inserted in hole #2 for cars having the following types of aerial.

1. Cars having an insulated steel top connected at the factory for use as an aerial.
2. Cars using insulated running boards as the aerial (1937 Buicks and Oldsmobiles).
3. Cars using some insulated part of the car as the aerial. For example, insulated trunks, rear-deck covers, spare tire covers, etc.

The Antenna Trimmer Adjustment:

With the set tuned to a weak station at about 1500 kilocycles, turn the adjusting screw to the point affording maximum volume. A weak station must be used to prevent the AVC action of the receiver from interfering with accurate peaking. If a peak cannot be reached with the trimmer, the capacity of the car's antenna may be such that the other antenna tap adjustment should be used.

"F"	15 mc (rock)	15 mc	400 ohms	Ant. Term.	C3	Translator	40
"F"	6 mc	6 mc	400 ohms	Ant. Term.	-	-	350

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

Note that the 1400 kc alignment is to be repeated after the 600 kc padder adjustment.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

The high frequency limit of the Broadcast band is 1750 kc although the last dial marking is 1800 kc. This dial marking is only to obtain symmetry of appearance in the dial.

BATTERY REPLACEMENT:

The dry "A" battery should be replaced when its voltage drops to 3.4 volts, under load. Approximately 610 hours of service can be expected before the "A" battery voltage drops to this value (based on 3 to 4 hours a day use). If the storage "A" battery is used, it should be recharged every 3 to 4 weeks. Approximately 375 hours of service can be expected from the "B" batteries supplied. Since this receiver uses a class "B" output stage the "B" drain will vary with the volume at which the radio is played. The customer should be informed of this fact and told that for longest "B" battery life the radio should not be played louder than necessary. The "B" batteries should be replaced when the voltage of the 90 volt block has dropped to 68 volts, under load. For longer uninterrupted service, heavy duty "B" batteries should be recommended.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc.

DIFFERENCES IN TONE CONTROLS:

Earlier production used a tone control knob having only two positions marked, "HI", "LO". Later production used three positions marked, "HI", "MED", "LO". In both types of set the Tone Control switch is a three position one and the medium tone adjustment can be had with the two position knob by turning the knob so that the marker pin is between "HI" and "LO".

"AM"	600 kc (rock)	600 kc	.0002 mfd.	*	C8	Padder	50
"FOR"	13 mc (rock)	13 mc	400 ohms	*	C5	Translator Trimmer	70

IMPORTANT ALIGNMENT NOTES

* Push a pin through the attached antenna wire at a point near where it comes out of the chassis so that the pin makes contact with the antenna wire inside the insulation. Connect the generator output lead to the pin. The generator output connection should not be made to the free end of the attached antenna wire.

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a broadcast station at about 900 kc and, if necessary, shift the dial pointer to the station's frequency marking on the dial.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to choose the new IF frequency as near to 465 kc as possible.

POWER TRANSFORMER:

An auto-transformer is used. Therefore, under certain conditions, the chassis may be above ground potential. Do not allow any grounded object to come into contact with the chassis while the line cord is plugged in. Also, be careful when working on the chassis out of its cabinet, to avoid shocks.

"F"	16 mc (rock)	16 mc	400 ohms	Ant. Term.	C6	Translator	15
"F"	7 mc	7 mc	400 ohms	Ant. Term.	-	-	60

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the adjustment, where indicated by the word, "Rock", in the alignment chart.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

The sensitivities indicated are for 115 volt operation. For 6 volt operation, these figures should be multiplied by 1.8.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as close to 465 kc as possible.

For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as close as possible to 465 kc.

THE NOISE SUPPRESSION EQUIPMENT:

Two condensers and a suppressor are supplied for eliminating the electrical interference created by the gasoline engine that drives the 32 volt lighting plant generator.

In single cylinder installations, cut the high tension wire going to the spark plug and screw the suppressor onto the two ends of the wire. In multi-cylinder installations, cut the high tension wire going to the center terminal of the distributor cap and screw the suppressor onto the two ends of the wire.

Connect one of the condensers between the two generator brushes. Ground the generator frame. Connect the other condenser from the battery side of the ignition coil to ground.

IMPORTANT ALIGNMENT NOTES

* Before attempting to align the receiver check to see that the dial pointer is in a horizontal position at the low frequency end of the dial scale when the gang condenser is in full mesh.

After adjusting the I.F. trimmers C7, C8, C9 and C10, go back and repeat the adjustment, since the setting of each trimmer will have some effect on others. When adjusting L1, antenna trap trimmer, increase generator output to obtain clearly defined trimmer setting for a minimum.

** When aligning the broadcast band padder C5 at 600 KC. it is necessary to adjust the trimmer while slowly rocking the gang condenser through a small distance. Rocking the gang is essential if maximum sensitivity is to be obtained.

B	ANY POINT WHICH DOES NOT AFFECT SIGNAL	465 KC.	250 MMFD.	ANTENNA TERMINAL	1 MINIMUM OUTPUT		BAND A (Counter-clock-wise)
C	1500 KC.	1500 KC.	250 MMFD.	ANTENNA TERMINAL	C6, C3	30	BAND A (Counter-clock-wise)
D	** TUNE TO 600 KC. GEN.SIG.	600 KC.	250 MMFD.	ANTENNA TERMINAL	C9	20	BAND A (Counter-clock-wise)
E	** *** 16 MC.	16 MC.	400 OHM.	ANTENNA TERMINAL	C7, C2	65	BAND F (Clock-wise)

IMPORTANT ALIGNMENT NOTES

* Before attempting to align the receiver check to see that the dial pointer is in a horizontal position at the low frequency end of the dial when the gang condenser is in full mesh.

After adjusting the I.F. trimmers C13, C14, C16 and C17, go back and repeat the adjustment, since the setting of each trimmer will have some effect on others. When adjusting L1, antenna trap trimmer, increase generator output to obtain clearly defined trimmer setting for a minimum.

** When aligning the broadcast band padder C9 at 600 KC. and the short wave detector trimmer C2, it is necessary to adjust the trimmers while slowly rocking the gang condenser through a small distance. Rocking the gang is essential if maximum sensitivity is to be obtained.

*** When aligning the short wave bands, care should be taken in adjusting trimmer C7, since two possible adjustments of this trimmer will result in signal peaks. The proper peak is that which occurs with the trimmer screw farthest out.

IMPORTANT ALIGNMENT NOTES

The variable should be rocked back and forth a degree or two while making the adjustment, where indicated by the word, "Rock", in the alignment chart.

The alignment procedure should be repeated in the original order, step by step, to insure greater accuracy.

Always keep the output power from the generator at its lowest possible value to prevent the AVC of the receiver from interfering with accurate alignment.

GENERAL INFORMATION

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as close to 465 kc as possible.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

SILVERTONE BATTERY CHARGERS AVAILABLE:

The customer should be told about the SILVERTONE GAS-O-POWER and the SILVERTONE SUPER AIR-CHARGER. Either of these units provides an economical means of keeping the storage battery charged.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

Values shown under, "Microvolts", are only approximate.

PHONOGRAPH PICK-UP JACK: A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert the mount the jack in this hole. Insulate the jack from the chassis by means of the two insulating washers supplied in the kit. The Schematic Section shows the connections to the jack. In addition, changes must be made in the wiring to the speaker socket and the electrolytic condenser. As the Schematic Section shows, these wiring changes and the connections to the jack are as follows:

Disconnect the jumper between prongs 1 and 5 of the speaker socket.

Disconnect the jumper between prong #2 of the speaker socket and the anode (center terminal) of the wet electrolytic.

There is a lead running from the 40 ohm resistor, mounted on the terminal board near the power transformer, to the cathode (can terminal) of the wet electrolytic. Disconnect this lead from the electrolytic and connect it to terminal #2 of the speaker socket.

Run a lead from terminal #1 of the speaker socket to the cathode (can terminal) of the electrolytic.

Run a lead from terminal #1 of the jack to the cathode prong of the 6B6G tube.

Connect the .05 condenser from terminal #3 of the jack to the junction of R10 and C19. This junction is at the end lug of the terminal board mounted under the IF output transformer.

Connect the 500M ohm resistor from terminal #3 of the jack to the end of R14 that is connected to the blank prong of the 6B6G socket.

Connect prong #4 of the jack to prong #1 of the speaker socket.

The radio Volume Control and Tone Control will operate for the phonograph pick-up.

EARPHONE JACK: Mount the jack in the hole in the back of the chassis. The jack frame must be grounded to the chassis. Therefore, do not use the insulating washers.

Connect the .05 condenser from terminal #2 of the jack to the grid prong of the 6V6G output tube.

Connect terminal #3 of the jack to terminal #3 of the speaker socket.

Connect terminal #4 of the jack to terminal #5 of the speaker socket.

This is the only wiring necessary. The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.

With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired to have the loud speaker operate at the same time the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

Phono. Installation
Wave-trap Data

SEARS ROEBUCK & CO.

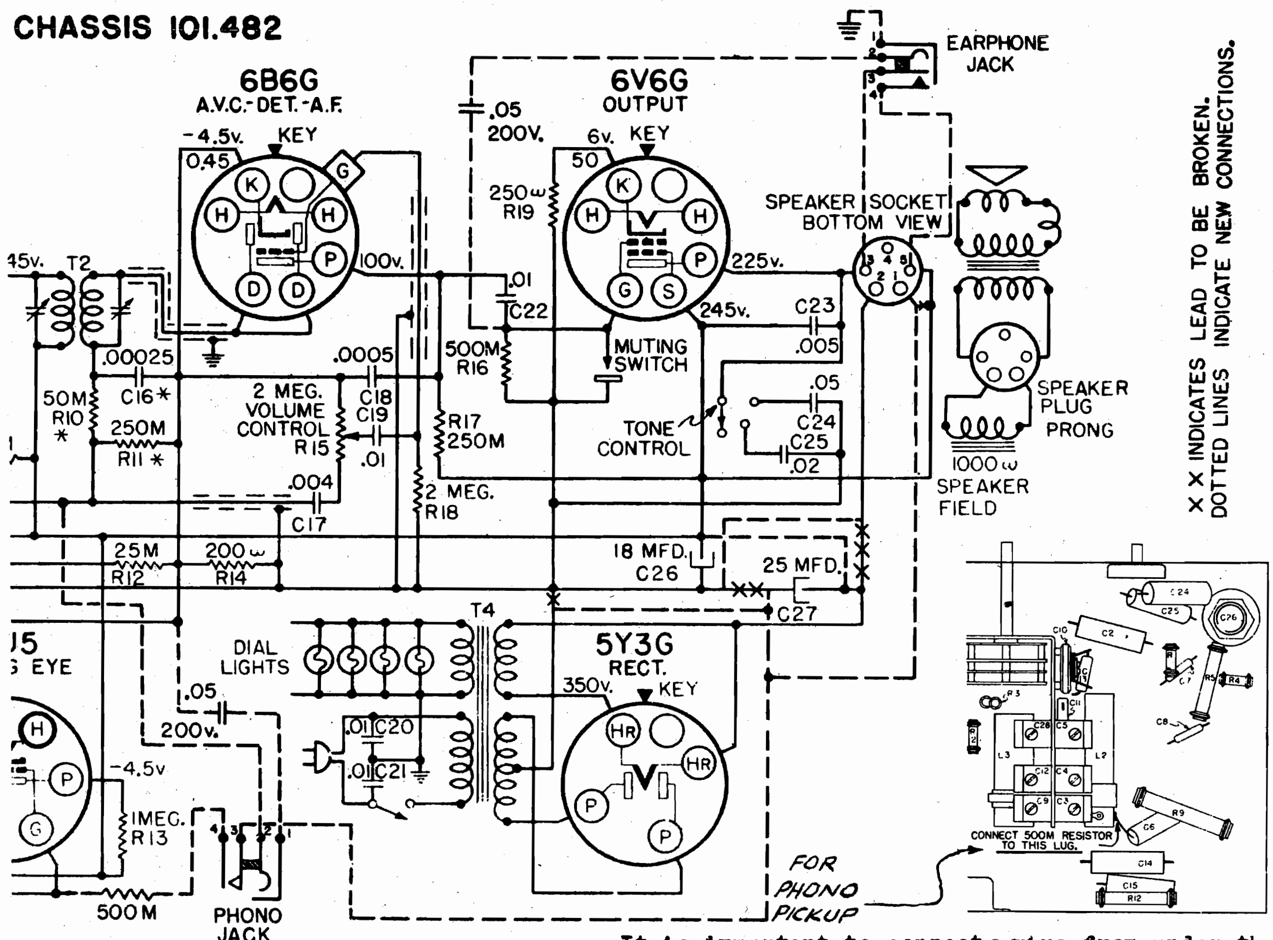
MODELS 4610,4669,4769
4789. Chassis 101.482

PHONOGRAPH PICK-UP JACK: A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert and mount the jack in this hole. Insulate the jack from the chassis by means of the two insulating washers supplied in the kit. The Schematic Section shows the connections to the jack. In addition, changes must be made in the wiring to the speaker socket and the electrolytic condenser.

The radio Volume Control and Tone Control will operate for the phonograph pick-up.

EARPHONE JACK: Mount the jack in the hole in the back of the chassis. The jack frame must be grounded to the chassis. Therefore, do not use the insulating washers.

CHASSIS 101.482



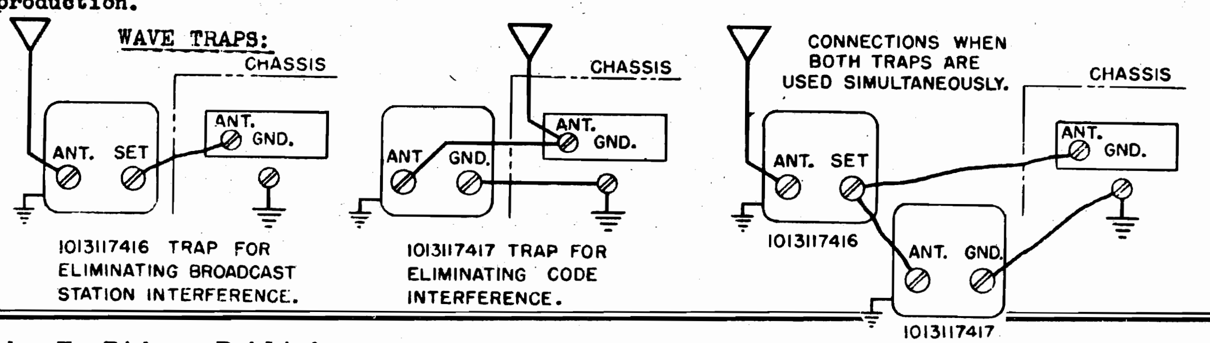
It is important to connect a wire from under the head of one of the wood screws to the chassis so that the wave trap shield becomes grounded to the chassis.

The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.

With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired to have the loud speaker operate at the same time the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

ADDING A .01 MFD. CONDENSER TO ELIMINATE DISTORTION AT LOW VOLUME:

Distortion at low volume can be corrected by adding a .01 mfd. - 300 volt condenser from the cathode of the 6B6G tube to ground. This condenser is C39 in the wiring diagram. Chassis marked with the letter, "B", or a subsequent letter have had this change incorporated in production.



MODELS 4680,4790
Chassis 101.479
LO-NOISE Cont.
Data, Notes

SEARS ROEBUCK & CO.

IMPROPER OPERATION OF THE LO-NOISE CONTROL CIRCUIT:

Insufficient difference between the "break-in" and "drop out" points can be corrected by changing the 6Q7G Whisper Tuning tube. The 6A8G IF tube also has an effect. Try interchanging the 6Q7G "Lo-Noise" control tube with the 6Q7G Second Detector tube.

Another change that will improve the action of the "Lo-Noise" control circuit is replacement of the 700 ohm resistor, R17, with a 300 ohm one. This change has been incorporated in production in chassis stamped with the letter, "F", or a subsequent letter.

If further improvement is required, the 150 ohm resistor, R2, may be shorted out. This change will also increase the sensitivity of the AMERICAN band and the minimum sensitivity of the Tuning Eye about ten times.

Hum, occurring when the front control knob is in the "Lo-Noise" position, can be corrected by changing the 6Q7G "Lo-Noise" control tube. Sometimes, shifting the position of the heater leads to this tube will also minimize hum.

INCREASING THE SENSITIVITY OF THE TUNING EYE:

The minimum sensitivity of the Tuning-Eye can be increased about ten times by shorting out the 150 ohm resistor, R2, as mentioned in the preceding paragraphs. Another change that will increase the sensitivity of the Tuning Eye without changing the sensitivity of the set or the action of the "Lo-Noise" control is to replace the 1 megohm resistor, R11, with a 250M ohm resistor. This resistor is incorporated in the Tuning Eye cable socket. This change has been incorporated in production in chassis stamped with the letter, "C", or a subsequent letter.

CORRECTING AF OSCILLATION:

Audio oscillation sometimes occurs due to the 6Q7G Second Detector grid lead being close to the adjacent 6V7G output tube. It can be corrected by moving the 6Q7G grid lead.

INSTRUCTIONS FOR INSTALLING PHONOGRAPH PICK-UP OR EARPHONE JACK:

If both phonograph pick-up connections and earphone connections are wanted, it will be necessary to use two kits. It will also be necessary to drill an additional hole in the back of the chassis for the additional jack.

PHONOGRAPH PICK-UP JACK: A hole, covered with a brass insert, is provided in the back of the chassis. Remove the brass insert and mount the jack in this hole. Insulate the jack from the chassis by means of the two insulating washers supplied in the kit. The Schematic Section shows the connections to the jack.

Connect the .05 condenser between lug #1 of the jack and the plate prong of the 6Q7 tube socket that is just above the LO-NOISE control rheostat.

Connect lug #2 of the jack to ground.

There is a terminal board mounted under the IF Input transformer. Connect the terminal on this board nearest the back of the chassis to lug #3 of the jack.

Connect lug #4 of the jack to the LO-NOISE control rheostat.

The radio Volume Control and Tone Control will operate for the phonograph pick-up.

EARPHONE JACK: Mount the jack in the hole in the back of the chassis. The jack frame must be grounded to the chassis. Therefore, do not use the insulating washers.

Connect the .05 condenser from terminal #2 of the jack to the grid prong of the 6V6G output tube.

Connect terminal #3 of the jack to terminal #5 of the speaker socket.

Connect terminal #4 of the jack to terminal #3 of the speaker socket.

This is the only wiring necessary. The wiring changes mentioned above for connection of the phonograph pick-up jack are not to be done if only an earphone jack is used.

With the connections as described, the loud speaker will not operate when the earphones are plugged in. If it is desired to have the loud speaker operate at the same time the earphones are plugged in, the connections to terminals 3 and 4 of the jack should be omitted.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as close as possible to 465 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

THE LO-NOISE CONTROL - HOW TO SET IT UP:

When properly adjusted, the "Lo-Noise" control will make it possible to tune between favorite selected stations, of sufficient strength to insure good daylight reception, without inter-station noise while tuning. With the front control knob in the "Lo-Noise" position the receiver is insensitive until a sufficiently strong station is received. An important difference between this circuit and the ordinary variable sensitivity control circuit is that once the signal has "broken-in" the receiver sensitivity can increase considerably beyond the "break-in" point before the station "drops out". This makes it possible to hold a station that is fading moderately without having the station keep "breaking in" and "dropping out". When the front knob is turned to the "Normal" position the receiver acts as a conventional one.

To make the "Lo-Noise" adjustment, turn the control at the rear of the receiver all the way to the right (as you face the rear of the receiver). Turn the front control knob to the "Lo-Noise" position. Tune in your favorite strong stations that give satisfactory reception during the day and night and set the Volume Control to the desired level. Leave the Volume Control at this setting. Now tune from station to station and at the same time turn the rear control to the left until the noise between stations is reduced sufficiently to be not objectionable, and yet permits reception of the selected stations. Turning the rear control too far to the left may result in failure to receive some of the selected stations. If the selected stations are not very strong, a compromise may have to be made between the amount of noise and the number and distance of stations that can be tuned in with the knob in the "Lo-Noise" position.

The knob should always be in the "Normal" position when tuning for distant broadcast and short wave stations or for any station that cannot be heard when the control is in the "Lo-Noise" position. If a station "breaks-in" and then "drops out" with the knob in the "Lo-Noise" position, it indicates that the station is fading too badly for proper reception with the knob in the "Lo-Noise" position and should be listened to with the knob in the "Normal" position.

THE LO-NOISE CONTROL - HOW IT WORKS:

The following is intended as an understandable explanation of the "Lo-Noise" circuit without involving the details of the circuit.

The "Lo-Noise" circuit makes use of a 6Q7G tube. The effective plate voltage applied to this tube (and therefore the plate current) is adjustable by means of a potentiometer, which is the "Lo-Noise" control at the rear of the receiver. The plate current of this tube creates a voltage drop that is used to put a negative bias on the control grids of the RF, translator and IF tubes, reducing their gain. This negative voltage is also applied to the diodes of the Second Detector, preventing detector action and quieting the set.

A portion of the IF signal is fed to the diode of the 6Q7G "Lo-Noise" control tube. The resulting diode current creates a voltage that is applied to the grid of the tube to provide negative bias. When a sufficiently strong signal is tuned in, the negative bias applied to the grid of the 6Q7G tube will be enough to decrease the plate current of the tube. The voltage drop due to this plate current is biasing off the receiver, as explained in the previous paragraph. Therefore, the decrease in bias will increase the sensitivity of the RF, translator and IF stages. This increased sensitivity will permit more diode current flow in the "Lo-Noise" control tube thereby decreasing the plate current still further until the plate current is practically cut off. This action takes place in a fraction of a second so that the station seems to "break-in" instead of gradually building up in volume.

The strength of the signal necessary to create sufficient negative grid voltage on the "Lo-Noise" control tube to cut off the plate current depends upon the plate voltage of the tube which in turn is determined by the setting of the potentiometer. Therefore, this setting determines the "break-in" point of the receiver. The "drop out" point depends upon the plate current - grid voltage characteristic of the tube. This differs from the "break-in" point because at the "drop out" point the plate current of the tube is at a maximum; at the "break-in" it is at a minimum; and the plate current - grid voltage characteristic of the tube is different at these two extremes. When the front control knob is turned to the "Normal" position the plate circuit of the 6Q7G "Lo-Noise" control tube is opened so that it cannot put any negative bias on the other tubes.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the AVC action of the set from interfering with accurate alignment.

The shield plate that covers the coil assembly should be left in place while making the alignment adjustments. The trimmer screws are accessible through the holes in the shield.

Only the dummy antenna indicated in the chart for any particular band should be used. Remove the dummy antenna used for alignment of any other band.

No connection should be made to the doublet terminal on the antenna connection block.

IMPORTANT ALIGNMENT NOTES

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

It is advisable to repeat the entire alignment procedure band by band and in the original order to insure greater accuracy.

Always keep the output from the test oscillator at its lowest possible value. As the sensitivity is increased by alignment, the generator output should be reduced correspondingly.

Values shown under, "Microvolts", are only approximate.

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to select the new IF frequency as close as possible to 465 kc.

Align the IF at the new frequency and then realign the rest of the receiver as described under, "ALIGNMENT PROCEDURE".

ALIGNMENT PROCEDURE

PRELIMINARY

Before attempting to align the receiver check to see that the dial pointer is opposite the last scale division on the low frequency end of the dial when the gang condenser is in full mesh. Also when the gang condenser is in full mesh the stop pin on the left side of the tuner should be resting against the forward stop. If after examination it is found that the gang is in full mesh and the stop pin is against the forward stop, but the pointer is set to the wrong position, it will only be necessary to loosen the set screw on the dial drive gear at the left side of the mechanism. Then grasp the large drum on the same side of the tuner and turn it until the pointer is set correctly. Now retighten the set screw in the gear being careful to see that the gear is meshing properly.

On the other hand if the stop pin does not rest against the forward stop with the gang condenser in full mesh, loosen the set screw on the gang condenser side of the flexible coupler. Then turn the tuning knob until the stop pin rests against the forward stop on the tuner. Now tighten the set screw in the flexible coupler and proceed to set the pointer to its correct position by the method described in the previous paragraph.

Output meter connections....................Across voice coil leads

Output meter reading to indicate 0.5 watt output....................1.0 volts

Average sensitivity in microvolts for 0.5 watt output....................See chart below

Generator ground connection....................Receiver Chassis

Connection of generator output lead....................See chart below

Generator modulation....................30%, 400 cycles

Position of volume control....................Maximum clockwise

-IMPORTANT-

1.-TONE CONTROL MUST BE IN SHARP POSITION.

2.-ALLOW RECEIVER TO WARM UP 15 MINUTES BEFORE ALIGNING.

3.-A.F.C.-ON-OFF SWITCH MUST BE IN THE CENTER NON-A.F.C. POSITION EXCEPT WHERE OTHER POSITION IS SPECIFIED.

ORDER OF ALIGN.	DIAL POINTER POSITION	SIGNAL GENERATOR FREQUENCY	DUMMY ANTENNA	SIGNAL GENERATOR CONNECTION	TRIMMER NUMBER	SENSITIVITY (MICRO-VOLTS)	BAND SWITCH POSITION
A	ANY POINT WHICH DOES NOT AFFECT SIGNAL	465 KC.	.1 MFD.	6L7-G CONTROL GRID	A-B-C-D-F-G	85	BAND A (Counter-clockwise)
B	ANY POINT WHICH DOES NOT AFFECT SIGNAL	465 KC.	400 OHM CARBON RESISTOR	ANTENNA TERMINAL	H MINIMUM OUTPUT		BAND A (Counter-clockwise)
C	1500 KC.	1500 KC.	400 OHM CARBON RESISTOR	ANTENNA TERMINAL	C22-C10 C4	7	BAND A (Counter-clockwise)
D	* TUNE TO 600 KC. GEN.SIG.	600 KC.	400 OHM CARBON RESISTOR	ANTENNA TERMINAL	C25	6	BAND A (Counter-clockwise)
E	THE A.F.C. SYSTEM MUST NOW BE ALIGNED. SEE "A.F.C. ALIGNMENT" AT TOP OF NEXT PAGE FOR PROCEDURE.						
F	** 5 MC.	5 MC.	400 OHM CARBON RESISTOR	ANTENNA TERMINAL	C23-C9 C3	7	BAND P (Center)
G	* ** 16 MC.	16 MC.	400 OHM CARBON RESISTOR	ANTENNA TERMINAL	C24-C8 C2	8	BAND F (clockwise)

* When aligning the American band padder C25 at 600 KC. and the short wave detector trimmer C8 at 16 MC. it is necessary to adjust the trimmers while slowly rocking the gang condenser through a small distance. "Rocking" the gang is essential if maximum sensitivity is to be obtained.

** When aligning the short wave or police bands, care should be taken in adjusting trimmers C23 or C24, since two possible adjustments of this trimmer will result in signal peaks. The proper peak is that which occurs with the trimmer screw farthest out.

IMPORTANT:- The following adjustment must be made after every re-adjustment of the I.F. and broadcast band trimmers.

The A.F.C. discriminator should now be adjusted as follows:

1. Place the A.F.C. (Moto-Matic) switch in the center (non A.F.C.) position
2. Loosely couple the output of the signal generator output lead to the insulation on the control grid wire. Set the signal generator to about 465 KC. Then carefully adjust signal generator to resonance with I.F. system by tuning the signal generator dial for maximum output meter deflection.
3. When doing this be sure that the receiver dial is at some point where it has no tuning effect on the generator signal. Switch off the modulation of the signal generator.
4. With the signal generator connected and operating as in #2, connect an antenna to the "A" terminal lug on the back of the chassis and manually tune in a powerful local station in region of 1000 KC. or lower. (Avoid stations around 930 KC. which might beat with second harmonic of the test oscillator.)
5. Adjust the receiver tuning dial to obtain "zero beat" between the test oscillator and the incoming signal. (A very slight adjustment is all that is required. Be careful not to tune off signal.)
6. Turn the A.F.C. (Moto-Matic) switch to the extreme clockwise position (Motor).
7. Adjust the secondary of the discriminator transformer using trimmer E to restore zero beat. NOTE: This trimmer should be adjusted to the point where the frequency of the beat note increases rapidly if the trimmer is turned in either direction. Other zero beat points may be found with the trimmer all the way out or all the way in, but these settings are incorrect!

If the above operation has been performed correctly, turning the A.F.C. switch from center to clockwise position (Regular to Motor) should not change the beat note by more than a slight rumble.

Note: Where a second signal generator is available step #4 above may be varied as follows:

Connect second signal generator (set at about 1000 KC.) to antenna and tune in its signal. Switch off modulation and proceed as before.

This method is somewhat preferable to the first as the zero beat setting is more easily determined when both signals are unmodulated.

HOW TO TEST THE A.F.C. SYSTEM

Connect the antenna and tune in a powerful local station. See that the A.F.C. switch is in the center position. (A.F.C. off)

Next, detune the receiver dial until the music or speech becomes somewhat distorted. Throw the A.F.C. switch into the A.F.C.-on (clockwise) position. This should improve the quality of the program being received.

Similarly detune the receiver in the opposite direction, with A.F.C. switch in center position. Place A.F.C. switch in clockwise position and again check for improved quality of reception.

It will be noted that the correction for mis-tuning afforded by the A.F.C. system is not as marked at stations near the low frequency end of the dial scale as it is at the higher broadcast frequencies. This is characteristic of A.F.C. systems. However, if throwing the A.F.C. switch into the extreme clockwise position has no effect on the signal, or is effective for mistuning in one direction only, check the receiver as follows:

1. Re-align I.F., broadcast band, and discriminator trimmers.
2. Check all tubes in the receiver. Defective 6H6 and 6J7 tubes, also the R.F.,1st Detector and I.F. tubes may cause poor A.F.C. action.
3. If the above procedure fails to remedy the defect in A.F.C. action, check the entire A.F.C. circuit itself for possible troubles.

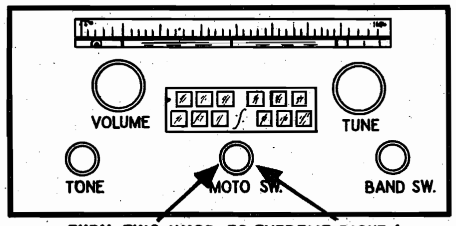
Moto-Matic Tuner
Adjustments,Operations

SEARS ROEBUCK & CO.

THE MOTO-MATIC TUNER

HOW TO SET UP STATIONS ON THE TUNER:-

1. Before setting up the "automatic tuner" it is necessary that the receiver be operated for about 20 minutes in order that all internal parts reach a constant temperature and all operating conditions are fully stabilized.



TURN THIS KNOB TO EXTREME RIGHT!

2. Turn the MOTO-MATIC SWITCH knob (lower center control) to the extreme right hand position. When the knob is in this position the word "MOTOR" will appear illuminated in the indicator just below the dial scale.

Turn the tone knob (lower-left-hand control) to the extreme left until pointer is pointing to "Sharp" on the indicator and leave this control set to this position during the entire following procedure of setting up the "Moto-Matic Electric Tuner."

3. Remove the large knob on the station selector shaft which is the control in the upper right hand corner of the receiver panel. (see fig. 6) This knob may be removed by simply pulling it away from the panel. As this knob is removed another small knob on the same shaft, partly hidden behind the panel face, will appear.

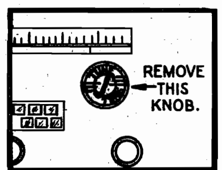


FIG. 6

4. Grasp this knob and pull it out as far as it will go and at the same time "rock" it so that the gears in the mechanism at the rear will mesh properly (see fig. 7).

5. The knob should now be rotated to the right (clockwise) as far as it will go. Keep turning the knob to the right even though it becomes harder to turn as it nears the end of its rotation. The knob will turn rather stiffly and the dial pointer will travel over to the left side of the dial scale. After the pointer reaches the end of the scale continue to turn the knob clockwise about 3/4 of a turn until it reaches a definite stop. This last twist releases the mechanism controling the tuner. THE KNOB MUST BE TURNED AS FAR AS IT WILL POSSIBLY GO OTHERWISE THE MECHANISM WILL NOT BE RELEASED AND IT WILL BE IMPOSSIBLE TO SET THE TUNER TO STATIONS.

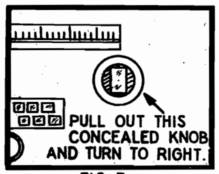

FIG. 7

6. Push any button which you wish to set to a particular station. Be sure the button is pushed all the way in (see fig. 8).

7. Set "Moto-Matic" switch to "Manual", grasp the small station selector knob again and tune the receiver to the desired station. Tune carefully, making use of the tuning eye to be sure that you are correctly tuned to the station in question.

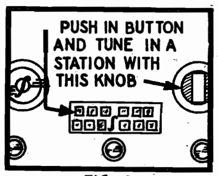

FIG. 8

8. The depressed button is set to the station as soon as it is released in either of the two following ways depending on whether you wish to set up more buttons or whether only the one button is to be set up.

A. <u>IF NO MORE BUTTONS ARE TO BE SET UP.</u> Proceed as described under No. 11, 12 and 13.

B. <u>IF ADDITIONAL BUTTONS ARE TO BE SET UP.</u> Turn the "Moto-Matic" switch to "Motor". Release the first button by pushing in the next button you wish to set up and proceed as follows:

THE DEPRESSED BUTTON HAS NOW BEEN SET TO A STATION. CONTINUE TO SET UP AS MANY BUTTONS AS DESIRED BY FIRST PUSHING IN A BUTTON AND THEN TUNING IN A STATION.

FIG. 9

9. Set "Moto-Matic" switch to "Manual", tune in the station that you wish to receive with the button that is now depressed, again making use of the tuning eye to be sure that you are correctly tuned to the station.

10. Continue to set up as many other buttons as desired in the same manner, that is, push in the button, set the "Moto-Matic" switch to "Manual", tune in the station, set the "Moto-Matic" switch to "Motor", then push the next button.

11. In order to release the last button which now remains depressed, grasp the knob on the station selector shaft and push it back into the cabinet as far as it will go and then pull it out again. Do not forget to "rock" the control when pulling it out in order that its gears may mesh properly (see fig. 10).

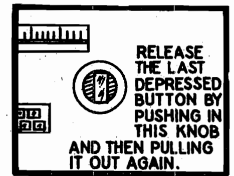

FIG. 10

12. Turn the knob to the LEFT until you reach a definite stop. A firm pressure must be applied otherwise you will not lock all of the internal controls (see fig. 11) The knob will turn rather stiffly and the dial pointer will travel over to the right side of the scale. Continue to turn the knob to the left even after the pointer reaches the end of the dial scale. APPLY A FIRM PRESSURE UNTIL THE KNOB REACHES A DEFINITE STOP.

13. Push the small station selector knob back into the cabinet again and put on the large knob that was originally pulled off of this shaft at the start of operations (see fig. 11).

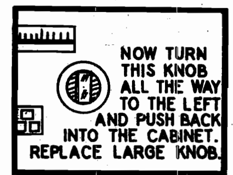

FIG. 11

14. Your "automatic tuner" is now ready for operation. Labels bearing the names of all stations are supplied for use in labeling the push buttons. To label the push buttons you must first remove the cap of the push button. The cap is pulled off by pulling on the top end which has a small hump that holds the cap. Remove the white cardboard tab and insert the label for the station to which the button was set. In replacing the cap start at the bottom and press on the top.

15. YOU DO NOT NEED TO ADJUST THE AUTOMATIC TUNER AGAIN UNLESS YOU DESIRE TO SET ANY ONE OR MORE OF THE BUTTONS TO DIFFERENT STATIONS.

In order to reset one or more buttons of the "automatic tuner" to different stations, it is only necessary to repeat operations No. 3, 4 and 5; then push in the button that you wish to reset and tune in the new station. Repeat this operation with any other buttons to be changed and then "lock up" the mechanism as explained in operations No. 11, 12 and 13. THE REMAINING BUTTONS WHICH YOU HAVE NOT DISTURBED WILL REMAIN "SET-UP" TO THEIR ORIGINAL STATIONS.

16. It is not advisable to set up the "automatic tuner" for operation on short wave or police band. However, the "tuner" may be set up for stations on the police band but extremely accurate tuning such as is obtainable on the broadcast band cannot be expected. In this case the automatic tuner will only serve to give the approximate location of the station.

HOW THE TUNER OPERATES:-

The "Moto-Matic Tuner" is a mechanical device which has for its prime purpose the accurate noiseless and speedy tuning of a station, by the push of a button. This function is performed in the following manner.

As the push button on the keyboard is depressed, a pawl arm at the rear of the tuner comes forward and rests against a circular cam. It will be noted that these cams have two different heights (that is, a high and a low side). The purpose of the two different levels will be self-evident as this explanation progresses.

Projecting from the rear of the unit is a set of switches which are motivated by a Bakelite switch operating cam and arm. This arm is in turn operated by the movement of the pawls. Therefore, it is readily seen that the position of the pawl arm will control the setting of the electrical contacts of the switches in question.

Since the contacts of this switch are frequently referred to, it is advisable that we designate each set of contacts by name as follows: Reading from the front of the switch to the rear:-

1. <u>REVERSING CONTACTS</u>:- For reversing the direction of motor rotation.
2. <u>STARTING CONTACTS</u>:- For opening and closing the motor power supply line.
3. <u>MUTE CONTACTS</u>:For silencing the audio system to prevent noise coming through to the speaker during automatic tuning.
4. <u>A.F.C. CONTACTS</u>:- The A. F. C. contacts are closed in order to remove A.F.C. until the station is tuned in, thus eliminating the possibility of "grasping" the wrong station before the tuner comes to rest. (A.F.C. is again restored when the mechanism comes to rest).

SEARS ROEBUCK & CO.

Also located directly above the tuning shaft will be found an auxiliary pair of contacts known as the power contacts. These contacts are the last ones to close when the tuner goes into operation thus allowing all switches to reach their proper settings before any power is actually turned on.

Before any button is depressed or with the tuner in the manual tuning position all contact switches are in the position shown in Figure 13.

Now as the button is depressed the corresponding pawl arm will come forward to rest upon either the high or low side of a cam depending upon the cams position. If the pawl arm comes to rest on the high side of a cam, the bakelite arm will come up only a short distance and the reversing contacts will make in the forward position. If it comes to rest on the low side of a cam, the bakelite arm will come up further and the reversing contacts will make in the rear position. These positions are indicated in figures 14 and 15. Thus it can be seen that the position of the pawl arm, whether on high or low side of cam, will determine the direction of rotation of the motor.

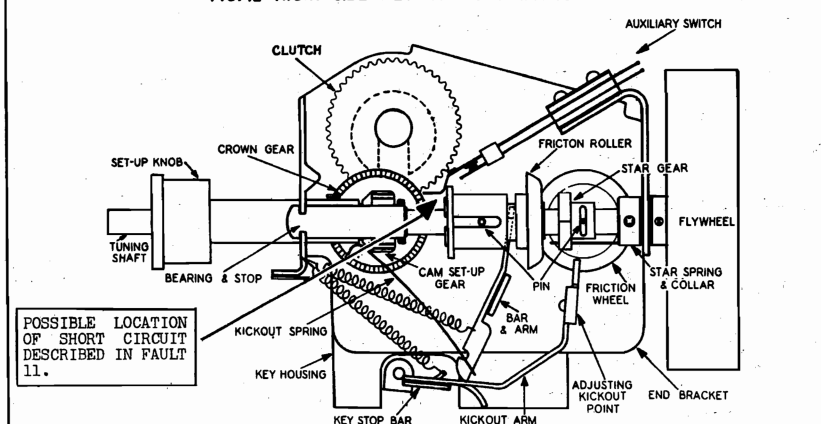
Regardless of whether the pawl is on the high or low side of the cam, the bakelite arm will close the starting contacts, mute contacts, and A.F.C. contacts.

Also after all of the above contacts have been made the power contacts over the tuning shaft will close thus causing the motor to run.

We now have the tuner in operation and the motor proceeds to drive the mechanism to the proper position for the desired station and the following events will occur.

First, the pawl arm will fall into a notch in the circular cam. This in turn causes the Bakelite cam to set the rear contact switches in a new position. The starting contacts then open and the motor stops. Since the pawl is in the notch the mechanism cannot move further. The shock of the sudden stop is taken up by the clutch shown in Figure 12.

FIG. 12 RIGHT SIDE VIEW OF MOTO-MATIC TUNER



The A.F.C. and mute contacts are both open, thus allowing the signal to come through the receiver and also allowing the A. F. C. to function which in turn puts the finishing touches on a perfectly tuned-in program. This position of the switch showing the station tuned-in is shown in Figure 16

Thus we have completed one entire cycle from push button to the completely tuned program, utilizing the Moto-Matic tuner.

We wish to call your attention to the control mechanism on the right side of the tuner, (see Figure 12) which disengages the manual tuning mechanism when automatic tuning is used. The most important features here are the "kickout arm" and the friction roller.

The friction roller must disengage from the friction wheel when the tuner motor is in operation. This is accomplished by a projection on the push button itself which, when pushed in, pushes the "bar and arm" assembly backward. Since the bar and arm assembly rotates on a pivot, it will cause the upper end of the bar to disengage the friction roller from the rubber friction wheel. The lower end will go backward allowing the kickout arm to come up until the adjustable tip touches a valley in the star-wheel. It may now be seen that the motor does not now have to drive the tuning shaft which eliminates the turning of the tuning knob while the motor is running.

Now when you again grasp the tuning knob to tune manually the star wheel, which is touching the adjustable tip of the kickout arm, will rotate and push the kickout arm down. The kickout arm true to its name "kicks out" the push button and releases the pawl which was engaged with a cam. The mechanism is thus again entirely free to turn and the friction roller and rubber friction wheel are again engaged. Thus by turning the tuning knob you can also tune your station manually, provided the A.F.C. knob is placed in the manual position.

GENERAL SWITCH CONTACT ADJUSTMENT

The moto-matic tuner has two sets of switches, "back switch" and "side switch", which are the heart of the automatic control system. The successful operation of the tuner depends to a considerable degree upon the proper operation of these switches.

The following discussion explains in detail the necessary operations for adjustment of the various switch contacts and should be used in conjunction with figures 13, 14, 15 and 16 appearing on the next page. (Please note that two sets of diagrams are given since a change was made in the design of the bakelite switch operating cam and the back switch. To distinguish which set to use on the receiver that you are repairing, it will only be necessary for you to read the notes at the head of the two pages showing these drawings).

①-BEFORE MAKING ANY ADJUSTMENTS TURN OFF THE POWER.

②-IN ORDER TO PLACE THE MECHANISM IN ANY OF THE POSITIONS SHOWN IN FIGS. 13,14,15,OR 16,IT IS ONLY NECESSARY TO PULL THE SET-UP KNOB OUT, UNLOCK THE CAMS, AND TURN THE SET-UP KNOB TO THE DESIRED POSITION.

ADJUSTMENT OF BACK SWITCH

It is highly important that all contacts of this switch be set in exactly the right position. The contacts should make and break as shown in figures 13, 14, 15 and 16 for any button. Minor adjustments of the switch to secure these settings may be obtained by bending the various blades.

If more than minor adjustments are necessary the following instructions should be carried out in every detail.

1. The back switch should be so positioned as to require a minimum of bending of the switch blade.

2. The contact pressure of all contacts should be such as to cause about 1/64 inch travel of all contacts after they close. This provides adequate wiping action to keep the contact surface clean and insure positive contact.

3. With the back switch in the positions indicated in either figures 13, 14, 15 or 16 the contacts should be adjusted such that:-

(a) The mute contacts should close before the motor contacts do and open after them to provide quiet tuning. To accomplish this the mute contacts should not open as far as the starting contacts do.

(b) Minimum opening of the motor contacts is desirable. This keeps the power on as long as possible and permits the pawl to fall completely into the notch in the cam. On the other hand the contacts must break clean -- far enough apart to prevent excessive arcing.

SEARS ROEBUCK & CO.

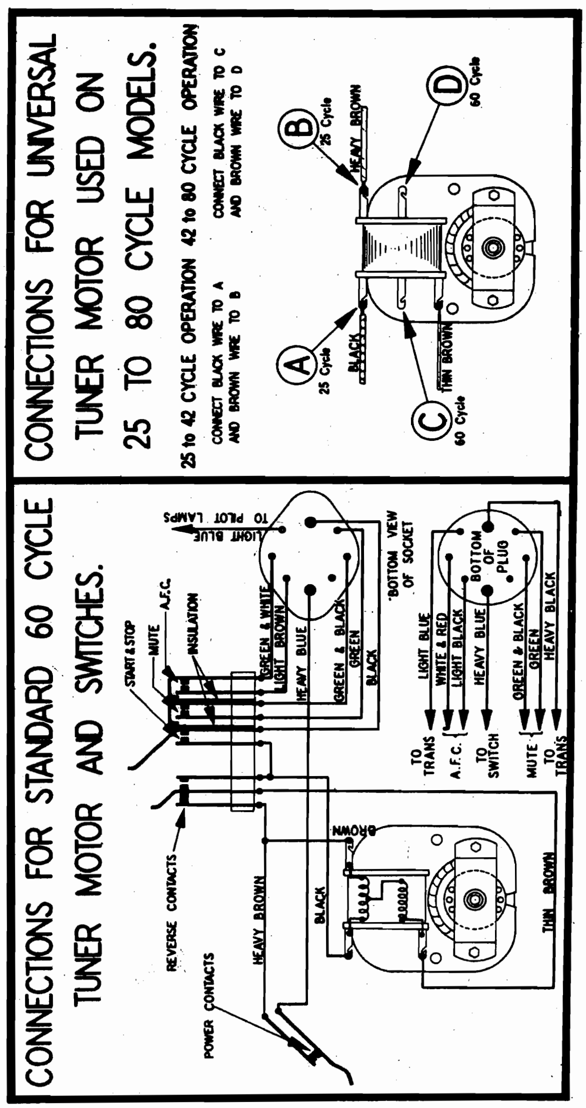
(c) The mute and A.F.C. operating blades should not press against each other or against the switch operating arm, but just barely touch. Otherwise they may cause the bakelite cam to bind or "hang".

4. If the back switch arms require too much bending for proper adjustment it will be necessary to loosen the two switch bracket mounting screws and reset the entire switch. The switch should then be set with the mechanism in the position shown in figure 16, with the switch operating arm resting just on the top edge of the hump marked check point "X" in figure 16. If the switch is set too high the operating arm will not come up out of the notch on the bakelite cam far enough to cause the contacts to open. If the switch is set too low the operating arm will open the contacts and cut the power off too soon.

Now to further check the proper position of the back switch, push in another button which will cause a pawl to fall on the high side of its station selector cam as shown in figures 14. The tips of the operating arms of the main and reversing contacts should be approximately 1/16 of an inch from the bottom of the valley in the bakelite cam as shown in figure 14 check point "Y". If this distance is less than this amount, an excessive pressure is exerted on the bakelite cam when in the position shown in figures 13 and 16, thus causing it to bind or "hang". If the distance is greater than that shown here, there is insufficient contact movement for good switch adjustment.

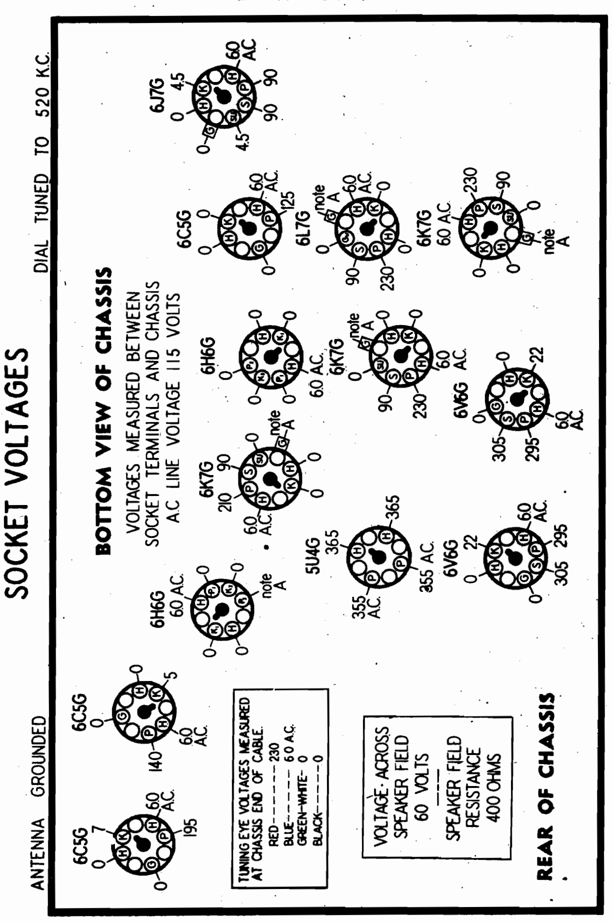
Check each button for the settings outlined above, using the set-up knob to turn the cam shaft rather than turning the power on. Due to slight variations in the pawls, it will not be possible to adjust for all buttons so that the switch operating arm rests exactly at the "check points" referred to, but, all buttons must cause the back switch operating arm to come up out of the notch in the bakelite cam when a pawl falls into its notch on the station selector cam.

In order to check the reversing contacts, run the dial pointer to the high frequency end of the dial, and then push each button in, in turn. Check the reversing contacts to see that they take the position shown in figure 15. The two outside blades of this group must not be in contact with the center blade at the same time, otherwise the 6 volt winding of the power transformer may be short circuited. Make such slight adjustments as may be necessary to secure the proper contact settings by bending the switch blades.



Use a high resistance voltmeter of 1000 ohms per volt.

NOTE A: The bias for the control grids of the 6L7-G, 6K7-G, R.F., 6K7-G first I.F., 6K7-G second I.F. and the diode of the 6H6-G 2nd detector tube is -4.5 volts measured across resistor R26.



SEARS ROEBUCK & CO.

ADJUSTMENT OF SIDE SWITCH

The purpose of the side switch is to keep the power supply for the motor open until the back switch contacts have all had time to reach their proper positions.

To secure such a sequence of contact closing the bakelite ring on the friction roller assembly should not come forward under the operating arm of the side switch until all of the contacts of the back switch are closed. To make this adjustment bend the switch mtg. bracket in such a manner that the switch operating arm will be carried forward or backward relative to the bakelite ring on the friction roller, as the situation may require. This is done in order that the back switch contacts shall all have had time to make contact.

If this adjustment is not obtained, when a button is pushed in slowly or only part way the motor may start too soon or run the wrong direction.

HOW TO RESTRING THE DIAL CORDS

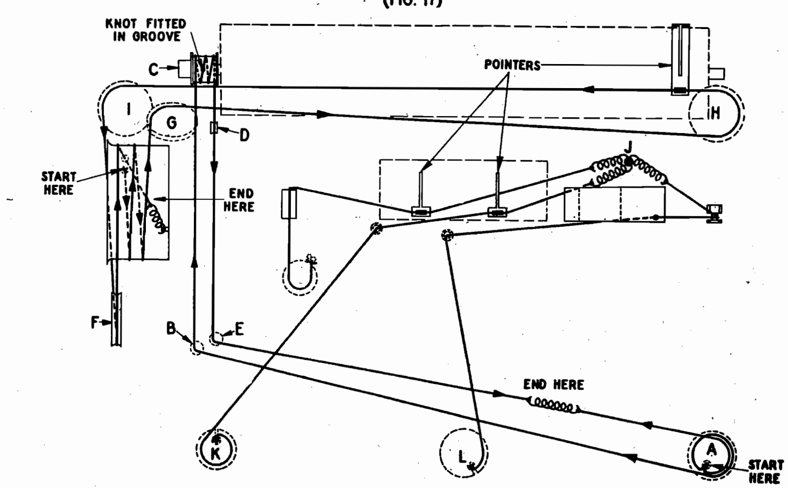
MAIN DIAL POINTER DRIVE CORD

The cord for the main pointer drive system is approximately 65 inches in length. Before attempting to restring this drive cord, the large drum on the left side of the mechanism must be placed in the position shown in the diagram. That is, the two small holes in the drum must be on the back of the drum near the top.

Now put a knot in one end of the cord and thread the cord through the lower of the two holes in the drum, (see point marked "Start Here" in figure 17) leaving the knotted end inside of the hole in the drum. Wind the cord down the back side of the drum in a counter-clockwise direction (when viewed from the left side) until 1-3/4 turns have been made. The cord is now carried up and around pulley G, then across the dial to pulley H. Proceed to carry the cord up around pulley H (see figure 17). After leaving the top of pulley H proceed across to pulley I and then down behind the large drum to pulley F. Carry the cord up around pulley F and back to the front side of the large drum. Wind the cord up over the drum, using the outer (left) edge, until the upper hole in the drum is reached. Thread the cord through the hole and tie the tension spring to its end in such a manner that when the spring is clipped into position the spring will be extended to about 1-1/8 inches.

The main dial pointer should now be clipped on the upper strand of cord that is now stretched between pulleys H and I. The pointer should be clamped in position just opposite the last dial division on the high frequency end of the dial.

(FIG. 17)



RANGE SWITCH AND ROLLER SCALE DRIVE

The cord for restringing the roller scale range indicator drive should be approximately 55 inches long. To restring this drive cord place the range switch in the American (A) position. Tie a knot approximately 6 inches from one end. Then tie a second knot exactly 27-1/2 inches from the first knot.

Now place the first knot in the slot in pulley A allowing the short end of the cord to project to the right. Take the long end of the cord and wind one complete turn around pulley A in a clockwise direction. Then continue across to the bottom of pulley B and up to the front of pulley C. Wind one complete turn around pulley C in a counter-clockwise direction looking at it from the left end of the mechanism. Now rotate the dial drum until the slot in the pulley exactly meets the knot which you previously tied in the cord and which appears at this point in the winding. Place the knot in the slot in pulley C and taking the free end of the cord proceed to wind one more complete turn around pulley C in the same direction (counter-clockwise).

Now take the cord down over pulley D to the bottom of pulley E. Proceed from pulley E to the right and allow the cord to remain loose until you have finished the following steps.

Take small short end of the cord that extends to the right of pulley A and wind it up over the pulley counter-clockwise and tie the tension spring to its end. Then take the cord that is extending from the left side and tie it to the other side of this tension spring so that the spring is extended to about 1-1/8 inches.

You have now completed the cord circuit, but the rotating scale may not be in the correct position. Since the range switch is in the American position the roller dial should present the American scale to the escutcheon face. If it does not loosen the set screw in pulley C and rotate the drum to the desired position. Then retighten the set screw.

MOTOR-REGULAR-PHONO INDICATOR DRIVE CORD

This cord is approximately 22 inches in length. Start to restring by placing the moto-matic switch in the phono (Maximum counter-clockwise) position.

Now tie a knot in one end of the cord. Tie a second knot exactly 15 inches from the first. Then place the first knot in the slot in the pulley on the moto-matic switch shaft. Wind the cord up around the pulley (1/2 turn counter-clockwise) and up to the eyelet hole in the frame (just under the volume indicator). Then carry the cord to the right and thread it through the hole in the movable section of the Motor-Reg.-Phono indicator. The knot in cord should just reach the back of this movable celluloid slider.

Now taking the cord, which extends from the front of the hole in the slider, tie the tension spring to its end so that the spring will be extended to about 1-1/8" when clipped in position on holder J. (see figure 17.)

OFF-ON AND VOLUME INDICATOR DRIVE

The length of this cord should be approximately 18 inches. Put the volume control and off-on switch in the "off position" (maximum counter-clockwise). Tie one end of the cord around the set screw on the collar appearing on this shaft. Then wind the cord clockwise around the shaft and over the pin about 3/4 of a turn. (Do not wind the cord around the pin itself). Then take the cord up through the last remaining hole in the frame and over to the volume indicator. Clamp the pointer, for this indicator, on the cord so that it points to the word "off" on the indicator. Tie the remaining end of the cord to the tension spring so that when the spring is clipped to hole J (see figure 17) it will be extended to a length of 1-1/8 inches.

TONE AND SELECTIVITY DRIVE CORD

The length of this cord should be approximately 20 inches. Start by placing the tone switch in the bass position (maximum counter-clockwise). Place a knot in one end of the cord and put the knot in the slot in the pulley on the tone switch shaft.

Then wind one complete turn around the pulley on the tone shaft in a clockwise direction. Carry the cord up to the hole in the frame (next to the tuning eye). Take the cord to the right until it is under the tone selectivity indicator. Then holding the cord taut clip the pointer, for this indicator, tightly to the cord so that it points to the word bass on the indicator. The remaining cord should be tied to the tension spring which is then clipped to the hole marked J (see figure 17).

Tuner Faults and Remedies

SEARS ROEBUCK & CO.

FAULTS-CAUSES-REMEDIES:-

POINTER DOES NOT MOVE WHEN BUTTON IS PUSHED IN

FAULT	PROBABLE CAUSE	REMEDY
(1) Motor hums but does not run	(a) Reversing contacts on back switch not closing.	(a) To correct this fault you must make a thorough check of all switch adjustments as explained under "General Switch Adjustment" and check carefully to see that the reversing contacts are set correctly when the mechanism is in the positions shown in figures 14 and 15.
	(b) Motor stalled due to mechanical overload and clutch not slipping.	(b) Such an overload may be caused by any one or a combination of the following: (1) binding of the dial pointer against the dial, dial frame, or cabinet. Also rough, rusty or bent pointer slide rail. (2) pointer drive cable too tight. (3) jammed or stuck guide pulleys (4) crossed dial cord on dial drum. (5) drive drum gear out of mesh. (6) misalignment or tight cam shaft bearings. (7) cam shaft sprung or bent. (8) collar on left end of cam assembly binding against left end bracket. (9) excessive friction between pawl and station selector cam due to rough or burred surfaces. (10) set-up crown gear assembly binding. (11) gang condenser drive gears out of mesh and binding. (12) tight, jammed or sticking gang condenser. The remedy for any of these faults is fairly obvious and no mention will be made here other then stating that a complete write up on how to restring any part of the dial cord drive is included in following pages of this service manual.
	(c) Defective motor.	(c) Replacement of motor necessary.
	(d) Low line voltage or improper frequency.	(d) Proper line voltage is imperative for operation of the tuner. A special universal motor may be obtained where the frequency of the power supply is other than 60 cycles; see the parts list at rear of manual.
(2) Motor runs but pointer does not move.	(a) Clutch slipping.	(a) This may be due to a mechanical overload or a defective clutch. First examine the clutch (see figure 12) to see that the horse shoe shaped spring has not been weakened or broken also see that no oil or grease is present (If grease is present wash surface clean with carbon tetrachloride). If the fault is due to a mechanical overload you should refer to fault (1) cause (b) for remedies. If the remedies given fail, replace the horseshoe shaped clutch spring. (Part No. 10054111138). Clutch Springs now supplied are somewhat heavier than those used on earlier sets. Later type clutch assemblies have the spring staked to the hub (see illustration).  If desired such a staked type of Clutch (Part No. 10054111146) can be installed as follows. 1. Remove the L shaped horizontal brace on the back of the Dial Frame. This is the part supported by the brackets screwed to the sides of the chassis. 2. Take the Side Switch Mounting Screws out and swing the switch out of the way. 3. Drive out the pin through the Friction Roller Assembly. Pull out the pin in the Star Wheel. Loosen the set screws in the Star Spring Collar and Flywheel. The Tuning Shaft can now be pulled out. (NOTE that there is a groove around the tuning shaft. The set screw of the Star Spring Collar fits into this groove, thus fixing the lateral position of the shaft with respect to the End Bracket.) 4. Take the Set-up Knob off. Remove the Tuning Shaft Bearing and pull the Sleeve and Set-up Gear out of the End Bracket. 5. Take the Retaining Ring off the Set-up Crown Gear Stud and remove the Crown Gear Assembly. 6. Remove the Right End Bearing and Bracket 7. Take the Knurled Crown Gear off the Extension Shaft 8. Loosen the Clutch Set Screw, disassemble the Clutch and slide the Collar and Gear Sections off the Cam Shaft to the right.
	(b) Pointer drive gear slipping on shaft or out of mesh.	(b) Tighten set screw in gear or remesh gears.
	(c) Pointer loose on cord.	(c) Tighten clips on pointer slider.

FAULT	PROBABLE CAUSE	REMEDY
	(d) Pointer sticking on guide rail due to rust.	(d) Clean guide rail carefully with piece of emery cloth and oil.
(3) Motor does not hum and tuner does not move with button in.	(a) Power contacts on side switch not closing.	(a) Adjust power contact as explained under "General Switch Adjustment", and adjust carefully to see that power contacts are set correctly with the mechanism positions shown in figures 13 and 16.
	(b) Starting contacts on back switch not closing.	(b) Adjust starting contacts on back switch as described in, "General Switch Adjustment", and check carefully to see that starting contacts are set correctly for the mechanism position shown in figures 14 and 15.
	(c) Loose silver contact on switch contact blade.	(c) Replace entire switch.
	(d) Bakelite back switch operating cam binding on contact arms, or out of position.	(d) If the bakelite cam binds against the switch operating arms it will indicate that the cam is either rough or the tension in the spring at its side is insufficient. Cut off several turns of this spring to increase tension and then replace the spring.
(4) Pointer stops at wrong point.	Improper setting up of mechanism. Mechanism not locked up properly.	Set up mechanism again, being careful to tune to stations, using tuning eye to determine exact set-up position. In locking the mechanism be sure to force the set-up knob all the way to the left counter-clockwise until you are positive the knob will not turn further.
(5) Pointer stops at proper point but: (a) No signal is heard.	(a) Mute contacts on back switch not opening: (No noise will be heard in this case)	(a) See paragraph on "General Switch Adjustment", and check carefully to see that the mute contacts are set correctly with the mechanism in the positions shown in figures 14 and 15.
	(b) Tuning backlash.	(b) For remedies see fault 12 which covers in detail all possible causes.
	(c) Gang condenser drive gears out of mesh or slipping on shaft.	(c) Re-mesh gears and tighten set screw.
	(d) Flexible coupling slipping on shaft.	(d) Tighten set screw for flexible coupler.
	(e) Station not broadcasting or too weak as in daytime or during period of fading.	(e) Be sure aerial is adequate. Do not attempt to tune this station until reception is suitable.
(b) Signal is not heard clearly.	(a) A.F.C. contact on back switch not opening.	(a) Check A.F.C. contacts with the mechanism in the position shown in figure 16. See that A.F.C. contacts are open in this position.
	(b) A.F.C. not functioning.	(b) Change discriminator or control tube, re-align A.F.C. system, lastly, make check of entire system.
	(c) Weak signal or no aerial.	(c) Do not attempt to set buttons to weak signal stations. Install adequate antenna.
(c) Wrong station comes in.	(a) Desired signal off, weak or faded.	(a) Set up button to another station if desired or wait for next broadcast period of station before attempting to use this button. If the signal is very weak or fading do not attempt to set up button for that station.
	(b) Not set-up properly.	(b) Reset up for the particular station in question.
	(c) Set off calibration.	(c) For incorrect calibration see fault 13 which itemizes in detail the causes for this miscalibration.
(d) Motor continues to run.	(a) Pawl doesn't fall far enough into the station selector cam to cut power off.	(a) It is probable that the starting contacts are not opening properly, i.e. before the pawl has fallen as far into the cam notch as it should. Check switch contact adjustments as described under, "General Switch Adjustment". Burrs on the pawl or cam will also aggravate this condition. Anything that makes the bar carrying the bakelite cam operate stiffly should be corrected also.
	(b) Starting contacts on back switch not adjusted properly.	(b) Check starting contacts with mechanism in position shown in figure 16 to see that starting contacts are open with mechanism at rest. Also, read, "General Switch Contact Adjustments".

SEARS ROEBUCK & CO.

MODELS 4688, 4788, 4799
Chassis 100.159
Tuner Faults and Remedies
Part 2

FAULT	PROBABLE CAUSE	REMEDY
(6) Pointer stops at different place each time for a certain button.	(a) Mechanism not locked up tight.	(a) Reset button, being sure to lock mechanism tightly by forcing set-up knob counter-clockwise until you are sure that the knob will not turn further.
	(b) Dial pointer slipping on cord.	(b) Tighten clips holding dial cord to pointer slider
(continued on next page)	(c) Left end bracket bearing loose.	(c) Re-tighten bearing bracket mounting bolts.
	(d) Pointer drive gears slipping out of mesh or slipping on shaft.	(d) Re-set pointer drive gears so that they mesh properly and tighten their set screws firmly so they will not slip.
	(e) Loose set screws.	(e) Re-tighten all set screws to insure against slipping.
(7) Pointer stops off station occasionally.	(a) Pointer back-lash, (Note, pointer back-lash will cause apparent rather than actual mis-tuning.)	(a) Check to see that back-lash is at a minimum at the pointer drive gear on the left side of the mechanism. Also, see that bearing bracket is tight, not moving, which would also cause apparent back-lash.
	(b) Pawl does not fall far enough into station selector cam.	(b) Starting contacts opening too soon. Check switch contact adjustments. Check for burrs on pawl or cam.
(8) Pointer goes to end of dial and motor stalls and hums, or continues to run by slipping the clutch.	(a) Station selector cam turned around beyond its normal operating range.	(a) First unlock cams and then turn station selector cam around so that notch faces pawls.
	(b) Reversing contacts on back switch not adjusted properly.	(b) Check switch contact adjustment with mechanism in position shown in figure 16 and also read paragraph on, "General Switch Adjustments".
	(c) Bakelite cam binding on contact arm, or out of position.	(c) Check bakelite cam for rough spots. Increase spring tension of side operating spring for bakelite cam by clipping off several turns.
(9) Motor continues to operate, moving the pointer back and forth over a short distance after tuning to the approximate frequency to which the button is set.	(a) Reversing contacts on back switch are not adjusted properly - set too close.	(a) Since the reversing contacts are set too close the slightest movement of the operating arm will cause the motor to reverse, therefore the switch contact arms must be spread slightly in order that small movements of the center arm will not cause motor to reverse or "hunt".
(10) Motor starts before button is pushed in far enough to catch. Motor starts in wrong direction then corrects itself as button is pushed the rest of the way in.	(a) Side switch, power contacts are being closed too soon.	(a) Read paragraph on, "General Switch Adjustment", and check to see that power contacts make contact after all of the rear switch contacts have been made or button has been pushed all the way in.
(11) Intermittent operation of motor, lights, etc.	(a) Insufficient contact pressure or dirty contacts on back or side switch.	(a) Check all switch contacts for proper contact pressure. This may be done by noting that the contact is first made and then there is a continued movement of the contact arm in which the first contact wipes the second and both contacts move backward about 1/64 of an inch.
	(b) Loose silver contact on switch blade.	(b) Repair if possible; or, replace entire switch.

FAULT	PROBABLE CAUSE	REMEDY
(12) Tuning back-lash (Note the high tuning ratio greatly exaggerates the effect of most of these conditions)	(a) Clutch slips	(a) This may be due to mechanical overload or a defective clutch. First examine the clutch, (see figure 12) to see that the horse shoe shaped spring has not been weakened or broken, also, see that no oil or grease (if grease is present wash surfaces clean with carbon tetrachloride). If fault is due to mechanical overload you should refer to fault 1, cause (b) for remedies.
	(b) Play between gang condenser drive gears due to insufficient compression in thrust spring in flexible coupling.	(b) Release set screw on flexible coupler and push auxiliary shaft forward until drive gears mesh properly. Retighten set screw.
	(c) Play between gears due to improper setting of anti-back-lash spring.	(c) Check to see that separate sections of the gears having anti-backlash spring ar spread against the spring tension before they are meshed in order that backlash will not occur.
	(d) Play between gear and stud.	(d) See that the stud is not shaky or loose in its mounting and see that the gear is mounted on its shaft snugly so that "wabble" does not take place.
	(e) Gang condenser sways.	(e) Mount more securely by tightening gang condenser mounting bolts.
	(f) Loose set screw in coupling or gear.	(f) Retighten all set screws. Check to see that gears are not slipping on shaft.
	(g) Loose or worn bearings.	(g) Tighten bearing mounting plates. Replace worn bearings.
	(h) Friction roller rotates slightly relative to tuner shaft.	(h) Replace the pin holding the friction roller on the shaft using a larger pin.
(13) Calibration incorrect.	(a) Dial pointer or gang condenser drive gears jump teeth, slip on cam shaft or are out of mesh.	(a) Check to see that gang condenser drive gears mesh properly. Also, see that set screws of these gears are tightened properly so that slipping cannot occur.
	(b) Dial pointer slips on dial cord.	(b) Tighten dial cord clips on pointer slider so that slider will not slip along cord.
	(c) Left end bearing bracket loose.	(c) Retighten mounting bolts for bearing bracket.
	(d) Excessive pointer back-lash.	(d) Tighten dial cord by shortening slightly and re-tying to tension spring inside of drum. Also, check drive gear on left side of mechanism to see that backlash is not occurring.

BUTTON DOES NOT STAY IN OR DOES NOT RELEASE

FAULT	PROBABLE CAUSE	REMEDY
(14) Button will not stay in when pushed in.	(a) Kickout pointer tip improperly adjusted.	(a) Adjust the tip of the kickout bar so that a key will be held in place when pushed in and the adjustable tip just touches a valley in the star wheel.
	(b) Kickout spring bent out too far.	(b) Adjust kickout spring to position shown in figure 12 with mechanism in manual tuning position.
(continued on next page)	(c) Insufficient tension in key stop bar return spring.	(c) Clip off several turns of this spring to increase its tension and replace. See figure 12.

MODELS 4688, 4788, 4799
Chassis 100.159
Tuner Faults and Remedies
Part 3

SEARS ROEBUCK & CO.

FAULT	PROBABLE CAUSE	REMEDY
	(d) Jammed or stuck key stop bar.	(d) Check to see that the adjustable tip of the key stop bar is not stuck on the side of the star wheel, thus causing it to bind or stick.
	(e) Star wheel stuck or not moving freely on tuning shaft.	(e) The wire spring engaging the star wheel may be broken or severely bent; Replace. Burrs between star wheel and tuning shaft may also cause binding.
	(f) Bent or sprung key stop bar.	(f) In this instance replace the key stop bar.
(15) Depressed button does not release when another button is pushed in.	(a) Kickout tip jams against star wheel.	(a) Check to see that end of kickout tip is not catching on tip of star wheel.
	(b) Stuck or jammed pawl.	(b) A pawl may be jammed so tightly into its slot in a cam that it will not release of its own accord. Release the pawl by pulling it out of the slot and check to see that it will not stick when operated again. If it sticks again use sand paper or an oil stone to remove burrs which have evidently caused sticking.
	(c) Stuck or jammed key.	(c) The key may be bent thus causing jamming. Straighten and align key.
(16) Depressed button will not release when tuning knob is turned.	Kickout tip not engaging star wheel.	Adjust the kickout tip so that it will touch the bottom of the valley of the star wheel when a button is pushed in.

DIFFICULTIES OCCURRING DURING SET UP BUT NOT IN NORMAL OPERATION

FAULT	PROBABLE CAUSE	REMEDY
(17) Button does not release when set up knob is worked in or out.	Kickout spring set too far from kickout arm.	Check to see that kickout spring is in position shown in figure 12 when set is on manual tuning.
(18) Mechanism locks up during setting up of a station.	Defective locking mechanism.	Put some oil between the cams and friction washers. If you are sure that you have forced the set-up knob to a maximum clockwise position, and the mechanism still locks up, it will be necessary to replace parts of the locking mechanism.

MANUAL TUNING DIFFICULTIES

FAULT	PROBABLE CAUSE	REMEDY
(19) Set tunes very broadly.	"Moto" switch in "Motor" position.	"Moto" switch should be turned to "Manual" to cut out AFC action.
(20) Tuning knob sticks and catches in going from "automatic" to "manual" tuning.	(a) Burrs on the tip of kickout arm, or star wheel.	(a) Use piece of emery cloth to carefully clean tip of kickout arm and any burrs which might remain on the teeth of the star wheel.
	(b) Adjustable tip of kickout arm set improperly.	(b) Adjust the tip on the kickout arm so that it will just contact a valley in the star wheel when a button is depressed and when all buttons are released be sure the tip of the star wheel does not contact the adjustable tip on the kickout arm.
(21) Pointer does not move when tuning knob is turned although works OK in automatic position.	(a) Oil or grease on rubber drive ring, on friction wheel.	(a) Clean the rubber drive ring with carbon tetrachloride until it is free from all oil or grease.
	(b) Jammed bar and arm assembly.	(b) If possible straighten the bar and arm, or; if severely bent replacement will be necessary. (continued on next page)
	(c) Insufficient tension in bar and arm assembly return spring.	(c) Clip off several turns of the return tension spring of the bar and arm assembly to increase the tension.
	(d) Bent tuning shaft.	(d) Carefully examine tuning shaft to see if it is bent. If found to be bent it will be necessary to replace the tuning shaft.

MISCELLANEOUS TUNER TROUBLES

FAULT	PROBABLE CAUSE	REMEDY
(22) Dial and automatic lights go out and set is silenced momentarily when a button is pushed in or released.	(a) Both reversing contacts on back switch close at once and short six volt winding of the power transformer.	(a) Examine reversing contacts to see that arms are not spaced too closely and also to see that when reversing contact breaks in one direction it makes a clean break before making contact in the other direction. If the center arm of the reversing switch is still in contact with the front arm when the rear contact is made a momentary short circuit will result.
	(b) Operating arm of the side switch grounding against friction roller assembly at point indicated by arrow and note in figure 12. This will cause momentary short circuit each time a button is pushed.	(b) Bend the tip of the switch operating arm upward slightly so that it will not contact the metal on the friction roller assembly which is probably causing the short circuit.
(23) Gears noisy during automatic tuning.	(a) Motor pinion and first reduction gear not meshing properly.	(a) Check to see that gears are meshed properly.
	(b) Too much compression in the anti-backlash springs in gears.	(b) Unmesh the gear, and rotate one of the gear sections with respect to the other so that the compression in the anti-backlash spring between the gears is reduced slightly. Then remesh the gears.
	(c) Burrs, bent teeth, and other irregularities on gears, especially those that operate at higher speeds.	(c) Inspect gears for such irregularities and if necessary, replace.
(24) Black ground lead near 6H6 tube under chassis heats up and smokes.	(a) Operating arm of side switch grounded against friction roller at point indicated by note in figure 12.	(a) Repair the fault which is causing the ground at the point indicated.
	(b) Tuning shaft bearing stop out of place and grounding power blade of side switch.	(b) Check to see that bearing stop is not out of its clip and sliding back on the tuning shaft thus causing a short. If this is true pull the bearing stop forward and clip it into its socket in the mounting bracket.
	(c) Any short from the 6 volt power line on the tuner mechanism to ground.	(c) Locate short.
(25) Slight hum is heard when motomatic switch is in the "Motor" position.	Unbalance in A.F.C. control circuits due to 6H6-G discriminator tube.	Replace 6H6-G discriminator tube which is causing difficulty.
(26) Signals are heard when tuning from one station to another automatically.	Mute contacts on back switch not closing making poor contact.	Check mute contacts with mechanism in positions shown in figure 14 and 15.
(27) Set noisy electrically in starting and stopping during automatic tuning.	Set used with insufficient antenna or mute contacts on back of switch closing too late and opening too soon.	Read paragraph on "General Switch Adjustments" and install adequate antenna.
(28) Mechanism reaches a definite stop before pointer reaches end of dial.	Cam assembly stop pin and the gang condenser stop are not set so they will reach their respective stop at approximately the same time.	Release the set screw on the flexible coupler, close the gang condenser then proceed to turn tuning knob clockwise until cam assembly stop in on left side of the mechanism is touching its front stop, then retighten set screw being sure that the gears at the end of the auxiliary shaft are properly meshed.

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

MOTO-MATIC TUNER PARTS

Part Number	Description	Selling Price Each
10054111700	Automatic tuning unit only less dial and drive mechanism	35.00
10054112734	Automatic tuning unit complete with dial and drive mechanism	56.00
10054111627	Bar and arm assembly	.60
10054111526	Bearing - on tuning shaft	.50
10054111176	Bracket - left side of cam shaft	.20
10054111547	Bracket - with studs (right side)	.90
10054111569	Bracket - push button escutcheon mtg.	.15
10054111162	Bushing - left end of cam shaft	.18
10054111576	Button washer - in push button	.005
10054111577	Button spring - in push button	.005
10054111613	Button - push button base	.10
10054111614	Button cap - for push button	.08
10054111880	Button window - celluloid per dz.	.07
10054111633	Button speed - nut - inside push button	.02
10054112023	Call letter tabs - for labelling push buttons	.60
10054111168	Cams - station selector	.50
10054111617	Cam - bakelite for master switch operation (with arm)	.62
10054112563	Cam - bakelite, less operating arm, used on Model 4788-with serial Nos. above 939,000 Model 4688-with serial Nos. above 934,302 Model 4799-all chassis.	.10
10054111146	Clutch - bushing, spring and gear	.55
10054111160	Collar - retaining, (less set screw) left side of cam shaft	.15
10054111161	Collar - retainer for pawls	.10
10054111616	Collar & spring - for star wheel	.36
10054111882	Collar - for spring locking cam	.08
10054111137	Drive ring - rubber	.05
10044111565	Escutcheon - around push buttons(on cabinet)	1.76
10044111670	Escutcheon - push buttons (metal)	1.20
10054111310	Flywheel - with set screws	1.25
10054111549	Friction roller - on rear end of tuning shaft	.30
10054111402	Friction wheel - with rubber ring	.66
10054111145	Gear - and pinion (reduction)	.45
10054111157	Gear - crown & pinion for "setting up"	.75
10054111640	Gear - for releasing & setting up (on tuning shaft	.35
10054112733	Housing - with keys	5.00
10054112522	Key stop - kickout assembly	.50
10054111632	Knob - for setting-up	.31
10054111408	Lock - saw tooth (adjacent to cam)	.40
10054111548	Lock - saw tooth with gear	.70
10054111380	Motor - 6 volt - 60 cycles	6.15
10054112354	Motor - 6 volt, 25 to 80 cycles	6.75
10054111491	Pawl and bushing - single unit	.20
10054111887	Pawls & shaft - assembly	3.00
10054111148	Pin - cam shaft, left side	.05
10054111409	Pin - for friction roller	.04
10054111410	Pin - in star wheel	.04
10054111411	Pin - cam shaft - right side	.04
10054111883	Pin - inside or lock	.03
10054111152	Retaining ring - for idler gear	.02
10054111153	Retaining ring - for crown gear	.02
10054111557	Retainer - for left side of pawl shaft(brass)	.03
1005475032	Screw - #4 for kickout tip per C	.50
1005485040	Screw - #6 hex. head for mtg. frame per C	.35
1005488707	Screw - binder head for mtg. push button escutcheon per dz.	.06
10054111673	Screws - (through master switch)	.01
1005485827	Set screws - 8/32 sq. hd. on clutch collar	.02
10054111403	Set screw - 8/32, fluted, head	.12
10054111554	Set screw - #4 headless (for pawl collar)	.01
10054111588	Set screw - for collar & spring mtg. (6/32)	.11
10054112138	Set screw - 8/32 round head	.03
10054111166	Shaft - for pawls	.20
10054111405	Shaft - for key stop bar	.18
10054111406	Shaft - for bar and arm assembly	.18
10054111641	Shaft - tuning	.35
10054111890	Shaft & cam - assem. (with right end bracket)	12.50

Part Number	Description	Selling Price Each
10054112630	Socket & bracket - for electrical connections to mechanism	.75
10054111169	Spacer - between cams	.11
10054111440	Star wheel - on tuning shaft	.25
1005485815	Spring - between reduction gear sections (next to motor)	.02
1005489086	Spring - between sections of dial drive gear on left side of mechanism	.01
10054111138	Spring - horseshoe shaped (on clutch)	.02
10054111151	Spring - key stop shaft retainer	.01
10054111528	Spring - coil (inside of lock)	.01
10054111552	Spring - flat, with tongue, on lock	.04
10054111555	Spring - for key and pawls	.06
10054111609	Spring - kickout	.05
10054111933	Spring - coil, keystop return	.03
10054112465	Spring - between reduction gear sections (next to cam shaft)	.01
10054112568	Spring - bakelite cam return	.05
10054111618	Switch - side; two contact	.37
10054111644	Switch - at rear; used on Model 4688 with serial Nos. below 934,302 Model 4788 with serial Nos. below 939,000	1.30
10054112564	Switch - at rear; used on Model 4688 with serial Nos. above 934,302 Model 4788 with serial Nos. above 939,000 Model 4799 all chassis	1.25
10054112521	Tip - adjustable for key stop & kickout arm	.06
1005476999	Washer - lock; for kickout tip per C	.50
1005477113	Washer - flat for kickout tip per C	.50
10054111553	Washer - spring retainer	.02
10054112483	Wrench - for fluted hd. set screws #6	.07
10054112484	Wrench - for fluted hd. set screws #8	.07
10054117466	Spring bender - for sw. adj.	.75

DIAL DRIVE AND MISCELLANEOUS PARTS

PRICES SUBJECT TO CHANGE WITHOUT NOTICE

Part Number	Description	Selling Price Each
10040111671	Background - (white) vol. & tone indicator	.07
10054111601	Bearing - self aligning	.12
10054111692	Bearing retainer - plate; copper	.06
10054111694	Bearing assembly - self aligning; supports gang extension shaft	.40
10054111939	Bearing plate and stud - for left side drive and gear support	.56
10054112629	Belt - metal; for range switch drive	.05
1005475153	Bolt - chassis mtg. (10-32 x 3/4")	.005
1005477969	Bolt - chassis mtg. (1/4-20 x 1-3/8")	.06
1005488831	Bracket - range switch shaft support(under chassis)	.02
10054111669	Bracket - for escutcheon mtg.	.15
10054111684	Bracket - for motor-Reg.-Phono mtg. strip	.07
10054111893	Bracket and mounting plate - for tuner mechanism	3.10
10054111937	Bracket - for mtg. vol. & tone indicator	.50
10054111892	Bushing - hard rubber; tuner mechanism mtg. to chassis	.02
10055111908	Cable & plug - tuning eye	1.10
1005489912	Clip - grounding for tube base	.02
10054110808	Clip - for tuning eye support	.14
10054111664	Clip - right hand end cup retaining	.10
10054111658	Clip - for pulley retaining	.01
10054111944	Collar & Pin - on vol. cont. shaft	.12
10054110782	Cord - for band ind. 55 in. reg. for Band indic. 18 in. reg. for vol. indic. 20 in. reg. for tone indic. 22 in. reg. for motor indic. Supplied in 6Ft. Lgths. per ft.	.04
10054111302	Cord - dial drive (6 ft. lengths)	.30
10054111973	Cushion - rubber mtg.	.06
10054111940	Drum & gear - dial cord drive	.52
10054111941	End cup - left side of dial scale	.22
10054111942	End cup - right side of dial scale	.22
10044111558	Escutcheon - dial	4.90
10054111690	Felt - oil wick for bearing	.05
10054112542	Flexible coupler - for gang to unit cplg.	.75
10054111608	Gear - knurled (right side of cam shaft)	.20

SEARS ROEBUCK & CO.

Part Number	Description	Selling Price Each
10054111629	Gear - dial drive (left side of cam shaft)	.52
10054111631	Gear - crown; knurled on extension gang shaft	.36
10039111560	Knob - tuning	.24
10039111561	Knob - volume	.24
10039111562	Knob - tone	.24
10039111563	Knob - motor - phono - regular	.17
10039111564	Knob - band switch	.17
10041111667	Pointer - main dial	.19
10041111668	Pointer - volume indicator or tone indicator	.12
10054110413	Plug button - chrome plate	.08
10054110496	Plug - speaker (4 prong)	.12
10054112633	Plug - for mechanism connecting (8 prong)	.20
10054111622	Pulley - dial cord drive	.35
10054111656	Pulley - on range switch or motor-phono shafts	.37
10054111918	Pulley - on left end of dial drum	.24
10054111943	Pulley, idler - for band indicator drive	.12
10054112628	Pulley - for range swith (under chassis)	.20
1005484214	Retaining ring - for shafts or dial drum	.02
10040111566	Scale - for vol. & tone indicator	.16
10040111567	Scale - motor, regular, phono (movable)	.10
10040111568	Scale - motor, regular, phono (stationary)	.27
10040111650	Scale - dial (celluloid roll)	1.80
1005488707	Screw - binder hd. for mtg. push button escutcheon per dz.	.06
10054111116	Screw - #5 x 5/8; mechanism mtg. (tuner)	.02
10054185827	Set screw - for range switch pulley mtg.	.02
10054112138	Set screw - 8/32 slotted head	.03
10054111677	Shaft - extension(between gang cond. & unit)	.10
1005388161	Shield - tube (short section)	.08
1005388164	Shield cap - tube, grid type	.06
1005388165	Shield cap - for tubes (plain)	.06
1005389911	Shield - tube base	.04
10054111085	Sleeve - (felt) for tuning eye	.03
1001885427	Socket - octal base	.15
10054111008	Socket - push button lamp	.12
10018110501	Socket - 4 prong (for spkr.)	.16
10054111985	Socket - lamp	.26
10054111090	Spacer - steel; mechanism mtg. to chassis	.02
10054111570	Spacer - hard rubber; for tuner mechanism mtg. to chassis	.02
10054111862	Spring - drive cord tension	.03
10054111927	Spring - indicator drive tension	.06
10054112544	Spring - between flexible coupler	.01
10054112672	String guide - post	.05
10054112666	Stud - pulley mtg. (right side or dial)	.06
10054112667	Stud - for pulley mtg. (left side)	.10
1005485066	Terminal strip - G.D.A.	.20
10054111581	Terminal strip - phono	.13
1005487568	Washer - embossed (for mtg. electrolytic)	.05
1005489027	Washer - spring type (for range shaft)	.01
1005489747	Washer - paper; behind knobs	.01
10054111262	Washer - flat steel mtg. (15/16" O.D.)	.02
10054111672	Washer - flat steel, mtg. (7/8" O.D.)	.01
10054111972	Washer - extension and top (for mtg.)	.05
10042111559	Window - celluloid for dial escutcheon	1.50

ELECTRICAL PARTS

ELIMINATING WHISTLE AT 930 KC:

A whistle, due to a beat between the second harmonic (930 kc) of the 465 kc IF, and a 930 kc signal may be experienced. In localities where the 930 kc station is one that is frequently listened to, it will be desirable to shift the whistle to some other point where it will not be objectionable. This can be done by shifting the IF frequency of the receiver.

Determine at what point between 900 kc and 960 kc the whistle will be least objectionable. Dividing this frequency by two will give the new IF frequency to which the receiver should be aligned. For example, if it is determined that a whistle at 915 kc would not be objectionable, the IF should be realigned at 915/2 or 457.5 kc. Try to choose the new IF frequency as near to 465 kc as possible.

IMPORTANT ALIGNMENT NOTES

* Push a pin through the attached antenna wire at a point near where it comes out of the chassis so that the pin makes contact with the antenna wire inside the insulation. Connect the generator output lead to the pin. The generator output connection should not be made to the free end of the attached antenna wire.

Where indicated by the word, "Rock", the variable should be rocked back and forth a degree or two while making the adjustment.

The figures given in the "Microvolts" column are only approximate.

The alignment procedure should be repeated stage by stage, in the original order, for greatest accuracy. Always keep the output from the test oscillator at its lowest possible value to make the AVC action of the receiver ineffective.

After the alignment procedure has been completed, tune in a broadcast station at about 900-kc and, if necessary, shift the dial pointer to the station's frequency marking on the dial.

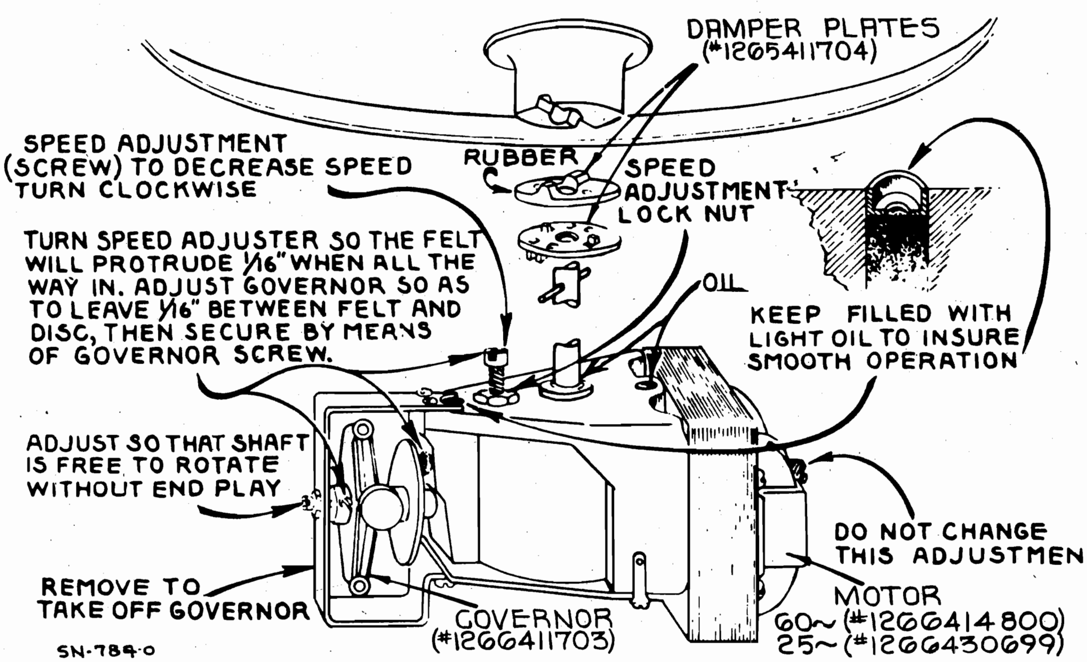
DETAILS OF MOTORBOARD



DETAILS OF MOTOR

MOTOR ADJUSTMENTS:

The phonograph motor is of the governor induction type and is designed to be simple and foolproof. Occasionally, however, certain adjustments may be required. These adjustments are shown and explained in the illustration. Application of oil to the felt pad which rubs against the governor disc will insure smooth operation.

LOUDSPEAKER:

Centering of the loudspeaker is made in the usual manner with three, narrow-paper feelers, after first removing the front dust cover. This may be removed by softening its cement with a light application of acetone, using care not to allow the acetone to flow into the air gap. The dust cover should be cemented back in place with ambroid upon completion of adjustment.

DIAL POINTER AND CONDENSER DRIVE HOOK-UP:

The drive hook-up for the dial pointer and the variable condenser is illustrated.

IMPORTANT ALIGNMENT NOTES

**Use maximum capacity peak if two peaks can be obtained.

*Use minimum capacity peak if two peaks can be obtained.

Where indicated by the word "Rock," the variable tuning condenser should be rocked back and forth a degree or two while making this adjustment.

Each step of the alignment should be repeated in its original order for greater accuracy. Always keep the output from the generator at its lowest possible value, to prevent the a-v-c action of the set from interfering with accurate alignment.

Adjustment locations are shown on the top and bottom parts location views of chassis.

Only the dummy antenna indicated in the chart for any particular band should be used. Remove the dummy antenna used for alignment in any other band. Grid cap leads should remain in place during alignment.

Values shown under, "Microvolts," are only approximate.

MODEL 4700
Schematic, Adjustments

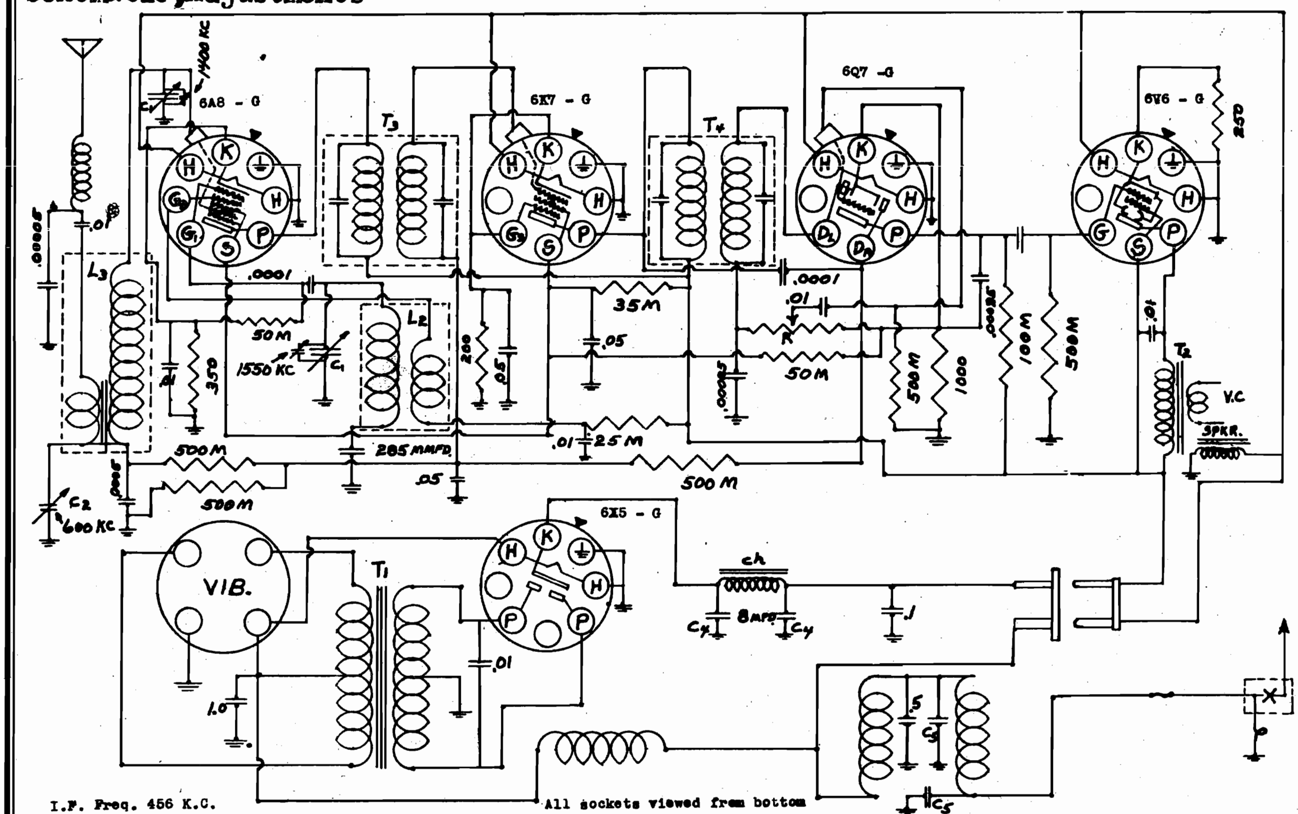
Alignment



ANTENNA ADJUSTMENTS

See that a suitable aerial has been provided, place the radio on the floor of the drivers compartment and temporarily connect it so that it can be turned on and operated. The control cables and head should be assembled and fastened to the receiver. The case of the radio will have to be grounded against some metal part such as brake or gear shift lever.

Turn on receiver and tune in a station at about 600 on the dial. Near the point where the aerial is connected to the set a plug button will be found. This can be removed and by means of a small screw driver adjust the small screw found under the plug button. Turn this screw for maximum sensitivity. Now replace the plug button and turn the dial to about 1400 KC. Near the front of the case are two plug buttons, one being red color. Do not under any circumstance disturb the adjustment under the red button. This ordinarily does not need adjustment but should it be necessary, only a qualified radio technician must be engaged to make this adjustment. The other adjustment under the button which is of the same color as the case, is to be made for maximum sensitivity.

It is easier to make these adjustments when the receiver is on the floor of the car than after it is mounted and not so accessible.

CIRCUIT: A four tube tuned radio frequency AC-DC receiver.

ALIGNMENT PROCEDURE:

Turn tuning knob to the extreme right in a clockwise direction so that the variable condenser is at minimum capacity. Apply a 1720 KC note to the antenna and adjust both trimmers on the variable condenser to maximum gain. Next, tune to the low frequency end and check tracking of coils for maximum gain. It may be necessary to bend plates to increase sensitivity.

THE ALIGNMENT PROCEEDURE

The following alignment instructions are given with the assumption that the service station has an oscillator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be 0 to 3 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the 42 power tube in series with an 8 MFD paper condenser.

I THE I.F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6L7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are the trimmers in the three I.F. cans. (See pictorial).

THE I.F. STAGES MUST BE ALIGNED WITH THE FIDELITY CONTROL IN THE SHARP POSITION, THAT IS WITH THE SHAFT TURNED ALL THE WAY TO THE LEFT.

The sensitivity of the I.F. system in the sharp position is about 200 microvolts. In the high fidelity position the sensitivity is about 20 microvolts.

Always use as low an output as possible from the signal generator when making the various adjustments.

II ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the condenser shaft to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can be lined up by removing dial glass and setting hand with screw in center of dial.

1. Set the test oscillator to 17 megacycles.

2. Turn wave band switch all the way to right for highest S.W. band, and set dial hand to 17 M.C.

3. Peak trimmer condenser C-35 of the oscillator coil (See pictorial) to resonance with 17 M.C. fed into antenna.

4. Adjust antenna and R.F. coil trimmers C-20 and C-23 to same frequency after the above mentioned oscillator trimmer has been set.

5. Turn dial hand to 6 M.C. on same band and peak padding condenser C-26 to 6 M.C.

III SHORTWAVE BAND 1.7 TO 5.5 M.C.

1. Set band switch to this band and dial hand to 5 M.C.

2. Peak trimmer C-36 to 5 M.C.

3. Peak antenna and R.F. trimmers C-21 and C-24 to 5 M.C.

4. Rotate dial to 1.7 M.C. and adjust Padding Condenser C-27 to 1.7 M.C.

NOTE: After adjusting the two high bands at 17 megacycles and 5 megacycles the test oscillator input to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximatly 16.9 M.C.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 M.C.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 M.C.

Reduce signal voltage from generator, go back to 17 M.C. and slightly correct this last trimmer adjustment.

The same thing applies to the 5 M.C. adjustment.

IV THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400KC (the top scale).

2. Peak oscillator trimmer C-37 to 1400 KC and R.F. circuit trimmers C-22 and C-25 to same frequency.

3. Set dial hand to 550 KC and adjust oscillator padding condenser C-28 to 550 KC.

4. Recheck dial at 1400 KC as in number (1) and (2).

5. Points in the middle of the dial may be checked and if necessary the plates of the front section of variable condenser may be bent for alignment.

V NOTES

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the schematic for the voltages at the tube sockets.

Alignment, Socket Voltage

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis and inside of and accessible through the holes found in the top of the catacomb shield (mounted on top and in the left front corner of the receiver) will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.

2. Place the band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.8 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and then tune in the 18.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.8 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.8 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillation trimmer at 18 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.8 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.8 megacycles. Then vary the receiver dial slightly to the right and left of 17.8 megacycles, and if the fundamental peak was used in aligning at 18.8 megacycles the test oscillator signal will be heard at approximately 17.8 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.8 megacycle oscillator trimmer must be properly readjusted.

3. With band selector switch set for operation on 5.8 to 18.8 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 15 MEGACYCLES. Adjust 15 megacycle antenna and R.F. trimmers to maximum 15 megacycle signal sensitivity.

4. Leave band selector switch for operation on the 5.8 to 18.8 megacycle band, tune the receiver dial and set the test oscillator frequency to approximately 6 megacycles. While rocking gang condenser slightly to right and left adjust 6 megacycle oscillator padder for maximum sensitivity.

5. Place band selector switch for operation on 1.8 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES.

Rotate gang condenser so that plates are completely out of mesh and then BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 5.8 megacycle oscillator trimmer.

6. With the band selector switch set for operating on 1.8 to 5.8 Megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna and R.F. trimmers for maximum 5 megacycle signal sensitivity.

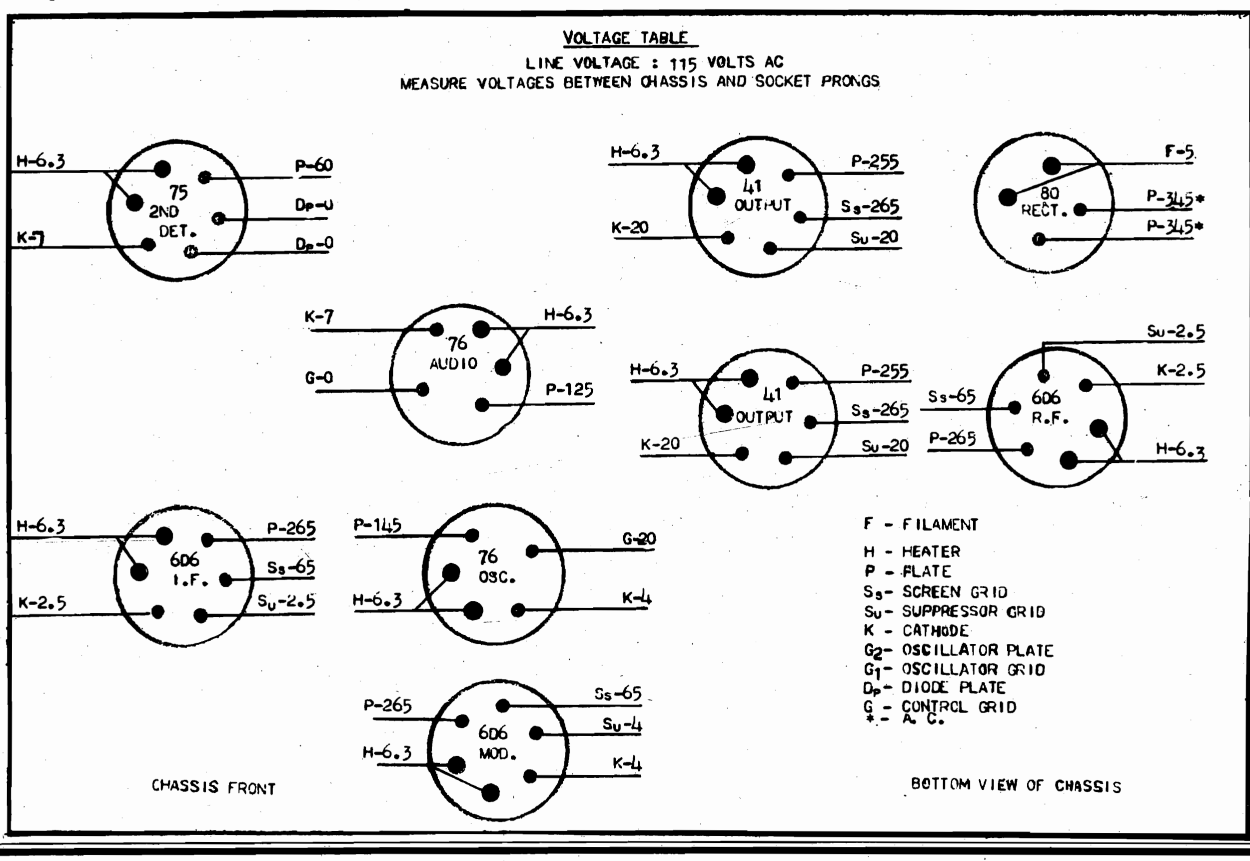
7. Leave band selector switch for operation on 1.8 to 5.8 megacycle band, tune receiver dial and set test oscillator frequency to approximately 2 megacycles. While rocking gang condenser slightly to right and left adjust 2 megacycle oscillator padder for maximum sensitivity.

8. Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1730 kilocycle band and set test oscillator frequency to EXACTLY 1730 KILOCYCLES.

Rotate gang condenser so that plates are completely out of mesh and BRING IN THE 1730 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1730 KILOCYCLE OSCILLATOR TRIMMER.

9. With band selector switch placed for operation on the 540 to 1730 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycles R. F. and antenna trimmers for maximum 1400 kilocycle signal sensitivity.

10. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.



SENTINEL RADIO CORP.

Model 66B
Eight Tube
Six Volt Battery Operated Superheterodyne Receiver

ALIGNING I.F.STAGE AT 465 KILOCYCLES:

(a) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid cap of the 6A7 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.
(b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.
(c) Peak each of the second I. F. transformer trimmers.
(d) Peak each of the first I.F. transformer trimmers.
To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

ALIGNING 1720-536 KILOCYCLE BAND:

(a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.
(b) Remove test oscillator lead from grid of 6A7 tube and connect to receiver antenna post through a .00025 Mfd. series condenser.
(c) Adjust band selector switch for operation on the 1720-536 kilocycle band.
(d) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles, and BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.
(e) Tune receiver dial and set test oscillator frequency to EXACTLY 1500 kilocycles. Adjust 1500 K.C., R.F. and antenna trimmers for maximum sensitivity.
(e) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K. C. oscillator padder for maximum signal response.

ALIGNING 1.58-5.75 MEGACYCLE BAND:

(a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor.
(b) Adjust band selector switch to 1.58-5.75 megacycles, tune receiver dial and set test oscillator frequency to EXACTLY 5.75 megacycles. Bring in 5.75 megacycle test band signal to maximum output by adjusting 5.75 M.C. oscillator trimmer.
(c) Tune receiver dial and test oscillator frequency to EXACTLY 5 Megacycles, and adjust 5 M.C. antenna and R.F. trimmers for maximum sensitivity.
(d) Set test oscillator and receiver dial to approximately 1.8 megacycles. Then while rotating gang condenser slightly to right and left adjust 1.8 megacycle oscillator padder.

ALIGNING 5.65-20.25 MEGACYCLE BAND:

(a) Leave 400 ohm resistor in series with test oscillator lead and place band selector switch for operation on 5.65-20.25 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 20.25 megacycles.

(b) Adjust 20.25 M.C. oscillator trimmer to bring in 20.25 megacycle test signal to maximum output.

NOTE: When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 20.25 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 20.25 megacycles always check to see if the proper peak has been used. To do this leave test oscillator frequency at 20.25 megacycles, increase the output of the test oscillator and tune receiver dial to approximately 19.25 megacycles. Then vary the receiver dial slightly to the right and left of 19.25 megacycles, and if the fundamental peak was used in aligning at 20.25 megacycles the test oscillator signal will be heard at approximately 19.25 megacycles on the receiver dial.

(c) Tune receiver dial and set test oscillator frequency to EXACTLY 18 megacycles.

(d) Rock gang condenser slightly to right and left and adjust 18 M.C. antenna and R.F. trimmers for maximum 18 megacycle test signal response.

Model 44A
Six Tube A. C. Superheterodyne Receiver

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6A7 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18.1 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18 MEGACYCLES.

Bring in the 18 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER at 18 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in.

3. With band selector switch set for operation on 5.8-18.1 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 15 MEGACYCLES. Adjust 15 megacycle antenna trimmer to maximum 15 megacycle signal sensitivity.
4. Replace the 400 ohm resistor in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 1720-540 kilocycle band and set test oscillator frequency and receiver dial to EXACTLY 1720 KILOCYCLES. BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.
5. With band selector switch placed for operation on the 1720-540 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 antenna trimmer for maximum 1400 kilocycle signal sensitivity.
6. Leave band selector switch for operation on 1720-540 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycles padder for maximum sensitivity.
7. Place band selector switch for operation on the 390-140 kilocycle band, and set test oscillator frequency and receiver dial to EXACTLY 390 KILOCYCLES. BRING IN THE 390 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT WITH 390 KILOCYCLE OSCILLATOR TRIMMER.
8. With band selector switch set for operation on 390-140 kilocycle band, tune the receiver dial and set test oscillator frequency to EXACTLY 350 KILOCYCLES. Adjust 350 kilocycle antenna trimmer for maximum 350 kilocycle signal response.
9. Leave band selector switch for operation on the 390-140 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 150 kilocycles. Then while rocking gang condenser slightly to right and left adjust 150 kilocycle padding condenser for maximum sensitivity.

Model 46A Eight Tube A. C. Superheterodyne Receiver

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the test oscillator output to the control grid of the 6D6 modulator tube through a .02 Mfd. condenser. Leave the grid cap connected to the grid terminal of the tube, and connect the ground side of the test oscillator to the receiver ground.
2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).
3. Align the second intermediate transformer by turning one of the trimmer screws accessible through holes in the top of the transformer shields up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.
4. Adjust the first intermediate transformer in the same manner as the second I. F. transformer.

TO ALIGN THE VARIABLE CONDENSER:

It is important when aligning the gang condenser, padding and trimmer condensers to follow the procedure carefully, otherwise the receiver will be insensitive and the dial calibration will be incorrect. The padding and trimmer condensers located underneath the chassis will be referred to by their function as indicated on the circuit diagram.

1. Connect the high output side of the test oscillator through a 400 ohm resistor to the receiver antenna lead and the low side to the set ground.
2. Place the band selector switch for operation on the 5.8 to 18.1 megacycle band, tune the receiver dial, and set the test oscillator frequency to EXACTLY 18.1 MEGACYCLES.

Tune in the 18.1 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE 18.1 MEGACYCLE OSCILLATOR TRIMMER. When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER at 18.1 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.1 megacycles always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 18.1 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.1 megacycles, and if the fundamental peak was used in aligning at 18.1 megacycles the test oscillator signal will be heard at approximately 17.1 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.1 megacycle oscillator trimmer must be properly re-adjusted.

3. With band selector switch set for operation on 5.8 to 18.1 megacycle band tune the receiver dial and set test oscillator frequency to EXACTLY 16 MEGACYCLES. Adjust 16 megacycle antenna trimmer for maximum 16 megacycle signal sensitivity.
4. Place band selector switch for operation on 1.7 to 5.8 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 5.8 MEGACYCLES. BRING IN 5.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 5.8 megacycle oscillator trimmer.
5. With the band selector switch set for operation on the 1.7 to 5.8 megacycle band tune receiver dial and set test oscillator frequency to EXACTLY 5 MEGACYCLES. Then adjust 5 megacycle antenna trimmer for maximum 5 megacycle signal sensitivity.
6. Replace the 400 ohm resister in series with test oscillator lead with a 200 Mmfd. condenser, place the band selector switch for operation on the 540 to 1720 kilocycle band, tune receiver dial, and set test oscillator frequency to EXACTLY 1720 KILOCYCLES. NEXT BRING IN THE 1720 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.
7. With band selector switch placed for operation on the 540 to 1720 kilocycle band set test oscillator frequency and receiver dial to EXACTLY 1400 KILOCYCLES. Adjust 1400 kilocycle preselector and antenna trimmers for maximum 1400 kilocycle signal sensitivity.
8. Leave band selector switch for operation on 540 to 1720 kilocycle band, tune receiver dial and set test oscillator frequency to approximately 600 kilocycles. While rocking gang condenser slightly to right and left adjust 600 kilocycle oscillator padder for maximum sensitivity.

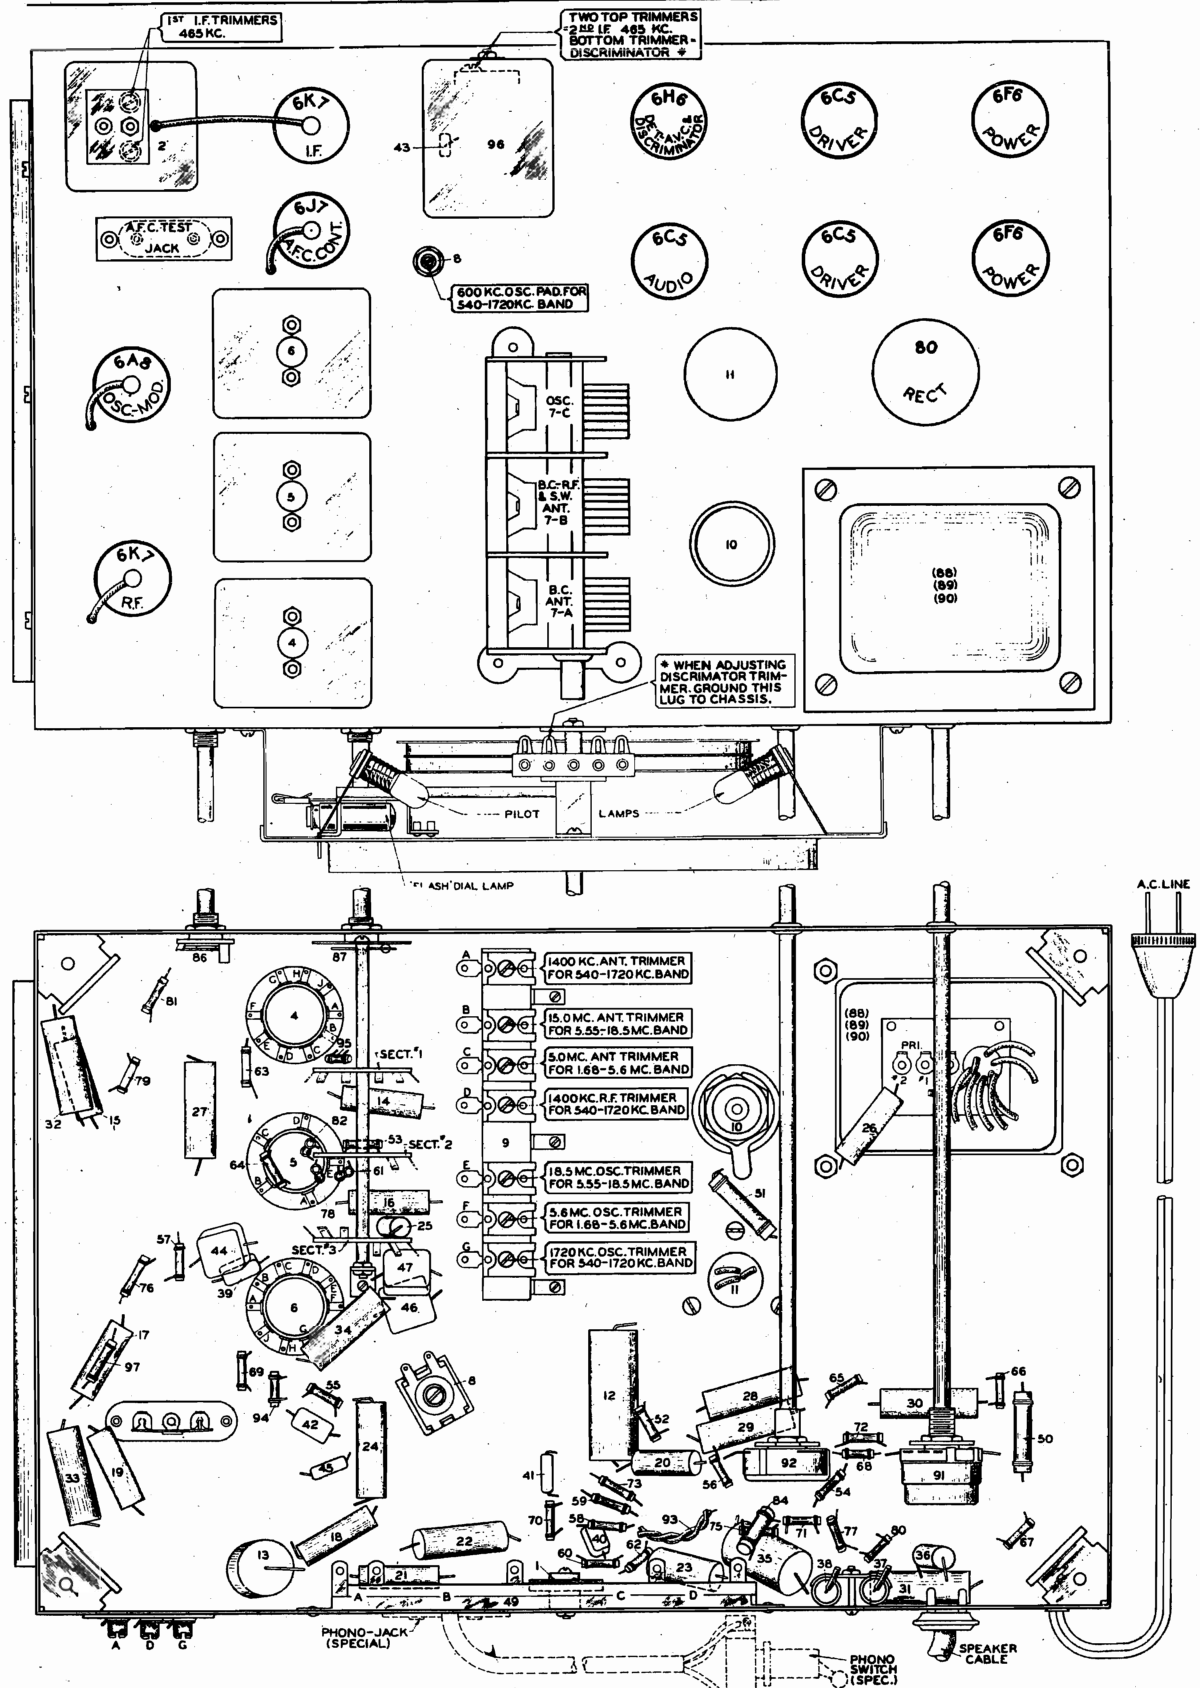
PARTS LAYOUT FOR MODEL 76-A RECEIVER.



SENTINEL RADIO CORP.

ALIGNING I.F. STAGE AT 465 KILOCYCLES:

(a) Place automatic frequency control in the maximum left hand A.F.C. "off" position.

(b) Attach the ground lead of the test oscillator to the chassis. Connect the other lead to the grid cap of the 6A8 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.

(c) Set test oscillator to EXACTLY 465 kilocycles and turn volume control on full.

(d) Remove shields held in position by snap fasteners over A.F.C. test jack and over trimmer screw holes in the first and second I.F. transformer shield cans.

(e) Peak second I.F. transformer trimmers for maximum 465 kilocycle output by adjusting the two trimmers accessible through the two top holes in the second I.F. transformer shield can. DO NOT TOUCH DISCRIMINATOR (BOTTOM) SCREW.

(f) Peak each of the first I.F. transformer trimmers for maximum 465 kilocycle signal output.

ALIGNING 1720-540 KILOCYCLE BAND:

(a) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line, move needle to correct position.

(b) Remove test oscillator lead from grid of 6A8 tube and connect to receiver "A" antenna post through a .00025 Mfd. condenser.

(c) Adjust A.F.C. control to maximum left hand A.F.C. "off" position and band selector switch for operation on the 1720-540 kilocycle band.

(d) Set test oscillator frequency and receiver dial to EXACTLY 1720 kilocycles, and BRING IN 1720 KILOCYCLE TEST OSCILLATOR SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING 1720 KILOCYCLE OSCILLATOR TRIMMER.

(e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles. Adjust 1400 K.C. R.F. and antenna trimmers for maximum sensitivity.

(f) Set test oscillator frequency and receiver dial to approximately 600 kilocycles. Then while rocking gang condenser slightly to right and left, adjust 600 K.C. oscillator padder for maximum signal response.

ALIGNING DISCRIMINATOR CIRCUIT:

(a) After completing 1720-540 kilocycle adjustment, set test oscillator to EXACTLY 465 KILOCYCLES and connect to grid of 6A8 tube through a .02 Mfd. Condenser—insert lead of double scale 0 to 1 and 0 to 5 milliammeter into A.F.C. test jack located on top of chassis adjacent to the 6L7 tube. To avoid possibility of damaging the meter should one of the milliammeter leads short to the metal chassis, ALWAYS TURN OFF RECEIVER WHEN INSERTING OR REMOVING MILLIAMMETER LEADS FROM A.F.C. TEST JACK.

(b) Short out A.F.C. mute switch by grounding the second from the left (looking at the front of the chassis) of the four lugs mounted on top of the dial assembly. The proper lug to ground is indicated in the "Note X" on chassis top parts view.

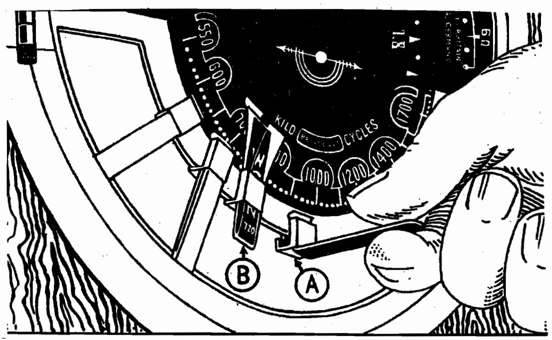
(c) Turn receiver on, place A.F.C. switch knob in A.F.C. "on" position and if meter needle jumps off scale adjust output of test oscillator until an approximate 2 M.A. deflection is obtained on the 0 to 5 milliammeter scale.

(d) Place band selector switch for operation on 1720-540 K.C. broadcast band—and set receiver dial somewhere near 1000 kilocycles at a point where no station is heard.

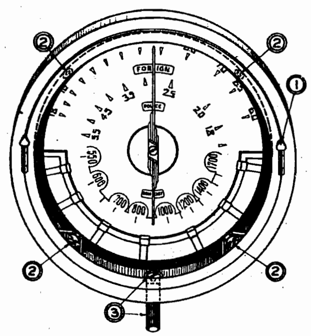
(e) Rotate A.F.C. switch knob from A.F.C. "on" to A.F.C. "off" position and note whether the milliammeter reading changes as the position of the A.F.C. switch is changed. No change in reading indicates probable proper discriminator trimmer adjustment, while a noticeable change indicates improper discriminator trimmer adjustment.

(f) IMPORTANT: DO NOT ADJUST DISCRIMINATOR TRIMMER UNLESS IT IS ABSOLUTELY NECESSARY. Place A.F.C. switch in A.F.C. "off" position and note milliammeter reading, then place A.F.C. switch in A.F.C. "on" position and CAREFULLY ADJUST DISCRIMINATOR TRIMMER UNTIL MILLIAMMETER READING IS EXACTLY THE SAME AS IT WAS WITH THE A.F.C. SWITCH IN THE "OFF" POSITION.

NOTE: As the discriminator trimmer screw is screwed in (increasing capacity) the milliammeter reading should decrease and as the discriminator trimmer is unscrewed (decreasing capacity) the milliammeter reading should increase. IF WHEN ADJUSTING THE DISCRIMINATOR TRIMMER THE MILLIAMMETER READING DOES NOT SHARPLY INCREASE OR DECREASE AS THE TRIMMER IS ADJUSTED EVEN AFTER SEVERAL TURNS OF THE TRIMMER SCREW, THIS DOES NOT INDICATE PROPER BALANCING BUT DOES INDICATE INCORRECT ADJUSTMENT AND THE DISCRIMINATOR TRIMMER SHOULD BE SET TO ABOUT ½ CAPACITY AND THE ADJUSTMENT OF THE DISCRIMINATOR TRIMMER MADE ALL OVER AGAIN.



Above Diagram shows method of inserting and setting tabs.



ALIGNING 1.68-5.6 MEGACYCLE BAND:

(a) Replace .00025 Mfd. test oscillator antenna lead series condenser with a 400 ohm resistor.

(b) Adjust band selector switch to 1.68-5.6 megacycles, tune receiver dial and set test oscillator frequency to EXACTLY 5.6 megacycles. Bring in 5.6 megacycle test signal to maximum output by adjusting 5.6 M. C. oscillator trimmer.

(c) Tune receiver dial and test oscillator frequency to EXACTLY 5 Megacycles and adjust 5 M.C. antenna trimmer for maximum sensitivity.

ALIGNING 5.55-18.5 MEGACYCLE BAND:

(a) Leave 400 ohm resistor in series with test oscillator lead and place band selector switch for operation on 5.55-18.5 megacycle band, tune receiver dial and set test oscillator frequency to EXACTLY 18.5 megacycles.

(b) Adjust 18.5 M.C. oscillator trimmer to bring in 18.5 megacycle test signal to maximum output.

NOTE: When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.5 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the FIRST peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.5 megacycles, always check to see if the proper peak has been used. To do this leave test oscillator frequency at 18.5 megacycles, increase the output of the test oscillator and tune receiver dial to approximately 17.5 megacycles. Then vary the receiver dial slightly to the right and left of 17.5 megacycles, and if the fundamental peak was used in aligning at 18.5 megacycles the test oscillator signal will be heard at approximately 17.5 megacycles on the receiver dial.

(c) Tune receiver dial and set test oscillator frequency to EXACTLY 15 megacycles.

(c) Rock gang condenser slightly to right and left and adjust 15 M.C. antenna trimmer for maximum 15 megacycle test signal response.

To assure more accurate trimmer setting, repeat all above adjustments several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

PROCEDURE FOR REMOVING RECEIVER FROM CABINET.

1. Unscrew the two knurled head screws mounted on front of the glass frame and then holding onto the screws pull dial glass away from the cabinet.
2. Swing 'rapid tuning' lever to center position as shown, **loosen** (do not remove) **screw thru hole in bottom center,** and remove lever knob.
3. Loosen set screws on all five tuning knobs, and remove knobs from shafts. (Not shown in sketch).
4. Remove four bolts at bottom side of chassis mtg. shelf (not shown in sketch.)
5. Remove wood screws on the pressure brackets at rear of chassis (not shown in sketch) and then slide receiver out of cabinet.
6. When replacing receiver in cabinet, reverse entire procedure given above.

ELIMINATION OF INTERFERENCE CAUSED BY A 32-VOLT LIGHT PLANT

General

Two kinds of static-like noise may be heard when you operate your 32 volt radio at the same time the generating plant is charging the plant batteries.

Static-like noise, due to the action of the brushes on the commutator, may reach the set through the supply lines. Such noise can generally be eliminated by the use of .5 Mfd. 200 volt condensers, as shown in Figs. 1 and 3.

Static-like noise, due to the operation of the high tension circuit may radiate through the air to the antenna of the set. Radiation has been found to extend a half mile in extreme cases. Proper placement of the antenna, along with the use of a spark plug suppressor and correct shielding will entirely eliminate this type of noise.

When eliminating these electrical disturbances always apply the remedies given in the order in which they appear.

Usual Installations

Install spark plug suppressor on the spark plug and connect the high tension lead to the suppressor, as shown in Figure 3.

For four cylinder plants use four spark plug suppressors, one attached to each spark plug.

CAUTION: Disconnect batteries from generator before attaching suppressor equipment.

Connect one .5 Mfd. 200 volt condenser between one positive brush and the generator frame and one condenser between one negative brush and the generator frame as shown in Figure 1.

FOUR CYLINDER PLANTS. For four cylinder plants attach a condenser to the positive and negative brushes as shown in Figure 2.

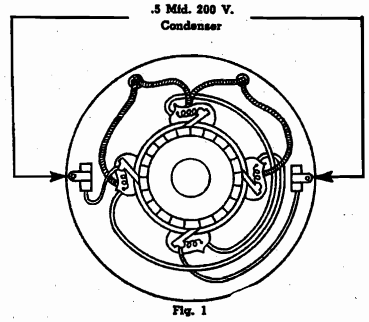

Fig. 1

Extreme Cases

To determine if the high tension wiring is radiating into the antenna disconnect the antenna and ground from the receiver and if the noise is eliminated or materially reduced, the noise is being picked up by the antenna. In such a case, obtain a piece of electrician's loom which will just slide over the high tension wire and a piece of copper braid shielding which will just slip over the loom. Cut a piece of loom just long enough to cover the high tension wire from the coil to the spark plug suppressor. Cut a piece of shielding that will be one inch shorter than the loom when the shielding is extended over the loom.

Ignition Noise on Battery Leads

Sometimes the ignition interference will travel up the battery leads. This condition can be corrected as follows: Attach a .5 Mfd. condenser between the POSITIVE terminal at the top of the control box and the frame of the box. (Be sure the frame of the box is well grounded to the generator frame.) Attach a .5 Mfd. condenser between the NEGATIVE terminal at the top of the control box and the control box frame.

Ignition Interference on Supply Leads

In extreme cases the ignition interference will travel up the supply leads to the radio receiver. This condition can be corrected by attaching a .5 Mfd. condenser between the ungrounded side of the line (in the main switch box) and ground (or the grounded side of the line if one side of the line is grounded).

Grounding

Some cases may require a thorough grounding of the system. This may be accomplished by running a No. 12 B. & S. gauge wire from the generator frame to a good ground. Conduit and metal switch boxes should also be grounded.

If it is necessary to ground one side of the supply lines, first ground them temporarily, one at a time through a 32 volt lamp. One side of the line will light the light, the other will not. The side which WILL NOT light the light should be grounded.

DO NOT apply any of the remedies listed under "Extreme Cases", before trying the ones listed under "Usual Cases".

Slip the loom over the high tension lead. Slip the shielding over the loom so that it is one-half inch from each end of the loom. Wrap some fine copper wire around the shielding near the end of the shielding to hold the shielding in place. Solder the wire to the shielding so it will not slip due to plant vibration. The shield may be taped in place if the tape is very adhesive. DO NOT USE FRICTION TAPE.

Solder a short braid pig-tail to the shielding and ground it under the nearest screw in the generator frame.

This receiver is designed for operation on 32 volt battery plants only and must not be used on battery plants of a HIGHER RATED VOLTAGE than 32 volts without a voltage regulator.

The power plug attached to the end of the power cord must be inserted correctly IN THE 32 VOLT POWER SUPPLY OUTLET OR RECEPTACLE, OTHERWISE THE SET WILL NOT OPERATE. If after inserting the plug and turning the receiver on, the set does not operate after approximately two minutes, remove this plug and turn it half-way around and reinsert it in the power receptacle.

A 4 AMPERE FUSE is located on the back of the chassis underneath receptacle marked "Fuse" and protects the receiver from damage should a defect occur in the set or if it is connected to the improper power supply. Continued burning out of fuses on the proper power supply is indicative of some defect. THE WARRANTY IS VOID IF THE RECEIVER IS OPERATED WITH THE FUSE SHORTED OUT OR WITH A FUSE LARGER THAN 4 AMPERES.

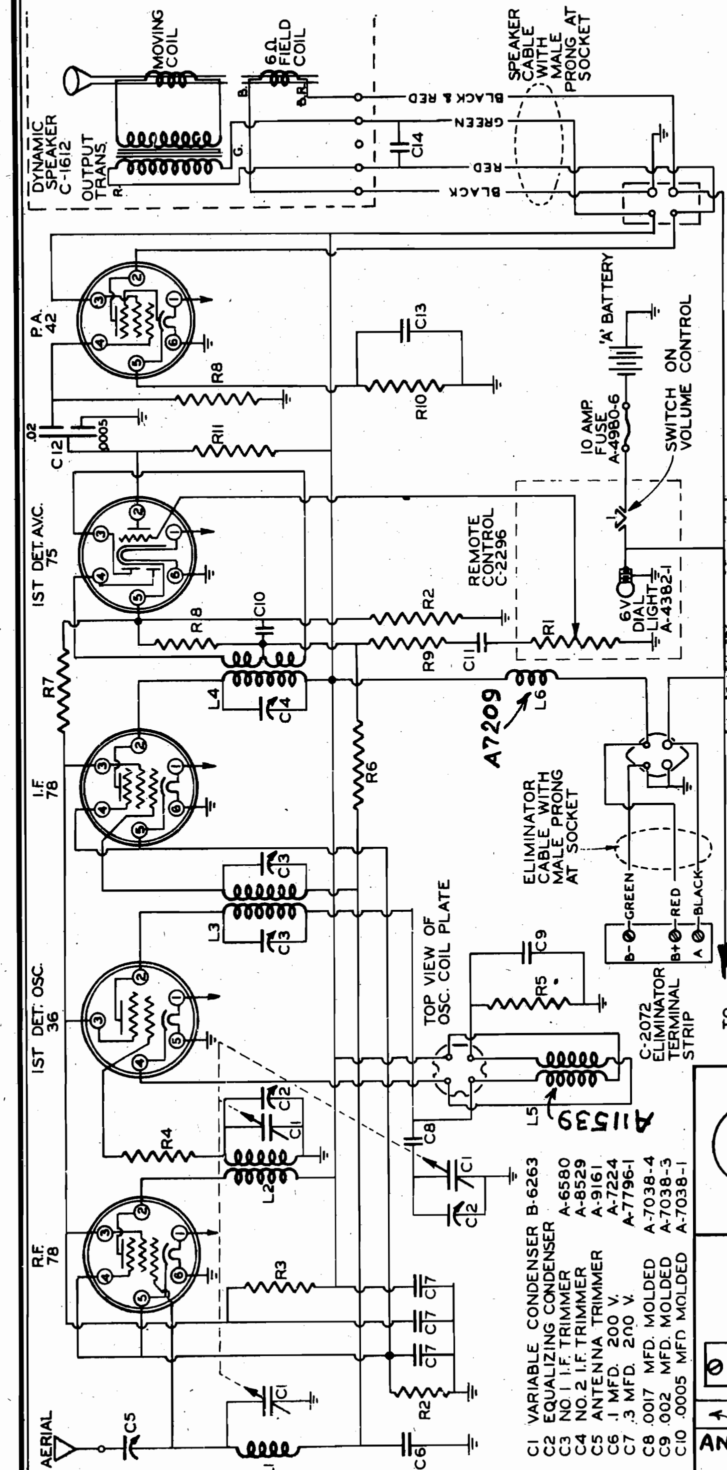
Trimmers, Alignment

Generator at 172.5 KC, connected to grid cap of 36, align IF trimmers to peak. Connect Generator to ANT and Gnd of receiver (Same frequency), align OSC trimmer to maximum peak. Reset generator to 2200 KC, align RF to maximum peak. After set has been installed, tune in a signal of approximately 2200 KC and peak the antenna trimmer for maximum response. Repeat adjustments for maximum performance.



FREQUENCY 172.5 K.C.

SPARTON RADIO

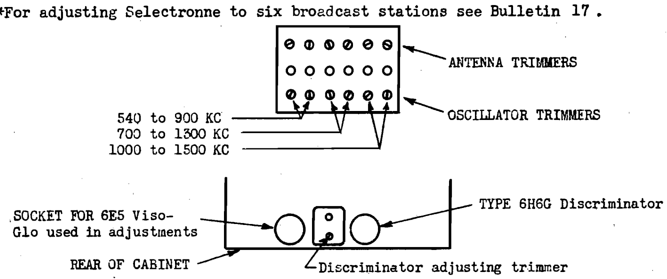
ADJUSTMENT OF
THE SPARTON SELECTRONNE
AND
ALIGNMENT OF
MODEL 738.

ALIGNMENT

OPERATION	ALIGNMENT OF	GENERATOR CONNECTED TO	DUMMY ANTENNA	GENERATOR FREQUENCY	TRIMMER	REMARKS
1	I.F.	6A8 Grid	.1 mf.	456	C13A C12A C12B	2nd I.F. (Pri.) 1st I.F.
2	Discriminator	6A8 Grid	.1 mf.	456	C13B	Adjust to MAXIMUM with bakelite screwdriver.*
3	Rejector	Ant.	200 mmf.	456	C1	Adjust to minimum
4	Selectronne**	Ant.	200 mmf.	1500	C3 (1000 to 1500 KC) Osc. C2 (1000 to 1500 KC) R.F.	
5	Selectronne**	Ant.	200 mmf.	1000	C3 (700 to 1300 KC) Osc. C2 (700 to 1300 KC) R.F.	
6	Selectronne**	Ant.	200 mmf.	600	C3 (540 to 900 KC) Osc. C2 (540 to 900 KC) R.F.	
7	Check AFC by noting output on output meter, then short out AFC by grounding the grid return circuit of 6J7G control tube at a point between L4 R.F. choke and C10 .2 mf. condenser. If output changes appreciably touch up C13B (Discriminator trimmer) until there is no change in output as the short is alternately connected to and removed from the AFC circuit.	6A8 Grid	.1 mf.	1400	C3 (1400 KC) Osc. C2 (1400 KC) R.F.	
8	(Check operations 1 to 7 inclusive)					

* This Discriminator circuit is different than used in Models 1068, 1268, 1568, etc. Do not confuse.

**For adjusting Selectronne to six broadcast stations see Bulletin 17.



WARNING - Never attempt to adjust the Selectronne with the 6H6G Discriminator tube in the socket.

Unless the 6H6G Discriminator tube is removed when the Selectronne is adjusted, automatic frequency control will prevent correct trimmer adjustments, with the result that unsatisfactory reception of stations may occur. With the 6H6G Discriminator tube left in the socket, automatic frequency control action will bring in the station and close the Viso-Glo before the trimmers have been completely adjusted.

HOW TO ADJUST THE SPARTON SELECTRONNE IN THE MODEL 738 "SELECTIME"

WARNING: All final adjustments of the Selectronne trimmers should be made in the customer's home, with the receiver connected to the regular antenna system with which it will be used.

1. Select six favorite nearby broadcast stations and detach the corresponding call letter tabs from the station call letter tab sheets.
2. Remove the Selectronne escutcheon plate from the front of the cabinet by means of the two screws. This exposes the steel plate with the slots for holding the station call letter tabs.

3. The six buttons of the Selectronne are arranged in three groups according to frequency limits - 540 to 900 kc., 700 to 1300 kc. and 1000 to 1500 kc. (See illustration also back cover of selectronne box). The six tabs corresponding to the six broadcast stations which have been chosen must be arranged in the steel plate so that the frequency (kilocycle) of each station will be included in the frequency limits of the proper group.

For example: A station having a frequency of 610 kc. should be placed in the 540 to 900 kc. group; a station at 950 should be placed in the 700 to 1300 kc. group, etc.

Note: Each group has considerable overlap to allow for the selection of six stations which may have frequency allocations comparatively close together.

4. Remove type 6H6G tube (Discriminator) from chassis (see illustration).
5. Adjust Selectronne trimmers for each one of the six stations as follows:

(A) Two trimmers are provided for each one of the six stations. They are reached through the two holes arranged in rows one above the other in the back cover of the Selectronne.

(B) Obtain 6E5 Viso-Glo from your dealer and insert in 6E5 socket for use as an indicating meter (This tube is not supplied with set).

(C) Now from the back of the cabinet, with an ordinary screw-driver adjust the oscillator trimmer (bottom hole) in the row corresponding to the proper station, until the station is heard. This station may be heard faintly until the remaining trimmer has been adjusted.

It is important that the correct station is heard with this adjustment and not some other network station carrying the same program. Screw this trimmer to the right or left until the station is loudest.

Care should be taken in turning the adjusting screws so that they will not become disengaged from the trimmers by being turned out too far.

(D) In the same manner adjust the antenna trimmer (top hole) to this same station.

Note: Perfect adjustment of these trimmers is easily obtained by observing the Viso-Glo tube so that every adjustment of the trimmers may be watched. Perfect adjustment is obtained when further turning of the trimmers will not result in any smaller shaded area between the green light sections of the Viso-Glo.

(E) Re-adjust the oscillator trimmer (bottom hole) while watching the Viso-Glo to see if the shaded area can be made smaller.

6. Repeat the procedure in paragraph 5 for each of the six stations.

7. When all trimmers have been properly adjusted, replace type 6H6G Discriminator tube and attach Selectronne escutcheon plate to front of cabinet.
8. Any of the six stations to which the SPARTON Selectronne has been adjusted, may now be instantly received simply by pushing the Selectronne button for the desired station with the Band Switch knob pushed in; that is, in the automatic position.

NOTE: In case all six of the buttons should become depressed through improper manipulation of the Selectronne, simply reach into the Selectronne box (from the back of the cabinet) through the side, and apply a slight pressure of the fingers under the latching bar which runs across the frame work in front of the trimmer box. This will immediately release all buttons.

IMPORTANT

Always check the discriminator circuit to see if it is in proper adjustment and adjust it if necessary before adjusting the Selectronne.

TO CHECK THE ADJUSTMENT OF THE DISCRIMINATOR CIRCUIT, note carefully the Viso-Glo, then pull Discriminator tube out and see if the Viso-Glo opens or closes. If it opens, the Selectronne is not adjusted right. If it closes, the Discriminator is not adjusted accurately.

IMPORTANT: The Type 6H6G Discriminator tube must be in its socket when adjusting the discriminator circuit, and out of its socket when adjusting the Selectronne trimmers.

TO ADJUST THE DISCRIMINATOR CIRCUIT, tune in a strong station so that the Viso-Glo closes as much as possible. Then put Discriminator tube in and insert an insulated (bakelite) screw driver in the hole nearest the back of the chassis in the aluminum can located between the 6H6G Discriminator tube and the 6E5 Viso-Glo. Turn the Discriminator circuit trimmer very slightly one way or the other until the Viso-Glo closes as far as possible. Then pull Discriminator tube out. The Viso-Glo should show the same position. If it does not, adjust more accurately with Discriminator tube in socket.

CAUTION: The blade of the screw-driver positively must be an insulated (bakelite) one.

WARNING - Do not attempt to adjust the other trimmer in this last can or a trimmer in any of the other cans. Only adjust the trimmer nearest the back of the chassis and in the can located between the 6H6G and 6E5 tubes.

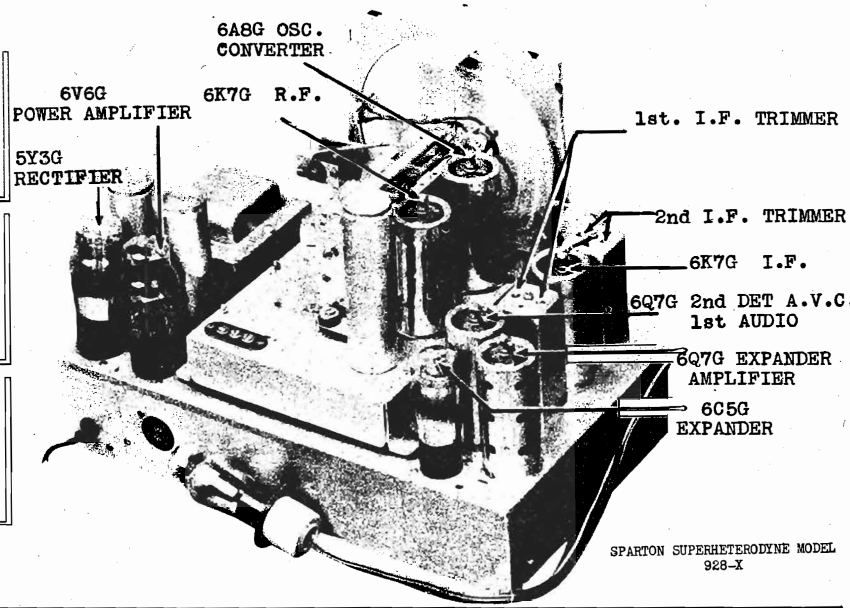
TRIMMER LOCATIONS (under chassis)



SPARTON SUPERHETERODYNE MODEL 928-X

HOW TO ADJUST THE SPARTON SELECTRONNE IN THE MODEL 678-A

WARNING: All final adjustments of the Selectronne trimmers should be made in the customer's home, with the receiver connected to the regular antenna system with which it will be used.

1. Select six favorite nearby Broadcast Stations and detach the corresponding call letter tabs from the station call letter tab sheets.
2. Remove the Selectronne escutcheon plate from the front of the cabinet by means of the two screws. This exposes the steel plate with the slots for holding the station call letter tabs.

3. The six buttons of the Selectronne are arranged in three groups according to frequency limits – 540 to 900 kc., 700 to 1300 kc. and 1000 to 1500 kc. (See illustration also back cover of Selectronne box). The six tabs corresponding to the six broadcast stations which have been chosen must be arranged in the steel plate so that the frequency (kilocycle) of each station will be included in the frequency limits of the proper group.

For example: A station having a frequency of 610 kc. should be placed in the 540 to 900 kc. group; a station at 950 should be placed in the 700 to 1300 kc. group, etc.

Note: Each group has considerable overlap to allow for the selection of six stations which may have frequency allocations comparatively close together.

4. Adjust Selectronne trimmers for each one of the six stations as follows:

(A) Two trimmers are provided for each one of the six stations. They are reached through the two holes arranged in rows one above the other in the back cover of the Selectronne.

(B) Tune in the station in the usual way using manual tuning, watching the Viso-Glo so that the station will be perfectly "tuned in".

(C) Turn the "manual-automatic" switch knob to the "automatic" position.

(D) Push in the Selectronne button which corresponds to the station just tuned in.

(E) Now from the back of the cabinet, with an ordinary screw-driver adjust the oscillator trimmer (bottom hole) in the row corresponding to the proper station, until the same station that was tuned in manually is heard. This station may be heard faintly until the remaining trimmer has been adjusted.

It is important that the same station is heard with this adjustment and not some other network station carrying the same program. Screw this trimmer to the right or left until the station is loudest.

Care should be taken in turning the adjusting screws so that they will not become disengaged from the trimmers by being turned out too far.

(F) In the same manner adjust first the antenna trimmer (top hole) to this same station.

Note: Perfect adjustment of these trimmers is easily obtained by removing the Viso-Glo tube and socket from its clamp and turning the tube toward the back of the cabinet so that every adjustment of the trimmers may be watched in the Viso-Glo. Perfect adjustment is obtained when further turning of the trimmers will not result in any smalle shaded area between the green light sections of the Viso-Glo.

(G) Re-adjust the oscillator trimmer (bottom hole) while watching the Viso-Glo to see if the shaded area can be made smaller.

(H) Check the above adjustments by turning the "manual-automatic" switch to the "manual" position and without touching the manual tuning controls, observe if the Viso-Glo shows any difference in the amount of shaded area in the tube as compared to the shaded area with the switch knob in the "automatic" position. If the shaded area is larger with the switch in the "automatic" position, re-adjust the Selectronne trimmers until the shaded area is equal to that obtained with the switch knob in the "manual" position.

5. Repeat the procedure in paragraph 4 for each of the six stations.

6. When all trimmers have been properly adjusted, replace Viso-Glo tube and socket in clamp, and attach Selectronne escutcheon plate to front of cabinet.

7. Any of the six stations to which the SPARTON Selectronne has been adjusted, may now be instantly received simply by pushing the Selectronne button for the desired station with the switch knob in the automatic position.

Note: In case all six of the buttons should become depressed through improper manipulation of the Selectronne, simply reach into the Selectronne box (from the back of the cabinet) and apply a slight pressure of the fingers under the latching bar which runs across the frame work in front of the trimmer box. This will immediately release all buttons.

Model 977

JUNE 1, 1936

MODEL 977
Voltage,Resistance
Alignment

SPARKS-WITHINGTON CO.

A. Alignment of Intermediate-Frequency Stages.

(1) Turn on receiver and test oscillator and allow both to operate several minutes before attempting to adjust any condensers.

(2) Turn the band selector switch to the No. 1 (broadcast) position and turn the station selector knob until the rotor plates are completely out of mesh with the stator plates.

(3) Connect "antenna" of test oscillator to grid cap of Type 6A7 1st detector-oscillator tube and "ground" of test oscillator to chassis frame of receiver. Connect output meter "low tap" across voice coil of speaker. Note: It is advisable to read carefully the operating instructions included with the test oscillator.

(4) Tune test oscillator to obtain a signal of 456 kilocycles.

(5) Turn the volume control of receiver on full and adjust I.F. condensers C4, C3 and C2 which are reached from the top of the chassis. (See Fig 21). Note: The intermediate frequency circuits are quite selective and care must be taken to insure proper adjustment.

B. Alignment of Broadcast Band.

(1) Disconnect "antenna" lead of test oscillator from grid cap of first detector-oscillator tube and connect in series with a 150 mmf. condenser dummy antenna to the antenna terminal of the chassis.

(2) Tune test oscillator to obtain a signal of 1350 kilocycles.

(3) Turn the station selector of the receiver to 1350 kilocycles and without disturbing the setting of the test oscillator or the station selector, adjust condensers C5A, C7B and C9 in the order given.

(4) Tune test oscillator and receiver to 600 kilocycles and adjust condenser C5B, at the same time the station selector knob is moved back and forth to obtain maximum deflection of the output meter.

(5) Retune test oscillator and receiver to 1350 kilocycles and check the adjustments of condensers C5A, C7B and C9.

(6) Calibration of the broadcast band should also be checked at 900 kilocycles and 600 kilocycles.

C. Alignment of Band No. 4 (6.5 to 20 Megacycles).

(1) Turn the band selector switch to the third short wave band (blue section of the dial).

(2) Disconnect "antenna" lead of test oscillator from antenna terminal, remove the 150 mmf. condenser and replace with a 400 ohm non-inductive resistor dummy antenna and connect to grid cap of Type 78 R.F. tube.

(3) Tune test oscillator and receiver to 18 megacycles and adjust condenser C8 and condenser C7A.

CAUTION: On this band care must be taken to adjust the various condensers to the fundamental of the signal and not to the image. The image signal is equal to the fundamental minus twice the intermediate frequency of the receiver. A set that is adjusted to the image frequency instead of to the fundamental may be detected by tuning over the band and checking the sensitivity at various points. If a dead spot appears near the center of the band, the adjustable condensers for that band have probably been adjusted to the image instead of the fundamental.

This type of mis-alignment may also be detected by tuning the test oscillator to a frequency of 15 megacycles and the station selector to approximately 15,900 kilocycles. If a strong signal is found approximately at this frequency, it indicates that the band has been adjusted to the image frequency. The normal image frequency for 15,000 kilocycles would be 15,000 kilocycles minus twice 456 kilocycles or approximately 14,100 kilocycles. Therefore a signal of this frequency may be found with the test oscillator generating a 15,000 kilocycle signal.

(4) Disconnect the "antenna" of the test oscillator from the grid cap of the Type 78 (Type 6K7 in Model 966) R.F. tube and, using the 400 ohm resistor in series, connect to the antenna terminal.

(5) Adjust condenser C6A. Note: Due to the inter-action between the various circuits, it is necessary to move the station selector knob slightly while adjusting these trimmers in order to realize the maximum possible gain.

(6) Retune the test oscillator and receiver to 9 megacycles and check sensitivity and calibration.

D. Alignment of Band No. 3 (3.2 to 8.0 Megacycles).

(1) Turn the band selector switch to the second short wave band (red section of the dial).

(2) Tune test oscillator and receiver to 7.2 megacycles.

(3) Adjust condenser C6B.

(4) Tune test oscillator and receiver to 3.6 megacycles and check calibration and sensitivity.

E. Alignment of Band No. 2 (1.3 to 3.8 Megacycles).

Note: There are no adjustable condensers for this band. However, it is advisable to check the calibration of the dial and the general operation of the receiver at both 1.7 megacycles and 3 megacycles. CAUTION: All adjustments should be rechecked to assure accuracy and stability of adjustment and calibration.

9	(Repeat operation 7)							
10	(Check calibration and sensitivity at 6 MC and 1.95 MC)							
11	2nd Short Wave Band	Ant.	100 ohm 200 mmf. series	18 MC.	2nd S.W.	18 MC.	C10 Osc.	Rock dial slightly while adjusting
							C7 RF	
							C4 Ant.	
12		Ant.		6 MC.	2nd S.W.	6 MC.	C13 Pad	
13	(Repeat operation 11)							
14	(Check calibration and sensitivity at 18 MC. and 6 MC.)							
15	(Check operations 1 to 14 inclusive)							

* Check AFC by connecting generator to converter grid cap and tuning generator and receiver to 1500 KC. Note output meter reading with AFC switch "off". Switch AFC "on" and if output changes appreciably, touch up discriminator trimmer until there is no change in sensitivity.

NOTE: Check to see that dial pointer is parallel to horizontal lines on dial when variable condenser rotor plates are fully meshed with stator plates.

Five Tube A.C. All Wave Superheterodyne X8

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the rear gang condenser trimmer (oscillator circuit) to peak. After this has been carefully done, the next step is to adjust the center and front trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6A7 tube and the front condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located on the left hand end of the chassis near the 6D6 tube.

Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers on the short wave coil located on the top of the chassis. Set the test oscillator to 14,000 KC. The oscillator coil is located near the 1st I.F. Transformer and the antenna or R.F. coil is located directly in front of the Short Wave oscillator coil and about midway between the 1st I.F. Transformer and the 6A7 tube. These two trimmers should be adjusted for peak at 14,000 KC and as the inherent design of the circuit has been expressly designed for simplicity in servicing, no other adjustments are necessary for aligning this band. **Note:** Always start this procedure by having the oscillator coil trimmer loose (out all the way), and the antenna coil trimmer fairly tight (in all the way); otherwise it is possible to make a false alignment on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND There is only one adjustment to be made in the alignment of the Police Band. Due to the circuit design and correct matching of the coils, no oscillator adjustment is necessary.

Set the dial pointer to 4000 KC (also the test oscillator) and adjust the antenna coil trimmer to resonance. The two police band coils are under the chassis, but the antenna coil trimmer for this band is on top of the chassis and is located at the left front corner along side of wave band switch.

Important: This is the only adjustment necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band, otherwise the Broadcast Band will be thrown out of alignment.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator ouput as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

Alignment Procedure

SPIEGEL, INC.

Seven Tube A. C. All Wave Superheterodyne

This receiver is designed to operate over three tuning ranges: the broadcast range which extends from 540 to 1700 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1700 to 5000 Kilocycles (KC) (52 to 175 Meters) and the International Short Wave Band which extends from 5800 to 15,200 Kilocycles (KC) (18.5 to 52 meters). This latter range is the one which includes the four internationally assigned bands —the 19, 25, 31 and 49 meter bands.

This receiver is designed to operate from a power supply main of 110-120 volts, 60 cycle alternating current (AC). **Never plug into a DC outlet.**

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1800, 4000, 6000, and 14,000 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tubes (6L7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all six I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT Adjust the oscillator to 1400 KC and connect the output to the antenna post marked "A" through a .0001 mfd. mica condenser to give the equivalent of an antenna about 60 feet. Set the receiver pointer to 1400 KC and adjust the oscillator trimmer to peak. This trimmer is mounted on the oscillator coil and is located directly under the 6C5 socket. (This adjustment must be made from the bottom of the chassis.) After this has been carefully done, the next step is to adjust the center and rear trimmers of the gang condenser to peak. The center gang section tunes the R.F. or grid coil of the 6L7 tube and the rear condenser section tunes the pre-selector stage circuit.

Next, re-set the dial pointer on the receiver and the test oscillator to 600 KC. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated but is the easiest way to adjust the oscillator to the pre-selector or R.F. section. The padding condenser is located in the left end of the chassis. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

If it is found that in returning to 1400 KC the pointer is accurately on scale, the only readjustments that should be made (in this recheck) are the center and rear trimmers of the gang condenser. If the pointer is found off scale it may be corrected and put on scale by realignment of the oscillator trimmer. Alignment of the pointer can **only** be corrected by adjustment of the oscillator trimmer.

This completes the correct sequence of operations in properly aligning the receiver for the Broadcast Band, and **must always be done before** attempting to align the Short Wave Bands.

FOREIGN BAND The Foreign Band of 19 to 49 meters can be adjusted by the two trimmers located on the top of the chassis. The R.F. trimmer is located directly on top of the R.F. or Antenna coil and the oscillator trimmer is mounted on the chassis near the front of the oscillator coil. Set the test oscillator to 14,000 KC. In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with the .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment. The next operation is to adjust the R.F. and oscillator trimmers for peak at 14,000 KC and as the inherent design of the circuit has been expressly engineered for simplicity in servicing, no other adjustments are necessary for aligning this band.

Note: In order to prevent alignment on the image frequency, it is suggested that alignment be started with the antenna coil trimmer screwed down tightly. To check this adjustment, readjust the pointer to 13100 KC where the image frequency should be found. If properly aligned, the image frequency will be found to be weaker. If, however, the signal at 13100 KC is found to be stronger than the signal at 14000 KC, it signifies that alignment was incorrectly made on the image frequency.

Important: Do not attempt any adjustment of the gang condenser trimmers in aligning the Foreign Band as this will throw the Broadcast Band out of alignment.

POLICE BAND In preparing the test oscillator for alignment of this band, connect a 400 ohm carbon resistor in series with a .0001 mfd. condenser on the output lead of the test oscillator. This resistor is used with the test oscillator only on the Short Wave Bands and should not be used for Broadcast Band alignment.

Set the receiver pointer to 4000 KC (also test oscillator) and adjust the oscillator circuit trimmer to peak. The oscillator trimmer is mounted on the oscillator coil, which is located underneath the chassis. The oscillator coil is wound with enamel wire and is mounted to the front edge of the chassis. After this has been carefully done, the next step is to adjust the antenna trimmer to peak. The antenna trimmer is attached to the antenna coil; also mounted underneath the chassis and wound with enamel wire. The antenna coil is located nearest the power transformer. Now reset the dial pointer and the test oscillator to 1800 KC in preparation for adjusting the police band padding condenser. This padding condenser is mounted on the underside of the chassis, directly underneath the gang condenser. Slowly increase or decrease the oscillator padding condenser and at the same time continuously tune back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment seems a little complicated, but is the easiest way to correctly adjust the oscillator to the R.F. or antenna section.

Return to 4000 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made 1800 KC.

If it is found that in returning to 4000 KC the pointer is accurately on scale, the only readjustment that should be made (in this recheck) is the trimmer on the enamel wire antenna coil located underneath the chassis near the power transformer. If the pointer is found off scale, it may be corrected and put on scale by readjustment of the oscillator trimmer. Alignment of the pointer can only be corrected by adjustment of the oscillator trimmer.

Important: There are only three trimmer adjustments necessary for the Police Band. Do not attempt any adjustment of the gang condenser trimmers in aligning the Police Band; otherwise, the Broadcast Band will be thrown out of alignment.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. An approximate normal minimum oscillating voltage for the plate of the 6C5 (oscillator tube) at 115 volt line potential is as follows:

Broadcast Band	600 KC	124 Volts
	1400 KC	106 Volts
Foreign Band	6000 KC	137 Volts
	14000 KC	140 Volts
Police Band	1700 KC	128 Volts
	4000 KC	110 Volts

Another way of ascertaining whether the tube is oscillating is to ground the grid of the 6C5. If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

Provisions have been made in this receiver for all types of antennas.

REGULAR ANTENNA Use a standard outside antenna of at least 50 feet including lead-in. Connect to antenna post marked **"A."**

In remote locations that are far away from powerful broadcasting stations, a longer antenna may be used for increased receiving range. Antennas as long as 150 to 200 feet may be employed in "dead spots." (Longer antennas increase sensitivity and decrease selectivity slightly.)

THE ALIGNMENT PROCEEDURE

The following alignment instructions are given with the assumption that the service station has a signal generator capable of accurately covering the range of the receiver.

The only other apparatus necessary is a meter connected in the output stage to indicate resonance. This can be a 0 to 3 volt AC meter connected across the voice coil of the speaker or preferably an output meter connected in the plate circuit of the 42 power tube in series with an 8 MFD paper condenser.

The schematic circuit of the set will be found on the back side of the chassis.

1. THE I.F. STAGES

The I.F.'s are aligned by the usual system of feeding the intermediate frequency of 465KC into the grid of the 6A7 tube.

The two trimmers in each of the I.F. cans should be very carefully peaked to resonance as they are very critical and will greatly affect the performance of the set. These are trimmers number C1, C2, C3, C4. (See pictorial diagram).

The sensitivity of the I.F. stages will be 25 microvolts for a 50 milliwatt output.

Always use as low an output as possible from the signal generator in making the various adjustments.

2. ALIGNMENT OF SHORTWAVE BAND 5.5 TO 18 M.C.

First check the position of the dial hand by rotating the tuning knob to the left to full capacity. At this point the dial hand should be straight across in line with the lines dividing the scale in half. If the hand is off position it can easily be lined up by removing the dial glass to get at the screw holding the dial hand.

1. Turn wave band switch all the way to the right for the Short Wave Band.

2. Tune dial hand to 17 megacycles.

3. NOTE: FOR ADJUSTMENT AT 17 MEGACYCLES THE OUTPUT FROM THE SIGNAL GENERATOR MUST NOT BE COUPLED DIRECT TO THE ANTENNA LEAD OF THE SET. FOR TRUE ALIGNMENT STRETCH OUT THE RADIO ANTENNA LEAD IN SUCH A MANNER THAT IT WILL PICK UP THE SO CALLED "WILD" SIGNAL OF 17 MEGACYCLES EMITTING FROM THE GENERATOR. IT IS ALSO IMPORTANT THAT THIS SIGNAL ONLY BE STRONG ENOUGH TO JUST BE HEARD.

4. When the above set-up is arranged peak oscillator condenser C5 to the 17 megacycle weak signal.

5. After adjusting the oscillator trimmer, peak the S.W. antenna condenser C6 to 17 megacycles.

NOTE: After adjusting the short wave band at 17 megacycles, the signal generator output to antenna should be increased and receiver dial advanced to .9 megacycle lower and note if test oscillator signal is heard.

In case there is no response the oscillator trimmers have been pulled down too tightly. The trimmers should be released until this condition exists then go back to original point of alignment - reduce antenna input voltage and correct the trimmer adjustment.

EXAMPLE: The receiver has been adjusted to 17 megacycles. Tune receiver to approximately 16.9 MC.

Increase oscillator signal by "opening up" the attenuator. Move the dial back and forth at 16.9 MC.

If no signal is heard, let oscillator trimmer off until it is heard at 16.9 MC.

Reduce signal voltage from generator, go back to 17 MC and slightly correct this last trimmer adjustment.

3. THE BROADCAST BAND

1. Turn wave band switch all the way to left and dial hand set to 1400 KC (the top scale). The signal generator may be coupled direct to the antenna lead on this band, through a standard 200 MMFD Condenser.

2. Peak oscillator trimmer C7 to 1400 KC from the signal generator.

3. Peak antenna trimmer C8 to 1400 KC after adjusting oscillator.

4. Set dial hand to 550 KC and adjust oscillator padding condenser C9 to 550 KC.

5. Recheck dial at 1400 KC as in Section 1.

6. Points in the middle of the dial may be checked and if necessary the plates of the back section (oscillator) of the variable condenser may be bent for alignment.

4. NOTES

1. Seal all trimmers after their final adjustment.

2. Be sure that the settings are being made to the true fundamental signal from the oscillator and not on a harmonic or image frequency.

3. Refer to the chart included for the voltages at the tube sockets.

Six Tube 6 Volt Battery Superheterodyne
Z5 Chassis

This receiver is designed to operate over three tuning ranges. The broadcast range which extends from 545 to 1715 Kilocycles (KC) (175 to 550 meters), Police and Aviation Band which extends from 1715 to 5350 Kilocycles (KC) (56 to 175 Meters) and the International Short Wave Band which extends from 5760 to 16200 Kilocycles (KC) (18.5 to 52 meters). This short wave range is the one which includes the four internationally assigned bands—the 19, 25, 31 and 49 meter bands.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 175, 600 and 1400 K.C., and an output meter to be connected across the primary or secondary of the output transformer. If possible, all alignment should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) transformers should be aligned properly as the first step.

I.F. ALIGNMENT Adjust the test oscillator to 175 K.C. and connect the output directly to the grid of the first detector tube (6A7), without the use of any series condenser or resistor; the omission of series condenser and resistor to block out the AVC action. The ground on the test oscillator can be connected to the chassis ground. Align the trimmers of the first and second I.F. transformers to peak or maximum reading on the output meter.

OSCILLATOR ALIGNMENT Adjust the test oscillator to 1400 K.C. and connect the output to the antenna through a .0001 mfd. mica condenser to give the equivalent of a low capacity type average auto antenna. Set the dial pointer to 1400 K.C. and adjust the oscillator trimmer to peak. (Front section of gang condenser.)

R.F. ALIGNMENT The next step is to adjust the center and rear trimmers of the gang condenser to peak. The center section of the gang condenser tunes the R.F. antenna amplifier stage (6D6 tube), and the rear condenser section tunes the detector grid coil of the 6A7 tube.

LOW FREQUENCY PADDING Next, reset the dial pointer on the control head and the test oscillator to 600 K.C., adjust the antenna compensator condenser to peak. This adjustment is best reached from the bottom of the chassis and the location of the condenser will be found near the volume control.

The adjustment of the antenna compensator should again be gone over after the auto set has been again installed in the car, to compensate for the difference that may exist in the capacity of the car antenna and the .0001 mfd. capacitor used with the test oscillator.

ALIGNMENT DATA AND SERVICING

GENERAL DATA The alignment of this receiver requires the use of a test oscillator that will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, 16,000 and 18,100 KC and an output meter to be connected across the primary or secondary of the output transformers. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE The intermediate frequency (I.F.) stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure, after which, either or both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT With the wave switch in the Broadcast Band and the gang condenser set at minimum push in the white button until it locks. Adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6A7) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align the first four I.F. trimmers to peak or maximum reading on the output meter.

After the first two I.F. transformers have been tuned, the discriminator transformer should be aligned. This is a critical adjustment and must be performed with care.

First — connect a 0-200 micro ammeter between the ungrounded cathode of the 6J5G tube serving as a diode rectifier, and ground. This cathode is indicated as point "A" in the circuit diagram. Then place a .0001 mfd. mica condenser across the secondary of the discriminator transformer. These terminals are indicated as points "D1" and "D2" on the circuit diagram. This condenser is used to detune completely the secondary circuit during the following primary adjustment.

The primary is tuned by impressing an I.F. signal on the convertor (6A8-G) grid and adjusting the trimmer marked "DISC. PRI." on the chassis layout diagram, to give maximum audio output. Signal strength should be the same as in an ordinary aligning operation. For this particular receiver about 30-micro volts of I.F. signal is required for standard output. (50 milliwatts). At this point it would be well to go over the adjustments of the two other I.F. transformers and bring the entire system to maximum sensitivity. Now without further adjustments of either the frequency setting of the signal generator or the I.F. transformer trimmers the "DISC. SEC." trimmer should be tuned.

After removing the .0001 mfd. mica condenser from the 6J5G grids "D1 and D2" increase the I.F. signal input to the maximum that the signal generator will supply (at least 100,000 micro volts). Then, with the volume control turned down to limit the audio output, slowly turn the "DISC. SEC." trimmer until a sudden, sharp drop in current as indicated by the micro ammeter is seen. The meter will now probably read in reverse and off scale. The trimmer should be reversed and the meter reading brought to zero. If a metallic screw driver is used it will be necessary, continually, to lift the screw driver away from the trimmer screw after each slight adjustment to observe the meter reading.

It is sometimes convenient to use an offset of "remote zero" setting of the micro ammeter in making this adjusment so that the zero current setting is higher on the scale than the conventional zero point.

After the current has been brought to zero by the above described method the I.F. alignment and discriminator tuning is completed and the R.F. tracking may be done.

BROADCAST BAND ALIGNMENT Connect the output of the signal generator to the antenna lead (blue) through at .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "preselector" and "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the preselector of the R.F. section. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

POLICE BAND ALIGNMENT The police band is adjusted by first replacing the .0002 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit of this frequency as described in the instructions for padding the broadcast circuits.

SHORT WAVE BAND ALIGNMENT The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC, tune in the signal and adjust the "short wave antenna" trimmer to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

CONTROLS AND OPERATION

RIGHT HAND KNOB **(Three Position Wave Band Selecting Switch)**—Turned to the right, it is set for Standard Broadcast Band; turned to the extreme left, it is set for Foreign and American Short Wave Reception; when in the center position, it is set for reception of Police, Aviation, Amateurs, and Ships at Sea.

SHORT WAVE TUNING

When tuning short wave stations, the selector knob must be turned more slowly and carefully, due to the sharp selectivity of the receiver in these bands. If you tune rapidly, many stations will be skipped entirely. When a response is heard, work the dial a little from left to right until you hit a point where the station comes in at maximum volume. This critical tuning is necessary if results are to be expected. It may require a little patient experimenting to become accustomed to short wave tuning. The use of a short wave "log" will be of great assistance in picking up short wave stations. Such logs are available from any of the leading radio magazines. They list the location, frequency and operating time schedules of short wave stations all over the world.

LEFT HAND KNOB **(Manual Volume Control and "On-Off" Switch**—Turn the left hand knob to the extreme right. The switch will click and the dial will become illuminated. Wait about one-half minute for the tubes to become heated.

LEFT CENTER KNOB **(Continuous Variable Tone Control**—The tone control permits tonal regulation to meet individual musical taste. When turned completely to the right the normal proportion of high to low notes is obtained. Upon turning the control from the extreme right position toward the center a gradually increasing emphasis of the low notes is noted. Further, increase in this direction serves to eliminate the more extreme "highs" which result in a greater apparent bass increase. A very useful application of this particular type of tone control is its ability to compensate for apparent lack of base at low volume levels. If when listening to a musical program at a low volume level the tone control is set at a position half way between its extreme settings a very pleasing effect is obtained.

INSTRUCTIONS FOR ADJUSTMENT AND OPERATION OF THE ELECTRIC TUNER

It is very important to read the following instructions carefully before attempting to adjust the electric tuner.
The electric tuner is made up of three integral units:

PUSH BUTTON SWITCH: The push button switch consists of one (1) white button (extreme left), and eight (8) brown buttons whose numerical sequence is reckoned from left to right. The white button is provided for converting the set from automatic electric push button tuning to manual knob tuning. The brown buttons are provided for automatic electric tuning.

SELECTOR MECHANISM: The selector mechanism is made up of the selector plate, eight (8) thumb screws, and the adjustment light bulb.

ELECTRIC MOTOR: The power for this tuner is provided by a small, efficient electric motor, of the brushless variety. It is fitted with an automatic clutch and a silent gear train. The bearings and the oil retainer hold sufficient oil to lubricate the motor for a lifetime.

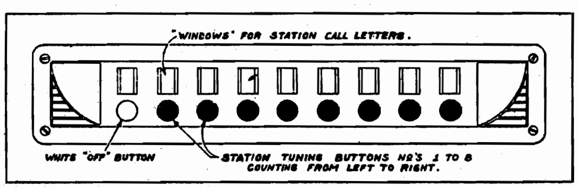

Fig. 1

The first step to take in adjusting the electric push button device incorporated into this receiver is to choose eight (8) of the most powerful local stations, stations which are free from excess fading. Turn on the receiver (broadcast band) and press in the white button; tune in the station of the **lowest frequency**, using the station selector knob. Now hold the white button in and press in button number one (1), next to the white button. (See Figure 1). Both buttons are now locked into place; a small pilot lamp located at the rear of the chassis will light up unless the thumb screw at the rear accidently happens to be correctly set. Loosen thumb screw number one (See Figure 2 for order of thumb screws) enough to allow it to slide freely back and forth until the light goes out. Now tighten the thumb screw; the adjustment for the first station is now complete. Out of the station call letter sheet supplied remove the proper station call block and insert into the window directly above button number one. Now release button number one by pressing the white button in as far as it will go.

With the white button still in, tune in the station of the next highest frequency and holding the white button, press in button number two. Both buttons are now locked into place. Loosen thumb screw number two (see Figure 2) and slide back and forth until a point is reached at which the pilot lamp in the rear goes out; tighten the thumb screw. Insert the proper station call into the window of button number two.

Follow this same procedure for the remaining stations, always choosing the station with the next highest frequency. After all eight (8) stations have been adjusted, check each adjustment by tuning in each station. Note: In the window above the white button insert the word "OFF" found in the call letter sheet.

HOW TO TUNE IN STATIONS USING THE ELECTRIC PUSH BUTTON TUNER

In order to operate the receiver satisfactorily—using the electric push button tuner, the white button must be in released position, that is, all the way out. To tune in a station, merely press the selector button which designates the station desired. **Note:** Should the station fail to come in clearly, check the adjustment by following the adjustment procedure described in the paragraph above. If by chance all of the buttons are pressed in, they may be released by pressing any one button all the way in.

To change from electric tuning to manual selecting, simply press in the white button. When the white button is in, the set may be tuned as a conventional receiver. **Note:** If it is desired to tune Short Wave or Police while the set is being operated with push buttons, it is not necessary to change over from push button tuning to manual tuning. Simply turn the band switch and proceed to tune with the selector knob. When the band switch is returned to broadcast the station last selected by button will automatically tune in by itself.

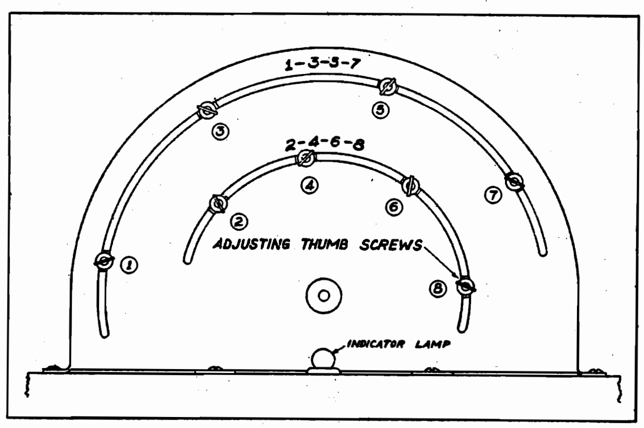

Fig. 2

NOTE: The white push button must be pressed in, in order to tune the set manually.

RIGHT CENTER KNOB **(Station Selector)**—Rotate the indicator needle slowly over a narrow range of the dial at a point where the desired station is located, until the station is received with maximum volume; then re-adjust the volume control to the proper level. **Never** use the station selector to adjust volume as this practice results in distorted tone quality and deficient bass response. The Volume Control **only** is to be used for this purpose. For maximum clarity the indicator needle should be adjusted to the center of the area covered by the station being tuned.

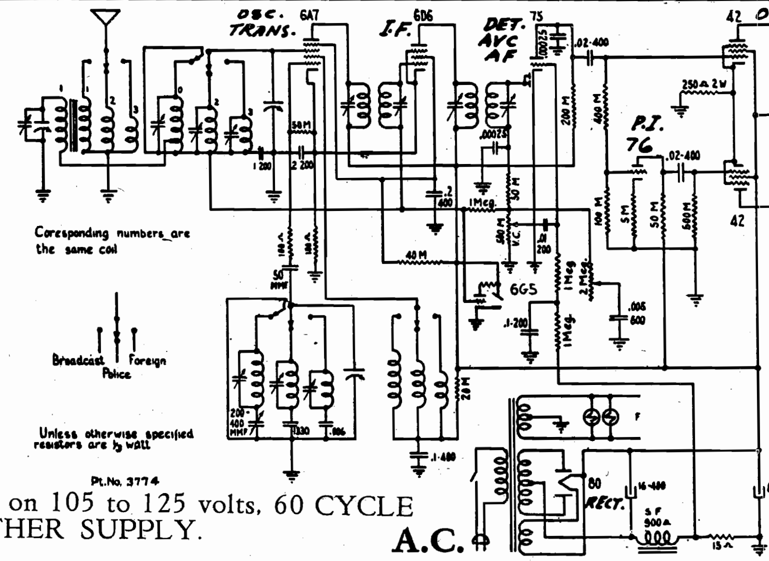
I.F. PEAK 456KC



This receiver is designed to work on 105 to 125 volts, 60 CYCLE A.C. ONLY. DO NOT USE ANY OTHER SUPPLY.

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an ouput meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

RF. (See above diagram for location of trimmers.) Using 200 mmf condenser in series with the generator, feed 1660 kc to antenna lead and adjust broadcast oscillator trimmer for top frequency. Set generator to 1400 kc, tune receiver and adjust the *two* antenna trimmers. Set generator to 600 kc, tune receiver to signal and adjust padder. The tuning condenser should be rocked back and forth through the signal while the padder is being set in order to secure perfect alinement.

Using 400 ohm resistor in series with generator, set band selector in center position, set generator to 5400 kc and adjust oscillator trimmer for top frequency. Set generator to 5000 kc, tune receiver to signal and adjust antenna trimmer.

Turn band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc—screw trimmer down tight, then unscrew to *second* peak. Set generator to 15,000 kc, tune receiver to signal and adjust antenna trimmer—Screw trimmer down tight, then unscrew to *first* peak, rocking the tuning condenser back and forth through the signal while the adjustment is being made. **Above procedure for alinement at 15,000 kc must be followed exactly to insure proper tracking. A dead spot at about 12,000 kc will result if antenna and oscillator circuits are not set in proper relation to each other.**

ALINEMENT PROCEDURE

Connect a high impedance AC voltmeter across loud-speaker terminals. Volume control should be set a few degrees back of maximum volume position. Use a weak signal from generator, strong signals tend to cause improper adjustments.

IF. Connect generator ground to received ground. Using .1 mfd condenser in series with "high" side of generator, apply 456 kc signal to grid of 6S7G and adjust second IF transformer; same for first IF, applying signal to grid of 6D8G. (See above diagram for location of tubes and transformers.)

RF. (See above diagram for location of trimmers.) Using 200 mmf condenser in series with the generator, feed 1660 kc to antenna lead and adjust broadcast oscillator trimmer for top frequency. Set generator to 1400 kc, tune receiver and adjust the *two* antenna trimmers. Set generator to 600 kc, tune receiver to signal and adjust padder. The tuning condenser should be rocked back and forth through the signal while the padder is being set in order to secure perfect alinement.

Using 400 ohm resistor in series with generator, set band selector in center position, set generator to 5400 kc and adjust oscillator trimmer for top frequency. Set generator to 5000 kc, tune receiver to signal and adjust antenna trimmer.

Turn band selector to extreme clockwise position. Using 400 ohm resistor in series with generator, set oscillator top frequency for 15,750 kc—screw trimmer down tight, then unscrew to *second* peak. Set generator to 15,000 kc, tune receiver to signal and adjust antenna trimmer—Screw trimmer down tight, then unscrew to *first* peak, rocking the tuning condenser back and forth through the signal while the adjustment is being made. **Above procedure for alinement at 15,000 kc must be followed exactly to insure proper tracking. A dead spot at about 12,000 kc will result if antenna and oscillator circuits are not set in proper relation to each other.**

IF ALIGNMENT - Wave change Sw. in BC position. Gang cond. set to minimum, test oscillator at 456 KC, to CG of 6D8G thru .05 MFD cond., GND to set, Align IF.

BROADCAST - Gen. connected to ANT lead thru 200 MMFD condenser, Gang at minimum. Osc. to 1730 KC, and adjust OSC. trimmer of set. Shift Gen. and dial to 1400 KC, and adjust ANT trimmer. Generator at 600 KC, pad oscillator to maximum peak.

POLICE - Replace 200 MMFD cond. with 400 ohm resistor, Generator at 5600 KC, Gang condenser at minimum, trim Osc. circuit, Gen. at 4000 KC, trim ANT trimmer. Gen. at 1800 KC and pad Police Oscillator circuit to maximum peak.

SHORT WAVE - Generator at 18100 KC, gang condenser at minimum, adjust oscillator trimmer to peak, Generator at 16000 KC adjust SW ANT trimmer to peak. No padding required on this band but check 6000 KC for alignment & sensitivity. For maximum performance, all above adjustments should be repeated. Rock Gang condenser for padding adjustments.

ALIGNMENT DATA AND SERVICING

GENERAL DATA

The alignment of this receiver requires the use of a test oscillator which will cover the frequencies of 456, 600, 1400, 1730, 1800, 4000, 5600, 6000, and 18,000 KC and an output meter which is to be connected across the primary or secondary of the output transformer. If possible, all alignments should be made with the volume control on maximum and the test oscillator output as low as possible, to prevent the AVC from operating and giving false readings.

CORRECT ALIGNMENT PROCEDURE

The intermediate frequency (I.F. stage should be aligned properly as the first step. After the I.F. transformers have been properly adjusted and peaked, the Broadcast Band should always be the next procedure; after which, both of the Short Wave Bands may be aligned.

I.F. ALIGNMENT

With the wave switch in the broadcast band and the gang condenser set at minimum, adjust the test oscillator to 456 KC and connect the output to the grid of the first detector tube (6D8G) through a .05 or .1 mfd. condenser. The ground on the test oscillator can be connected to the chassis ground. Align all four I.F. trimmers to peak or maximum reading on the output meter.

BROADCAST BAND ALIGNMENT

Connect the output of the signal generator to the antenna lead (blue) through a .0002 mfd. mica condenser. Set the gang condenser to minimum and the oscillator to 1730 KC and adjust the "oscillator trimmer" to receive this signal. Make no other adjustments at this frequency. Then set the generator to 1400 KC and tune in this signal by rotating the gang to 1400 on the dial. Adjust the "antenna" trimmer to maximum signal. Set the signal generator to 600 KC and tune in the signal on the receiver. **Note:** Approximately the same sensitivity should be noted at this point as was at 1400 KC. The signal strength may sometimes be improved by padding the circuits. This is done by slowly increasing or decreasing the oscillator padding condenser and, at the same time, continuously tuning back and forth across the signal with the receiver until the maximum reading is obtained on the output meter. This adjustment may seem a little complicated but is the easiest way to adjust the oscillator to the antenna. Return to 1400 KC and again go over the adjustments of this frequency to be certain that they were not put slightly out of alignment when adjustment was made at 600 KC.

POLICE BAND ALIGNMENT

The police band is adjusted by first replacing the .0002 dummy with a 400 ohm resistor and setting the generator to 5600 KC. With the gang set at minimum, adjust the "police oscillator trimmer" to receive this signal, then set the signal generator to 4000 KC and adjust "police antenna trimmer" to give maximum output. Next, set the oscillator to 1800 KC and "pad" the circuit at this frequency as described in the instructions for padding the broadcast circuits.

SHORT WAVE BAND ALIGNMENT

The short wave band is adjusted by setting the generator to 18,100 KC and with the gang at minimum, adjust the "short wave oscillator trimmer" to receive the signal. Set the generator at 16,000 KC and adjust the "short wave antenna" to give maximum output. As there is no variable low frequency padding condenser on this band, the sensitivity of the receiver should be checked at 6000 KC to determine whether the circuits are in line at this frequency. Should the receiver lack sensitivity at 6000 KC, the antenna and oscillator coils, as well as the .004 mica padding condenser, should be tested for defects as sometimes these components become subject to mechanical or electrical injuries, despite their rugged construction and liberal ratings.

SERVICE DATA FOR ALL BANDS

If it is suspected that the oscillator has stopped but is doubtful due to the presence of the usual amount of noise level, it is suggested that the oscillator plate voltage be checked. To ascertain whether the tube is oscillating, ground the oscillator grid of the 6D8G (short stator and rotor plates of oscillator section on gang condenser). If oscillating properly, grounding the grid will cause an appreciable drop in oscillator voltage.

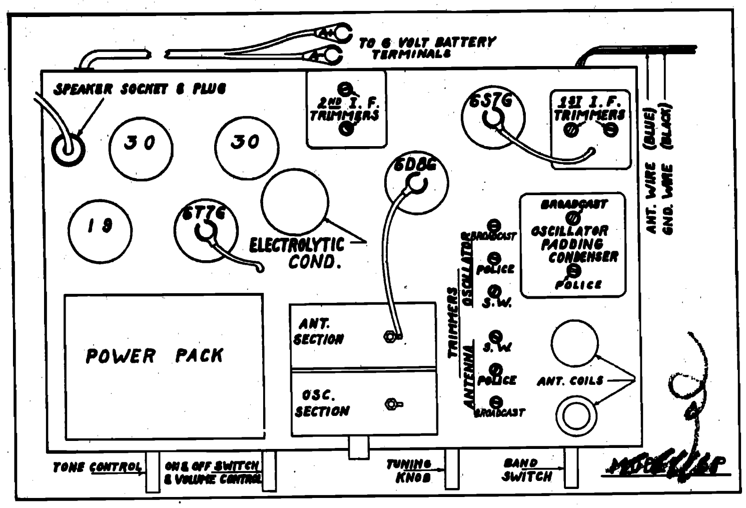
Notes,Parts

SPIEGEL, INC.

This receiver is designed to operate over three tuning ranges; the broadcast range which extends from 550 to 1700 Kilocycles (KC) (176 to 545 meters), Police and Aviation Band which extends from 1700 to 5400 Kilocycles (KC) (56 to 176 Meters) and the International Short Wave Band which extends from 5600 to 18,100 Kilocycles (KC) 16.5 to 53 Meters). This latter range is the one which includes the four internationally assigned bands —the 19, 25, 31 and 49 meter bands.



NOTICE — MICROPHONIC NOISE CORRECTION
If this radio instrument appears to be microphonic during operation, loosen the four (4) mounting screws that secure the chassis to the cabinet and remove the two (2) wooden strips that are underneath the chassis. This allows the chassis to float and rest on the four (4) rubber pads used for this purpose.
After the strips have been removed, adjust the chassis in the cabinet so that the dial will be in the center of the front escutcheon plate. Do not retighten the mounting screws.
"Should this radio set be moved any great distance, it is best to put the wooden strips back under the chassis and have the mounting screws securely tightened. If this is not done, damage may be done to the instrument, cabinet or tubes."

INSTALLATION

BATTERY CONNECTIONS At the rear of the receiver there will be found extending from the right end of the chassis, the battery connecting cable. Observation will show that 5 wires are brought out from the braided cable. The **red** and **red with black tracer wires** are joined together and should **both** be securely fastened to the positive (+) terminal of the 6 volt storage battery. The other 3 wires which are **brown, black with green tracer** and **Metallic shield lead** are also joined together and should be securely connected to the negative (—) post of the battery.

Note: It is extremely important that only the best possible means of obtaining a secure connection to the **battery terminals be employed. If a battery with automobile** terminal posts is used, the **large** post is the positive (+) post; the **smaller post** is the **negative** (—) terminal. It is suggested, when using a battery with auto type posts that large heavy lead covered battery clips be used in making connections. Make sure that **all wires** are firmly connected to clips (solder if possible). Also see that the jaw teeth of the clips are clean, and firmly bite into the post. It is very important that the battery posts and battery clip teeth be cleaned at frequent intervals to assure maintaining good connections. Corrosion may be readily removed by cleaning with a solution of 3 tablespoons of bicarbonate of soda (baking soda) and one cup of water. This solution neutralizes the acid coating that causes the corrosion and leaves a protective condition that retards further corrosion. **It is important that this solution** does not in any way enter the interior of the battery.

ANTENNA

REGULAR ANTENNA Use a standard outside antenna of at least 50 feet including lead-in. Connect the antenna to the "Blue" lead.
In remote locations that are far away from powerful broadcasting stations, a longer antenna may be used for increased receiving range. Antennas as long as 150 to 200 feet may be employed in "dead spots." (Longer antennas increase sensitivity and decrease selectivity slightly.)

GROUND **This receiver requires a good ground.** Water pipes make a very desirable ground connection. Where the wire makes contact, the pipe must be clean and free of paint or corrosion. The ground wire should be connected to the "Black" lead.

Where the above mentioned ground facilities are not available, a good outside ground may be had by sinking a metal pipe or ground rod about six feet into moist earth. An excellent bed can be prepared by digging a hole and filling with charcoal, in which the ground rod is placed. The charcoal bed surrounding the ground rod will maintain a desirable moist condition throughout the year.

IMPORTANT NOTE: The battery must never be charged while set is in operation. If a windcharger is used, it should always be disconnected from the battery when the receiver is being used. An inexpensive single pole switch can be used for disconnecting the windcharged from the battery. This will increase the life of the tubes and give additional economy to the use of the receiver.

MODELS 4508, 9905, 9911
Chassis 20C5
Socket, Voltage, Resistance
Alignment, Drive Cord Data

SPIEGEL, INC.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 4.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 4. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 4.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

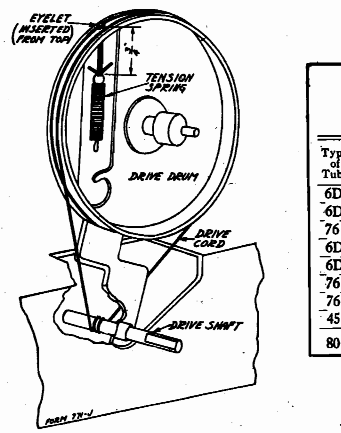

Fig. 4—Drive Cord Replacement

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately ¾" from the flange of the drum as shown in Fig. 4. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

Phono Connections

Phonograph connections can be made as shown in Fig. 5. A single pole double throw switch and double pin jack are required. These should be mounted on the back panel of the chassis close to the 2nd detector. The connections are made by opening the diode circuit at the point shown in the illustration and completing the connections to the switch and pin jacks as indicated. A high impedance pick-up should be used. If a low impedance pick-up is used a step-up transformer will be required for sufficient volume. The volume control of the set will regulate the phono volume.

Change in Early Models

In the early models of this receiver the side of the trimmer condenser C27 which is shown in Fig. 1 as connected to ground was connected to the B+ side of the 3rd I. F. coil primary.

Condenser Alignment

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 456 K. C. and accurately calibrated signals over the broadcast and short wave bands, 530-1740 K. C. and 5.8-18.3 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans - See Fig. 2. The openings to these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION - Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 2 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K.C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2. If a maximum output peak cannot be reached, it may be due to the fact that the antenna and 1st detector short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum output.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 2 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

Voltage, Alignment
Resistance, Sensitivity

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings to these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION - Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the top panel of the chassis as shown in Fig. 2 and the adjustment screw is reached through a hole in the top panel.

Standard Wave Band Adjustment

The standard-short wave switch should be in the standard wave position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator standard wave trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the standard wave band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector standard wave trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the standard wave band alignment as described above has been made, do not change the adjustment of any of the standard wave band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K. C. higher in frequency than the signal.

Turn the standard-short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2. If a maximum output peak cannot be reached, it may be due to the fact that the antenna and 1st detector short wave trimmers are screwed down too far. Back off these two trimmer screws two or three turns and then adjust the oscillator short wave trimmer for maximum output.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 2 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

SERVICE NOTES
for the
BATTERY OPERATED
SEVEN TUBE SUPERHETERODYNE RECEIVER

ALIGNMENT PROCEDURE: For properly aligning either the intermediate transformer or the gang condenser it is necessary that an accurately calibrated oscillator be used with some type of output measuring device.

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 106 tube leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver chassis.

2. Set the test oscillator frequency to 465 kilocycles (this must be accurate).

3. Align the first intermediate ansformer by turning one of the trimmer screws up and down until maximum reading is obtained on the output meter, and then adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the second intermediate transformer in the same manner.

NOTE: Two type intermediate transformer trimmers have been used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for adjusting one trimmer, the other intermediate trimmer being adjusted with the trimmer screw located inside of the brass hex nut. Regardless of which type trimmer is used the procedure is the same.

TO ALIGN THE VARIABLE CONDENSER: It is important when aligning to follow the procedure carefully, otherwise the receiver will lack sensitivity and the dial calibration will be incorrect.

1. Connect the high output side of the oscillator to the receiver antenna lead and the ground to the chassis.

2. Place the band selector switch for operation on the short wave band, tune the receiver to exactly 15 megacycles on the dial and set the test oscillator frequency to exactly 15 megacycles. THEN TUNE IN THE 15 MEGACYCLE SIGNAL BY ADJUSTING THE TRIMMER MOUNTED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER TO MAXIMUM OUTPUT.

Looking at the front of the receiver the oscillator section is the rear section of the gang condenser.

3. Set the band selector switch for operation on the broadcast band, adjust the test oscillator frequency to 1400 kilocycles and set the receiver dial to exactly 1400 kilocycles. NEXT, BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER LOCATED UNDERNEATH AND NEAR THE CENTER FRONT OF THE CHASSIS.

4. After making this adjustment tune the dial to 1720 kilocycles and set theoscillator frequency to 1720 kilocycles. If the 1720 kilocycle signal cannot be received reduce the 1400 kilocycle trimmer capacity until the 1720 kilocycle signal is brought in.

5. Next, set the receiver dial and test oscillator to exactly 1400 kilocycles, and adjust the trimmer located on the front section of the gang condenser for maximum sensitivity.

6. Leave the band selector switch for operation on the broadcast band, tune the receiver and set the oscillator to approximately 600 kilocycles. Then adjust the 600 kilocycle padding condenser, which is located on and accessible through the small hole in the front of the chassis, for maximum sensitivity. As this adjustment is quite critical it is necessary to rock the condenser slightly to the right and left to find the point of greatest sensitivity.

7. Place the band selector switch for operation on the short wave band, adjust the test oscillator frequency to exactly 15 megacycles and set the receiver dial to 15 megacycles. Turn the receiver on its back with the dial up and adjust the trimmer, which is mounted on the top of the coil underneath and near the right hand side of the chassis, for maximum output. Be sure to rock the condenser slightly to the right and left when making this adjustment.

This completes the alignment procedure. It is recommended that all of the adjustments be gone over again Generally it will be found that improved results can be obtained if this is done.

(Total "A" Drain 600 M.A.)
(Total "B" Drain 23 M. A. with no signal)

Comparative voltage only. Read all voltages from socket to chassis with 1,000 ohm per volt meter. When making voltage checks use batteries that deliver full voltage with the receiver turned on.

NOTE: NEVER LIFT THE RECEIVER BY GRASPING THE CATACOMB SHIELD, TO DO SO MAY MOVE THE SHIELD THEREBY DETUNING THE RECEIVER.

SPIEGEL, INC.

MODEL 4514
Chassis 9148
Alignment

INTERMEDIATE ALIGNMENT:

1. Connect the high side of the oscillator output to the control grid of the 1C6 tube, leaving the grid cap disconnected. Connect the ground side of the oscillator to the receiver ground post.

2. Set the test oscillator frequency to 465 kilocycles. (This must be accurate).

3. Align the first intermediate transformer by turning one of the trimmer screws up and down (increasing and decreasing capacity) until maximum reading is obtained on the output meter, after which adjust the other trimmer screw of the same transformer for maximum sensitivity.

4. Adjust the other intermediate transformers in the same manner.

TO ALIGN THE VARIABLE CONDENSER:

Adjustment of the trimmer condensers, located inside of and accessible through the holes found in the top of the catacomb (mounted on top and in the left hand front corner of the receiver) will be referred to by numbers as indicated on the circuit diagram showing the relative location of these trimmers.

1. Connect the high output side of the oscillator through a 250 mmfd. (.00025 Mfd.) to the receiver antenna post and the ground to the ground post.

2. Place the band selector switch for operation on the 1520 to 535 kilocycle band (broadcast), tune the receiver to exactly 1400 kilocycles on the dial and set the test oscillator frequency to exactly 1400 kilocycles. THEN BRING IN THE 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING TRIMMER MARKED No. 2 ON CATACOMB DIAGRAM, after which adjust No. 1 and No. 3 trimmers in the order named for maximum sensitivity.

3. Leave the band selector switch for operation on the broadcast band (1520-535 kilocycles) and tune the receiver and set the test oscillator to approximately 600 kilocycles. Then while rocking the condenser slightly to the right and left adjust the 600 kilocycle padding condenser No. 11, which is located on and accessible through the hole provided on the left hand side of the chassis, for maximum sensitivity.

4. Recheck the alignment at 1400 kilocycles as the 600 kilocycle adjustment may have changed the alignment at 1400 kilocycles.

5. Place the band selector switch for operation on the 1.5 to 4.2 megacycle band and set the test oscillator frequency and tune the receiver dial to EXACTLY 3.8 MEGACYCLES. THEN TUNE IN THIS 3.8 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING CATACOMB TRIMMER NO. 7. Next adjust catacomb trimmer No. 4 for maximum sensitivity.

6. With the band selector switch in the same position (1.5-4.2 megacycle band) tune the receiver dial and set the oscillator frequency to approximately 1600 kilocycles, and then while rocking the variable condenser slightly to the right and left adjust the 1600 kilocycle trimmer No. 12 located on the left hand side of the chassis for maximum sensitivity.

7. Recheck 3.8 megacycle adjustments.

8. Adjust the band selector switch for operation on the 4 to 11 megacycle band and tune the receiver dial and set the oscillator frequency to exactly 10.5 megacycles. When adjusting catacomb trimmer No. 5 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 10.5 MEGACYCLES. First back off catacomb trimmer No. 5 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you areto use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 5 to BRING IN THE 10.5 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 10.5 megacycles, increase its output, and tune the receiver dial to approximately 9.5 megacycles. Vary the receiver dial slightly to the right and left of 9.5 megacycles and if the fundamental peak was used in aligning at 10.5 megacycles the test oscillator signal will be heard at approximately 9.5 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 10.5 megacycle adjustment of trimmer No. 5 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 5 adjustment adjust catacomb trimmer No. 6 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 6 to the one that requires the most capacity.

9. With the band selector switch adjusted for operation on the same band (4-11 megacycles) set the test oscillator frequency and tune the receiver dial to approximately 4.8 megacycles. Then while rocking the variable condenser slightly to the right and left adjust the 4.8 megacycle trimmer No. 10, located on the left hand side of the chassis for maximum sensitivity.

10. Recheck the 10.5 megacycle adjustment.

11. Adjust the band selector switch for operation on the 10 to 20 megacycle band, tune the receiver dial and set the oscillator frequency to exactly 19 megacycles. When adjusting catacomb trimmer No. 8 two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 19 MEGACYCLES. First back off catacomb trimmer No. 8 to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust catacomb trimmer No. 8 to BRING IN THE 19 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 19 megacycles, increase its output, and tune the receiver dial to approximately 18 megacycles. Vary the receiver dial slightly to the right and left of 18 megacycles and if the fundamental peak was used in aligning at 19 megacycles the test oscillator signal will be heard at approximately 18 megacycles on set dial. If it is not possible to receive the signal then the fundamental peak was used and the 19 megacycle adjustment of trimmer No. 8 must be gone over and properly adjusted. After correctly completing catacomb trimmer No. 8 adjustment adjust catacomb trimmer No. 9 for maximum sensitivity. Should two peaks be noticed with this trimmer always adjust trimmer No. 9 to the one that requires the most capacity.

12. Some code and aircraft signals are broadcast on a frequency exactly the same or near the IF frequency of the receiver. To eliminate interference from these signals a 465 kilocycle filter (mounted in the coil shield located underneath and towards the front of the chassis) is incorporated in the set. To adjust, set the oscillator frequency (with oscillator output connected to set antenna and ground) TO EXACTLY 465 KILOCYCLES, turn the receiver on end and adjust the trimmer located on and accessible through the top of the filter shield for MINIMUM 465 KILOCYCLE SIGNAL.

1935

INTERMEDIATE ALIGNMENT

Align at 465 kc. Two types of i-f trimmers are used in this receiver. One type has two parallel holes in the top of the shield, one for each trimmer. The other type has a brass hex nut for one trimmer, the other intermediate trimmer being adjusted by means of the trimmer screw located within the brass hex nut.

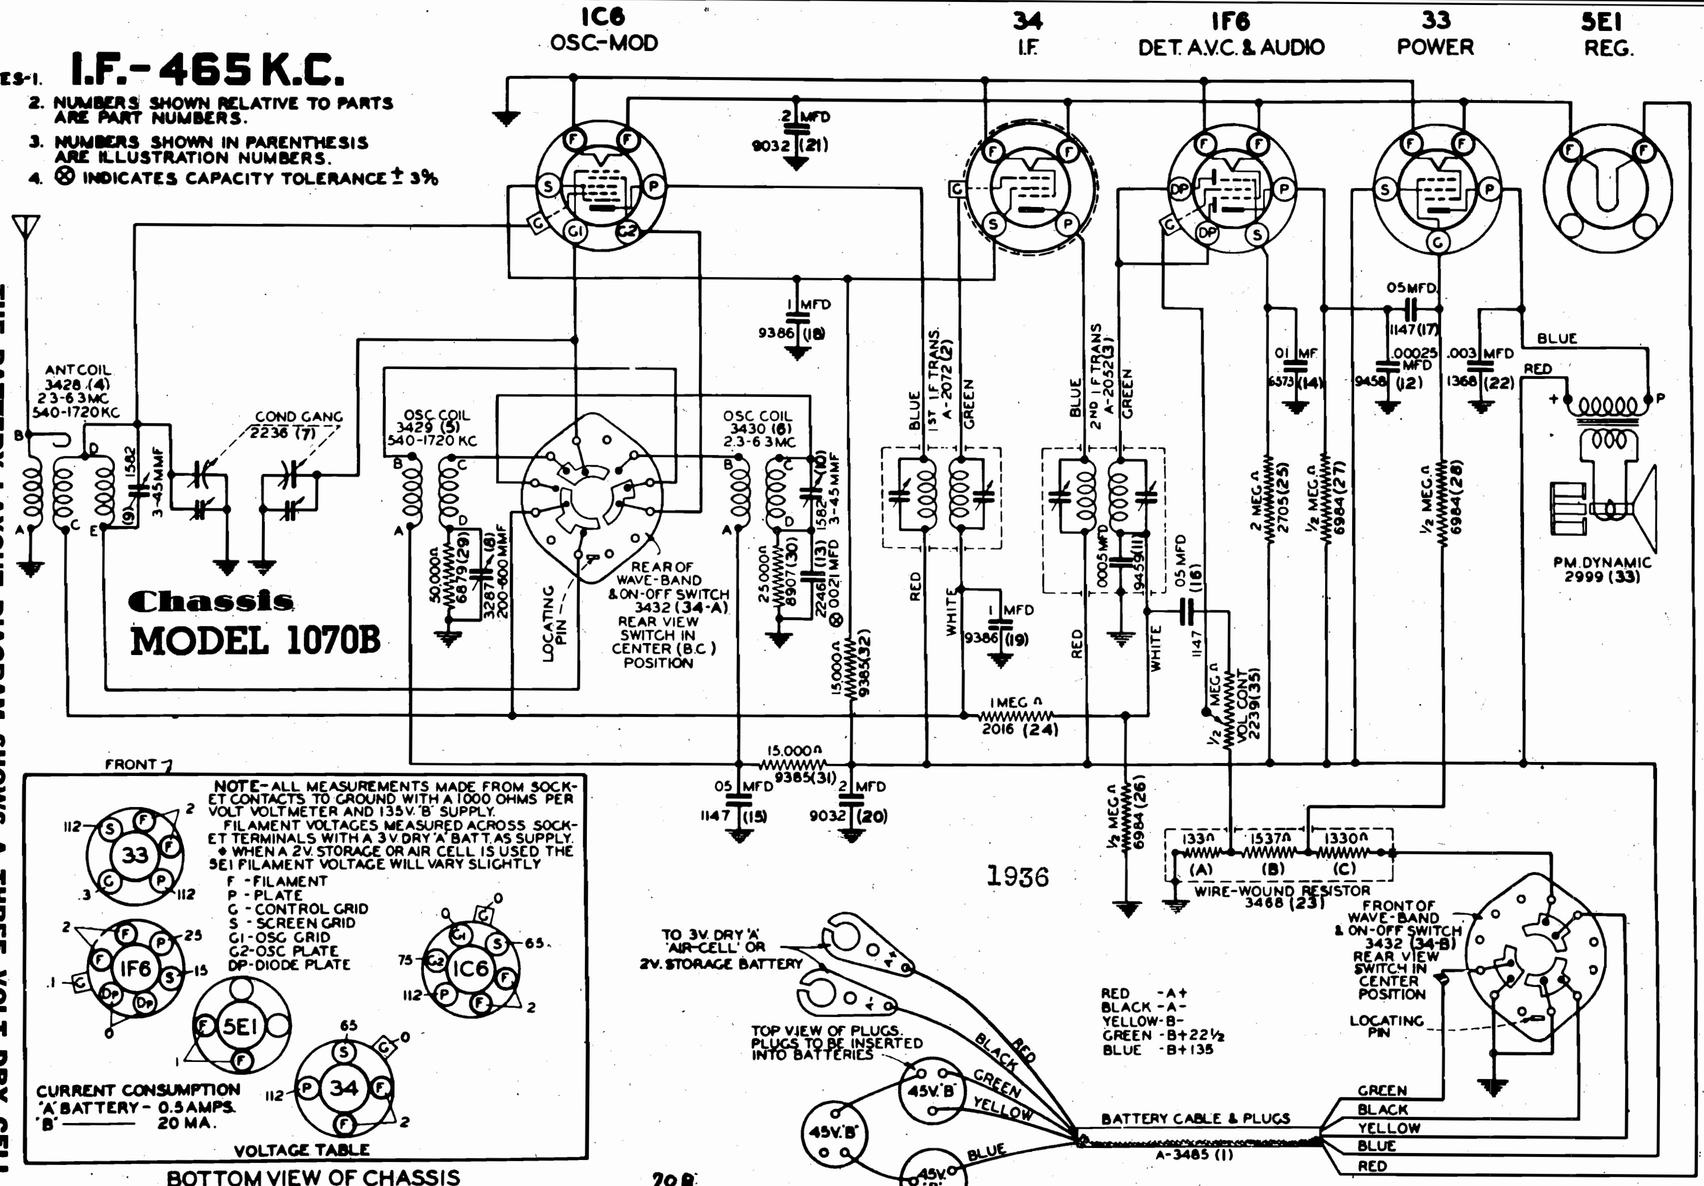
MIXER-OSCILLATOR ALIGNMENT

Connect test oscillator to antenna post and ground or chassis. Set test oscillator and receiver dial to 1720 kc. Then adjust trimmer condenser located on top of the oscillator (front section) unit of the gang condenser.

Then tune the receiver to 600 kc. and reset the test oscillator to this frequency. Then rock the tuning condenser slightly to the right and left, while adjusting the 600 kc. oscillator padding condenser, which is accessible through the hole provided on the front of the chassis. Repeat all the adjustments for maximum output.

MODEL 5102
Chassis 1070B
Schematic, Voltage
Socket

SPIEGEL, INC.



THE BATTERY LAYOUT DIAGRAM SHOWS A THREE VOLT DRY CELL "A" BATTERY, BUT A TWO VOLT WET STORAGE BATTERY OR AN AIRCELL BATTERY MAY BE USED AS THE "A" SUPPLY.

AIR CASTLE

CONNECT THE SET BATTERY CABLE WIRES exactly as indicated on the cable markers and shown on the battery hookup diagram. DO NOT PERMIT ANY CABLE WIRES TO COME IN CONTACT WITH THE RECEIVER CHASSIS OR ANY BATTERY TERMINAL OTHER THAN THAT TO WHICH IT IS TO BE CONNECTED. To do so may destroy one or more of the tubes.

MODEL 5102
Chassis 1070B
Alignment, Parts
Batt. Connections

SPIEGEL, INC.

Alignment of this receiver should never be necessary unless one of the coils has been replaced.

Lack of sensitivity, selectivity or poor tone quality may be due to any one or a combination of causes such as weak or defective tubes or speaker, open or grounded bias resistor, bypass condenser, inadequate or excessively long antenna, improperly connected or low batteries, etc. Never attempt to realign set until all other possible sources of trouble have been first thoroughly investigated and definitely proven not to be the cause.

NOTE: BE SURE TO FOLLOW PROCEDURE CAREFULLY WHEN ALIGNING, OTHERWISE THE RECEIVER WILL BE INSENSITIVE AND THE DIAL CALIBRATION WILL BE INCORRECT. THE TRIMMER AND PADDING CONDENSERS WILL BE REFERRED TO BY THEIR FUNCTION.

IT IS ABSOLUTELY NECESSARY THAT AN ACCURATELY CALIBRATED TEST OSCILLATOR WITH SOME TYPE OF OUTPUT MEASURING DEVICE BE USED WHEN ALIGNING THE RECEIVER.

ALIGNING I. F. STAGE AT 465 KILOCYCLES:

(a) Connect the ground lead of the test oscillator to the chassis or set ground lead. Connect the other lead of the test oscillator to the grid cap of the 1C6 tube through a .02 Mfd. series condenser. DO NOT REMOVE GRID CLIP.

(b) Set test oscillator to EXACTLY 465 kilocycles and turn receiver volume control on full.

(c) Peak each of the second I.F. transformer trimmers.

(d) Peak each of the first I.F. transformer trimmers.
To assure most accurate trimmer setting repeat above adjustment several times always using lowest possible test oscillator output consistent with readable output meter scale deflection.

ALIGNING 1720-540 KILOCYCLE BAND:

(a) Remove test oscillator lead from grid of the 1C6 tube and attach it to the receiver antenna lead through a .00025 Mfd. series condenser.

(b) Check tuning dial adjustment by turning gang condenser until plates touch maximum capacity stop (completely in mesh), at which point the dial needle must be exactly even with the last line at the low frequency end of the dial calibration. If the dial needle does not point exactly to the last line move needle to correct position.

(c) Set receiver dial and test oscillator frequency to EXACTLY 1720 kilocycles.

(d) Bring in 1720 KC test oscillator signal to maximum output by adjusting the trimmer condenser mounted on top of the oscillator section of the gang condenser.
Looking at the front of the receiver the rear section of the gang condenser is the oscillator section.

(e) Tune receiver dial and set test oscillator frequency to EXACTLY 1400 kilocycles.

(f) Adjust trimmer on top of the front section gang condenser (antenna section) for maximum 1400 kilocycle test signal response.

(g) Tune receiver dial and set test oscillator frequency to approximately 600 kilocycles.

(h) While rocking the tuning condenser back and forth adjust 600 KC oscillator padder condenser which is accessible through the hole in the top of the chassis adjacent to the gang condenser for maximum 600 kilocycle signal response.

ALIGNING 2.3-6.3 MEGACYCLE BAND:

(a) Replace .00025 Mfd. condenser in series with test oscillator lead with a 400 ohm resistor.

(b) Place band selector switch for operation on 2.3-6.3 megacycle band, tune the receiver dial, and set test oscillator frequency to EXACTLY 6.3 MEGACYCLES.

(c) BRING IN 6.3 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT by adjusting 6.3 megacycle oscillator trimmer, which is mounted on top of coil located underneath chassis.

(d) Tune receiver dial and set test oscillator frequency to EXACTLY 6 MEGACYCLES.

(e) Adjust 6 megacycle antenna trimmer which is mounted on coil located on top of chassis for maximum 6 megacycle signal sensitivity.

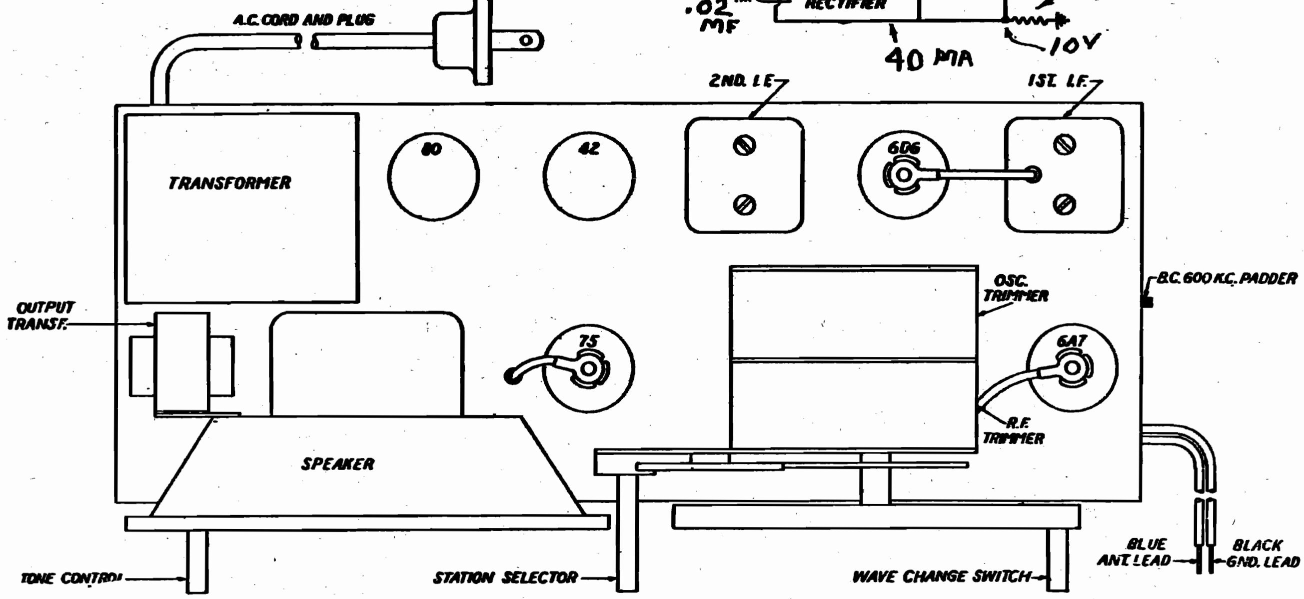
SCHEMATIC DIAGRAM
B1 CHASSIS
5 TUBE A.C. 2 BAND — BC-540 TO 1720 K.C. / S.W.-2000 TO 7000 K.C.
I.F. = 456 K.C.
SWITCH SHOWN IN B.C. POSITION
ALL VOLTAGES SHOWN TO GROUND



ALIGNMENT

INTERMEDIATE FREQUENCY - Connect the Signal Generator to grid of 6A7 tube through a .05 MFD condenser. Ground Generator to Ground of chassis. Set Generator at 456 KC and adjust trimmers on IF transformers for Max. Peak.
BROADCAST BAND - Connect the Generator to the antenna of receiver through a 1000MMFD condenser. Ground Generator to ground of chassis. Range switch in Broadcast position. Set Generator to 1400 KC and adjust Oscillator and RF trimmers to maximum peak. Dial of receiver set on 1400 KC. Pad the Broadcast band at 600 KC, rocking gang condenser during the adjustment.
SHORT WAVE BAND - Set Receiver and Generator to 6000 KC. Range switch in SW position. Adjust SW antenna trimmer for maximum peak. No padding adjustment is required on this band.

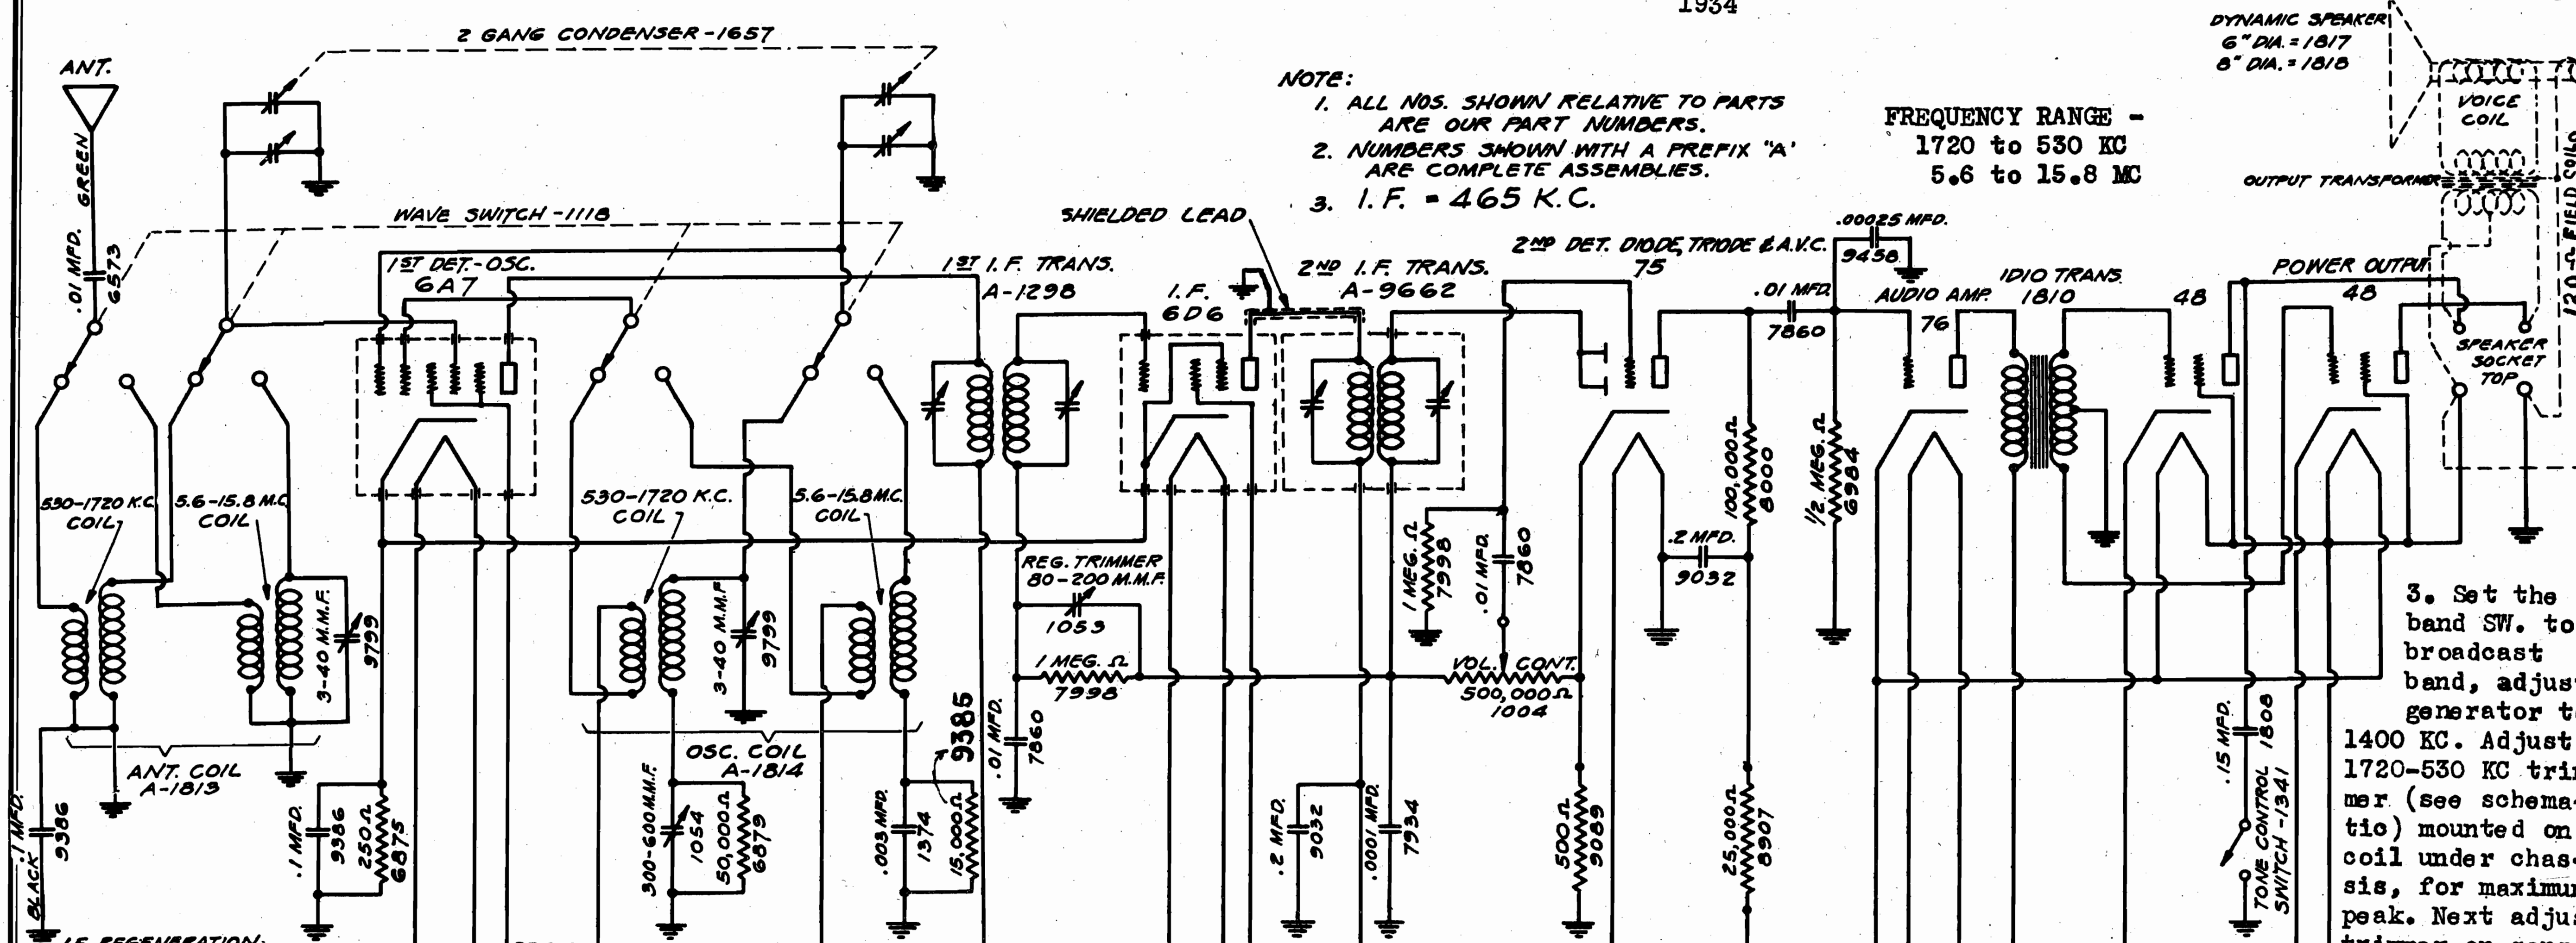
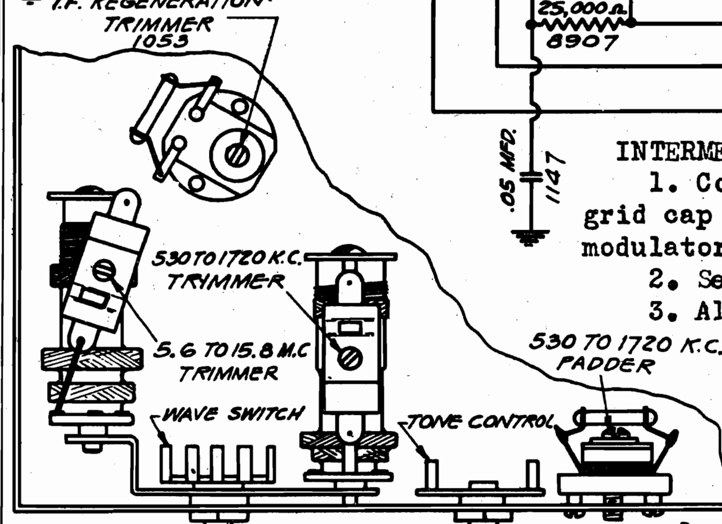
Chassis 6946 Schematic, Voltage

NOTE:
1. ALL NOS. SHOWN RELATIVE TO PARTS ARE OUR PART NUMBERS.
2. NUMBERS SHOWN WITH A PREFIX "A" ARE COMPLETE ASSEMBLIES.
3. I.F. = 465 K.C.

FREQUENCY RANGE - 1720 to 530 KC 5.6 to 15.8 MC





LOCATION OF PADDERS & TRIMMERS IN LEFT HAND (FRONT) BOTTOM OF CHASSIS

INTERMEDIATE ALIGNMENT -

1. Connect generator output to control grid of the 6A7. Leave grid cap disconnected, then connect a 1 megohm resistor from the modulator grid to chassis ground.
2. Set generator frequency to 465 KC 9 must be accurate).
3. Align 1st I-F transformer by adjusting each transformer.
4. Adjust 2nd I-F transformer in the same manner.
5. Adjust the I-F regeneration trimmer located under chassis for maximum 465 KC signal. If adjustment of this trimmer causes receiver to oscillate, always adjust to point where oscillation just stops, then back 1/8 turn.

ALIGNMENT OF VARIABLE CONDENSER

1. Connect generator thru 250 MMF condenser to set antenna lead and the ground to chassis.
2. Place band selector SW. on 15.8 to 5.6 MC band, tune the receiver to exactly 14 MC. Then bring receiver to maximum output by adjusting trimmer condenser located on top of gang condenser (OSC section). When adjusting this trimmer, two peaks, the fundamental and image peak will be noticed. Care must be taken that the fundamental is used for the adjustment. Back trimmer to minimum capacity, next screw down until 1st peak (fundamental) is obtained. When fundamental peak is obtained adjust trimmer to maximum output at 14 MC.
3. Set the band SW. to broadcast band, adjust generator to 1400 KC. Adjust 1720-530 KC trimmer (see schematic) mounted on coil under chassis, for maximum peak. Next adjust trimmer on gang condenser (front section) to peak.
4. Next tune the receiver to the generator at 600 KC, adjust padder trimmer located on, and accessible thru small hole at front of chassis.
5. Recheck 1400 KC signal setting.
6. Place band SW. on 15.8 to 5.6 MC band, generator frequency to 14 MC. While rocking the variable gang condenser adjust the 5.6 to 15.8 trimmer, mounted oneone of the coils underneath the chassis.

CONVENTIONAL ALIGNMENT
(see special section)

Chassis 14-136EA, 14-152ES

I. F. Alignment

The I.F. frequency of this receiver is 456 K.C. For realignment, use the following procedure.

It is necessary to use an accurately calibrated signal generator. Couple the signal generator to the grid of the 6A7 tube with a tenth microfarad condenser in series with the "high" lead of the signal generator. Connect the ground side of the signal generator to the chassis. Set the signal generator to 456 K.C. Be sure the wave switch of the set is in the broadcast position and the volume control set at maximum. Attenuate the signal generator so that the signal is just audible in the speaker. If an output meter is used, it should be connected across the voice coil terminals of the speaker. Use ½ volt as standard output.

Adjust the 2nd I.F. transformer first. Each screw should be adjusted for maximum output. After number two I.F. has been adjusted, number one I.F. should be adjusted for maximum output. After both transformers have been adjusted, it is necessary to recheck No. 2 transformer and then recheck No. 1.

See TUBE LAYOUT for location of I.F. and R.F. trimmers and padder.

R. F. Alignment

To align the broadcast band, proceed as follows: First, connect the ground side of the signal generator to the chassis. Connect the high side of the signal generator with a .00025 condenser, in series, to the antenna lead of the set. Make sure the band switch of the set is in the broadcast position. Set the volume control to maximum. Turn the station selector to the highest frequency (as far as it will go). Set the signal generator to 1720 K.C. Adjust the oscillator trimmer until the signal is heard. After the oscillator has been set at 1720 K.C., turn the station selector to 1400 K.C. Set the signal generator to 1400 K.C. When the signal is heard, adjust the first detector trimmer for maximum output.

When the set has been adjusted at 1400 K.C., turn the station selector dial to 600 K.C. Set the signal generator to 600 K.C. When the signal is heard, adjust the padder condenser by rocking the selector back and forth. While adjusting the padder screw, it is necessary to move the selector so that the signal may be kept in tune while adjusting the padder screw. This procedure should be followed until maximum output is obtained.

The foregoing procedure should be repeated. That is, the set is to be rechecked at 1720, 1400 and 600 K.C.

When aligning the R.F., use the same output standard as was used on the I.F. alignment.

Short Wave Alignment

Turn the band selector switch of the set to short wave. Set the signal generator to 6000 K.C. Connect a 400 ohm resistor in series with the .00025 condenser. Tune the set until the signal is heard. If two signals are heard, always align to the highest frequency heard on the receiver. Adjust the small trimmer on the antenna coil for maximum output.

This receiver is designed to work on 105 to 125 volts, 60 CYCLE A.C. ONLY DO NOT USE ANY OTHER SUPPLY.

VAR. COND. ALIGN.

1-Connect Test Osc. to ANT & CHASS.

2. Place the band selector switch for operation on the 16 to 5.2 megacycle band, tune the receiver to EXACTLY 14 megacycles on the receiver dial, and set the test oscillator frequency to EXACTLY 14 megacycles. THEN TUNE IN THE 14 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE TRIMMER CONDENSER LOCATED ON TOP OF THE OSCILLATOR SECTION OF THE GANG CONDENSER. Looking at the front of the receiver the first section of the gang condenser tunes the antenna coil and the second section the oscillator coil. When adjusting this trimmer two peaks (the fundamental and the image peak) will be noticed. CARE MUST BE TAKEN SO THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 14 MEGACYCLES. First back off the trimmer to minimum capacity, next screw down the trimmer (add capacity) until the first peak which is the fundamental and the one you are to use is tuned in. If the trimmer is screwed down beyond the point where this first peak is received the incorrect image peak will be tuned in. When the first peak has been located adjust the trimmer to BRING IN THE 14 MEGACYCLE SIGNAL TO MAXIMUM OUTPUT. After completing this adjustment always check to see if the proper peak has been used. To do this leave the test oscillator frequency at 14 megacycles and increase the output of the test oscillator and then tune the receiver dial to approximately 13 megacycles. Vary the receiver dial slightly to the right and left of 13 megacycles and if the fundamental peak was used in aligning at 14 megacycles the test oscillator signal will be heard at approximately 13 megacycles on the set dial. If it is not possible to receive the signal then the fundamental peak was not used and the 14 megacycle adjustment of the trimmer must be gone over and properly adjusted.

3. Place the band selector switch for operation on the 1715 to 535 kilocycle band, set the oscillator to EXACTLY 1400 kilocycles and tune the receiver dial to EXACTLY 1400 kilocycles. BRING IN THIS 1400 KILOCYCLE SIGNAL TO MAXIMUM OUTPUT BY ADJUSTING THE SMALL TRIMMER CONDENSER which is located underneath near the center and towards the front of the chassis.

4. Next adjust the trimmer condenser on top of the antenna section of the gang condenser (front section) for maximum 1400 kilocycle signal output.

5. Leave the band selector switch for operation on the 1715 to 535 kilocycle band, set the test oscillator frequency to approximately 600 kilocycles, and adjust the receiver dial to approximately 600 kilocycles. Then while rocking the variable condenser slightly to the right and left adjust the 600 kilocycle padding condenser, which is located below the speaker and accessible through the hole in the front of the chassis for maximum output.

6. Recheck the 1400 kilocycle adjustment.

7. Place the band selector switch for operation on the 16 to 5.2 megacycle band, tune the receiver dial and set the oscillator frequency to EXACTLY 14 megacycles. Then adjust the trimmer condenser, which is located underneath and near the center of the right hand side of the chassis for maximum 14 megacycle signal output.

I.F. PEAK 465 KC.

I.F. ALIGNMENT

Connect Test Oscillator to 2A7 Cont. Grid and ground to chass. Leave grid clip lead off and connect a 1-Meg Resistor from 2A7 Cont. Grid to chassis. Adjust 1st I.F. Transf. and then the 2nd I.F. Turn NUT adj. to MAX. before turning the SCREW adj. to MAX.

Fig. 1—Schematic Circuit Diagram

Condenser Alignment

Correct alignment is extremely important in connection with all wave receivers. The receivers are all properly aligned at the factory with precision instruments and re-alignment should not be attempted unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide an accurately calibrated signal of 456 K. C. and accurately calibrated signals over the broadcast and short wave bands, 530-1740 K. C. and 5.8-18.3 M. C., is required. An output indicating meter is also necessary. It will be practically impossible to align the receiver if unsatisfactory apparatus is used.

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Attenuate the signal so that A. V. C. action is not obtained.

Then adjust the four I. F. trimmer condensers until maximum output is obtained. The adjusting screws for these condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings to the trimmer condensers are covered over by a small cover plate which is held in position by a screw. Loosen these screws until the cover plates can be swung around.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1740 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Attenuate the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the pointer screw and set the pointer at the 1500 K. C. mark on broadcast band scale. Retighten pointer screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

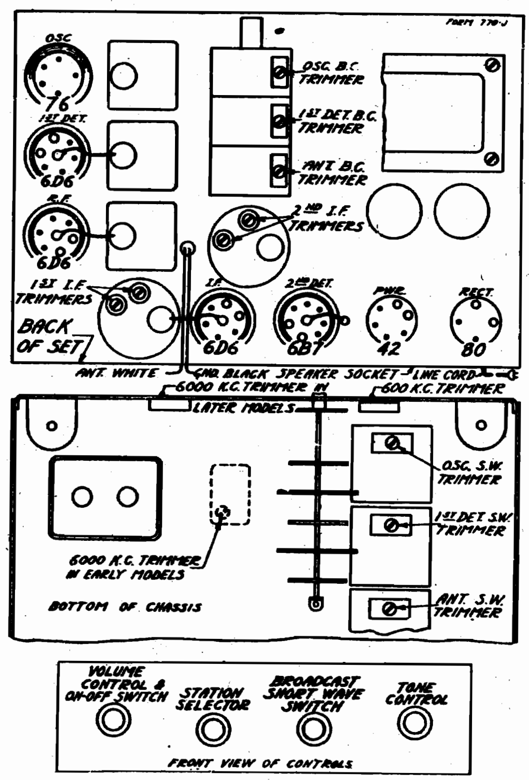

Fig. 2—Tube Arrangement and Location of Trimmers

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 2. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over

MODELS 9904, 9910, 9926, 9928
Chassis 27D
Voltage, Circuit Changes
Parts List, Drive Cord Data

SPIEGEL, INC.

this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

Turn the broadcast short wave switch to the short wave position. Turn the rotor to the full open position. As explained above, the volume control should be at the maximum position and the signal should be attenuated to prevent A. V. C. action. Set the signal generator for 18,300 K. C. Then adjust the oscillator short wave trimmer for maximum output. This trimmer is reached from under the chassis and its position is shown in Fig. 2.

Next set the signal generator for 15,000 K. C. Turn the rotor until the dial pointer is at the 15,000 K. C. mark on the short wave portion of the dial scale. Then adjust the antenna and 1st detector short wave trimmers until maximum output is obtained.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K.C. higher in frequency than the signal.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. In the first models of this receiver, this condenser was located at the point shown in Fig. 2 in dashed lines. In the later models it is reached through a hole in the front panel of the chassis as shown in the same illustration. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained. In the early models this adjustment is broad while in the later models it is more critical.

Caution

The can of electrolytic condenser C16 is not at ground potential. Therefore in any work on the chassis, care should be taken not to touch this can and any other grounded point such as the other electrolytic condenser can.

Replacing Drive Cord

Remove chassis from cabinet.

Take off the pilot light assembly by lifting off the two sockets and spring clips.

Detach the large pointer by removing the screw at the center of the dial.

Loosen the dial assembly by taking out the two screws which secure the bottom of this assembly to the chassis.

Then lay the complete dial assembly face downward in front of the chassis. It is not necessary to remove the volume control and tone control collars which hold the indicator cords of these two controls in position.

Turn the drive drum until the opening in this drum is approximately vertical and with the hole at the top as shown in Fig. 3.

Remove the tension spring and the old drive cord.

See that the eyelet is in the hole in the drive drum as shown in Fig. 3. Insert one end of the drive cord from the outside through the hole in the eyelet in the drive drum.

Voltages at Sockets
LINE VOLTAGE — 115
ANTENNA SHORTED TO GROUND

(1) Cathode to ground
(2) Subject to variation
(3) Read with 1,000,000 ohm meter
(4) As read across R15

Tie the end of the cord which has been inserted in the hole to one end of the tension spring.

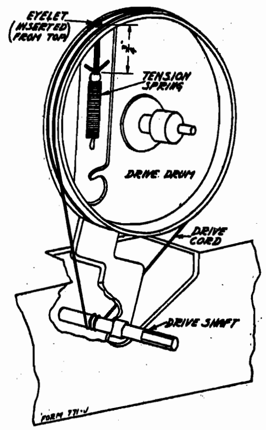

Fig. 3—Drive Cord Replacement

Wrap the cord in a clockwise direction (facing front of chassis) around the drive drum approximately one-half turn.

Then tilt the chassis up on its back panel and bring the cord mentioned in the previous paragraph down to the drive shaft. Wrap it two and one-half times around the drive shaft as shown in Fig. 3.

Then bring this cord up from the drive shaft and wrap it around the drive drum approximately one and one fifth turns in a clockwise direction until it is up to the hole in this drum as illustrated.

Insert the free end of the cord through the hole in the eyelet and tie it to the end of the tension spring. The end of the spring, when hanging free, should be approximately ¾" from the flange of the drum as shown in Fig. 3. Cut off the surplus length of cord after it is knotted.

Then secure the other end of the tension spring over the spur on the drive drum.

Replace the dial assembly and pointer.

Replace the pilot light assembly after which the chassis may be reinstalled in the cabinet.

Changes in Early Models

There are two points at which the early models of this receiver differ from the present models. These points are indicated in Fig. 1 and described below.

Power Unit

In the early models a separate filter choke was used in series at the point indicated in note A in Fig. 1. The values of the two filter condensers C16 and C17 were less than as used at present. The values of the old and new condensers are shown in the parts list. A different power transformer was also used with the early filter system and this is likewise shown in the parts list.

The two power transformers are not interchangeable and care must be taken in ordering for replacement purposes to order the correct one. The original chassis can be identified by the separate filter choke.

Short Wave Oscillator

Referring to Fig. 1 it will be noted that there is a tracking coil L2 and a trimmer condenser C21 connected in series between the short wave oscillator coil and ground. In the first models of this receiver these two units, which are required for tracking the short wave oscillator, are not used. Instead a series padding condenser was used at the point in the circuit indicated by note B in Fig. 1.

At the time this change was made a change was also made in the oscillator assembly and care must be taken in ordering for replacement purposes to order the correct one. Early models with the original oscillator assembly have no spot of paint or a green spot of paint on the 80 socket rivet. Later models with the new oscillator assembly and new tracking system have a red spot of paint on the 80 socket rivet.

Twenty-five Cycle Receivers

The twenty-five cycle receiver differs from the sixty-cycle receiver only in the fact that a different power transformer is used. The correct power transformer is shown in the parts list.

The twenty-five cycle chassis can be operated satisfactorily from a sixty-cycle power supply. However, the reverse is not true, the sixty-cycle receiver cannot be operated from a twenty-five cycle power supply.

A 110-220 Volt, 40-60 cycle Power Transformer is also available for this model.

REPAIR PARTS LIST FOR 7 TUBE BROADCAST AND SHORT WAVE RECEIVER

When ordering parts be sure and give the part number. Also give the series number which will be found in the License Notice label. If there is a spot of paint on the chassis, give this color.

Voltage,Resistance
Alignment

SPIEGEL, INC.

Condenser Alignment

Use a non-metallic screw driver for the adjustments. The complete procedure is as follows:

Intermediate Frequency Adjustment

Set the signal generator for 456 K. C. Connect the antenna lead of the signal generator to the grid of the 1st detector through a .05 mfd. condenser. Turn the tuning condenser rotor until the plates are completely out. The ground lead from the signal generator goes to the ground lead of the receiver. The volume control should be at the maximum position. Reduce the signal so that A. V. C. action is not obtained.

Then adjust the five I. F. trimmer condensers until maximum output is obtained. The adjusting screws for the 1st and 2nd trimmer condensers are reached from the top of the chassis and are in the round I. F. cans—See Fig. 2. The openings of these trimmer condensers are covered over by small cover plates which are held in position by screws. Loosen these screws until the cover plates can be swung around. **CAUTION—Use an insulated screwdriver for adjusting trimmers to prevent short circuiting to ground.** In the 3rd I. F. coil, only the primary has a variable trimmer condenser. This condenser is mounted on the back panel of the chassis as shown in Fig. 3 and the adjustment screw is reached through a hole in the back panel.

Broadcast Band Adjustment

The broadcast short wave switch should be in the broadcast position. Set the signal generator for 1730 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator is in this instance connected to the antenna lead of the receiver. Reduce the signal so that A. V. C. action is not obtained. Adjust the oscillator broadcast trimmer until maximum output is obtained. This trimmer is on the tuning condenser and its location is shown in Fig. 2.

Then set the signal generator for 1500 K. C. Turn the rotor until maximum output is obtained. Loosen the set screw in the pointer hub and set the pointer at the 1500 K. C. mark on the broadcast band scale. Retighten the hub set screw. Then adjust the antenna and 1st detector broadcast trimmers until maximum output is obtained.

Next set the signal generator for 600 K. C. and adjust the 600 K. C. trimmer. The adjusting screw is reached through a hole in the front panel of the chassis as shown in Fig. 3. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting at the same time adjusting the 600 K. C. trimmer screw until the highest output is obtained.

Short Wave Band Adjustment

CAUTION—After the broadcast band alignment as described above has been made, do not change the adjustment of any of the broadcast band trimmers.

In aligning the short wave band of the receiver, it will be noted that the signal will be heard with the signal generator set at two points 912 K. C. apart. That is, if the receiver is tuned to 15,000 K. C. a signal will be heard when the signal generator is set at 15,000 K. C. and again at approximately 15,912 K. C. This is due to image reception or the fact that a 456 K. C. beat is obtained when the signal is 456 K. C. lower than the receiver oscillator and also when the signal is 456 K. C. higher than the receiver oscillator. Care should be taken to see that the receiver is tracked with the signal generator adjusted to the lower of the two frequencies at which a signal is heard, in order that the oscillator in the receiver will be 456 K. C. higher in frequency than the signal.

Turn the broadcast short wave switch to the short wave position. As explained above, the volume control should be at the maximum position and the signal should be reduced to prevent A. V. C. actior.

Next set the signal generator for 15,000 K. C. Turn the rotor until maximum output is obtained. Then adjust the antenna and 1st detector short wave trimmers for maximum output.

Next set the signal generator for 6000 K. C. and adjust the 6000 K. C. trimmer. This condenser is mounted on the front panel of the chassis as shown in Fig. 3 and is reached through a hole in the front panel. Turn the tuning condenser rotor until maximum output is obtained. Then turn the rotor slowly back and forth over this setting, at the same time adjusting the 6000 K. C. trimmer screw until the highest output is obtained.

In the first models of this receiver a bypass condenser block (P-82600) containing condensers: C2, C4, C10, C14, C15 and C16 was used. Condenser C16 was removed in the later models and added as a separate tubular condenser (P-81132) while the other condensers remained in the block (P-82600-D).

A second condenser change from the earlier models was in the electrolytic filter block (P-82002). In this block section C24 was changed from an 8 mfd., 250 volt to a 2 mfd., 250 volt condenser.

On the Voltage Chart are given the voltages at the sockets with all tubes in and the set in operating condition. The antenna should be disconnected at the bayonet connector.

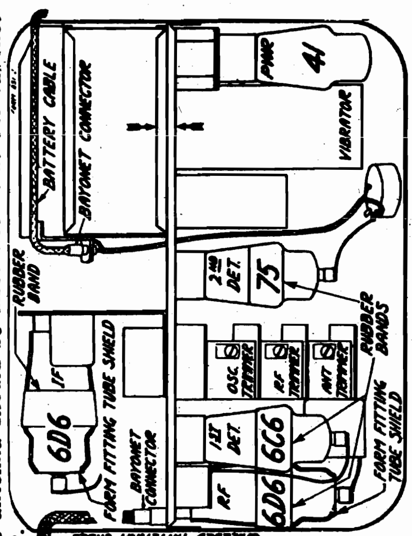

Fig. 2—*Location of Tubes and Vibrator*

MODEL 9930
Chassis 25Y
Alignment, Resistance
Drive Cord Data

SPIEGEL, INC.

Condenser Alignment

Misalignment or mistracking of condensers generally manifests itself as broad tuning and lack of volume at portions or all of the standard wave band. The receivers are all properly aligned at the factory with precision instruments and realignment should not be attemped unless all other possible causes of the faulty operation have first been investigated and unless the service technician has the proper equipment. A signal generator that will provide accurately calibrated signals over the standard wave band and an output meter are required for indicating the effect of adjustments.

First remove the cover of the box. Leave the antenna and battery cables connected to the chassis.

Disconnect the car antenna and connect antenna cable lead to the lead from the signal generator.

Set the signal generator for 1650 K. C. Turn the rotor to the full open position. The antenna lead from the signal generator adjustment is connected to the antenna lead of the receiver. Adjust the trimmer of the oscillator section of the 3 gang condenser until maximum output is obtained. The oscillator section is the one with the cut plate rotor.

Now set the signal generator for 1400 K. C. and turn the rotor until maximum output is obtained. Adjust the other two trimmers on the gang condenser for maximum output.

To calibrate the receiver, tune in a station of known frequency at about the center of the dial. Remove the escutcheon plate and glass. The pointer is held in position by friction. Grasp the pointer at the center and turn it until it points to the frequency of the station being received.

The use of the cut plate type of condenser eliminates the necessity of a 600 K. C. padder and, therefore, no adjustment at this frequency is required.

Adjusting Antenna Trimmer

After the receiver is installed and the car antenna is connected it will be necessary to adjust the antenna trimmer. Tune in a weak signal between 1200 and 1400 K. C. with the volume control about three-fourths on. Drop the chassis from the cover. The location of the antenna trimmer is shown in Fig. 2. Turn the adjusting screw of this condenser up or down until maximum output is obtained. CAUTION—Do not turn any of the other trimmer adjusting screws for this adjustment.

Removing Chassis From Case

First unsolder the black, brown, yellow, and green speaker leads which connect to the terminal strip adjacent to the vibrator unit. Next, notice the small length of braided shielding which is soldered to the solder lug that is secured to the chassis case between the dial scale and the station selector control shaft. Unsolder this shielding at the lug.

Remove the 4 screws which hold the chassis in the case — 2 are in the side and 2 on the speaker panel of the chassis case. (Do not remove the four speaker mounting screws.)

Remove the two control knobs by pulling them off of the shaft.

Next remove the volume control. To do this first loosen the hexagonal nut on the inside of the case with a flat wrench. Then unscrew and remove the round knurled nut from the front.

The chassis may then be taken out.

Replacing Vibrator Unit

The vibrator unit is plugged in in the same manner as a tube. This unit may, in case of failure, be readily replaced. CAUTION—Polarity, as explained in the label on the unit and in the label on the metal box in the chassis, must be observed when plugging in vibrator unit.

In replacing the vibrator unit be sure to replace the corrugated cardboard pad, which prevents the unit from working its way out of the socket.

When servicing this receiver, a new vibrator unit should be tried out in the same manner as a new set of tubes would be tried out.

One or more vibrator units should be kept on hand for replacement purposes.

Replacing Volume Control

To remove the volume control and the switch, first pull the knob from the volume control shaft. Next loosen the hexagonal nut on the inside of the case with a flat end wrench. Then unscrew and remove the round knurled nut from the front.

The old volume control and switch connections may now be unsoldered and the new unit put in its place and the leads resoldered.

Fasten the volume control to the case in the reverse order in which it was removed.

D. C. Resistance of Windings

Following are the D. C. resistances of the various windings in the chassis. The values given below will vary slightly in different sets.

Replacing Drive Cord

The drive cord in this receiver may be replaced as follows:

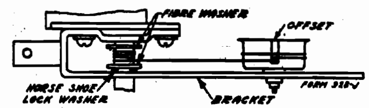

Fig. 3—Cord Drive—Top View

First remove the chassis from the case as explained on page 4.

Some of the first models did not have two fibre "end" washers on the drive shaft to protect the drive cord as shown in Fig. 3. If this is the case, these washers should be put on as follows:

Separate and take off the horse-shoe lock washer which holds the drive shaft in position. This may be done with a fine jawed long nose plier.

Now pull the drive shaft out just far enough to permit the two fibre washers to be slipped over the end of the shaft.

Then slip the shaft back into place and replace the horse-shoe lock washer.

Knot one end of the new drive cord and with the condenser plates in a completely closed position, slip the drive cord through the small hole "A" in the drive drum — see Fig. 4. The knot will then be on the inside of the drum.

Now wrap the cord around the lower half of the drive drum as indicated and bring it up to the drive shaft. Proceed by wrapping it in a clockwise direction (from front) around the drive shaft three and one-quarter turns between the two fibre washers, progressing towards the front of the chassis. Be sure that the condenser plates are kept in a closed position and that the cord is held tight.

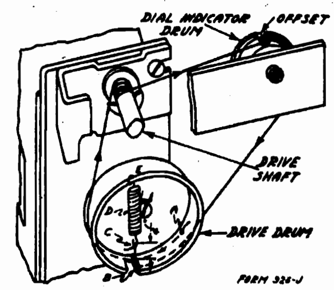

Fig. 4—Cord Drive Replacement

Set the dial indicator drum so that the offset is at the top or a little to the right of the center — see Fig. 4.

Wrap the cord from the drive shaft once around the offset in the dial indicator drum and then approximately one and one-half turns around the drum itself in a clockwise direction, progressing toward the back.

From the dial indicator drum draw the cord over the lower right hand quarter of drive drum as shown in Fig. 4.

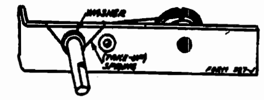

Fig. 5—Drive "Take-up" Spring

Then bring the cord inside of the drum by way of the turned-in portion of the flange at "B".

Tie the drive tension spring "D" to the loose end of the cord at the point "C" just above the top edge of the lip "B" as shown in the illustration. This should be done so that the lower hook of spring "D" at point "C" will be between ⅛" and ⅜" from top edge of the turned-in portion of the flange "B" in the flange of the drive drum. After the spring is hooked and the drive turned over several times the tension in the cord will cause this distance to become about ¼".

Now, by applying a tension on the drive spring "D", hook the other end of the spring into the small hole "E" near the top of the drive drum. Hook spring from the inside out.

After the cord has been put on it may be necessary to calibrate the receiver as explained in the article on condenser alignment.

All of the earlier models did not have drive shaft "take-up" springs. This spring will prevent any tendency toward change of setting should the receiver be subjected to vibration. To insert these springs and fibre washers on the drive shaft proceed as follows:

Remove the station selector knob by pulling it off of the shaft.

Slip the small fibre washer over the shaft and clip the "take-up" spring to the drive bracket as shown in Fig. 5.

The chassis may now be replaced into the case in the reverse order of the manner in which it was removed.

Alignment, Parts, Notes

STEWART WARNER CORP.

ALIGNING EQUIPMENT: For proper alignment, an output meter and an accurately calibrated oscillator with a tuning range from 175 KC. to 6 MC. are required.

Connect the output meter across the plates of the output tubes. Convenient points to make the plate connections are the yellow wires on the speaker terminal strip.

ALIGNING THE I.F. AMPLIFIER: Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure. Turn the range switch to the broadcast position (center position).

Connect the test oscillator output leads to the 1C7G control grid and chassis with a 1 mfd. condenser in series with the oscillator output. Set the oscillator to exactly 456 KC. Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.

BROADCAST BAND CALIBRATION AND ALIGNMENT: With the gang condenser in full mesh, the dial pointer should be on the yellow horizontal line below 530 KC. on the dial scale.

Leave the range switch in the center position. Connect a 400 or 500 ohm carbon resistor in series with the oscillator output and the receiver antenna lead (blue wire in the back of the chassis). Connect the grounded oscillator output wire to the receiver ground lead (black wire in back of chassis).

Adjust the test oscillator to exactly 1500 KC. Tune in the 1500 KC. oscillator signal or a station above 1300 KC. on the dial and determine whether the dial calibration is correct at the high frequency end of the dial. If the calibration is correct, do not adjust the broadcast oscillator shunt trimmer No. 5. If the calibration is incorrect, adjust trimmer No. 5 to give proper calibration.

Carefully tune the receiver to the 1500 KC. oscillator signal and adjust trimmer No. 6 for maximum output.

Adjust the test oscillator to 600 KC. and tune the receiver to the signal. Adjust trimmer No. 7 for maximum output. Then try to increase the output meter reading by detuning No. 7 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity even though the dial may be slightly off calibration at 600 KC.

Repeat the adjustment of Nos. 5 and 6 at 1500 KC.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT: Turn the range switch to the short wave band (maximum counter-clockwise position).

Adjust the test oscillator to exactly 6.0 MC.

Tune in the 6 MC. oscillator signal at or near 6 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 6 MC. If it is, do not adjust the short wave band oscillator shunt trimmer No. 8. If the calibration is incorrect, set the dial pointer to 6 MC. on the dial, and adjust the oscillator shunt trimmer No. 8 until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmer screw farthest out.

Carefully tune the receiver to the signal and adjust trimmer No. 9 for maximum output. Then try to increase the output by detuning No. 9 slightly and retuning the receiver. Continue detuning No. 9 and retuning the receiver until the output meter deflection is a maximum.

LONG WAVE BAND CALIBRATION AND ALIGNMENT: Turn the range switch to the long wave band position (maximum clockwise position) and adjust the test oscillator to exactly 350 KC.

Tune in the oscillator signal at or near 350 KC. on the receiver dial to determine whether the dial calibration is correct at this point. If it is, do not adjust trimmer No. 10. If the calibration is incorrect, set the receiver dial pointer to 350 KC. and adjust trimmer No. 10 for maximum output.

Carefully tune the receiver to the signal, then adjust trimmer No. 11 for maximum output.

Adjust the test oscillator to 175 KC. and tune in the signal at or near 175 KC. on the receiver dial. Adjust padder No. 12 for maximum output, then try to increase the output by detuning padder No. 12 and retuning the receiver dial.

Repeat the adjustment of trimmers Nos. 10 and 11 at 350 KC.

PROPER SIZE OF FUSE

The early production of this model was equipped with 3-ampere fuses. If one of these blow out, and if there is nothing wrong in the set to cause it to blow, replace with a 4-ampere fuse.

	89461	Knob—tone, tuning and volume controls	.25

The very low battery drain of 1.7 to 2.0 amperes is obtained by the use of two volt tubes and an efficient vibrator power supply. The filaments of the tubes and the dial bulbs are connected in parallel and the field coil of the dynamic speaker is used to reduce the voltage from six to two volts. Thus the set uses little current and also has the excellent tone quality made possible by the use of a dynamic speaker. 60 milliampere dial light bulbs are used. In replacing these, be sure to use the correct type. If ordinary 2.5 volt dial light bulbs or flashlight bulbs are used, the tube filaments will not receive the proper voltage.

Since a gas engine charger usually charges at a high rate, it is absolutely essential to stop the engine before turning on the radio set. However, when a Windcharger is used, ordinarily the voltage will not be excessive unless the set has been used very little or the wind has been blowing hard for some time. Thus, with a Windcharger it is usually satisfactory to operate the set while charging the battery although there is some danger of injuring the tubes if the battery is fully charged.

CIRCUIT DESCRIPTION

The R-167-S and R-168 chassis are identical with the exception of the size and location of the speaker and the physical location of a few other parts. The R-167-S, which is used in the table model cabinet, has a 5 inch speaker mounted on the chassis and the variable condenser, dial and the control shafts are located on the right side of the chassis. The R-168 is used in the console with a separate 8 inch speaker while the variable condenser, dial, and shafts are in the center of the chassis.

These receivers use a superheterodyne circuit which employs five glass tubes with octal bases. The intermediate frequency is 456 KC. The tuning range of this chassis includes, in addition to the standard broadcast band, the two police radio bands. The 2500 KC. police band can be tuned in around 1600 KC. on the broadcast dial with the range switch in the short-wave position (counter clockwise).

The volume control is double acting. It simultaneously changes the antenna signal input and the I. F. stage bias. Because of the sensitivity of this receiver, and due to the fact that it does not have A. V. C., it requires an antenna that is shorter than usual. The short antenna is particularly necessary where interference from powerful local stations is encountered, and where difficulty is experienced in properly controlling the volume.

When tuning on the short wave band, local broadcast stations can be heard in the background at their regular positions on the dial. This is a normal condition, and is due to the tapped coil method of tuning the antenna coil secondary to the short wave band. No aligning adjustments are required on the short wave band.

A wave trap is connected across the primary of the antenna coil to reduce code interference from stations with a frequency near 456 KC.

ALIGNING EQUIPMENT

For proper alignment of this receiver, an output meter and a high grade modulated service oscillator are essential. The oscillator should be capable of generating the frequencies of 456 KC., 600 KC. and 1400 KC. The test oscillator calibration should be checked; using broadcast station signals as standards. For trimmer adjustment, it is advisable to use an all bakelite screwdriver, although one with a small metal tip may be used.

ALIGNING THE I.F. CIRCUIT

1. (a) Connect the output meter in series with a .25 mfd. condenser between the plate of the 6K6G tube and ground, or across the voice coil, depending on the type of meter.

(b) Turn the volume control to the maximum volume position. (Note: The volume control should be kept in this position throughout the entire alignment procedure.) Ground the antenna lead to the chassis.

(c) Turn the range switch to the right (clockwise) to the broadcast position.

(d) Adjust the test oscillator to exactly 456 KC. and connect its output in series with a .1 mfd. condenser to the control grid of the 6K7G first detector tube and the chassis.

(e) Align I. F. trimmers No. 1, 2, 3 and 4 for maximum output as indicated on the output meter. No inward or sideward pressure should be applied to the alignment tool, or the condenser may spring back to a different setting as soon as the tool is removed.

(f) Repeat all I. F. trimmer adjustments since the changing of each trimmer may affect the others.

456 KC. WAVE TRAP ADJUSTMENT

2. (a) Disconnect the antenna lead from ground.

(b) Connect the test oscillator output in series with a .00025 mfd. condenser to the antenna lead, and connect the test oscillator ground lead to the receiver chassis. Ground the chassis.

(c) Without changing the test oscillator from the frequency setting used in aligning the I. F. stage, adjust trimmer No. 5 for **MINIMUM** output. Increase the test oscillator output as a minimum is reached, in order to obtain a clearly defined setting of the trimmer. NOTE: If code interference transmitted on a frequency slightly different than 456 KC. is troublesome, the wave trap should be adjusted for **MINIMUM** output with the test oscillator set to the same frequency as the signal that is causing interference.

DIAL CALIBRATION

3. (a) The dial pointer should indicate 530 KC. with the gang condenser in full mesh.

(b) Adjust the test oscillator to exactly 1400 KC.

(c) Tune in a broadcast station with a known frequency of about 1300 to 1400 KC. to determine whether the dial calibration is correct at the high frequency end of the dial. If no such station can be heard, tune in the 1400 KC. oscillator signal to check calibration.

(d) If the calibration is correct, do not adjust trimmer No. 6 (oscillator shunt trimmer). If the calibration is not correct, adjust trimmer No. 6 to give proper calibration at the high frequency end of the dial.

ALIGNMENT

4. (a) With the test oscillator set at 1400 KC. tune the receiver to the signal for maximum output.

(b) Adjust trimmer No. 7 for maximum output. Do not touch trimmer No. 6 as this will change the calibration.

(c) Adjust the test oscillator to exactly 600 KC. and tune the receiver to the signal. Adjust trimmer No. 8 for maximum output. Then try to increase the output by detuning the trimmer and retuning the receiver dial. If this reduces the output, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the dial until a maximum output meter deflection is secured. This operation is commonly known as "rocking." The object of this adjustment is to find the combination of trimmer adjustment and tuning condenser position which gives the maximum output. This adjustment should not be changed regardless of whether the dial reads exactly 600 KC. or slightly off 600 KC. for maximum output.

(d) Check the adjustment of trimmers No. 6 and 7 at 1400 KC.

No trimmers are provided for alignment on the short wave band.

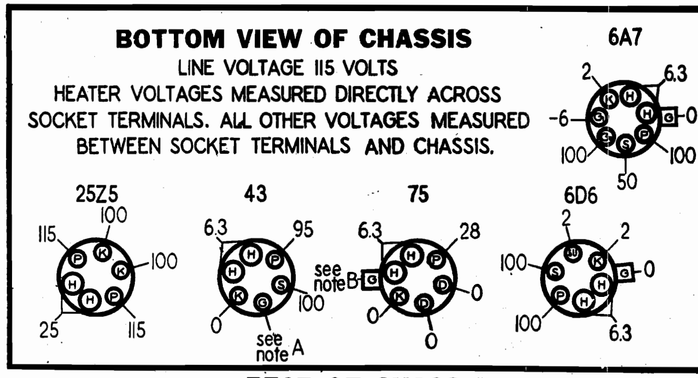
SOCKET VOLTAGES

VOLUME CONTROL ON FULL
RANGE SWITCH SET ON BROADCAST POSITION

ANTENNA GROUNDED
DIAL TUNED TO 535 KC.

BOTTOM VIEW OF CHASSIS

LINE VOLTAGE 115 VOLTS
HEATER VOLTAGES MEASURED DIRECTLY ACROSS SOCKET TERMINALS. ALL OTHER VOLTAGES MEASURED BETWEEN SOCKET TERMINALS AND CHASSIS.



REAR OF CHASSIS

IMPORTANT: Use a high resistance voltmeter of 1,000 ohms per volt.
NOTE A: The control grid voltage of the 43 output tube is —16 volts measured across choke 13.
NOTE B: The control grid bias of the triode section of the 75 tube is —1 volt as supplied by the bias cell (number 11), however, this voltage can be measured only with a vacuum tube voltmeter.

STEWART-WARNER CORP.

ALIGNING THE I.F. AMPLIFIER

(a) Turn the volume control to maximum volume position and keep it in this position throughout the entire alignment procedure.

(b) Turn the range switch to the broadcast position (fully clockwise).

(c) Connect the test oscillator output leads to the 6A7 control grid and chassis with a .1 mfd. condenser in series with the oscillator output.

(d) Set the oscillator to exactly 465 KC.

(e) Set the receiver dial at any point where it has no tuning effect on the oscillator signal.

(f) Adjust the four I.F. trimmers, Nos. 1, 2, 3 and 4, for maximum output meter deflection, then repeat the trimmer adjustment.

BROADCAST BAND CALIBRATION AND ALIGNMENT

(a) With the gang condenser in full mesh, the dial pointer should be on the horizontal line below 540 KC. on the dial scale.

(b) Turn the range switch to the clockwise position and connect the test oscillator output to the antenna lead of the receiver with a 400 ohm carbon resistor in series with the antenna lead and the oscillator output.

(c) Adjust the test oscillator to exactly 1720 KC. and turn the receiver dial pointer to 1720 KC. on the tuning dial.

(d) To calibrate the dial, adjust trimmer No. 5 for maximum output.

(e) Adjust the test oscillator to 1400 KC. and carefully tune the receiver to the signal.

(f) Adjust trimmer No. 6 for maximum output.

(g) Adjust the test oscillator to 600 KC. and tune the receiver to the signal.

(h) Adjust trimmer No. 7 for maximum output. Then try to increase the output meter reading by detuning No. 7 slightly and retuning the receiver dial. If the output goes down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured. This operation is commonly known as "rocking" and when performed as described will give maximum selectivity and sensitivity, even though the dial may be slightly off calibration at 600 KC.

(i) Check the adjustment of trimmer 5 at 1720 KC. and trimmer 6 at 1400 KC.

SHORT WAVE BAND CALIBRATION AND ALIGNMENT

(a) Turn the range switch to the short wave position (counter-clockwise).

(b) Adjust the test oscillator to exactly 6.0 MC.

(c) Tune in the 6 MC. oscillator signal at or near 6 MC. on the receiver dial to determine whether the receiver dial calibration is correct at 6 MC. If it is, do not adjust the oscillator shunt trimmer No. 8.

(d) If the calibration is incorrect, set the dial pointer to 6 MC. on the dial, and adjust the oscillator shunt trimmer No. 8, until the oscillator signal comes in at this point. If there are two peaks, the proper one is that with the trimmed screw farthest out.

(e) Carefully tune the receiver to the signal and adjust trimmer No. 9 for maximum output. Then try to increase the output by detuning No. 9 slightly and retuning the receiver dial. Continue detuning No. 9 and retuning the dial until the output meter deflection is a maximum.

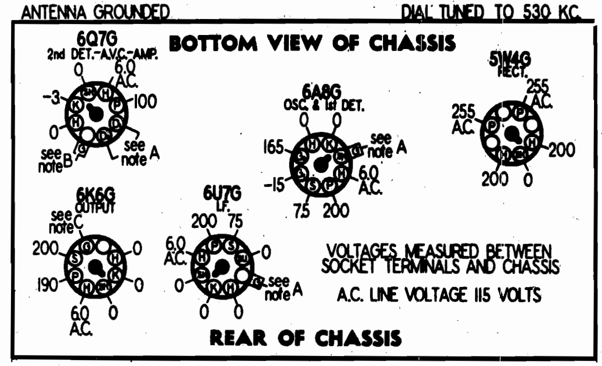
SOCKET VOLTAGES

ANTENNA GROUNDED — DIAL TUNED TO 530 KC.



IMPORTANT: Use a high resistance voltmeter of 1,000 ohms per volt.

NOTE A: The bias for the control grids of the 6A8-G, 6U7-G and the diode plates of the 6Q7-G is -3 volts measured across resistor 28.

NOTE B: The bias for the control grid of the 6Q7-G triode section is -5 volts measured across resistors 27 and 28.

NOTE C: The bias for the control grid of the 6K6-G tube is -14 volts measured across resistors 10, 27 and 28.

Chassis R-180
Alignment, Trimmers
Parts

STEWART-WARNER CORP.

MODEL R-180 CHASSIS (RECEIVER MODELS 1801 to 1809)

The Model R-180 chassis is a five tube, two band superheterodyne receiver. It has an intermediate frequency of 465 KC. and tuning ranges of 525 to 1750 KC. and 2200 to 7000 KC.

REMEDY FOR SLIPPING DIAL MECHANISM.

Slipping of the dial mechanism may be due to binding of the pointer hub against the hole in the dial scale. To remedy, remove the pointer by twisting it, then center the dial scale hole around the pointer shaft by moving the dial scale.

ALIGNMENT EQUIPMENT & PROCEDURE

For alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 6.0 MC. are required.

IMPORTANT: THE BROADCAST BAND MUST BE ALIGNED AFTER THE SHORT-WAVE BAND.

1— Connect the output meter across the voice coil or between the plate of the 6K6G tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)

2— Connect the ground lead of the signal generator to the chassis of the receiver.

3— Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

4— With the gang condenser in full mesh set the pointer on the horizontal black line below 530 KC. on the dial.

5— Using a bakelite screw driver proceed to align in exactly the same order as shown in the table below.

DUMMY ANT. IN SERIES WITH SIG. GEN.	CONNECTION OF SIG. GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	RANGE SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD. CONDENSER.	CONTROL GRID OF 6A8G TUBE (Do not remove grid clip)	465 KC.	BROADCAST (Clockwise)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1-2	1ST I.F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.
					3-4	2ND I.F.

Alignment, Trimmers, Parts
Dial Data

STEWART-WARNER CORP.

MODEL R-181 CHASSIS (RECEIVER MODELS 1811 to 1819)

ALIGNMENT EQUIPMENT & PROCEDURE

For alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 6.0 MC. are required.

1 — Connect the output meter across the voice coil or between the plate of the 6K6G tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)

2 — Connect the ground lead of the signal generator to the chassis of the receiver.

3 — Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

4 — With the gang condenser in full mesh set the pointer on the last scale division on the low frequency end of the dial. This may be accomplished by releasing the clip on the pointer slider; where it attaches to the dial cord.

IMPORTANT:—THE BROADCAST BAND MUST BE ALIGNED AFTER THE SHORT-WAVE BAND.

HOW TO REPLACE DIAL CORD

Before attempting to replace the dial cord, fully mesh the gang condenser. The holes in drum A should be in the top position as shown in the diagram above.

The pointer drive cord should be 33 inches or more in length. Place one end of the cord through the left hole in drum; then knot the end. Run the free end of the cord down around the drum and up to pulley B. Continue over pulley B to pulley C, then down to drum A. Bring the cord up around drum D. Tie the cord to the end of the tension spring so that the spring will be extended to about 1-1/8 inches, when hooked to the slot in the drum. Now place the pointer on its track so that it points to the last scale division on the low frequency end of the dial, then clip it to the cord.

MODEL R-182 CHASSIS (RECEIVER MODELS 1821 to 1829)

ALIGNMENT EQUIPMENT & PROCEDURE

For alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 18 MC. are required.

1— Connect the output meter across the voice coil or between the plate of the 6V6G tube and ground, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)

2— Connect the ground lead of the signal generator to the chassis of the receiver.

3— Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.

4— With the gang condenser in full mesh set the pointer on the last scale division on the low frequency end of the dial. This may be accomplished by releasing the clip on the pointer slider; where it attaches to the dial cord.

IMPORTANT:—THE BROADCAST BAND MUST BE ALIGNED AFTER THE SHORT-WAVE BAND AND POLICE BAND.

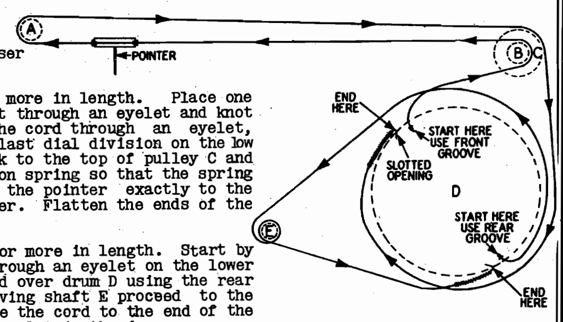
STEWART-WARNER CORP.

MODEL R-183 CHASSIS (RECEIVER MODELS 1831 to 1839)

HOW TO REPLACE THE DIAL CORD



Before attempting to replace either dial cord, fully mesh the gang condenser plates. The holes in drum D should be in the position shown in the diagram.

REPLACING THE POINTER DRIVE CORD: The pointer drive cord should be 40 inches or more in length. Place one end of the cord through the upper hole in the front groove of the drum. Put it through an eyelet and knot the end. Flatten the eyelet. Run the free end up over pulley B. Then thread the cord through an eyelet, the pointer slider, and another eyelet. (See diagram). Set the pointer to the last dial division on the low frequency end of the scale. After this run the cord up over pulley A and back to the top of pulley C and down around drum D, using the front groove. Tie the cord to the end of the tension spring so that the spring will be extended to 1-1/8 inches when hooked to the slot in the drum. Now set the pointer exactly to the last low frequency dial scale division and push the eyelets into the pointer slider. Flatten the ends of the eyelets to hold the slider in position on the cord.

CONDENSER DRIVE CORD: The cord for the main condenser drive should be 19 inches or more in length. Start by placing an end of the cord through the lower hole in the rear groove. Put it through an eyelet on the lower side of the drum and tie a knot in the end. Run the loose end of the cord up and over drum D into the rear groove. Then take the cord down to shaft E and wind 1-1/2 turns around it. Leaving shaft E proceed to the lower side of drum D and place the tension spring on the end of the cord. Tie the cord to the end of the tension spring so that the spring will be extended 1-1/8 inches when hooked to the slot in the drum.

ALIGNMENT EQUIPMENT & PROCEDURE

1. With the gang condenser in full mesh the dial pointer should stop opposite the last low frequency scale division. If the pointer is off not more than one scale division, release the setscrew on the flexible coupler and keeping gang closed, turn the tuning knob until the pointer stops in the correct position. Then retighten the setscrew. If the pointer is off several dial divisions it will be necessary that you release the cord at the slider and reset it.
2. Connect the output meter between the plate of the 6L6 and the chassis, or across the voice coil of the speaker, depending on the type of meter. The more sensitive type should be connected across the voice coil.
3. Connect the ground lead of the signal generator to the chassis and leave it there throughout the entire alignment procedure.
4. Turn the volume control to maximum volume position. Turn the tone control to the brilliant position.
5. KEEP THE GROUND AND DOUBLET CONNECTIONS, ON THE ANTENNA TERMINAL STRIP, CONNECTED TOGETHER THROUGHOUT THE ENTIRE ALIGNMENT PROCEDURE.

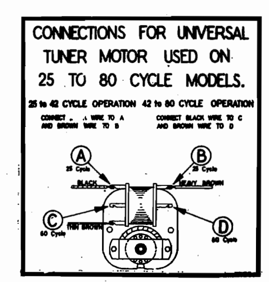
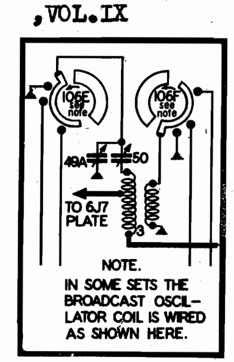
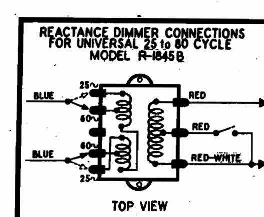
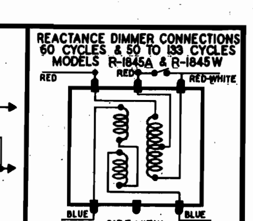
FOR "MAGIC KEYBOARD" TUNER

SEE INDEX ,VOL.IX





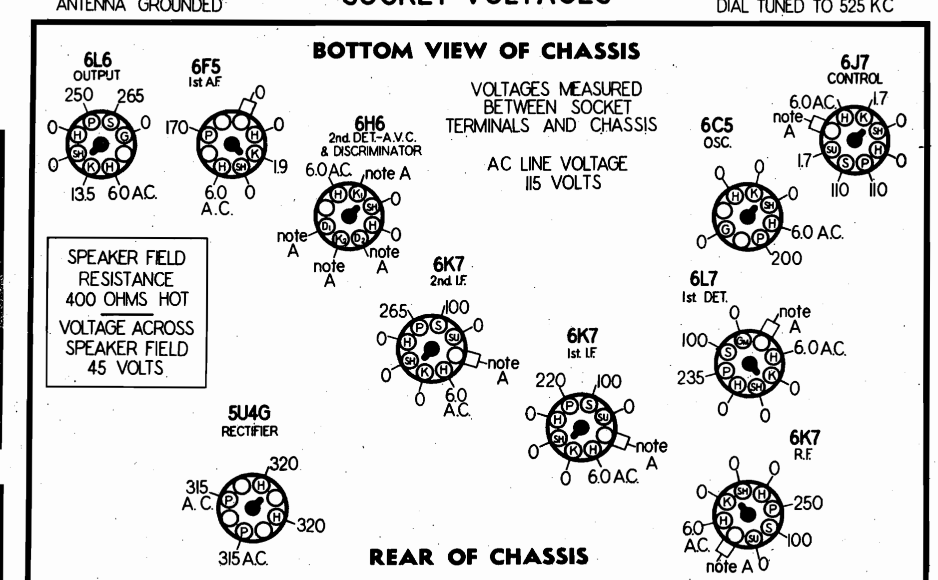




ANTENNA GROUNDED

SOCKET VOLTAGES

DIAL TUNED TO 525 KC



IMPORTANT: Use a high resistance voltmeter of 1000 ohms per volt.

NOTE A; The bias for the control grids of the 6L7 1st Det., 6K7 R.F., 6K7 1st I.F. and 6K7 2nd I.F. tubes, also the voltage on the 6H6 diodes and cathodes and the control grid of the 6J7, is -3.6 volts measured across resistor number 100.

Alignment STEWART-WARNER CORP. MODELS 1841-1849 incl. Chassis R-184

MODEL R-184 CHASSIS (RECEIVER MODELS 1841 TO 1849)

FOR INFORMATION ON TUNING MECHANISM, - MAGIC KEYBOARD SERVICE, SEE THE INDEX

The model R-184 chassis is a ten tube, three band, automatic tuning superheterodyne receiver. It has an intermediate frequency of 465 KC. and a tuning range of 525 KC to 18,100 KC. This chassis also incorporates such recent engineering refinements as a reactance dimmer tuning indicator, automatic frequency control, iron core I.F. transformers, a high efficiency R.F. unit, and the Stewart-Warner "Magic Keyboard" for automatic tuning.

ALIGNMENT EQUIPMENT & PROCEDURE

① — Before attempting to align the receiver check to see that the dial pointer is opposite the last scale division on the low frequency end of the dial when the gang condenser is in full mesh. Also when the gang condenser is in full mesh the stop pin on the left side of the tuner should be resting against the back stop. If after examination it is found that the gang is in full mesh and the stop pin is against the back stop, but the pointer is set to the wrong position, it will only be necessary to loosen the set screw on the dial drive gear at the left side of the mechanism; then grasp the large drum on the same side of the tuner and turn it until the pointer is set correctly. Now retighten the set screw on the gear being careful to see that the gear is meshing properly.

On the other hand if the stop pin does not rest against the back stop with the gang condenser in full mesh, loosen the set screw on the gang condenser side of the flexible coupler. Then turn the tuning knob until the stop pin rests against the back stop on the tuner. Now retighten the set screw in the flexible coupler and proceed to set the pointer to its correct position by the method described in the previous paragraph.

② — Connect the output meter between the plate of the 6L6 power output tube and ground or across the voice coil of the speaker, depending on the type of meter. The more sensitive type should be connected across the voice coil.

③ — Connect the ground lead of the signal generator to the chassis and leave it there throughout the entire alignment procedure.

④ — Turn the volume control to the maximum volume position.

⑤ — Keep the Ground and Doublet connections on the antenna terminal strip connected together throughout the entire alignment procedure.

TYPE OF DUMMY ANT. IN SERIES WITH SIG. GEN.	POINT TO CONNECT OUTPUT OF SIGNAL GENERATOR.	SIGNAL GENERATOR FREQUENCY	RANGE SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER (see diag. next page)	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT

					17	SHORT-WAVE ANTENNA	

IMPORTANT: ALLOW RECEIVER TO WARM UP 15 MINUTES BEFORE ALIGNING. SEE THAT NONE OF THE PUSH BUTTONS ARE DEPRESSED WHEN ALIGNING.

A.F.C. ALIGNMENT.

IMPORTANT: The following adjustment must be made after every re-adjustment of the I.F. and broadcast band trimmers.

The A.F.C. Discriminator should be adjusted as follows:

1. Be sure no buttons are depressed. Loosely couple the output of the signal generator to the 6L7 control grid by clipping the signal generator output lead to the insulation on the control grid wire, or connect to the grid clip through a 50 mmfd. mica condenser. BE SURE THE RANGE SWITCH IS IN THE BROADCAST (COUNTER-CLOCKWISE) POSITION.
2. Adjust the signal generator to resonance with I.F. system by tuning the signal generator dial for maximum output meter deflection. Be sure that the receiver dial is at some point where it has no tuning effect on the generator signal. Switch off the modulation.
3. With the signal generator connected and operating as in #2, connect antenna and manually tune in powerful local station in region of 1000 KC. or lower. (Avoid stations around 930 KC. which might beat with second harmonic of test oscillator.)
4. Adjust receiver tuning dial to obtain zero beat between the test oscillator and the incoming signal. (A very slight adjustment is all that is required. Be careful not to tune off signal.)
5. Refer to the figure on the right. It is now necessary to open the A.F.C. contacts & allow it to function. This may be done by placing a piece of smooth cardboard between the A.F.C. contacts as shown in the figure. Be careful not to bend or malform the switch in any way.
6. Now, adjust the secondary of the discriminator transformer (Trimmer #11) to restore zero beat. NOTE: This trimmer should be adjusted to the point where the frequency of the beat note increases rapidly if the trimmer is turned in either direction. Other zero beat points may be found with the trimmer all the way in or all the way out, but these settings are incorrect.

If this operation has been performed correctly, the opening or closing of the A.F.C. contacts on the side switch by inserting or removing the cardboard, should not change the beat note by more than a slight rumble.

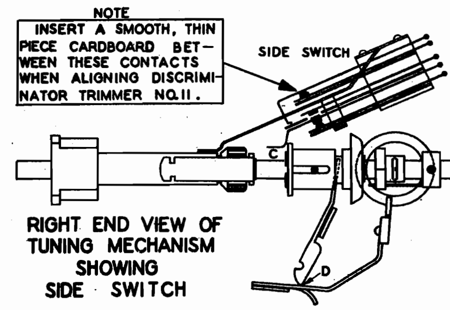
NOTE:- Where a second signal generator is available step #3 above may be varied as follows:

Connect second signal generator (set at about 1000 KC.) to antenna and tune in its signal. Switch off modulation and proceed as before.

This method is somewhat preferable to the first as the zero beat setting is more easily determined when both signals are unmodulated.

NOTE

INSERT A SMOOTH, THIN PIECE CARDBOARD BETWEEN THESE CONTACTS WHEN ALIGNING DISCRIMINATOR TRIMMER NO. 11.



RIGHT END VIEW OF TUNING MECHANISM SHOWING SIDE SWITCH

MODELS 1841-1849 incl. Chassis R-184 STEWART-WARNER CORP. AFC Data, Socket, Trimmers Tuner Data, R-1845-W Phono. Data

TESTING THE AFC SYSTEM

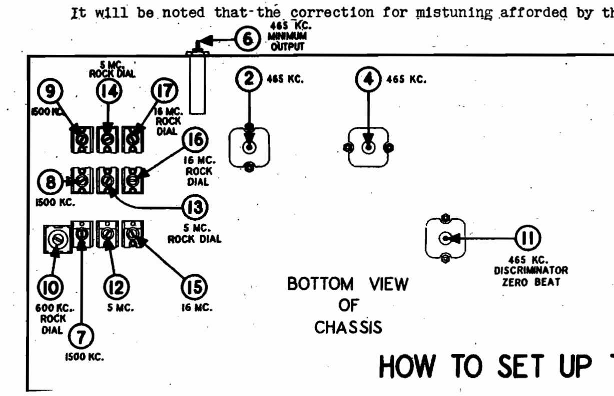
Connect the antenna and tune in a powerful local station. Remove the cardboard that you placed between the A.F.C. contacts on the side switch when aligning. The A.F.C. is now off.

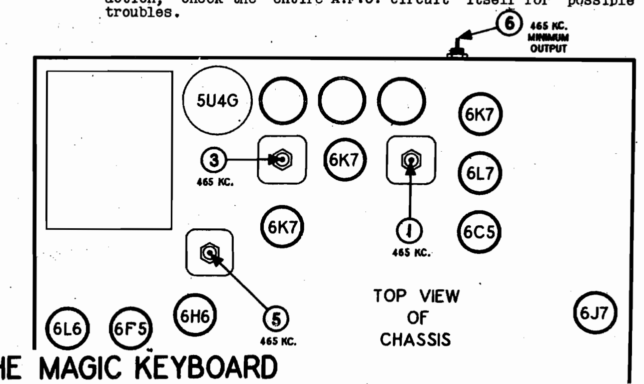
Next, detune the receiver dial until the music or speech becomes somewhat distorted. Now place a piece of smooth cardboard between the A.F.C. contacts on the side switch as shown in the illustration on the bottom of the previous page. This allows A.F.C. to function and it should improve the quality of the program.

Similarly detune the receiver dial in the opposite direction, with the cardboard removed from between the A.F.C. contacts (contacts closed). Then place the cardboard between the contacts again and check for improved quality of reception.

It will be noted that the correction for mistuning afforded by the A.F.C. system is not as marked at stations near the low frequency end of the dial scale as it is at the higher broadcast frequencies. This is characteristic of A.F.C. systems. However, if opening the A.F.C. contacts on the side switch (by inserting the piece of cardboard between the contacts) has no effect on the signal, or if it corrects for mistuning in one direction only, check the receiver as follows:

1. Re-align I.F., broadcast band, and discriminator trimmers.
2. Check all the tubes in the receiver. Defective 6H6 and 6J7 tubes, also the R.F., 1st Detector, and I.F. tubes may cause poor A.F.C. action.
3. If the above procedure fails to remedy the defect in A.F.C. action, check the entire A.F.C. circuit itself for possible troubles.





HOW TO SET UP THE MAGIC KEYBOARD

SELECTING THE PROPER STATIONS: When setting up the "Magic Keyboard" select powerful nearby stations. Avoid weak or fading stations.

LABELLING THE PUSH BUTTONS: Call letter labels are supplied with each set. To label any button remove the cap of the push button, BY PULLING ON THE TOP END. Remove the black cardboard disc, and insert the call letter tab. IN REPLACING THE CAP START AT THE BOTTOM AND PRESS ON THE TOP.

STEP BY STEP PROCEDURE:

1. Connect a good outside aerial to the receiver and allow the reiver to operate for 20 minutes before setting-up.

2. Pull off the large tuning knob. As this knob is removed another small "set-up" knob on the same shaft will appear partly hidden behind the panel face.

3. Pull out this set-up knob AS FAR AS IT WILL GO.

4. Rotate the set-up knob clockwise. After dial pointer reaches the end of the dial scale continue to turn the knob clockwise until you have forced it to a definite stop. This last twist unlocks the cams.

5. Push any button you wish to set to a station. The tuner will operate and carry the pointer to some new point on the dial scale.

6. Tune the receiver to the desired station with the metal set-up knob. TUNE CAREFULLY AND WATCH THE "REACTANCE DIMMER" FOR THE POINT OF MINIMUM ILLUMINATION SO THAT THE RECEIVER WILL BE CORRECTLY TUNED TO THE STATION.

7. Push in the next button you want to set up for a station. This automatically completes the setting up of the previous station, and causes its button to pop out. Do not push in any buttons that are already set up and which you do not wish to change, since pushing a button with the cams unlocked will shift its setting.

8. Tune in the station for the button that is now depressed.

9. Set-up other buttons as desired in the same manner, that is, push in the button, tune in the station, then push in the next button.

10. To release the last button grasp the set-up knob on the station selector shaft and push it in until the last button is released. Then pull the knob out again.

11. Turn the set-up knob to the LEFT (Counter-clockwise). CONTINUE TO TURN THE KNOB TO THE LEFT even after the pointer reaches the end of the dial scale. FORCE THE KNOB COUNTER-CLOCKWISE TO A DEFINITE STOP.

12. Push the "set-up" knob back into the cabinet again and replace the large tuning knob.

13. Your "Magic Keyboard" is now ready for operation.

Wherever the word RIGHT or LEFT appears in the following list, it is understood that you are standing in front of the receiver.

PART NUMBER	DESCRIPTION	LIST PRICE
111930	Band Indicator - and frame assembly	$ .40
112658	Belt - for range switch drive	.06
111261	Bolt - chassis mtg. (#14 X 1-1/4)	.03
111260	Bushing - rubber (for chassis mtg.)	.06
111892	Bushing - hard rubber, mystic mechanism mtg. to chassis	.02
111658	Clip - for pulley retaining	.01
110782	Cord - for band ind. (2 ft. required) Per Ft.	.04
111302	Cord - dial drive (6 ft. lengths)	.30
111226	Escutcheon - for dial (with glass)	3.00
111227	Escutcheon - around push button opening	1.20
111865	Frame - dial, with scale	2.50
111496	Knob - tuning or volume	.20
111497	Knob - range or tone	.20
111197	Lever - for band indicator (on shaft)	.12
111370	Link & Lever - for range sw. drive (used in early production)	.20
112633	Plug - for mechanism connecting (8 prong)	.20
110496	Plug - speaker (4 prong)	.12
111859	Pointer - for dial, with slider	.18
111622	Pulley - dial cord drive	.35
111630	Pulley & Bracket - for band indicator	.10
112628	Pulley - on range switch shaft under chassis	.20
84214	Retaining Ring - for dial drum shafts	.02
89837	Retaining Spring - for retaining escut. to cabinet	.01
111222	Scale - dial	1.20
110716	Screw - band indicator pivot	.03
111116	Screw - #5 X 5/8, mystic mechanism mtg.	.02
85827	Set Screw - 8/32 square head	.02
111403	Set Screw - 8/32, fluted head	.12
112138	Set Screw - 8/32 slotted head	.03
111373	Shaft - for range switch	.08
85427	Socket - octal base	.15
110501	Socket - 4 prong (for spkr.)	.16
110627	Socket - dial lamp & automatic lamp	.12
111008	Socket - reactance dimmer lamp	.12
112630	Socket & Bracket - for elect. conn. to mech.	.75
111232	Spring - torsion for band indicator	.05
111862	Spring - drive cord tension	.03
112490	Spring - in flexible coupler	.02
111676	Stud - lower left idler pulley	.10
112667	Stud - for pulley mtg. (for top pulleys)	.10
112005	Tabs - station call letters (6 sheets)	.60
85066	Terminal Strip - G.D.A.	.20
89709	Terminal Strip - Phono.	.15
67568	Washer - embossed (for mtg. electrolytic cond.)	.05
89746	Washer - (paper) for back of knobs	.005
89027	Washers - spring for range shaft	.01
111262	Washer - flat steel mtg. (15/16" O.D.)	.02

PART NUMBER	DESCRIPTION	LIST PRICE
112727	Mystic Mechanism - complete with all dials - ready to mount on chassis	$60.00
111350	Mystic Mechanism only, less dial frame assembly	35.00
112428	Button Body - for tuner	.10
112545	Button Cap - for push button	.06
111878	Button Window - celluloid for push button	.01
112547	Button Reinforcing Disc - for push button	.01
111633	Button Retaining Spring - inside push button	.02
111577	Button Spring - in push button	.005
111576	Button Washer - in push button	.005
112563	Cam - bakelite - less operating arm	.10
111146	Clutch - bushing, spring and gear	.55
111137	Drive Ring - rubber	.05
111380	Motor - 6 volt, 60 cycles	4.40
112354	Motor - 6 volt, 25 to 80 cycles	5.50
112736	Plug - with cable for tuner connections	.75
111138	Spring - horseshoe shaped on clutch	.02
111674	Switch Side - multiple contact (above tuning shaft)	.95
112564	Switch Back - (multiple contact)	1.25
112521	Tip - adjustable for key stop and kickout arm	.06
112483	Wrench - for fluted head set screws #6	.07
112484	Wrench - for fluted head set screws #8	.07
117468	Spring Benders	.75

Alignment

MODEL R-186 CHASSIS (RECEIVER MODELS 1861 TO 1869)

FOR THE MAGIC KEYBOARD SERVICE, — INFORMATION ON TUNING MECHANISM, SEE INDEX

The model R-186 chassis, is a 14 tube, three band, automatic tuning, superheterodyne receiver. It has an intermediate frequency of 465 KC. and tuning range of 525 KC, to 18,100 KC. The circuit is of the latest design incorporating such refinements as a special high efficiency R.F. unit automatic frequency control, reactance dimmer, tuning indicator, and iron core I.F. transformers.

ALIGNMENT EQUIPMENT AND PROCEDURE

(1) Before attempting to align the receiver check to see that the dial pointer is opposite the last scale division on the low frequency end of the dial when the gang condenser is in full mesh. Also when the gang condenser is in full mesh the stop pin on the left side of the tuner should be resting against the back stop. If after examination it is found that the gang is in full mesh and the stop pin is against the back stop, but the pointer is set to the wrong position, it will only be necessary to loosen the set screw on the dial drive gear at the left side of the mechanism; then grasp the large drum on the same side of the tuner and turn it until the pointer is set correctly. Now retighten the set screw on the gear being careful to see that the gear is meshing properly.

(2) On the other hand if the stop pin does not rest against the back stop with the gang condenser in full mesh, loosen the set screw on the gang condenser side of the flexible coupler. Then turn the tuning knob until the stop pin rests against the back stop on the tuner. Now retighten the set screw in the flexible coupler and proceed to set the pointer to its correct position by the method described in the previous paragraph.

(3) Connect the output meter across the two plates of the two 6V6 power output tubes or across the voice coil of the speaker, depending on the type of meter. The more sensitive type should be connected across the voice coil.

Connect the ground lead of the signal generator to the chassis and leave it there throughout the entire alignment procedure.

(4) Turn the volume control to the maximum volume position.

Keep the Ground and Doublet connections on the antenna terminal strip connected together throughout the entire alignment procedure.

TYPE OF DUMMY ANT. IN SERIES WITH SIG.GEN.	POINT TO CONNECT OUTPUT OF SIGNAL GENERATOR.	SIGNAL GENERATOR FREQUENCY	RANGE SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER (see diag. next page)	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
.1 MFD CONDENSER	CONTROL GRID OF 6L7 TUBE	465 KC.	BROADCAST (Counter-clockwise)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	1-2	1ST I.F.	Adjust for maximum output. Then repeat adjustment. The tone control switch must be in the SHARP-POSITION (Counter-clockwise), or the alignment will be incorrect.
					3-4	2ND I.F.	
					5	3RD I.F.	
					6	4TH I.F.	
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	465 KC.	BROADCAST (Counter-clockwise)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL	7	WAVE TRAP	Adjust for minimum output using a strong generator signal.
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	1500 KC.	BROADCAST (Counter-clockwise)	1500 KC.	8	BROADCAST OSCILLATOR (Shunt)	Adjust trimmer to bring in signal.
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	1500 KC.	BROADCAST (Counter-clockwise)	TUNE TO 1500 KC. GENERATOR SIGNAL	9	BROADCAST DETECTOR	Adjust for maximum output.
					10	BROADCAST ANTENNA	
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	600 KC.	BROADCAST (Counter-clockwise)	TUNE TO 600 KC. GENERATOR SIGNAL	11	BROADCAST OSCILLATOR (Series Pad)	Adjust for maximum output. Try to increase output by detuning trimmer and retuning receiver dial until maximum output is obtained.
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	5 MC.	POLICE (Center)	5 MC.	12	POLICE OSCILLATOR (Shunt)	Adjust to bring in signal. Check to see if proper peak was obtained by tuning in image at approx. 4.1 MC. If image does not appear realign at 5 MC. with trimmer screw farther out. Recheck image.
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	5 MC.	POLICE (Center)	TUNE TO 5 MC. GENERATOR SIGNAL	13	POLICE DETECTOR	Adjust for maximum output. Try to increase output by detuning trimmer and retuning receiver dial until maximum output is obtained.
					14	POLICE ANTENNA	
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	16 MC.	SHORT-WAVE (Clockwise)	16 MC.	15	SHORT-WAVE OSCILLATOR (Shunt)	Adjust to bring in signal. Check to see if proper peak was obtained by tuning in image at approx. 15.1 KC. If image does not appear realign at 16 KC. with trimmer screw farther out. Recheck image.
400 OHM CARBON RESISTOR	ANTENNA TERMINAL	16 MC.	SHORT-WAVE (Clockwise)	16 MC.	16	SHORT-WAVE DETECTOR	Adjust for maximum output. Try to increase output by detuning trimmer and retuning receiver dial until maximum output is obtained.
					17	SHORT-WAVE ANTENNA	

IMPORTANT
THE TONE SWITCH MUST BE IN THE SHARP COUNTER-CLOCKWISE POSITION AT ALL TIMES
SEE THAT NONE OF THE PUSH BUTTONS ARE DEPRESSED WHEN ALIGNING.
ALLOW RECEIVER TO WARM UP 15 MINUTES BEFORE ALIGNING.

A.F.C. ALIGNMENT.

IMPORTANT: The following adjustment must be made after every re-adjustment of the I.F. and broadcast band trimmers.

The A.F.C. Discriminator should be adjusted as follows:

1. Be sure no buttons are depressed. Loosely couple the output of the signal generator to the 6L7 control grid by clipping the signal generator output lead to the insulation on the control grid wire, or connect to the grid clip through a .50 mmfd. mica condenser. BE SURE THE RANGE SWITCH IS IN THE BROADCAST (COUNTER-CLOCKWISE) POSITION.
2. Adjust the signal generator to resonance with I.F. system by tuning the signal generator dial for maximum output meter deflection. Be sure that the receiver dial is at some point where it has no tuning effect on the generator signal. Switch off the modulation.
3. With the signal generator connected and operating as in #2, connect antenna and manually tune in powerful local station in region of 1000 KC. or lower. (Avoid stations around 930 KC. which might beat with second harmonic of test oscillator.)
4. Adjust receiver tuning dial to obtain zero beat between the test oscillator and the incoming signal. (A very slight adjustment is all that is required. Be careful not to tune off signal.)
5. Refer to the figure on the right. It is now necessary to open the A.F.C. contacts & allow the A.F.C. to function. This may be done by placing a piece of smooth cardboard between the A.F.C. contacts as shown in the figure. Be careful not to bend or malform the switch in any way.
5. Now, adjust the secondary of the discriminator transformer (Trimmer #18) to restore zero beat. NOTE: This trimmer should be adjusted to the point where the frequency of the beat note increases rapidly if the trimmer is turned in either direction. Other zero beat points may be found with the trimmer all the way in or all the way out, but these settings are incorrect.

If this operation has been performed correctly, the opening or closing of the A.F.C. contacts on the side switch by inserting or removing the cardboard, should not change the beat note by more than a slight rumble.

NOTE:- Where a second signal generator is available step #3 above may be varied as follows:

Connect second signal generator (set at about 1000 KC.) to antenna and tune in its signal. Switch off modulation and proceed as before.

This method is somewhat preferable to the first as the zero beat setting is more easily determined when both signals are unmodulated.

NOTE
INSERT A SMOOTH, THIN PIECE CARDBOARD BETWEEN THESE CONTACTS WHEN ALIGNING DISCRIMINATOR TRIMMER NO. 18.

STEWART-WARNER CORP.

AFC Data, Trimmers, Tuner Parts for Dial and Tuner
Chassis R-186W Phono. Data

TESTING THE A.F.C. SYSTEM.

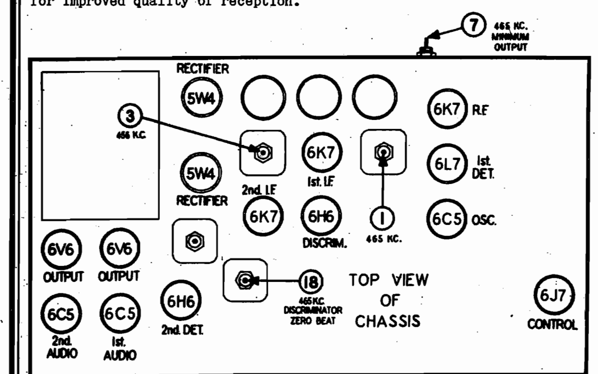
Connect the antenna and tune in a powerful local station. BE SURE THE TONE SWITCH IS IN THE MAXIMUM COUNTER-CLOCKWISE POSITION. Remove the cardboard that you placed between the A.F.C. contacts on the side switch when aligning. The A.F.C. is now off.

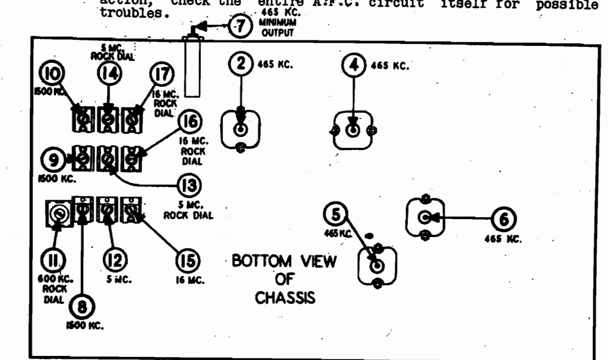
Next, detune the receiver dial until the music or speech becomes somewhat distorted. Now place a piece of smooth cardboard between the A.F.C. contacts on the side switch as shown in the illustration on the bottom of the previous page. This allows A.F.C. to function and it should improve the quality of the program.

Similarly detune the receiver dial in the opposite direction, with the cardboard removed from between the A.F.C. contacts (contacts closed). Then place the cardboard between the contacts again and check for improved quality of reception.

It will be noted that the correction for mistuning afforded by the A.F.C. system is not as marked at stations near the low frequency end of the dial scale as it is at the higher broadcast frequencies. This is characteristic of A.F.C. systems. However, if opening the A.F.C. contacts on the side switch (by inserting the piece of cardboard between the contacts) has no effect on the signal, or if it corrects for mistuning in one direction only, check the receiver as follows:

1. Re-align I.F., broadcast band, and discriminator trimmers.
2. Check all the tubes in the receiver. Defective 6H6 and 6J7 tubes, also the R.F., 1st Detector, and I.F. tubes may cause poor A.F.C. action.
3. If the above procedure fails to remedy the defect in A.F.C. action, check the entire A.F.C. circuit itself for possible troubles.





HOW TO SET-UP THE "MAGIC KEYBOARD"

SELECTING THE PROPER STATIONS: When setting up the "Magic Keyboard" select powerful nearby stations. Avoid weak or fading stations.

LABELLING THE PUSH BUTTONS: Call letter labels are supplied with each set. To label any button remove the cap of the push button, BY PULLING ON THE TOP END. Remove the black cardboard disc, and insert the call letter tab. IN REPLACING THE CAP START AT THE BOTTOM AND PRESS ON THE TOP.

STEP BY STEP PROCEDURE:

1. Connect a good outside aerial to the receiver and allow the receiver to operate for 20 minutes before setting-up.

2. Pull off the large tuning knob. As this knob is removed another small "set-up" knob on the same shaft will appear partly hidden behind the panel face.

3. Pull out this set-up knob AS FAR AS IT WILL GO.

4. Rotate the set-up knob clockwise. After dial pointer reaches the end of the dial scale continue to turn the knob clockwise until you have forced it to a definite stop. This last twist unlocks the cams.

5. Push any button you wish to set to a station. The tuner will operate and carry the pointer to some new point on the dial scale.

6. Tune the receiver to the desired station with the metal set-up knob. TUNE CAREFULLY AND WATCH THE "REACTANCE DIMMER" FOR THE POINT OF MINIMUM ILLUMINATION SO THAT THE RECEIVER WILL BE CORRECTLY TUNED TO THE STATION.

7. Push in the next button you want to set up for a station. This automatically completes the setting up of the previous station, and causes its button to pop out. Do not push in any buttons that are already set up and which you do not wish to change, since pushing a button with the cams unlocked will shift its setting.

8. Tune in the station for the button that is now depressed.

9. Set-up other buttons as desired in the same manner, that is, push in the button, tune in the station, then push in the next button.

10. To release the last button grasp the set-up knob on the station selector shaft and push it in until the last button is released. Then pull the knob out again.

11. Turn the set-up knob to the LEFT (Counter-clockwise). CONTINUE TO TURN THE KNOB TO THE LEFT even after the pointer reaches the end of the dial scale. FORCE THE KNOB COUNTER-CLOCKWISE TO A DEFINITE STOP.

12. Push the "set-up" knob back into the cabinet again and replace the large tuning knob.

13. Your "Magic Keyboard" is now ready for operation.

DIAL DRIVE & MISCELLANEOUS PARTS.

FOR A COMPLETE PARTS LIST SEE THE SPECIAL "MAGIC KEYBOARD" SERVICE MANUAL FORM 8529 WHICH MAY BE OBTAINED FROM STEWART-WARNER CORP.

Wherever the word RIGHT or LEFT appears in the following list, it is understood that you are standing in front of the receiver.

PART NUMBER	DESCRIPTION	LIST PRICE
111930	Band Indicator - and frame assembly	$ .40
112658	Belt - for range switch drive	.06
111261	Bolt - chassis mtg. (#14 X 1-1/4)	.03
111260	Bushing - rubber (for chassis mtg.)	.06
111892	Bushing - hard rubber, mystic mechanism mtg. to chassis	.02
111658	Clip - for pulley retaining	.01
110782	Cord - for band ind. (2 ft. required)----Per Ft.	.04
111302	Cord - dial drive (6 ft. lengths)	.30
111226	Escutcheon - for dial (with glass)	3.00
111227	Escutcheon - around push button opening	1.20
111865	Frame - dial, with scale	2.50
111496	Knob - tuning or volume	.20
111497	Knob - range or tone	.20
111197	Lever - for band indicator (on shaft)	.12
111370	Link & Lever - for range sw. drive (used in early production)	.20
112633	Plug - for mechanism connecting (8 prong)	.20
110496	Plug - speaker (4 prong)	.12
111859	Pointer - for dial, with slider	.18
111622	Pulley - dial cord drive	.35
111630	Pulley & Bracket - for band indicator	.10
112628	Pulley - on range switch shaft under chassis	.20
84214	Retaining Ring - for dial drum shafts	.02
89837	Retaining Spring - for retaining escut. to cabinet	.01
111222	Scale - dial	1.20
110716	Screw - band indicator pivot	.03
111116	Screw - #5 X 5/8, mystic mechanism mtg.	.02
85827	Set Screw - 8/32 square head	.02
111403	Set Screw - 8/32 fluted head	.12
112138	Set Screw - 8/32 slotted head	.03
111373	Shaft - for range switch	.08

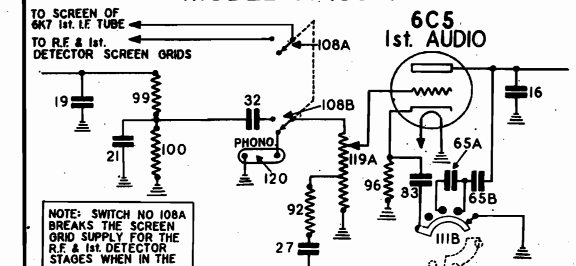
PHONOGRAPH CONNECTIONS FOR MODEL R-186-W



SELECTIVITY & TONE CONTROL SWITCH.

The lower left hand knob on the receiver panel is combination four point tone control switch and selectivity control. This switch controls the tone and selectivity simultaneously. As the switch is turned clockwise the tone is varied from base to treble. The selectivity is sharp in all positions except the maximum clockwise position (treble).

When the switch is in this position (clockwise), the auxilliary coils in the 1st and 2nd I.F. transformers are connected into the circuit to broaden the tuning.

All alignment and set-up operations must be made with the tone selectivity switch in one of the sharp positions.

STEWART-WARNER CORP.

MODEL R-188 CHASSIS (RECEIVER MODELS 1881 to 1889)

CIRCUIT DESCRIPTION

The model R-188 chassis is a 115 volt A.C. or D.C. six tube superheterodyne receiver. It has an intermediate frequency of 465 KC.; and tuning ranges of 540 to 1720 KC.; and 5.8 to 18 MC.

The incoming signal picked up by the antenna is induced in the tuned secondary of the antenna coil and impressed upon the control grid of the 6A7 first detector and oscillator. The 465 KC. output of the 6A7 is amplified in the I.F. stage using a 6D6 tube. The amplified voltage is then impressed upon the diodes of the 75 twin diode triode tube. The two diodes are tied together and function as a linear second detector and A.V.C. The direct current voltage developed across the 1/2 megohm diode load resistor is used as A.V.C. voltage and applied to the control grids of the 6D6 and 6A7 tubes through a resistance capacity filter system.

The potentiometer type volume control 46A serves as a continuous voltage divider of the audio frequency voltage developed. Hence any portion of the audio voltage developed can be applied to the control grid of the triode section of the 75 tube. It should be noted the grid bias of the 75 tube is obtained from a bias cell. The 75 tube is now resistance coupled to the 43 power output tube. Grid bias for the output tube is obtained across the filter choke number 2.

The heaters of all the tubes in the receiver are connected in series and are supplied by a type M-49-B ballast tube. The pilot lamp supply is taken from a tapped portion of the voltage drop across the ballast tube and resistor number 53 in series. The 25Z5 tube is used as a conventional half wave rectifier. When the receiver is operated on direct current the line cord plug must be so inserted that the plates of the rectifier are on the positive side of the line. Under this condition the rectifier acts as a device passing direct current to the plates of the other tubes.

ALIGNMENT EQUIPMENT & PROCEDURE

For proper alignment, an output meter and an accurately calibrated signal generator with a tuning range from 465 KC. to 18 MC. are required.

1. Connect the output meter between the plate of the 43 tube and ground, or across the voice coil, depending on the type of meter. (The more sensitive type should be connected across the voice coil.)
2. Connect the ground lead of the signal generator to the chassis of the receiver through a .1 mfd. condenser and keep it connected in this manner throughout the entire alignment procedure. Failure to do this may have serious results as one side of the power line may be grounded in the signal generator.
3. Turn the volume control to the maximum volume position and keep it in this position throughout the entire alignment procedure.
4. With the gang condenser in full mesh set the pointer on the black horizontal line below 550 KC. on the dial.
5. Proceed to align in exactly the same order as shown in the table below.

ORDER OF ALIGN.	DUMMY ANT. IN SERIES WITH SIG. GEN.	CONNECTION OF SIG. GENERATOR OUTPUT TO RECEIVER	SIGNAL GENERATOR FREQUENCY	RANGE SWITCH POSITION	RECEIVER DIAL SETTING	TRIMMER NUMBER	TRIMMER DESCRIPTION	TYPE OF ADJUSTMENT
A	.1 MFD. CONDENSER	CONTROL GRID OF 6D6 TUBE	465 KC.	BROADCAST (Clockwise)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL.	1 2	2ND. I.F.	ADJUST FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT.
B	.1 MFD. CONDENSER	CONTROL GRID OF 6A7 TUBE	465 KC.	BROADCAST (Clockwise)	ANY POINT WHERE IT DOES NOT AFFECT THE SIGNAL.	3 4	1ST. I.F.	ADJUST TRIMMERS 3 & 4 FOR MAXIMUM OUTPUT. THEN REPEAT ADJUSTMENT OF TRIMMERS NO. 1 & 2. SEE NOTE A BELOW.
C	400 OHM CARBON RESISTOR	ANTENNA LEAD	1700 KC.	BROADCAST (Clockwise)	1700 KC.	5	BROADCAST OSCILLATOR (Shunt)	ADJUST TRIMMER TO BRING IN SIGNAL.
D	400 OHM CARBON RESISTOR	ANTENNA LEAD	1500 KC.	BROADCAST (Clockwise)	TUNE TO 1500 KC. GENERATOR SIGNAL	6	BROADCAST ANTENNA	ADJUST FOR MAXIMUM OUTPUT.
E	400 OHM CARBON RESISTOR	ANTENNA LEAD	600 KC.	BROADCAST (Clockwise)	TUNE TO 600 KC. GENERATOR SIGNAL	7	BROADCAST OSCILLATOR (Series Pad)	ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETUNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.
F	400 OHM CARBON RESISTOR	ANTENNA LEAD	16 MC.	SHORT-WAVE (Counter-clockwise)	16 MC.	8	SHORT-WAVE OSCILLATOR (Shunt)	ADJUST TO BRING IN SIGNAL. CHECK TO SEE IF PROPER PEAK WAS OBTAINED BY TUNING IN IMAGE AT APPROX. 15.1 KC. IF IMAGE DOES NOT APPEAR REALIGN AT 16 MC. WITH TRIMMER SCREW FARTHER OUT. RECHECK IMAGE.
G	400 OHM CARBON RESISTOR	ANTENNA LEAD	16 MC.	SHORT-WAVE (Counter-clockwise)	TUNE TO 16 MC. GENERATOR SIGNAL	9	SHORT-WAVE ANTENNA (Shunt)	ADJUST FOR MAXIMUM OUTPUT. TRY TO INCREASE OUTPUT BY DETUNING TRIMMER AND RETUNING RECEIVER DIAL UNTIL MAXIMUM OUTPUT IS OBTAINED.

NOTE A: Now repeat adjustment of trimmers 3 and 4 again for greater sensitivity. This may cause oscillation. If oscillation occurs repeat steps A and B and disregard the repeat adjustment mentioned in this note.

STEWART-WARNER CORP.

STEWART-WARNER MAGIC KEYBOARD

(USED IN MODELS 1845 to 1869)

REFER TO INDIVIDUAL CHASSIS FOR OTHER DATA.

The Mystic Mechanism with the Magic Keyboard is used on Models 1845 to 1869 Stewart-Warner radios. It is an electrically driven device for automatically tuning the receiver to any one of fifteen preselected frequencies. The receiver can be tuned either automatically or manually without the need of turning a switch.

The operating mechanism of this tuning device consists of fifteen sets each of keys; station selector cams and pawls. In addition it has two multi-contact control switches.

The back switch, mounted on the rear of the tuner, has four sets of contacts. From front to rear, they are:

1. REVERSING: for reversing the direction of motor rotation.
2. POWER: for opening and closing the motor power supply line.
3. MUTE: for killing the audio system to prevent noises during automatic tuning.
4. A.F.C.: for cutting out A.F.C. during automatic tuning.

The side switch, mounted on the right end of the tuner, has two sets of contacts. From the top down, they are:

1. A.F.C.: for cutting out A.F.C. during manual tuning and during setting up.
2. POWER: for opening and closing the motor and automatic light power supply line.

With the tuner in the manual tuning position all switch contacts are in the position shown in figure 1. As a button is pressed in, its pawl is pulled against a station selector cam. It will be noted that these cams have two different heights, that is, a high and a low side. If the pawl comes to rest against the high side of the cam, the reversing contacts on the back switch are closed to the front for one direction of motor rotation. If the pawl comes to rest against the low side of the cam, the reversing contacts close to the back for the other direction of motor rotation. The direction of rotation will always be such as to bring the notch on the cam around to the pawl by the shortest route.

Regardless of whether the pawl rests against the high or low side of the station selector cam, the bakelite cam will close the Power, Mute and A.F.C. contacts on the back switch. After these and the reversing contacts have closed, the power contacts on the side switch close and cause the motor to run.

The motor drives the mechanism to the proper position for the desired station. Then the pawl falls into the notch on the selector cam and causes the bakelite cam to set the back switch contacts in new positions. The Power contacts open, shutting off the motor. The Mute contacts open allowing the signal to come in. The A.F.C. contacts open and A.F.C. puts the finishing touch to the automatic tuning operation.

A friction clutch in the gear train, driving the cam shaft, acts as a buffer and absorbs the shock of the sudden stop when the pawl falls into the notch on station selector cam.

During automatic tuning the manual tuning shaft is disengaged by moving the friction roller. This roller is slid away from engagement with a friction wheel as a button is pushed in. The arm that does this, also allows a kickout arm to engage a star wheel. To tune manually, a slight rotary movement of the tuning shaft causes the star wheel to force down the kickout arm. This releases the depressed button and slides back the friction roller into engagement with the friction wheel for manual tuning.

The flywheel on the back end of the tuning shaft provides a "spinner" action while tuning manually.

The station selector cams are prevented from turning on their shaft by an expansion and contraction type locking mechanism. The assembly is locked when the device is expanded or unmeshed as shown in figure 9B. Unlocking is accomplished by pulling out the set-up knob and turning it clockwise until a click is heard. This contracts the locking mechanism and allows the selector cams to turn on the shaft for setting up. See set-up instructions in section 45.

TROUBLE CHART

The following service chart lists the most typical troubles, gives the most likely causes, and indicates the figures and paragraphs in which information may be found to aid in correcting the troubles. While this chart is necessarily incomplete, its careful study will enable the serviceman to diagnose most of the service complaints he receives on the Mystic Mechanism.

No reference is made to failures of the Mystic Mechanism when such failures are due to broken leads, loose connections, etc. It must be borne in mind, however, that certain indications are common to both radio and tuner troubles. For examples, Automatic Frequency Control may not be functioning because of improper contact adjustment of the tuner switches or because of an electrical defect in the chassis. Therefore, when servicing the tuner, check the possibilities of radio troubles causing the same symptoms.

BUTTON DOES NOT STAY IN OR DOES NOT RELEASE

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
Button will not stay in when pushed in.	Kickout pointer tip improperly adjusted.	Section 34.
	Kickout spring bent down too far.	Section 35.
	Insufficient tension in key stop bar return spring.	Section 35.
	Jammed or stuck key stop bar.	
	Star wheel stuck or not moving freely on tuning shaft.	Section 37.
	Bent or sprung key stop bar.	
Depressed button does not release when another button is pushed in.	Kickout tip jams against star wheel.	Section 36.
	Stuck or jammed pawl.	Sections 25, 26 and 36.
	Stuck or jammed key.	
Depressed button will not release when tuning knob is turned.	Kickout tip not engaging star wheel.	Section 34.
	Also check those listed for previous fault.	Section 36.

POINTER DOES NOT MOVE WHEN BUTTON IS PUSHED

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
Motor hums but does not run.	Reversing contacts on back switch not closing.	Secs. 1 & 3 or 1 & 9
	Motor stalled due to mechanical overload and clutch not slipping.	Secs. 20 and 22.
	Defective motor.	
	Low line voltage or improper frequency	Section 49.
Motor runs but pointer does not move.	Clutch slipping.	Sections 20, 21 & 22.
	Pointer drive gear slipping on shaft or out of mesh.	Section 52.
	Pointer loose on cord.	
	Pointer sticking on guide rail due to rust.	
Motor does not hum and tuner does not move with button in.	Power contacts on back switch not closing	Secs. 1,4,5, or 1,10,11.
	Power contacts on side switch not closing	Sections 14, 15 & 16.
	Bakelite back switch operating cam binding on contact arms or out of position.	Section 13.

POINTER MOVES BUT DOES NOT TUNE STATION PROPERLY

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
Pointer stops at wrong point.	Improper setting-up of mechanism.	Sections 44, 45, 46 and 47.
	Not locked up tight.	
Pointer stops at proper point, but (A) No signal is heard.	Mute contacts on back switch not opening. (No noise will be heard in this case).	Secs. 1 & 5 or 1 & 11
	Tuning backlash.	See "Tuning Backlash" below.
	Gang condenser drive gears out of mesh or slipping on shaft.	Section 52.
	Flexible coupling slipping on shaft.	
	Station not broadcasting or signal too weak as in daytime or during period of fading.	
(B) Signal is not heard clearly.	A.F.C. contacts on back or side switch not opening.	1,5,17,57 or 1,11,17, 57.
	A.F.C. not functioning.	Sections 55 to 57.
	Weak signal or no aerial.	Section 44.
(C) Wrong station comes in.	Desired signal off, weak or faded.	Section 44.
	Not set up properly.	Sections 44, 45, 46 and 47.
	Set off calibration.	Sections 51 and 54.
(D) Motor continues to run.	Pawl does not fall far enough into station selector cam to cut power off.	Burrs on pawl or cam. Sticking pawl.
	Power contacts on back switch not adjusted properly.	Sections 1, 4, 5 or 1, 10, 11
Pointer stops at a different place each time for a certain button.	Mechanism not locked up tight.	Sections 31 and 44g.
	Dial pointer slipping on cord.	Section 53g.
	Left end bearing bracket loose.	Sections 54 and 60.
	Pointer drive gears slipping out of mesh or on shaft.	Sections 52.
	Loose set screw.	
Pointer stops off station occasionally.	Pointer backlash. (Note pointer backlash will cause apparent rather than actual mistuning.)	Section 60.
	Pawl does not fall far enough into station selector cam.	Sec. 1 & 5a, 1& 11a, and 24
Pointer goes to end of dial and motor stalls and hums, or continues to run by slipping the clutch.	Station selector cam turned around beyond its normal operating range.	Section 27.
	Reversing contacts on back switch not adjusted properly.	Secs. 1 & 3 or 1 & 9.
	Bakelite cam binding on contact arm or out of position.	Section 13.
Motor continues to operate, moving the pointer back and forth over a short distance, after tuning to the approximate frequency to which the button is set.	Reversing contacts on back switch are not adjusted properly - set too close.	Secs. 1 & 3 or 1 & 9.
Motor starts before button is pushed in far enough to catch.	Side switch power contacts are being closed too soon.	Section 16.
Motor starts in the wrong direction then corrects itself as the button is pushed the rest of the way in.		
Intermittent operation of motor, lights, etc.	Insufficient contact pressure or dirty contacts on back or side switch.	Sections 3a, 4b and 15 or 9a, 10b and 15.
	Loose silver contact in contact blade of switches.	
	Bakelite cam binding on contact arms or out of position.	Section 13.
Tuning backlash. (Note: the high tuning ratio greatly exaggerates the effect of most of these conditions.)	Clutch slips.	Sections 21 and 22.
	Play between gang condenser drive gears due to insufficient compression in thrust spring in flexible coupling.	Sections 41 and 42.
	Play between gears due to improper setting of anti-backlash springs.	Section 40.
	Play between gear and stud.	
	Gear stud loose.	
	Gang condenser sways.	Section 59.
	Loose set screw in coupling or gear.	
	Loose or worn bearings.	
	Friction roller rotates relative to tuning shaft.	
Calibration incorrect.	Dial pointer or gang condenser drive gears jump teeth, slip on cam shaft or out of mesh.	Sections 42 and 52.
	Loose set screw in gear or coupling.	
	Dial pointer slips on dial cord.	Section 53g.
	Left end bearing bracket loose.	Sections 54 and 60.
	Excessive pointer backlash.	Section 60.

MANUAL TUNING DIFFICULTIES

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
Set tunes very broadly	A.F.C. contacts on side switch not closing.	Section 17.
Tuning knob sticks and catches in going from automatic to manual tuning.	Burrs on tip of kickout arm and star wheel.	Sections 38 and 61.
	Adjustable tip of kickout arm set improperly.	Section 34.
Pointer does not move when tuning knob is turned, although works OK in automatic position.	Oil or grease on drive rubber on friction wheel.	Section 58.
	Jammed bar and arm assembly.	
	Insufficient tension in bar and arm assembly return spring.	Section 58.
Pointer does not move when tuning knob is tuned.	Bent tuning shaft.	
	Oil or grease on drive rubber of friction wheel.	Section 58.
	Jammed bar and arm assembly.	
	Insufficient pressure between friction wheel and friction roller.	Section 58
	Gear driving dial cord drum is out of mesh or slipping on shaft.	Section 52.
	Slipping clutch.	Sections 21 and 22.

DIFFICULTIES OCCURRING DURING SET-UP BUT NOT IN NORMAL OPERATION

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
Set tunes very broadly.	A.F.C. contacts on side switch not closing when set-up knob is out and a button is in.	Sec. 17 & Fig. 7.
Button does not release when set-up knob is worked in or out.	Kickout spring set too far from kickout arm.	Section 35.
Visual tuning indicator off or flickers on and off. (This applies only to chassis with visual indicator wired to side switch. See section 14.) Automatic light off or flickers on and off.	Improper adjustment of side switch.	Section 15.
	Loose silver contact on contact blade.	
Mechanism locks up during setting up of a station.	Was not completely unlocked.	Section 30.
	Defective locking mechanism.	Section 32.
	Station selector cam sticking.	Section 32.
	Turning the set-up knob too suddenly.	Section 32.

MISCELLANEOUS TUNER TROUBLES

COMPLAINT	PROBABLE CAUSE	FOR REMEDY SEE
During automatic tuning visual tuning indicator light is on or flickers on and off. (Applies only to chassis with visual indicator wired to side switch. See section 14.)	Improper adjustment of side switch.	Sections 14 and 15.
	Loose silver contact in switch blade.	
Dial and automatic lights go out and set is killed momentarily when a button is pushed in or released.	Both reversing contacts on back switch closed at once and shorting 6 volt winding of power transformer.	Section 3a or 9a.
	Short operating arm of side switch grounding against friction roller assembly at point C.	Figure 5A.
Gears noisy during automatic tuning.	Motor pinion and first reduction gear not meshing properly.	Section 39.
	Too much compression in anti-backlash springs in gears.	Section 40.
	Burrs, bent teeth, and other irregularities on gears, especially the higher speed ones.	
Black ground lead near 6H6 tube under chassis heats up and smokes.	Short operating arm of side switch grounding against friction roller assembly at point C.	Figure 5A.
	A short between hot 6-V. line and chassis.	
	Tuning shaft bearing stop out of place and grounding power ~~blade~~ of side switch.	Section 48.
Slight hum when button is depressed - not heard when button is released.	Poor or defective discriminator tube.	Change discriminator (6H6) tube.
Short in wiring when turning set-up knob.	Tuning shaft bearing stop out of place grounds power blade of side switch.	Section 48.
Signals are heard when tuning from one station to another automatically.	Mute contact on back switch not closing or making poor contact.	Sections 4b or 10b.
Set noisy electrically when starting and stopping during automatic tuning.	Set used with insufficient antenna or mute contacts on back switch closing too late and opening too soon.	Reduce spacing between mute contacts on Back Switch. (Figure 4).
Mechanism reaches a definite stop before the pointer reaches either end of the dial.	The cam assembly stop pin and the gang condenser stops are not set so they reach their respective stop points at approximately the same time.	Section 51.
Band indicator hangs up when changing ranges.	Knot on band indicator cord jams against visual tuning indicator light bulb.	
	Torsion spring slipped out of place.	
	Link on range switch over dead center.	

ADJUSTMENT OF THE BACK SWITCH

THE SUCCESSFUL OPERATION OF THE ENTIRE MECHANISM DEPENDS TO A LARGE DEGREE ON THE CORRECT ADJUSTMENT OF THE BACK SWITCH: For this reason it is highly important that all contacts be set exactly right.

Two different types of Back Switches, and associated Bakelite Operating Cams, have been used. To determine whether the Switch is of the early or later type, notice the shape of the Bakelite Cam. The shape of the Bakelite Cam used on early units is shown in figure 1A; on later units it is shaped as in figure 1B. The various operating positions of the early type are shown in figures 1A, 2A, 3A and 4A. The positions of the later type are shown in figures 1B, 2B, 3B and 4B. Details of the correct settings for the early type are explained in sections 2 to 6. Details of the correct settings for the later type are explained in sections 8 to 12. MINOR ADJUSTMENTS OF THE BACK SWITCH TO SECURE THESE SETTINGS MAY BE MADE BY BENDING THE VARIOUS BLADES OF THE SWITCH.

EARLY TYPE BACK SWITCH

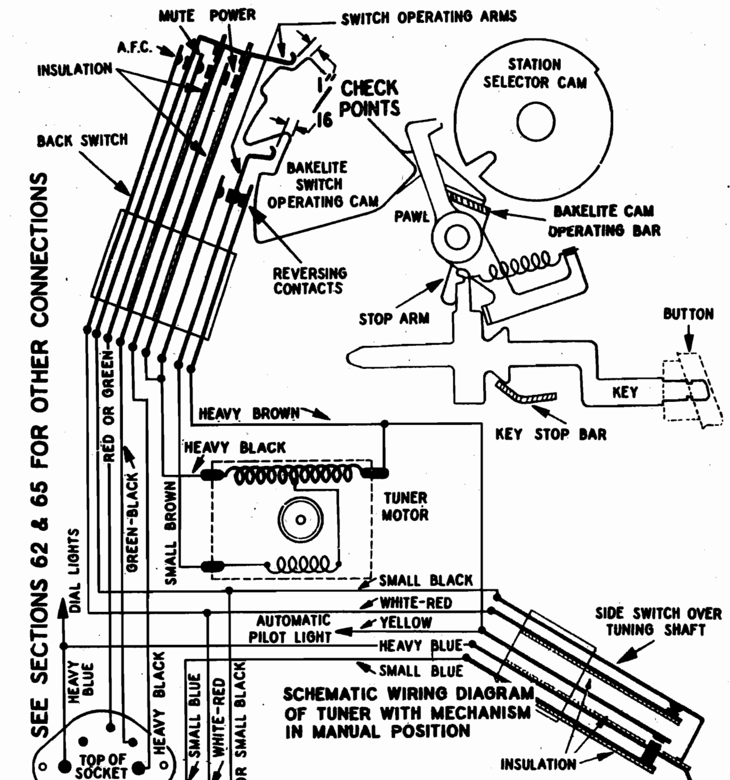
2 Run the dial pointer to 530 KC. Turn the power off. With the mechanism in the manual position, the Back Switch Operating Arms should clear the Bakelite Cam by the amounts indicated in figure 1A. Push any button so that the Pawl falls on the high side of the Station Selector Cam. The Reversing Contacts Operating Arm should clear the Bakelite Cam as indicated in figure 2A. IF THESE CLEARANCES ARE APPROXIMATELY CORRECT, PROCEED WITH SECTION 3. However, if the clearances are not as shown, slight discrepancies can be corrected by bending the Arms, but if the entire switch seems to be out of position, loosen the Bracket Mounting Screws (Figure 2A) and move the entire Back Switch assembly to give the proper clearances.

3 Release any depressed buttons. Move the Bakelite Cam up and down by hand to make sure that the Reversing Contacts make and break properly as follows. These are the three short switch blades nearest the Bakelite Cam.

a. With the Bakelite Cam down as in figure 2A, the center contact should make with the front contact, while with the Bakelite Cam pulled up as in figure 3A, the center contact should make with the Back Reversing Contact. After the instant of closing the blades should move slightly to show adequate contact pressure. IMPORTANT: Make sure that the center contact is not touching both the front and back contacts at any one time, since this may short circuit the 6-volt winding of the power transformer. If the Reversing Contacts do not make or break properly, bend the switch blades to secure proper operation.

b. With the dial pointer at 530 KC. push each button and make sure that the Reversing Contacts Operating Arm does not touch the Bakelite Cam. See figure 2A. The Pawl, in every case, should rest on the High Side of the Station Selector Cam.

c. Now pull out the Set-up Knob and run the pointer to the high frequency end of the dial by turning the Set-up Knob clockwise. Push each button to make sure that the center contact closes with the back Reversing contact. See figure 3A. In every case the Pawl should rest on the Low Side of its cam.

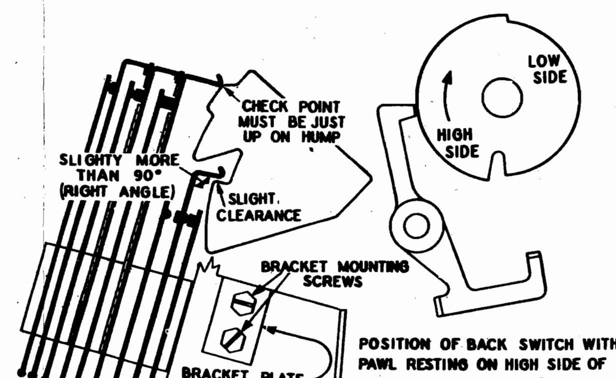


(EARLY TYPE BACK & SIDE SWITCHES)

FIG. 1A

a. The long Mute blade should barely hold the thin bakelite strip against the Power blade, and the long A.F.C. blade should barely hold the thin bakelite strip against the Mute blade.

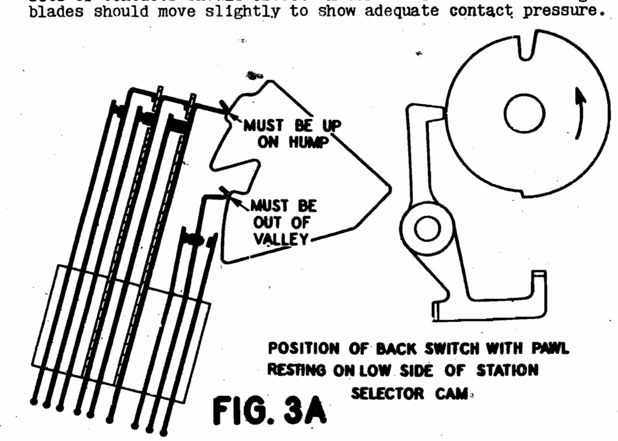
b. All three sets of contacts should be open approximately 1/64 to 1/32 of an inch. Move the Bakelite Cam up and down by hand and observe the action of the contacts. As the Bakelite Cam is moved up (to the position of figures 2A or 3A) all three sets of contacts should close. After the instant of closing the blades should move slightly to show adequate contact pressure.



POSITION OF BACK SWITCH WITH PAWL RESTING ON HIGH SIDE OF STATION SELECTOR CAM

FIG. 2A

4 Turn the Tuning Knob to release the depressed button. This puts the Bakelite Cam in the position shown in figure 1A. so the Power, Mute and A.F.C. contacts of the Back Switch can be checked as follows:

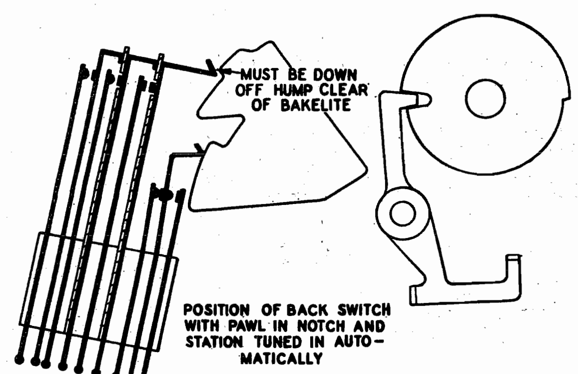


POSITION OF BACK SWITCH WITH PAWL RESTING ON LOW SIDE OF STATION SELECTOR CAM

FIG. 3A

5 To finish checking the setting; pull out the Set-up Knob, unlock the Cam Assembly by turning the Set-up Knob clockwise as far as it will go. A slight click should be heard as the mechanism is unlocked. Then proceed as follows:

a. Run the dial pointer to the low frequency end of the dial. Push any button so that the Pawl Falls on the High Side of the Station Selector Cam. The upper Back Switch Operating Arm should rest just up on the "Hump" of the Bakelite Cam, at the "Check Point" shown in figure 2A. If the Operating Arm is not in this position, bend the Arm slightly to secure such setting. If the Operating Arm is down off the "Hump", the Power, Mute or A.F.C. contacts may remain closed after a station is tuned in. If



POSITION OF BACK SWITCH WITH PAWL IN NOTCH AND STATION TUNED IN AUTOMATICALLY

FIG. 4A

the Operating Arm is farther up on the "Hump", the Power contacts may open and cut the power off befor the Pawl falls completely into the Notch.

b. Turn the Set-up Knob until the Pawl of the depressed button falls into the Notch on the Station Selector Cam. The Power, Mute and A.F.C. contacts should now be open at least 1/64 inch as shown in Figure 4A.

c. Repeat step 5a. with each of the other buttons then repeat step 5b. with each button. Due to slight variations in the Pawls, it may not be possible to adjust for all buttons so that the Back Switch Operating Arm comes exactly at the "Check Point" but make sure that the Power, Mute and A.F.C. contacts are open at least 1/64 of an inch for each button when the Pawl is in the Notch. Notice, too, that the bending of any switch blade or operating arm may throw out a preceding adjustment. For this reason it is well to check through the entire adjustment procedure a second time.

6 Lock up the Cam Assembly by turning the Set-up Knob as far counter-clockwise as possible. Turn on the power and check the operation of the unit.

REPLACING EARLY TYPE BACK SWITCH

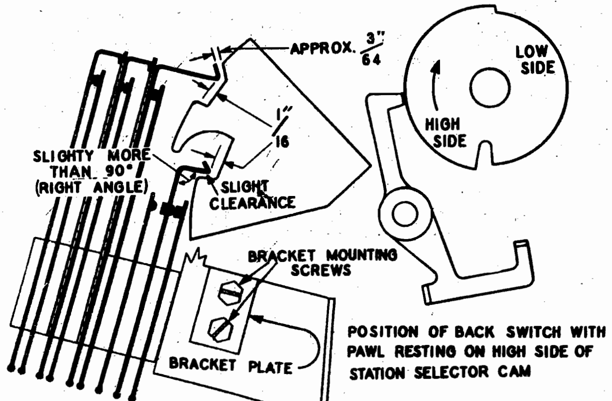
7 If it is necessary to replace the early type Back Switch with the later type, since we stock only the later type, part number 112564, it will also be necessary to change the Bakelite Cam to the later type, part number 112563. To make this change proceed as follows:

a. File off the two rivets holding the Bakelite Cam to its arm.

b. Put the new Cam in place and secure with two 6/32 machine screws.

c. Remove the two screws holding the Back Switch to its bracket and transfer the wires from the old switch to corresponding terminals on the new switch.

d. Fasten the new switch in place and adjust as described in sections 8 to 12.



POSITION OF BACK SWITCH WITH PAWL RESTING ON HIGH SIDE OF STATION SELECTOR CAM

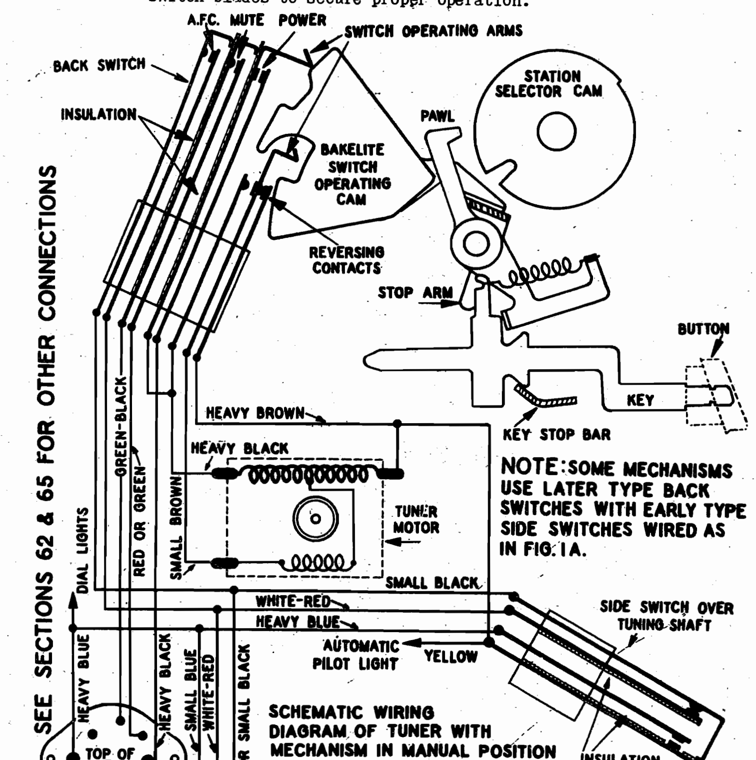
FIG. 2B

LATER TYPE BACK SWITCH

8 Run the dial pointer to 530 KC. Turn the power off. Push any button so that the Pawl falls on the High Side of the Station Selector Cam. The Back Switch Operating Arms should clear the Bakelite Cam by the amounts indicated in figure 2B. IF THE CLEARANCES ARE APPROXIMATELY CORRECT, PROCEED WITH SECTION 9. However, if the clearances are not as shown, slight discrepencies can be corrected by bending the Arms, but if the entire switch seems to be out of position, loosen the Bracket Mounting Screws (see figure 2B) and move the entire Back Switch assembly to give the proper clearances.

9 Move the Bakelite Cam up and down by hand to make sure that the Reversing Contacts make and break properly as follows. These are the three short switch blades nearest the Bakelite Cam.

a. With the Bakelite Cam down as in figure 2B, the center contact should make with the front contact, while with the Bakelite Cam pulled up as in figure 3B, the center contact should make with the back Reversing Contact. After the instant of closing the blades should move slightly to show adequate contact pressure. IMPORTANT: Make sure that the center contact is not touching both the front and back contacts at any one time, since this may short circuit the 6-volt winding of the power transformer. If the Reversing Contacts do not make or break, bend the switch blades to secure proper operation.



SCHEMATIC WIRING DIAGRAM OF TUNER WITH MECHANISM IN MANUAL POSITION (LATER TYPE BACK & SIDE SWITCHES)

FIG. 1B

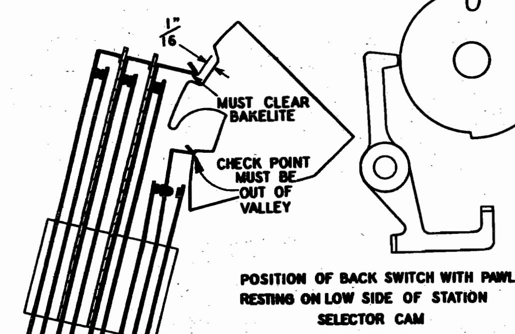
b. With the dial pointer at 530 KC. push each button and make sure that the Reversing Contacts Operating Arm does not touch the Bakelite Cam. See figure 2B. The Pawl, in every case, should rest on the High Side of the Station Selector Cam.

c. Now pull out the Set-up Knob and run the pointer to the high frequency end of the dial by turning the Set-up Knob clockwise. Push each button to make sure that the center contact closes with the back Reversing Contact. In every case the Pawl should rest on the Low Side of the cam. See figure 3B.

10 With the Pawl still resting on the Low Side of the Station/Selector Cam, the Power, Mute and A.F.C. contacts of the Back Switch are to be checked as follows:

a. Leave the Bakelite Cam in the Position of figure 3B. The long Mute blade should barely hold the thin bakelite strip against the Power blade, and the long A.F.C. blade should barely hold the thin bakelite strip against the Mute blade.

b. Move the Bakelite Cam up and down by hand and observe the action of the contacts. With the Bakelite Cam up as shown in figure 4B all three sets of contacts should be open approximately 1/32 of an inch. As the Bakelite Cam is moved down (to the position of figure 3B) all three sets of contacts should close. After the instant of closing the blades should move slightly to show adequate contact pressure.

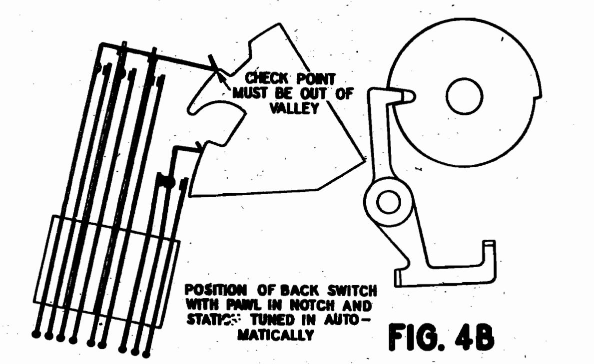


POSITION OF BACK SWITCH WITH PAWL RESTING ON LOW SIDE OF STATION SELECTOR CAM

FIG. 3B

11 To finish the checking Pull out the Set-up Knob. Unlock the Cam Assembly by turning the Set-up Knob clockwise as far as it will go. A slight click should be heard as the mechanism is unlocked. Then proceed as follows:

a. Push any button. Turn the Set-up Knob until the Pawl drops into the Notch on the Station Selector Cam. The upper Back Switch Operating Arm should rest just up out of the "Valley" on the Bakelite Cam (See "Check Point" on figure 4B), and



POSITION OF BACK SWITCH WITH PAWL IN NOTCH AND STATION TUNED IN AUTOMATICALLY

FIG. 4B

the Power, Mute and A.F.C. contacts should be open at least 1/32 of an inch. If the Operating Arm is not out of the "Valley" far enough to open the contacts properly, bend the Operating Arm down slightly. If the Operating Arm is farther out of the "Valley" than indicated by the "Check Point", the Power contacts may open and cut the power off before the Pawl falls completely into the Notch. If the Operating Arm does not come out of the "Valley" far enough, the Power, Mute or A.F.C. contacts may remain closed after a station is tuned in.

b. Repeat the above step for each of the other buttons. This is important. Due to slight variations in the Pawls, it may not be possible to adjust for all buttons so that the Back Switch Operating Arm comes exactly at the "Check Point" of figure 4B, but make sure that the Power, Mute and A.F.C. contacts are open at least 1/32 of an inch for each button, when the Pawl is in the Notch. Notice, too, that the bending of any switch blade or operating arm may throw out a preceding adjustment. For this reason it is well to check through the entire adjustment procedure a second time

12 Lock up the Cam Assembly by turning the Set-up Knob as far counter-clockwise as possible. Turn the power on and check the operation of the unit.

BAKELITE SWITCH OPERATING CAM

13 The Bakelite Cam may stick because of improper adjustment of the Back Switch. The clearances shown in figures 1A or 1B should be maintained. This prevents too much pressure by the Back Switch Operating Arms against the Bakelite Cam. See paragraph 4a or 10a. Other causes for the Bakelite Cam to stick are; rough edges on the Bakelite, and insufficient tension in the Bakelite Cam Return Spring (figure 13). Tension in the Return Spring may be increased, if found necessary, by simply cutting off a few turns and forming a new hook on the end.

The Stop Arm (figure 1B) on the bar carrying the Bakelite Cam, should hit against the Rubber Stop (figure 14). This keeps the Bakelite Cam from jumping too high and catching over the Reversing Contact Arm. If this Rubber Stop is missing, a couple of turns of friction tape around the shaft will serve the same purpose.

SIDE SWITCH ADJUSTMENT

14 There are two general types of Side Switches, namely the early type with five blades and the later type with only four blades. The Side Switch change was made after the Back Switch change, so that there are units equipped with the early Side Switch but with later type Back Switch.

The extra blade in the early Side Switch was used to switch the Visual Tuning Indicator light on during Manual tuning and off during Automatic Tuning. With the later Side Switch this light remains on during both Manual and Automatic tuning. In addition, with the later side switch the 6 volt line and Motor-Automatic light circuit wires were reversed. See figure 1A and 1B for circuit difference.

15 With the power off, adjust to secure the making and breaking of the contacts as illustrated. FOR EARLY TYPE SIDE SWITCH REFER TO FIGURES 5A, 6A AND 7A. FOR LATER TYPE SIDE SWITCH REFER TO FIGURES 5B, 6B and 7B. After the instant of closing the blades should move slightly to show adequate contact pressure. For some adjustments it may be better to bend the Long or Short Switch Operating Arms instead of the Switch blades.

FIG. 7A

MAGIC KEYBOARD
Clutch, Pawls, Cams, Keys
Cam lock, Bar and Arm

STEWART-WARNER CORP.

16 IT IS IMPORTANT THAT THE MOTOR CONTACTS ON THE SIDE SWITCH DO NOT CLOSE UNTIL AFTER THE REVERSING CONTACTS OF THE BACK SWITCH CLOSE. To secure such sequence of contact closing, the bakelite ring on the Friction Roller Assembly (figure 13) should not come farther forward, under the Short Operating Arm of the Side Switch, than shown at point B, figure 6. If loosening the Switch Mounting Screws does not permit enough movement of the switch to secure this positioning, it may be necessary to bend the Short Switch Operating Arm.

17 Care must be taken that the Automatic Frequency Control contacts on the Side Switch are open during automatic tuning and closed during manual tuning. If they are open when tuning manually the set will appear to tune broadly. The A.F.C. Contacts must be closed during setting up, or the Station Selector Cams may be set improperly. If the A.F.C. contacts do not open when tuning automatically, mistuning by the mechaanism will result in poor tone quality. In extreme cases of mistuning the station may not be heard at all.

18 When tuning automatically or during set-up, if the automatic Light does not come on and the Motor does not move or the Automatic Light flickers, bend the Side Switch blade, third from the top, down a little. If the blade is bend down too far the light will remain on all the time, even during manual tuning. Also the sequence of contact closing mentioned in section 16 will not be obtained.

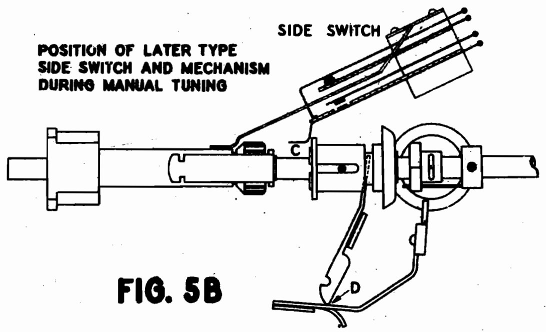

FIG. 5B

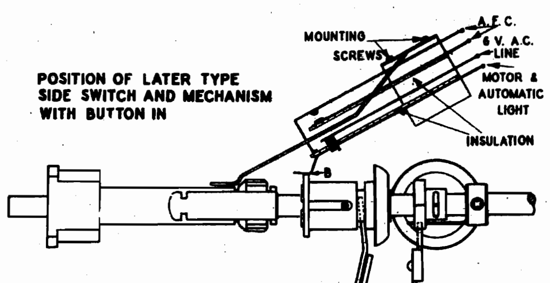

FIG. 6B

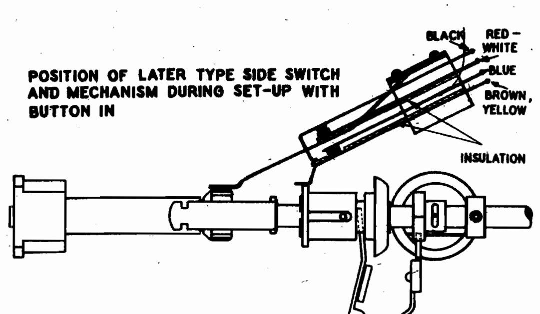

FIG. 7B

19 If the Visual Tuning Indicator Light flickers or goes out during set-up, when a button is pressed, the following may be the cause. The bakelite ring on the Friction Roller Assembly is probably lifting the Short Side Switch Operating Arm, causing it to open the Visual Tuning Indicator circuit. There should be a very slight clearance, about .01 of an inch, between the bakelite ring and the Operating Arm during set-up, with a button in, as shown in figure 7A. Either the end of the Long Switch Operating should be bent down, so it will press harder against the Set-up Gear, or the lifting hook (A, figure 7A) should be bent up slightly.

CLUTCH

20 The Clutch is purely a friction device. It is a standard anti-backlash gear held on a Collar by a flat, horseshoe shaped Spring Washer as shown in figure 8. The frictional resistance between Spring and Collar and the Gear normally can transmit enough power to drive the Cam Shaft, Dial Pointer and Gang Condenser. If an abnormal load is placed on the Clutch it should slip. If the Clutch becomes locked or stuck so it cannot slip when overloaded, other parts of the mechanism may be damaged because of the absence of the "shock absorber" action of the Clutch.

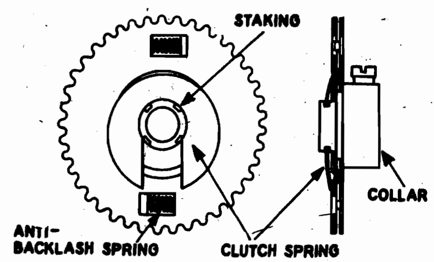

FIG. 8

21 THE CLUTCH MAY SLIP BECAUSE IT IS FULL OF OIL OR GREASE OR THE HORSESHOE SHAPED SPRING HAS CRACKED OR WEAKENED. If oil or grease is present, wash it off with carbon tetrachloride or similar cleaning fluid. The Spring can be slipped out and replaced without any dismantling of the mechanism. NOTICE THAT THE SET SCREW IN THE CLUTCH MUST BE SO POSITIONED, IF THE CLUTCH IS MOVED OR REPLACED, THAT IT WILL NOT JAM AGAINST THE SET-UP CROWN GEAR. Sometimes the Clutch may slip because the Pawl, although falling far enough into the Notch on its Station Selector Cam to prevent the shaft from rotating, does not fall far enough to operate the Back Switch and cut the power off. Check the Back Switch adjustment as outlined in sections 4 to 6 if an early type Back Switch is used, or sections 10 to 12 if the later type Back Switch is used. Also remove any rough edges from Pawl and Notch with emery cloth or a small oil stone.

22 OVERLOAD ON THE CLUTCH MAY ARISE FROM ANY <u>ONE OR COMBINATION</u> OF THE FOLLOWING CAUSES:

a. Binding of the Dial Pointer against the Dial, Dial Frame or cabinet, or rough, rusty or bent Dial Pointer Guide Rail.

b. Dial Pointer drive cable too tight.

c. Jammed or stuck dial cord guide pulley or pulleys.

d. Crossed dial cord on the Drum. Re-thread the dial cord correctly as shown in figure 11 and section 53.

e. Dial Cord Drum binding against Driver Gear or stuck on shaft.

f. The Pointer Driver Gear (figure 15) out of mesh and binding against the Drum Gear. Set Driver Gear to mesh with center of face of gear on Drum and check end play in Cam Shaft (See section 52.)

g. Misalignment or tight Cam Shaft Bearings. Loosen the screws holding the End Bearing Bracket (figures 10 and 15). Hold the Knurled Gears (figure 10) out of mesh by compressing the Flexible Coupling. Rotate the Cam Shaft back and forth a few times to permit the bearings to realign themselves. Then tighten the screws, taking care not to shift the Brackets while doing so. Be sure that both Right End Bearing Bracket Mounting Screws are tight, otherwise dial calibration cannot be maintained. Binding or tightness in the inner bearings is usually the result of sprung End Brackets, which should be straightened.

h. Cam Shaft sprung or bent. In most cases it will be necessary to replace the whole unit.

i. Collar on left end of Cam Shaft (figure 14) binding against Left End Bracket. Push the Cam Shaft as far to the left as it will go. Loosen the Collar Set Screw and reset the Collar so it will have from .006 to .010 of an inch clearance between it and the Left End Bracket.

j. Set-up Crown Gear assembly binding (Fig. 13).

k. Gang Condenser Drive Gears out of mesh and binding (figure 10).

l. Thrust Spring in Flexible Coupling compressed too much. The Thrust Spring should exert just enough pressure on the Condenser Drive Gears (Fig. 10) to prevent backlash.

m. Extension Shaft out of line and binding (Fig. 10).

n. Tight, jammed or sticking Gang Condenser.

If correcting the above conditions does not stop the Clutch from slipping replace the Clutch Spring, part number 111138. In extreme cases it may be necessary to replace the entire Clutch Assembly as indicated below.

23 TO REMOVE THE CLUTCH PROCEED AS FOLLOWS:
a. Remove the L shaped horizontal brace on the back of the Dial Frame. This is the part supported by the brackets screwed to the sides of the chassis.

b. Take the Side Switch Mounting Screws out and swing the switch out of the way.

c. Drive out the pin through the Friction Roller Assembly (Figure 13). Pull out the pin in the Star Wheel. Loosen the set screws in the Star Spring Collar and Flywheel. The Tuning Shaft can now be pulled out. (NOTE that there is a groove around the tuning shaft. The Set Screw of the Star Spring Collar fits into this groove, thus fixing the lateral position of the shaft with respect to the End Bracket.)

d. Take the Set-up Knob off. Remove the Tuning Shaft Bearing and pull the Sleeve and Set-up Gear out of the End Bracket.

e. Take the Retaining Ring off the Set-up Crown Gear Stud and remove the Crown Gear Assembly.

f. Remove the Right End Bearing and Bracket (Figure 10).

g. Take the Knurled Crown Gear off the Extension Shaft (Figure 10).

h. Loosen the Clutch Set Screw, disassemble the Clutch and slide the Collar and Gear Sections off the Cam Shaft to the right.

PAWLS

24 If a Pawl does not fall completely into the Notch on the Station Selector Cam, check the setting of the Back Switch. It is probable that the Power contacts are opening too soon. Notice that in order to fall into the Notch, the Pawl must work against the bar carrying the Bakelite Cam. Anything that makes this Bar operate hard should be corrected. See that the end of the Pawl and Notch on the Station Selector Cam are smooth and free from burrs. Then try closing up the Power contacts on the Back Switch a little more, but only after checking the above points. This may be done by bending the Power blade so the Power contacts are closer together, when the Bakelite Cam is in the position shown in figure 4. DO NOT CHANGE THE OUTLINE OF THE PAWL OR CAM NOTCH.

25 The Pawls can sometimes be made to jam when two Station Selector Cams are set to one station, especially if both Cams are not set exactly to the same frequency and an attempt is made to push one button, then the other button. The Motor will hum or the Clutch will slip until the button is released. What actually happens is this: When such a button is pushed that its Pawl, in falling directly into the Notch on the Station Selector Cam, binds against the high-side wall of the Notch, the Bakelite Cam assumes the position shown in figure 3. The Motor drives the Station Selector Cam tighter against the Pawl and prevents it from falling farther into the Notch. The jammed Pawl may be released by pushing another button and no damage is done. It is possible, with close adjustments of the Back Switch Contacts, to make the Pawls jam as indicated above even when they are set exactly to the same frequency. FOR THIS REASON THE SETTING OF TWO OR MORE BUTTONS TO ONE FREQUENCY ON DEMONSTRATOR SETS IS NOT RECOMMENDED AS GOOD PRACTICE

26 A similar condition may exist when the set is tuned to a station manually, and then the button set for that station is pushed.

STATION SELECTOR CAMS

27 The Cam Assembly is designed to operate through slightly less than 180°. The Cams though, can be rotated all the way around. Obviously then, it is possible to set a Cam so that its Notch will not pass under the Pawl. If a Cam were so set and the button pushed in, the Pointer would run to the end of the Dial and the Motor would continue to operate. This occurs because the Notch has not come around so the Pawl could fall in and cut the power off. TO CORRECT SUCH FAULT: Turn the power off. Pull out the Set-up Knob. Unlock the Cam Assembly by turning the Set-up Knob clockwise as far as it will go. A slight click should be heard as the mechanism is unlocked. Then push in the offending button. Rotate the Set-up Knob to run the Dial Pointer clear to the very end of the Dial in one direction then in the other. The Cam should now be in the proper position, ready to be set up to a station.

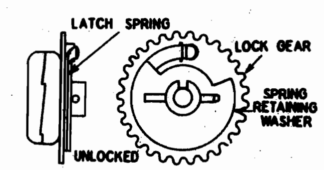
28 A similar condition is when a Cam is set to bring the Pointer to the very end of the Dial. The Pawl may lack just a very little bit of falling in far enough to cause the power to be cut off. Reset the Cam so the Pawl can fall in before the Cam Assembly Stop Pin (Figure 14) hits the stop.

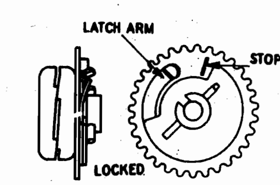
KEYS

29 It is quite unlikely that the Keys will require any adjustment. Their failure to work properly will usually be due to improper adjustment or operation of some other part or parts of the mechanism.

CAM ASSEMBLY LOCK

30 Refer to figure 9. The left saw-tooth section of the Lock, the Spring Retaining Washer and the Latch Spring are keyed to the Cam Shaft. The right saw-tooth section of the Lock and Lock Gear (Figure 13) are free to turn on the Cam Shaft, subject to certain limits. These limits are complete engagement of the teeth on the two sections of the Lock in one direction, and a stop on the Lock Gear in the other direction. Rotating the right half of the Lock counter-clockwise (by turning the Set-up Knob clockwise) will cause the two saw-tooth sections to assume the meshed or unlocked position shown in figure 9A. It should relieve the pressure on the Station Selector Cams and Friction Washers enough so that they can be turned on the Cam Shaft quite freely. In this position the flat Latch Spring Arm should be hooked over the Stop on the Lock Gear (Figure 9A). The Cam Assembly may then be rotated within its working range, by the use of the Set-up Knob, without causing the mechanism to lock up.





CAM ASSEMBLY LOCK

FIG. 9A FIG. 9B

31 The Cam Assembly will be locked up if the Set-up Knob is turned after the Cam Assembly Stop Pin (Figure 14) reaches the Back Stop on the Left End Bracket. This occurs because the Latch Arm slips over the Stop on the Lock Gear and permits expansion of the lock as shown in figure 9B. When fully unmeshed the lock has expanded about .030 of an inch. The stop on the Lock Gear would be against the stop portion of the Spring Retaining Washer, and only the tips of the teeth on the saw-tooth sections would be touching each other. The pressure exerted on the Station Selector Cams will depend upon the amount the saw-tooth sections are unmeshed. When unmeshed (locked up) as far as possible, with the Stop on the Lock Gear against the Stop on the Retaining Washer, if there is still insufficient pressure being exerted to keep the Station Selector Cams from slipping, proceed as follows: Unlock the Cam Assembly and slip a horseshoe shaped shim, about .01 on an inch thick, down between the left Station Selector Cam and the Bushing (Figure 14). Do not make this shim too thick or the mechanism will tend to lock up while attempting to set up stations.

32 Locking up of the mechanism during set-up may be due to a Station Selector Cam not turning freely enough because of dirt, grit, etc. between the Cams and the Friction Spacer Washers. This may also result from defective Latch parts or a quick sudden turn of the Set-up Knob. TO REMOVE THE LATCH SPRING OR THE LOCK GEAR, first remove the Clutch as outlined in section 23. Then remove the Reduction Gears. Unlock the Assembly and pull out the pin through the Cam Shaft, to the right of the Lock (Figure 14). The Retaining Washer, Latch Spring and Lock Gear may now be slid off the right end of the Cam Shaft.

BAR AND ARM ASSEMBLY

33 The lower end of the Arm should rest right on the "hump" of the Kickout as shown at D in figures 5, with the mechanism in the manual tuning position. If the adjustment is correct any movement of the Arm, either forward or backwards, should allow the Kickout Arm to rise. This setting can usually be secured by moving the Friction Wheel in or out on the Motor Shaft, thus sliding the Friction Roller Assembly (Figure 13) backward or forward on the Tuning Shaft. The amount of adjustment possible by this method is limited by the movement of the Friction Wheel possible without causing it to interfere with the

STEWART-WARNER CORP.

MAGIC KEYBOARD
Key Stop Bar, Kickout Arm
Star Wheel, Motor, Gears
Coupling, Motor Connections
Dial Mechanism

Star Wheel, or the Motor Pinion becoming disengaged from the First Reduction Gear. Further adjustment, if necessary, may be made by bending the Arm slightly, preferably at its upper end. THE ADJUSTMENT SHOULD NOT BE CARRIED OUT TO THE DETRIMENT OF THOSE ADJUSTMENTS REQUIRED FOR THE SIDE SWITCH AS INDICATED IN SECTIONS 16 AND 19.

KEY STOP BAR AND KICKOUT ARM

34 The Adjustable Tip on the Kickout Arm in engaging the Star Wheel (Figure 6) determines the position of the Key Stop Bar (Figures 1B and 13), which holds the buttons in. If the Tip on the Kickout is set too low, the Key Stop Bar swings up so far that the buttons are hard to release. If the Tip is set too high the buttons will not stay depressed, since the Key Stop Bar (Figure 1B) cannot come up far enough to catch and hold the keys in. Therefore, the Adjustable Tip on the Kickout Arm should be set as high as possible and still allow the buttons to stay in.

35 Failure of buttons to stay depressed may also be due to: the Kickout Spring (Figure 13) being bent down too far (it should clear the Kickout Arm by about 1/16 of an inch when the mechanism is in the automatic position); insufficient tension in the Return Spring on the Key Stop Bar; or the Key Stop Bar is sprung down in the middle. Also see section 37.

36 If a button will not release when another is pushed, the Key Stop Bar may be jammed or sprung, or held from normal movement by the Kickout Arm being caught on the Star Wheel; or a Pawl may be sticking in its Station Selector Cam.

STAR WHEEL

37 The Star Spring Collar (Figure 13) should be set so that the spring holds the Star Wheel in such position that the Pin is midway between the ends of the slot in the Star Wheel hub. At the same time the set screw in the Collar should be in the groove around the tuning shaft, to locate the tuning shaft in the End Bracket. Within the limits of movement allowed by the Slot and Pin, the Star Wheel should turn quite freely on the Tuning Shaft except as restrained by the Spring. Otherwise the Tip of the Kickout Arm may sometimes engage one of the points of the Star Wheel and hold the Key Stop Bar down, thus preventing the Key from catching and staying depressed. (Sections 34 to 36 and Figure 6.)

38 All edges and corners of the Star Wheel must be smooth and free from burrs. If not, the Tip of the Kickout Arm (Figure 13) may catch and prevent the buttons from staying in or being released.

MOTOR

39 The Motor is mounted on the Right End Bracket by two Mounting Screws (Figure 13) through oversize holes in the Bracket. The size of the holes permit adjusting the meshing of the Motor Pinion and the First Reduction Gear for minimum noise. Noisy operation may be caused by either too tight or too loose meshing of the Gears. Too tight meshing will also load up the drives because of binding. See section 49 for details on "Universal" type motor.

ANTI-BACKLASH GEARS

40 There are two types of Anti-backlash Gears used in the Mystic Mechanism. One type is made up of two spur gear sections and two small coil springs. Such gears are used in the gear reduction train driving the Cam Shaft (Figure 13), the Clutch (Figure 8) and the Pointer Drive Gear (Figure 15). The springs in these gears should be compressed by displacing the two gear sections one or two teeth with respect to each other. DISPLACEMENT OF THE GEAR SECTION FACING YOU SHOULD ALWAYS BE CLOCKWISE WITH RESPECT TO THE OTHER GEAR SECTION. Too little compression in the springs cause play and backlash. Too much compression causes binding, tending to load up the driver, and noisy operation. The First Reduction Gear (next to the motor pinion, Figure 13) uses light springs, part number 85815; the Second Reduction Gear (next to the Clutch, Figure 13) uses heavier springs, part number 112465; the Clutch and Pointer Drive Gear use still heavier springs, part number 89086. The correct displacement between sections of these gears, when equipped with the proper springs, should be not less than one nor more than two teeth.

41 The other type of gear is used to drive the Gang Condenser (Figure 10). The teeth of such gears are so shaped that, when the gears are kept tightly meshed together, backlash is prevented.

FLEXIBLE COUPLING

42 This device permits some misalignment of the Gang Condenser Shaft and the Extension Shaft (Figure 10), without causing binding in the bearings supporting the shafts. Inside of it is a coiled compression spring which keeps the Knurled Gears in mesh and prevents backlash. TO ADJUST THIS SPRING: Set the Coupling so the end of the Gang Condenser Shaft is flush with the inside edge of the back coupling collar. Tighten the set screw in the back coupling collar. Put the Knurled Gears in mesh, then compress the spring in the Coupling slightly and tighten the set screw in the front collar of the coupling. There now should be just enough thrust by the compressed coil spring to keep the Knurled Gears in mesh and free from backlash. If not, loosen the front set screw in the coupling, compress the spring a little more and retighten the set screw.

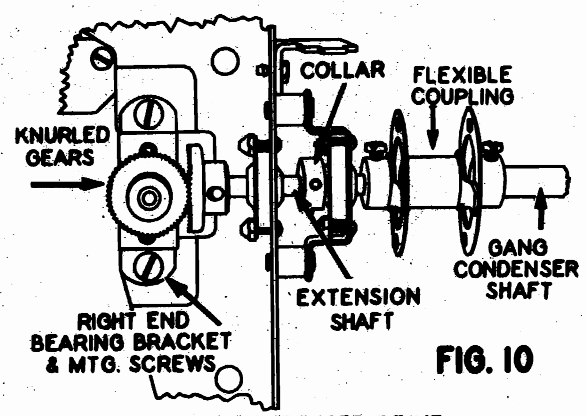


FIG. 10

GANG CONDENSER DRIVE

43 A few of the early chassis used a single section coupling. Later sets use a double section coupling, part number 112450, as shown in figure 10. This latter type is more flexible than the former and consequently, causes less binding when the Extension and Gang Condenser shafts are badly out of line. Only the later type is carried in stock. Therefore, if it is necessary to replace the older type, it will also be necessary to use Spring, part number 112490, and Extension Shaft, part number 112488, with the new coupling. Or in place of the new shaft, the old shaft may be used by cutting off 1/16 of an inch and chamfering the end like the piece which was cut off. The new shaft should be 2 3/16 inches long.

SETTING UP

44 THE FOLLOWING POINTS MUST BE OBSERVED DURING THE SETTING UP AND USE OF THE AUTOMATIC MECHANISM IF BEST RESULTS ARE TO BE OBTAINED.

ON MODELS 1865 AND 1866 THE TONE CONTROL BROADENS THE TUNING WHEN IN THE TREBLE POSITION, MAXIMUM CLOCKWISE, THEREFORE THIS POSITION POSITIVELY MUST NOT BE USED DURING SET-UP.

a. Use a GOOD antenna.

b. Allow the set to warm up for twenty minutes before setting it up.

c. Set up the buttons from left to right, that is, the right hand buttons should be the last to be set up.

d. Avoid setting buttons on weak or fading signals.

e. Tune carefully when setting up.

f. After a button is set up, do not push that button again until the mechanism is locked. To do so will spoil the setting of that button.

g. Lock up tight. Continue to force the Set-up Knob in a counter-clockwise direction even after it seems to reach a definite stop. If you do not use force, the settings of the buttons may change.

45 Detailed, illustrated instructions for setting up the Mystic Mechanism are included with each receiver. In brief, the setting up procedure is as follows:

a. Pull off the Tuning Knob. This reveals the Set-up Knob (Figure 13). Pull the Set-up Knob out. Unlock the mechanism by turning the Set-up Knob clockwise until a slight click is heard.

b. Push in a button. After the Pointer has stopped moving, grasp the Set-up Knob and tune in the station to which the button is to be set.

c. Push in another button. After the pointer has stopped moving, again grasp the Set-up Knob and tune in the Station to which this button is to be set.

d. Continue to push in buttons and tune in the stations until as many are set up as desired. Then release the last button set up, by pushing the Set-up Knob part way in.

e. Pull the Set-up Knob back out. Lock up the Cam Assembly by turning the Set-up Knob counter-clockwise as far as it will go. Continue to force the Set-up Knob in a counter-clockwise direction even after it seems to reach a definite stop. If you do not use force, the settings of the buttons may change.

f. Push in the Set-up Knob and replace the Tuning Knob.

46 Occasionally a unit may be encountered in which it is difficult to set up accurately, the extreme right hand buttons. In such case, they should be set to stations at the low frequency end of the dial, or used to locate short wave bands.

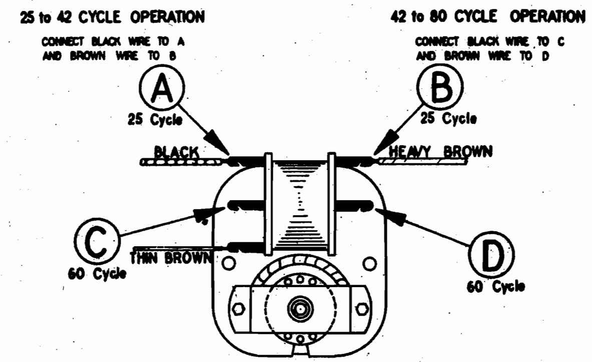
47 In case of complaint that a button set for some frequency, does not tune to that point within 10 K.C., or more, after locking up, it usually develops that the Station Selector Cam has inadvertently been moved before it was locked. This may come about by turning the Set-up Knob slightly when releasing the button, preparatory to locking the mechanism. Another possibility, if the Back Switch is not adjusted properly, is that by pushing a second button the motor will start before the pawl falls clear of the first cam, thus causing this cam to be shifted slightly before it is locked in place.

48 A short may occur in the unit due to the Tuning Shaft Bearing Stop (Figure 13) getting out of place. It then catches on the Set-up Gear. When the gear is turned counter-clockwise it forces the Bearing Stop against the hot blade of the Side Switch. Solder the Bearing Stop in place.

UNIVERSAL MODELS CONNECTIONS

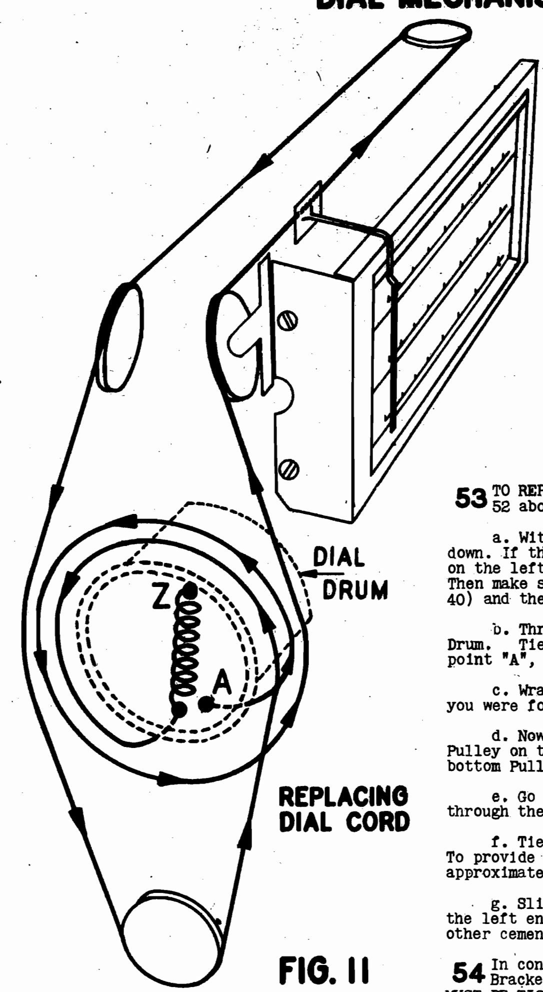
49 The tuner motor may not operate if the line voltage drops very much below 105 volts. The motor used in the 60 cycle models will only operate properly on 50 to 60 cycles. Special motors, used in the B and W models, can be connected for operation on other frequencies as shown below.

MOTOR CONNECTIONS FOR TUNER MOTOR USED ON 25-80 CYCLES UNIVERSAL MODELS.



50 The connections for the Reactance Dimmer, both standard 60 cycles, and universal 25 to 80 cycle types are shown on the various chassis service manuals.

DIAL MECHANISM AND CALIBRATION



REPLACING DIAL CORD

FIG. 11

51 The Cam Assembly Stop Pin, located on the left end of the Cam Assembly (Figure 14), allows approximately 180° of rotation of the Assembly and provides a strong, positive stop for the mechanism during locking and unlocking. It also protects the less rugged stops on the Gang Condenser. This Pin should strike the Stop just before the Gang Condenser is in full mesh or fully open. If it does not, to establish the correct relation between these two sets of stops: Loosen the set screw in the Knurled Condenser Drive Gear (Figures 10 and 15) on the Cam Shaft. Turn the Cam Assembly until the Stop Pin on it points to the back and is resting against the Stop on the Left End Bracket (Figure 14). Close the Gang Condenser to full mesh, then open it up just the least bit to relieve the Condenser Stop and tighten the set screw in the Knurled Gear. This allows the heavy Cam Assembly Stop Pin to reach its Stop first in each direction, since its working arc is slightly less than that of the Gang Condenser. See chassis service manual for complete calibration instructions.

52 The Knurled Gear (Figure 10) driving the Gang Condenser should be set on the Cam Shaft so that the center of its face engages the Crown Gear on the Extension Shaft. The dial Drive Gear, located on the left end of the Cam Shaft, (Figure 15) should engage the center of the face of the gear on the Dial Cord Drum. Check the end play in the Cam Shaft to see that these two sets of gears will not become unmeshed. If there is excessive end play in the Cam Shaft, move the collar (Figure 14) in closer to the Left End Bracket. There should be approximately .010 of an inch play between the Collar and Bracket.

53 TO REPLACE THE DIAL CORD: First check the points outlined in sections 51 and 52 above, then refer to figure 11 and proceed as follows:

a. With the Gang Condenser closed, the holes in the Dial Cord Drum should be down. If they are not, loosen the set screw in the Pointer Drive Gear (Figure 15) on the left end of the Cam Shaft, and rotate the Dial Cord Drum so that they are. Then make sure that the anti-backlash springs are compressed one tooth (section 40) and the gears are meshing properly before tightening the set screw.

b. Thread one end of the Dial Cord through the front hole of the two on the Drum. Tie a knot near the end of the inside of the Drum. This is the starting point "A", figure 11.

c. Wrap one and one quarter turns around the Drum counter-clockwise as though you were following the threads of a left hand screw.

d. Now go up over the front Pulley on the left end of the Dial; around the Pulley on the right end; over the back Pulley on the left end; down around the bottom Pulley and up to the front of the Drum.

e. Go around the Drum three quarters of a turn counter-clockwise and up through the back hole.

f. Tie the Tension Spring on and hook it over the hook on the Drum at "Z". To provide proper tension in the Dial Cord the extended spring should measure approximately 1 1/4 inch in length over all, when the Cord system is equalized.

g. Slip the Pointer clip under the Cord, set the Pointer at the last mark on the left end of the Dial Scale, close the clip and put on a drop of household or other cement on the Cord and clip junction.

54 In connection with Calibration, notice that movement of the Left End Bearing Bracket (Figure 15) changes the Pointer setting. BOTH SCREWS IN THIS BRACKET MUST BE TIGHT.

MAGIC KEYBOARD
A.F.C.and Mechanism Notes
Manual Tuning,Parts

STEWART-WARNER CORP.

CHECKING A.F.C.

55 In order to determine if the Automatic Frequency Control System is working, either of the following methods may be employed without removing the chassis from the cabinet.

a. Select a local station whose signal is fairly strong and which operates on a frequency below 1000 KC. Tune manually to a frequency slightly above that of the selected station, but close enough to the signal that it can be heard somewhat distorted.

b. Open the A.F.C. (two upper) contacts on the Side Switch, by reaching into the back of the set with a pointed stick and forcing the contacts apart.

c. A.F.C. should then pull the signal in clearly and hold it, while the contacts remain open.

d. Now tune below the station frequency a few KC. and open the A.F.C. contacts again. Again A.F.C. should pull the signal in clearly.

56 The same check on Automatic Frequency Control action can be made from the front of the set by proceeding as follows:

a. Pull off the Tuning Knob. Pull out the Set-up Knob. Unlock the mechanism by turning the Set-up Knob clockwise until a slight click is heard.

b. Push a button in. After the pointer stops, tune in a fairly strong station below 1000 KC. Then detune until the signal is somewhat distorted.

c. Now, push the Set-up Knob in and leave it in. This also releases the depressed button. Push the same button in again. This should open the A.F.C. contacts on the Side Switch, and allow A.F.C. to bring the signal in clearly.

d. Pull the Set-up Knob out. Push the same button in again. Detune the other side of the station and repeat paragraph c.

57 If Automatic Frequency Control does not appear to be working: First make sure that the A.F.C. contacts on the Back and Side Switches (Figure 1 to 7) are open when a station is tuned in automatically and that the A.F.C. contacts on the Side Switch are closed when tuning manually or setting up the mechanism. Then check the Discriminator, Control,R.F., Mixer, and I.F. tubes. Re-align the I.F., Broadcast and discriminator trimmers as explained in the chassis service manuals before attempting to locate a fault in the chassis.

MANUAL TUNING

58 There should be sufficient traction between the Friction Roller and the Friction Wheel (Figure 13) to provide positive movement of the mechanism when the Tuning Knob is turned, providing there is no mechanical overload in the system. If the Dial Pointer fails to move when tuning manually, first, try washing the Rubber Ring on the Friction Wheel with carbon tetrachloride, to remove any oil or grease. The traction between the Friction Roller and Friction Wheel may be increased slightly by sliding the Friction Wheel out farther on the Motor Shaft. The contact pressure between the Friction Wheel and Roller can be increased by shortening the Return Spring on the Bar and Arm Assembly (Figure 13). However, shortening this spring makes the buttons harder to push in.

59 Because of the exceptionally high tuning ratio used in this unit, the compounding effect on any slight lost motion is such that every precaution must be taken to keep backlash within satisfactory limits. Backlash will be at a minimum with proper adjustment of the various gears, as outlined in sections 40 and 41. Considerable lost motion will result if the Gang Condenser sways because of too loose mounting or because it turns too stiffly. Assuming the Clutch is in good working condition, it will only slip if mechanically overloaded.

60 In case of excessive Pointer backlash, check the following points; BOTH screws in the Left End Bearing Bracket must be tight. See that the Pointer Drive Gear(Figure 15) is not slipping on the Cam Shaft, that the anti-backlash springs in the gear are compressed at least one tooth, and that it does not slip out of mesh with the gear on the drum. The Dial Cord should be tight enough to extend the Tension Spring in the Drum so it measures about 1 1/4 inches long. See that the Pointer does not slip on the Cord and slides freely on the Guide Rail.

61 If the Tuning Shaft turns only a part of a revolution then catches, with a button depressed, it is probably due to burrs or rough edges on the Star Wheel or Adjustable Tip of the Kickout Arm (Figure 13). Or it may be that the buttons are too hard to push in, because of improper adjustment of the Kickout Arm tip. See sections 35 and 37.

CHANGING MECHANISM

62 The early production sets have the Mystic Mechanism wired directly to the chassis. Later sets are equipped with a socket and plug to facilitate removal of the mechanism. The socket on the later mechanism is mounted about four inches from the right end, and facing the rear, on the horizontal reinforcing member on the back of the Dial Assembly. It is connected in as shown in figures 1A or 1B, depending upon the type of Side Switch (See Section 14.)

63 To change the Mystic Mechanism and Dial Assembly, part number 112727, it is only necessary to unsolder the green and the green-black wires to the volume control, take the volume control off the bracket, slip the Visual Tuning Indicator Light socket off, pull the above mentioned plug, loosen the set screw in the Flexible Coupling (Figure 10) and take out the four screws holding the assembly to the chassis. If the assembly has no plug on it see section 65.

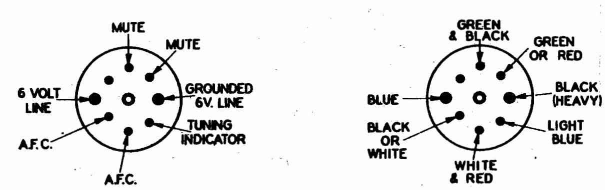
When installing the new Mystic Mechanism and Dial Assembly see section 51 for dial calibration instructions, and section 42 for information on adjusting the tension in the spring in the flexible coupling.

64 To change the Mystic Mechanism, part number 111350, only, it is necessary to remove the Dial Cord from the Drum (Figure 11), take out the four screws holding the two End Bearing Brackets to the frame, pull out the plug and take out the four screws holding the unit to the frame. The two front screws holding the unit to the frame can be reached by removing the second or third and the sixth or seventh button shells in the bottom row. If the unit has no plug on it see section 65.

When installing the new Mystic Mechanism, see section 22g for alignment of the End Bearings, sections 51 to 53 for restringing the dial cord and dial calibration, and section 42 for information on adjusting the tension in the spring in the flexible coupling.

65 If it is necessary to put one of the later mechanism, having the socket, on an early chassis, the Plug (Figure 12), part number 112736, must be wired to the chassis. The plug is provided with seven color coded wires of sufficient length to connect to the proper points on the under side of the chassis. Disconnect an old wire and connect the corresponding new wire, following the colors for identification, before disconnecting the next old wire. However, some of the cable wires may have a different color than the original chassis wires. Briefly the cable wires are:

Black (Heavy)	To grounded side of 6 volt winding of power transformer.
Blue (Heavy)	To other terminal of 6 volt winding of power transformer.
Light Blue	To one leg of the Reactance Dimmer Coil (The Visual Tuning Indicator Light is connected to the other leg.)
White - Red	On models R-184 and R-185 to A.V.C. cathode (the one with the white-green wire attached to it) of the 6H6 tube. On model R-186 to the ungrounded cathode of the discriminator (6H6) tube.
Small Black or White	On models R-184 and R-185 to other cathode of the 6H6 tube - the one with the brown wire attached to it. On model R-186 to ground.
Green - Black	On model R-184 to ground. On models R-185 and R-186 to one end of the audio input choke - the end connected to the control grid of one of the 6V6 output tubes with a green-black wire.
Green or Red	On model R-184 to the control grid of the 6L6 output tube. On models R-185 and R-186 to the other end of the audio input choke - the end connected to the control grid of the other 6V6 output tube with a green wire.



TOP VIEW OF PLUG

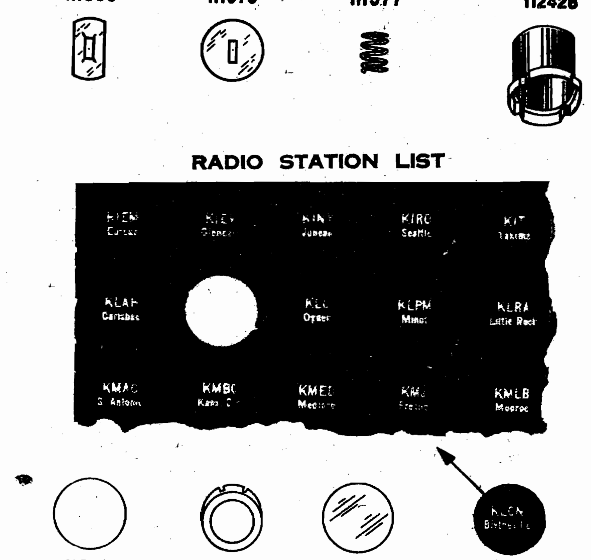
FIG. 12

SPECIAL TOOLS

66 A special spring adjuster tool, part number T117468, list price $0.75 may be obtained from the factory for adjusting the Back and Side switch blades, although a pair of duck-bill pliers or a screw driver can be used.

67 Wrenches can also be supplied by the factory for the fluted (Bristol) set screws used in various parts of the Mystic Mechanism. For the #6 (small) set screws, the wrench is part number 112483, and for the #8 (large) set screw, the wrench is part number 112484. These wrenches have a list price of 7 cents each.

PARTS LIST FOR MYSTIC MECHANISM



BUTTON RETAINING SPRING 111633 — BUTTON WASHER 111576 — BUTTON SPRING 111577 — BUTTON BODY 112428

BUTTON REINFORCING DISC 112547 — BUTTON CAP 112545 — BUTTON WINDOW 111878 — TABS,STATION CALL LETTERS 112005

Wherever the word "right" or "left" appears in the following list, it is understood that you are standing in front of the mechanism.

The Identification Numbers are to assist you in identifying parts shown on figures 13, 14 and 15 or to indicate in which figure the part can be seen. The identification is NOT TO BE USED in place of the part number, when ordering parts.

PART NUMBER	IDENTIFICATION NO.	DESCRIPTION	LIST PRICE
111591	1	Arm (long) - side switch operating	.05
111627	2	Bar & Arm Assembly	.60
111526	3	Bearing - on tuning shaft	.50
111176	4	Bracket - left end of mechanism	.20
111547	5	Bracket - with studs (right end of mechanism)	.90
111589	6	Bracket - push button escutcheon support	.08

PRICES SUBJECT TO CHANGE WITHOUT NOTICE.

PART NUMBER	IDENTIFICATION NO.	DESCRIPTION	LIST PRICE
111162	7	Bushing - left end of cam shaft	.18

DIAL MECHANISM AND MISCELLANEOUS PARTS LIST

Wherever the word "right" or "left" appears in the following list, it is understood that you are standing in front of the mechanism. The Identification Numbers are to assist you in identifying parts shown in figures 13, 14 and 15 or to indicate in which figure the part can be seen. The identification is NOT TO BE USED in place of the part number, when ordering parts.

PART NUMBER	IDENTIFICATION NO.	DESCRIPTION	LIST PRICE
111930		Band Indicator - and frame assembly	.40
111894	39	Bearing Assembly - self aligning, on right end of cam shaft and supports gang extension shaft	.40
111601		Bearing - self aligning	.12
111692		Bearing Retainer - plate, copper	.06
112558		Belt - for range switch drive	.06
111261		Bolt - chassis mtg. (#14 X 1-1/4)	.03
88831		Bracket - for range switch support (under chassis)	.02
111630	40	Bracket & Pulley - for band indicator cord	.10
111893	41	Bracket & Mounting Plate - for mystic mechanism	3.10
111894	39	Bracket & Bearing - right side of shaft	.40
111899	42	Bracket & Bearing - left side of shaft	.70
111260		Bushing - rubber (for chassis mtg.)	.06
111892		Bushing - rubber, mystic mechanism mtg. to chassis	.02
111658		Clip - for pulley retaining	.01
110762		Cord - for band indicator (2 ft. required) Per ft.	.04
111302		Cord - dial drive (6 ft. lengths)	.30
111864	43	Dial Drum - with gear	.50
111226		Escutcheon - for dial (with glass)	3.00
111227		Escutcheon - around push button opening	1.20
111690		Felt - oil wick for bearing	.05
112450		Flexible Coupling - with set screws	.80
111865		Frame - dial, with scale	2.50
111608	44	Gear - right end of cam shaft drives gang condenser	.20
111629	45	Gear - dial drive (left end of cam shaft)	.52
111631	44	Gear - crown, on extension gang shaft	.36
111496		Knob - tuning or volume	.20
111497		Knob - range or tone	.20
111197		Lever - for band indicator (on shaft)	.12
111370		Link & Lever - for range switch drive (used in early production)	.20
112633		Plug - for mechanism connecting (8 prong)	.20
112736		Plug and cable - for mechanism connecting	.75
111859		Pointer - for dial, with slider	.18
111622	46	Pulley - dial cord drive	.35
111630		Pulley & Bracket - for band indicator	.10
112628		Pulley - on range switch shaft under chassis	.20
84214		Retaining Ring - for dial drum	.02
89837		Retaining Spring - for holding escutcheon to cabinet	.01
111222		Scale - dial	1.20
110716		Screw - band indicator pivot (shaft)	.03
111116		Screw - #5 X 5/8, mystic mechanism mtg.	.02
85827		Set Screw - 8/32 square head	.02
111403		Set Screw - 8/32 fluted head	.12
112138		Set Screw - 8/32 slotted head	.03
110716		Shaft, band indicator	.03
112488		Shaft - extension (between gang condenser & unit) - Figure 10	.20
111373		Shaft - for range switch	.08
85427		Socket - octal base	.15
110501		Socket - 4 prong (for speaker)	.16
110627		Socket - dial lamp & automatic lamp	.12
111008		Socket - reactance dimmer lamp	.12
112630		Socket & Bracket - for electrical connections to mech.	.75
111090		Spacer - steel, mystic mechanism mtg. to chassis	.02
111570		Spacer - rubber, for mystic mechanism mtg. to chassis	.02
T117468		Spring Bender - (switch adjusting tool)	.75
89086		Spring - between sections of dial drive gear left side of mechanism	.01
111232		Spring - torsion for band indicator	.05
111862		Spring - drive cord tension- Fig. 11	.03
112490		Spring - in flexible coupling	.02
111676		Stud - lower left idler pulley	.10
112667		Stud - for pulley mtg. (for top pulleys)	.10
112005		Tabs - station call letters (6 sheets)	.60
84412		Terminal Strip - phono (model 186-P only)	.03
85066		Terminal Strip - G.D.A.	.20
89709		Terminal Strip - phono (for model 186-W only)	.15
112483		Wrench - for #6 fluted set screw	.07
112484		Wrench - for #8 fluted set screw	.07

CIRCUIT DESCRIPTION

The No. 150 Receiver is a twelve tube, "Adjustable High Fidelity" receiver employing metal tubes, including the new "Beam" power tubes. There are five tuning ranges in this receiver, one of which is the Ultra-Short Wave range. This range is also referred to as the Ultra-High Frequency (U. H. F.) range and also as the "D" band. This receiver uses a Carpinchoe high fidelity dynamic speaker, and has incorporated in it the exclusive "Patent Applied For" Stromberg-Carlson "Tri-Focal" tuning system and the exclusive Stromberg-Carlson "Acoustical Laboratories" revolutionary new development, the "Acoustical Labyrinth". This new device extends the bass response, provides reproduction only from the front of the cabinet, and eliminates all cabinet resonance. Audio reproduction is further improved in this receiver by employing sound diffusing vanes in front of the loud speaker opening which distribute the higher pitched tones, thereby providing excellent reproduction in all parts of the room by spreading out these directional frequencies.

Maximum selectivity between adjacent stations located in the standard broadcast band is obtained by the use of an additional tuned radio frequency ("Bi-resonator") circuit. When either the "X", "B", "C", or "D" ranges are in operation, this additional tuned radio frequency circuit is automatically cut out of the receiver circuit. Adjustable high fidelity is obtained from this receiver by means of the variable band width, intermediate frequency transformers which are used in the two intermediate amplifier stages.

The No. 160 Radio Receiver is a fourteen tube, "Adjustable High Fidelity" receiver employing metal tubes, including the new "Beam" power tubes. There are five tuning ranges in this receiver, one of which is the Ultra-Short Wave range. This range is also referred to as the Ultra-High Frequency (U. H. F.) range and also as the "D" band. This receiver uses a Carpinchoe high fidelity dynamic speaker, and has incorporated in it the exclusive "Patent Applied for", Stromberg-Carlson "Tri-Focal" tuning system and the exclusive Stromberg-Carlson Acoustical Laboratories' revolutionary new development, the "Acoustical Labyrinth". This new device extends the bass response, provides reproduction only from the front of the cabinet, and eliminates all cabinet resonance. Audio reproduction is further improved in this receiver by employing sound diffusing vanes in front of the loud speaker opening which distribute the higher pitched tones, thereby providing excellent reproduction in all parts of the room by spreading out these directional frequencies.

This receiver is also equipped with an "automatic tone control" circuit, which operates automatically to reduce the high frequency noise which is present when the receiver is tuned to weak signals. The tube which operates in this automatic tone control circuit is indicated on the schematic wiring diagram.

In addition to the above features, the No. 160-P Receiver is furnished with a highly efficient "Automatic Record Changer" Phonograph Unit, which is equipped with an entirely new type of pick-up suspension device.

Maximum selectivity between adjacent stations located in the standard broadcast band is obtained by the use of an additional tuned radio frequency ("Bi-resonator") circuit. When either the "X", "B", "C", or "D" ranges are in operation, this additional tuned radio frequency circuit is automatically cut out of the receiver circuit.

Adjustable high fidelity is obtained from this receiver by means of the variable band width, intermediate frequency transformers which are used in the two intermediate stages.

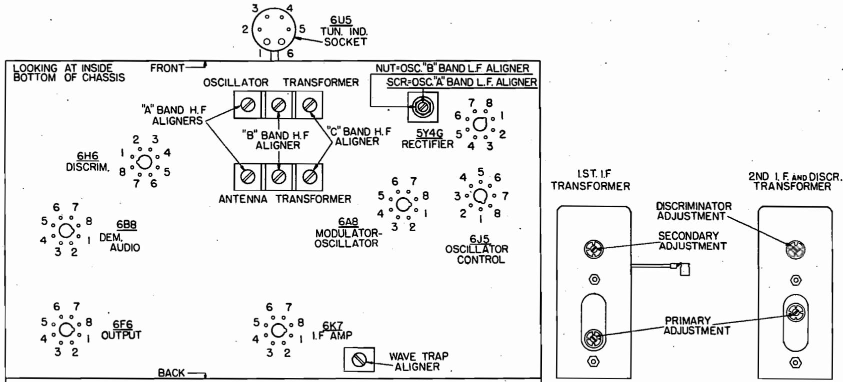
Socket, Trimmers
Voltage, Alignment



Terminal Layout for Voltage Measurement Chart and Location of the Aligning Adjustments for the R. F., I. F. and Discriminator Circuits.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: O-2.5, O-10, O-100, O-250, O-500, O-1000 volts except when an asterisk appears after any given voltage value in which the 250 volt scale was used.

			Terminals of Sockets								Heater Voltages Between Heater Terminals

Speaker Socket		—	+340	0	0	+340	+340	0	+300	—		

A. C. voltages are indicated by italics. Receiver tuned to 1000 Kc., no signal

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the procedure given in these instructions should be carefully followed. The preferred method of aligning these receivers is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

To accurately align circuits in these receivers, it is necessary to use a high grade signal generator capable of being modulated 30% and having an output voltage of at least 100,000 microvolts; it will also be necessary to have this output voltage controlled so that only a few microvolts may be fed into the receiver. In conjunction with the signal generator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker. In addition to this equipment, it will be necessary when making a final adjustment of the "Discriminator" tuned circuit to use a milliammeter having a range of 0 to 10 milliamperes connected in series with the cathode of the 6J5 oscillator control tube by means of an adaptor plug inserted between the tube and its socket. The leads to the meter should not be longer than 15", and should be shunted at the socket connections by a capacitor of not less than 0.25 Mfd.

In order to make the aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-27657 and P-27658 aligning tools be used.

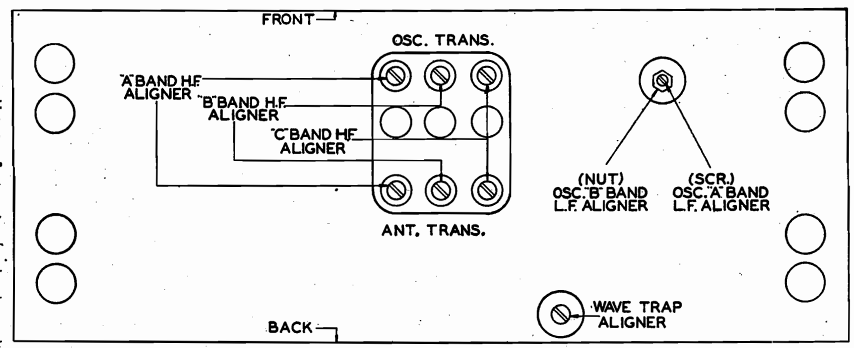
Before proceeding with the alignment of any circuits in these receivers, except when specifically directed, be sure that the "Signal Admission Control" is set for the maximum sensitivity position, and that the "Manual-Electric" control knob is set to the "Off" position. The "Off-On-Tone" control should also be set for the "Normal" position. In making any alignment adjustments always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained, except when specifically directed in these instructions. Figures Nos. 1 and 2, show the location of all the aligning capacitors or adjustments for this receiver. It will not be necessary to remove the chassis in this receiver from its cabinet in order to make any alignment adjustments. The alignment adjustments for the Intermediate Frequency circuits are accessible from the rear of the receiver, and the adjustments for the Radio Frequency circuits are accessible through apertures located in the bottom metal base plate of the chassis. These apertures are easily accessible through the bottom of the cabinet shelf. **Never align any of these receivers without having the metal base plate fastened to the chassis base.**

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Rapid Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve of these stages, it is recommended that unless it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system



View Through Chassis Mounting Shelf Showing Adjusting Screws for R. F. Aligning Capacitors.

which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed.

1. Operate the Range Switch of the receiver to the Standard Broadcast range position and set the tuning dial to its extreme low frequency position. Set the "Manual-Electric" control knob to the "Manual" position, and the "Off-On-Tone" control knob to its normal position.

   CAUTION: Never attempt to align the R. F. or I. F. circuits of this receiver with the "Manual-Electric" control knob set at the "Electric" position unless specifically directed in the following paragraphs. Also, do not make any aligning adjustments of the R. F., I. F., or "Discriminator" circuits with the A. F. C. switch (which is located on rear of the chassis base) set at the "set-up" position.

2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 465 kilocycles from the signal generator, using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or the ground binding post.

3. Now, noting from Fig. 1, the alignment adjustments for the First and Second I. F. transformers, align the I. F. circuits in the following order:

MODELS 235H, 235HB
235L, 235LB

STROMBERG-CARLSON TEL. MFG. CO.

Alignment, Phono. Tuner Adjustments

Adjust the Second I. F. transformer primary circuit for maximum output.

Adjust the First I. F. transformer primary circuit for maximum output.

Adjust the First I. F. transformer secondary circuit for maximum output.

Carefully make all of the above adjustments, watching carefully the output meter so that the peak reading is obtained for each adjustment. As each adjustment is made reduce the output of the test oscillator as required.

4. To adjust the Discriminator circuit proceed as follows:

Check the position of the "Manual-Electric" control knob which should be set to the "Manual" position.

CAUTION: **Before adjusting this circuit be sure that the I. F. amplifier is tuned exactly to 465 kilocycles.** With the signal generator still set at a frequency of 465 kilocycles, adjust the signal generator's output control so that a signal of 50,000 to 100,000 microvolts is fed into the No. 6A8 modulator-oscillator tube. Now, observe the reading of the milliammeter which is connected in series with the cathode of the No. 6J5 oscillator control tube, and rotate the "Manual-Electric" control knob to the "Electric" position, observing whether there is any difference in the reading of the milliammeter. When this circuit is correctly adjusted, there should be no difference in the reading of the milliammeter when the "Manual-Electric" control knob is rotated from the "Manual" to the "Electric" position. If there is any difference in the milliammeter reading while rotating this control knob from the "Manual" to the "Electric" position, and vice versa, adjust the "Discriminator" circuit by means of the screw adjustment located on the 2nd I. F.—Discriminator transformer until the meter reading has the same value regardless of whether the "Manual-Electric" control knob is rotated to the "Manual" or "Electric" position. When this condition is obtained, the Discriminator circuit is properly adjusted.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, the "Manual-Electric" control knob should be rotated to the "Manual" position, and the "Off-On-Tone" control knob should also be set for "Normal" operation.

Alignment of Short Wave Range (Also Referred to as "C" Band)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "C" range position, and set the test oscillator's frequency and the receiver's tuning dial to 17 megacycles.
2. Adjust the oscillator's "C" band high frequency aligner for maximum output.
3. Adjust the antenna's "C" band high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Medium Wave Range (Also Referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the "B" range position, and set the test oscillator's frequency and the receiver's tuning dial to 5 megacycles.
2. Adjust the oscillator's "B" band high frequency aligner for maximum output.
3. Adjust the antenna's "B" band high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Set the test oscillator's frequency and the receiver's tuning dial to 1.8 megacycles.
5. Adjust the oscillator's "B" band low frequency aligner (series aligner), and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
6. Reset both the test oscillator's frequency and the receiver's tuning dial to 5 megacycles and repeat operations Nos. 2 and 3.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbone type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. **Operate the Range Switch to the "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.4 megacycles.**
2. **Adjust the oscillator's "A" band high frequency aligner for maximum output.**
3. **Adjust the antenna's "A" band high frequency aligner for maximum output.**
4. **Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.**
5. **Adjust the oscillator's "A" band low frequency aligner (series aligner) for maximum output and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.**
6. **Reset both the test oscillator's frequency and receiver's tuning dial to 1.4 megacycles and repeat operations Nos. 2 and 3.**

Wave Trap Adjustment

In adjusting the wave trap circuit, the "Signal Admission Control" should be set for the most sensitive position (shaft rotated in the most counter-clockwise direction). Set the Range Switch of the receiver to the "A" range position, the tuning dial to 1000 kilocycles, and the "Manual-Electric" control knob to the "Manual" position. Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, 465 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

PROCEDURE FOR OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

In order to obtain reproduction of phonograph records in conjunction with the No. 235 Receiver, the following instructions should be followed.

To equip these receivers for phonograph operation, it will be necessary to purchase and install in the receiver a Stromberg-Carlson, P 28120 Switch Assembly. The rear of the chassis base of these receivers is already drilled for mounting this switch assembly. Complete instructions on how to install and operate this switch are furnished with each P-28120 Switch Assembly.

To obtain the best quality of phonograph reproduction when using an electric pick-up and phonograph unit with this receiver, a Stromberg-Carlson, No. 10 Record Player is recommended This record player is equipped with a correctly designed single record playing motor unit, and uses a crystal type pick-up in conjunction with a specially equalized circuit.

If the Stromberg-Carlson No. 10 Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a low capacity shielded cable between the three-prong socket mounted in the P-28120 Switch Assembly and the pick-up. This shielded cable should be of the low capacity type, in order to prevent excessive cutting of high frequencies which is caused when a shielded cable having high capacity is used. The length of the shielded cable used should be kept as short as possible.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong socket mounted in the P-28120 Switch Assembly, and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

INSTRUCTIONS FOR SETTING UP ELECTRIC TUNING ARRANGEMENT

1. **Before proceeding to set-up the stations for electric tuning, the radio receiver should be turned "on" for approximately twenty to thirty minutes.**
2. **Set the Range switch control knob to the proper position for the "Broadcast" range (arrow pointing in direction of "Cream" dot).**
3. **Remove the list of station letters from the P-28781 package assembly which is tacked inside of the cabinet.**
4. **Remove the two screws which hold the escutcheon plate to the front panel.**
5. **Remove from the escutcheon frame the strip of transparent material and the strip of paper on which the six stars are printed.**
6. **Remove the tuning indicator unit from its normal operating position.**

   IMPORTANT: Always use the tuning indicator unit when setting up stations for electric tuning, in order to determine when resonance with the desired station is obtained.
7. **From the lists of stations, remove the call letters of the six stations which it is desired to set up for electric tuning. These six stations should preferably be selected and set-up in the daytime so that the best service will be obtained at all times.**

   CAUTION: Each button adjustment for electric tuning has assigned frequency limits. These limits are designated for each adjustment on the rear plate which covers the tuning adjustments and are visible when looking at the rear of the receiver. See Figure 5. The six stations should be selected so that the frequency of each station will be within the frequency limits assigned to one of the buttons.

   It will be noted that the station letters are printed on partly cut squares to facilitate ease in removing the desired station letters. In setting up these six favorite stations, the following order should be followed: Looking at the front of the receiver, the call letters of the station having the highest frequency should appear in the farthest left-hand square of the escutcheon frame, and then in successive order according to frequency the call letters of the remaining stations should be inserted into the other frames; the call letters of the station having the lowest frequency being inserted in the farthest right-hand square of the escutcheon frame. After the six station call letters have been inserted into the escutcheon frame, the transparent strip should be replaced over the station call letters, and the escutcheon plate then fastened into position by means of the two screws. The tuning adjustments for the six favorite stations can now be made starting with the station having the highest frequency and proceeding as follows:
8. **IMPORTANT. By the aid of a screwdriver, rotate the slotted shaft of the "A. F. C." switch, which is located on the rear of the chassis base, so that the slotted shaft points in the direction of the word, "Set-up" (maximum clockwise rotation). See Figure 5.**

STROMBERG-CARLSON TEL. MFG. CO.

MODELS 235H, 235HB
235L, 235LB
Tuner Adjustments
Parts List

9. Rotate the knob marked "Manual-Electric" (located on the front panel of the receiver) so that the arrow points in the direction of the word "Manual" and tune the receiver in the conventional manner by means of the station selector knobs to the station having the highest frequency (of the six selected stations) and note carefully the program which it is broadcasting. Then rotate the knob marked "Manual-Electric" so that the arrow points in the direction of the word "Electric".

10. Push the farthest left-hand button (looking at the front of the receiver) which should be the button for the station having the highest frequency provided the frequency of the station is within the designated frequency limits of the tuning adjustments for this button. See Figure 5. Then, looking at the rear of the receiver, rotate the screw of the oscillator tuning adjustment which is designated 1560 to 1000 kilocycles to the position where the desired station is received. In order to check whether the program being received is from the desired station, simply rotate the "Manual-Electric" control to the "Manual" position, and with the receiver tuned in "Manually" to the desired station a quick check can be made; then, rotate the "Manual-Electric" control knob back to the "Electric" position. Exact resonance with the desired station should be obtained by observing the tuning indicator. When this adjustment has properly been made, the screw of the antenna tuning adjustment designated 1560 to 1000 kilocycles should be rotated to the position where maximum indication is again obtained on the tuning indicator tube. When these adjustments have been properly made the station having the highest frequency is correctly set-up for Electric Tuning by means of the push button.

11. Now proceed to set-up the remaining five stations in the same manner as mentioned in Pargraphs, 9 and 10 above, proceeding according to the frequency of the remaining stations.

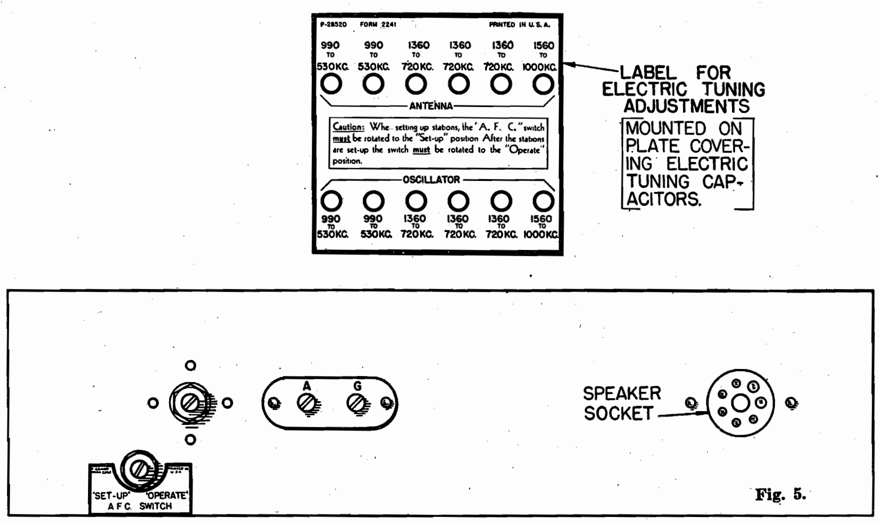


Fig. 5.

12. IMPORTANT: When all of the adjustments have properly been made for the six desired stations, the slotted shaft of the "A. F. C." switch, located on the rear of the chassis base, should be rotated so that the slotted shaft points in the direction of the word. "Operate" (maximum counter-clockwise rotation). With the electric tuning system in operation, the receiver will be automatically kept in tune with any one of the six favorite stations as long as the station is operating or provided it has no unusual fading characteristics. If a distant station which is very weak is set up in the electric tuning unit, it will be found that the automatic frequency control circuit will not hold this station if a strong signal is present in either adjacent channel. This same phenomenon will occur if two stations in adjacent channels are almost of equal signal strength with the weakest signal fading slightly; with this condition the strong signal will have a tendency to "pull in" when the receiver is tuned to the station which is slightly weaker and fading.

13. The tuning indicator unit should now be replaced in its proper operating position. Before placing this unit in its proper location, make sure that the tuning indicator tube is fully inserted into its accompanying socket.

REPLACEMENT PARTS

Piece Number	Schematic Circuit Designation	Part
18696	R36, R37	Resistor, Type "B", 10,000 Ohms
23517		Socket, 7 Prong
24166	C53	Capacitor, Type "O", 25 Mmfd.
24268		Cord (Power Supply)
24402	C7, C22, C51	Capacitor, .1 Mfd.
24405	C5, C21, C28, C31, C37, C44	Capacitor, .04 Mfd.

Frequency of Intermediate Amplifier ---------- 465 Kilocycles

The No. 240 Receivers are eleven tube "Adjustable High Fidelity" receivers employing metal tubes. These receivers have three tuning ranges, the frequency limits of each range being listed under the "Electrical Specifications." In order to obtain maximum performance on the Standard Broadcast Range ("A" Range) of these receivers, a "signal admission control switch" is provided. This control is located on the inside rear flange of the chassis base, and has a slotted shaft which protrudes through the base so that it may be adjusted by the use of a screwdriver. When either the "B" or "C" ranges are in operation, this "signal admission control" is automatically cut out of the circuit, allowing the receiver to function at its maximum sensitivity on these two ranges. When operating in the Standard Broadcast Range, maximum sensitivity is obtained when the slotted shaft of this control is rotated to its maximum counter-clockwise position. To properly set this control, place the receiver in operation and then adjust this control so that clearest reception is obtained. The control should remain in this position. Do not readjust this control for each frequency. The above adjustment should be made in the evening if best results are to be obtained.

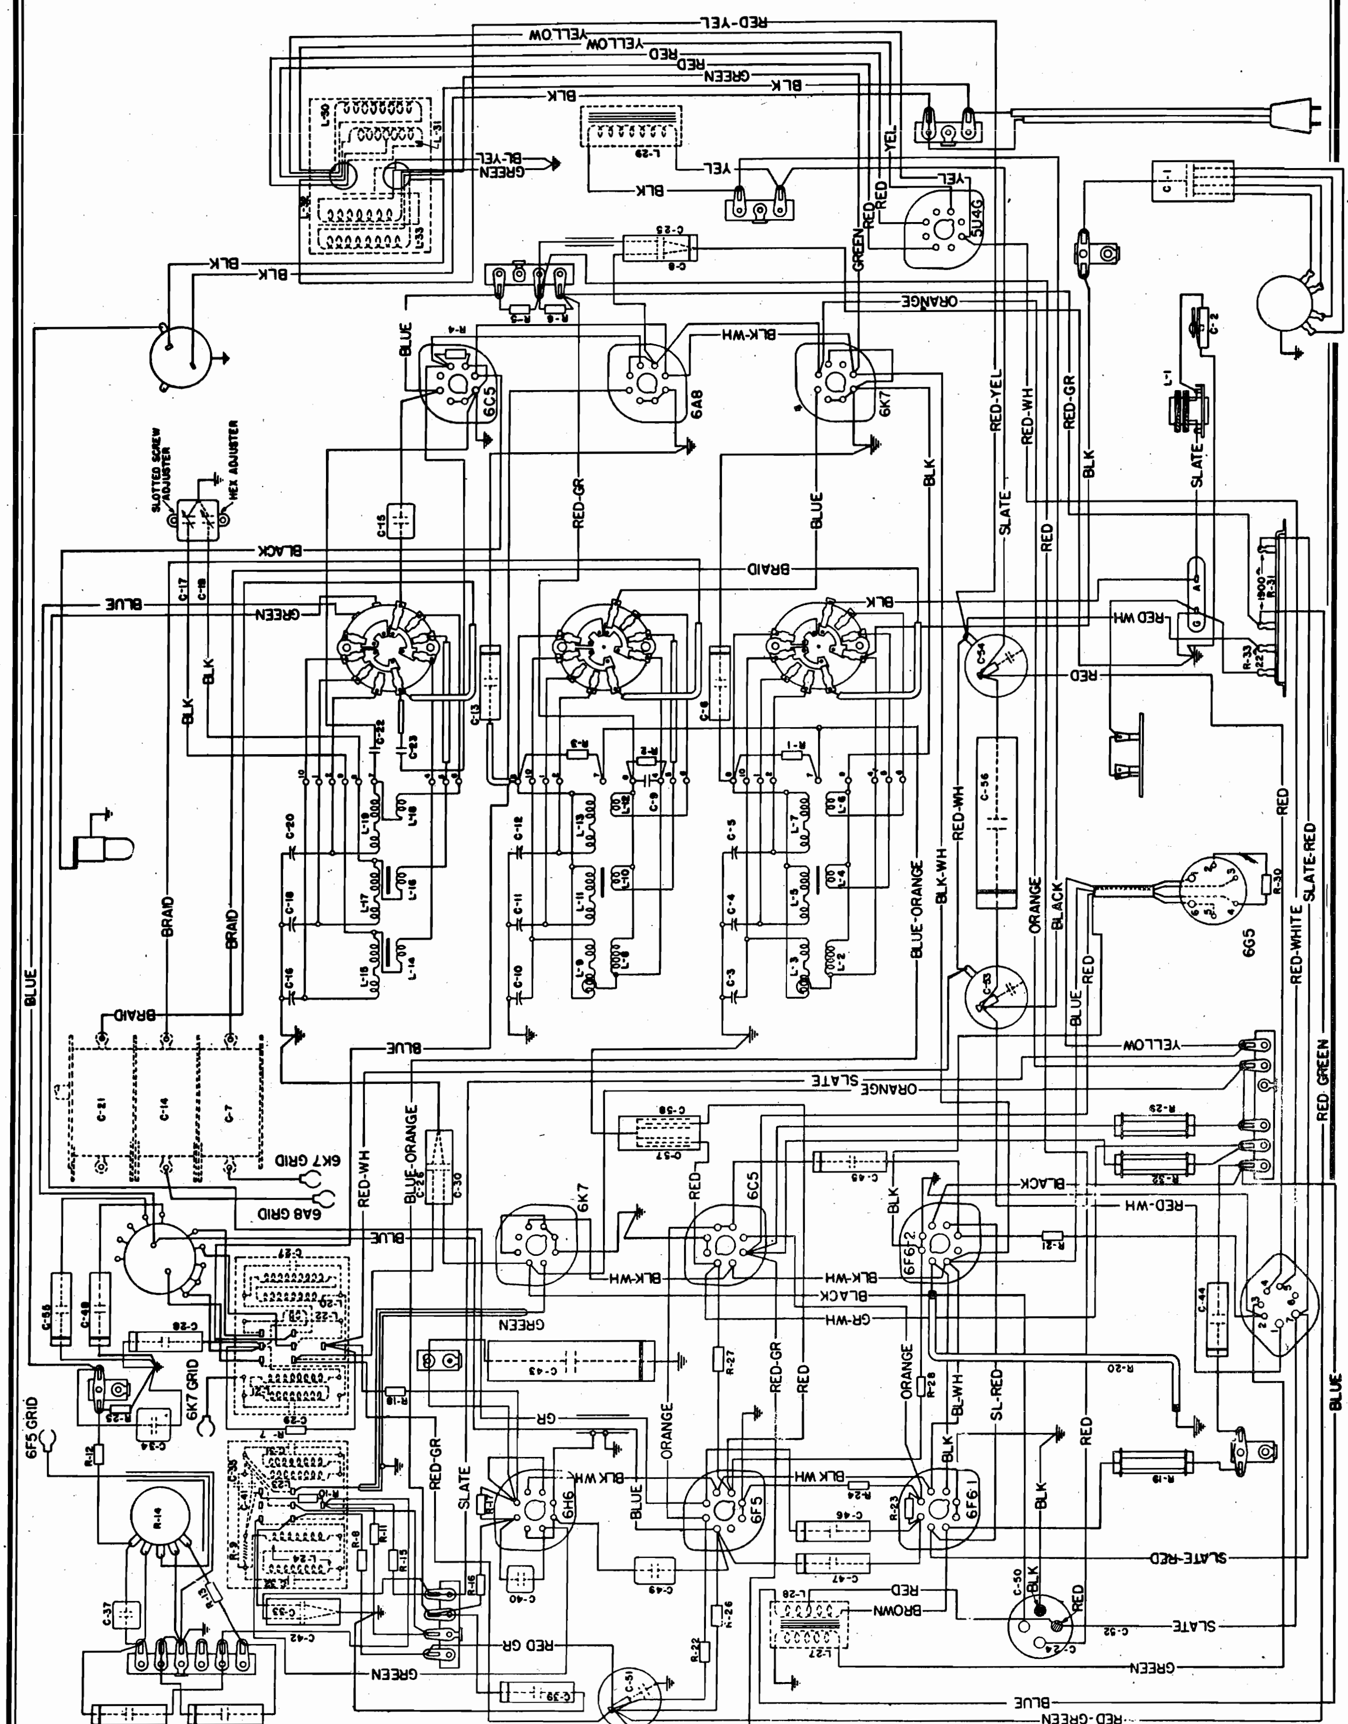

Fig. 4. Wiring Diagram, No. 240 Receiver

STROMBERG-CARLSON TEL. MFG. CO.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: O-2.5, O-10, O-100, O-250, O-500, O-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

			Terminals of Sockets								*Heater Voltages Between Heater Terminals*

STROMBERG-CARLSON TEL. MFG. CO.

When reception conditions warrant, the fidelity of this receiver can be increased by rotating the "Tone-Fidelity" switch control knob in a clockwise rotation from the normal position of this control. High Fidelity reproduction is obtained in two steps from the normal position of this control. These receivers are also provided with a low level bass frequency compensating circuit in conjunction with the volume control circuit, so that balanced reproduction is obtained for any setting of the volume control.

A metal guard frame is furnished on these receivers to prevent damage to the chassis components and also to facilitate ease of servicing should this become necessary. Do not turn the chassis over on its guard frame without first removing the tuning indicator unit which is secured to the metal guard frame. To remove the tuning indicator unit from the guard frame, first unscrew the knurled screw which holds the tuning indicator's clamp to the metal guard frame, which will then allow the tuning indicator unit to be removed from the guard frame.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the alignment procedure given in the following paragraphs should be carefully followed. In order to make these aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-27657 and P-27658 aligning tools be used.

To accurately align the circuits in these receivers, it is necessary to use a high grade, modulated test oscillator (Signal Generator), the output voltage of which can be varied. In conjunction with this test oscillator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker.

In making any alignment adjustments, always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained. Never attempt to make any alignment adjustments using a strong signal. Before proceeding with the alignment of any circuits in these receivers be sure that the "Signal Admission Control" is set for the maximum sensitivity position and that the "Fidelity" control knob is set for the "normal" position. The "Off-On-Bass" control knob should also be set for the normal position. Figure 1 shows the location of all the aligning capacitors or adjustments for this receiver.

It will not be necessary to remove the chassis in these receivers from their cabinets in order to make any alignment adjustments. The alignment adjustments for the intermediate frequency circuits are accessible from the rear of the receiver, and the adjustments for the radio frequency circuits are accessible through the apertures located in the bottom metal base plate of the chassis; these apertures are easily accessible either through the bottom of the cabinet or through the bottom of the cabinet shelf, depending upon the particular style of cabinet. See Figure 2. Never align any of these receivers without having the metal base plate fastened to the chassis base.

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Rapid Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

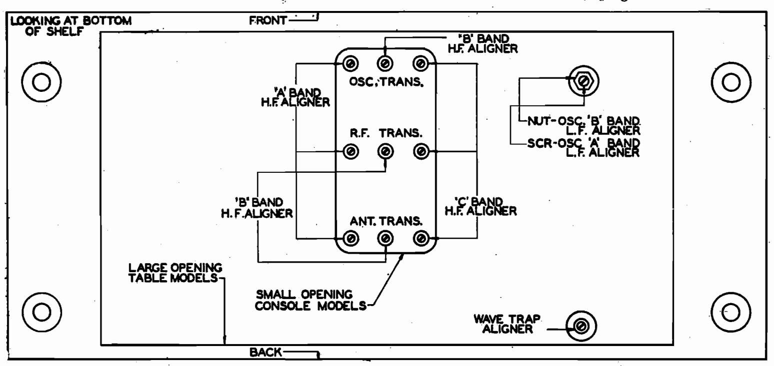

Fig. 2. View Through Chassis Mounting Shelf Showing Adjusting Screws for R. F. Aligning Capacitors.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve of these stages in a high fidelity receiver, it is recommended that unless it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed.

1. Operate the Range Switch of the receiver to the "A" range position and set the tuning dial to its extreme low frequency position. Set the "Fidelity" control knob to its "Normal" position, and the "Off-On-Bass" control knob to its normal position. **Never attempt to align the I. F. circuits of this receiver with the "Fidelity" control set at any position other than the "Normal" fidelity position.** Rotate the Volume Control knob to its maximum clockwise position (maximum volume).
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator tube, a modulated signal of 465 kilocycles from the test oscillator, using a 0.1 microfarad capacitor in series with the connection between the output terminal of the test oscillator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the test cillator should be connected to either the chassis base or the ground binding post terminal.
3. Now, noting from Figure 1 the aligning adjustments for the first and second I. F. transformers, align the I. F. circuits in the following manner:
   Secondary of second I. F. transformer.
   Primary of second I. F. transformer.
   Secondary of first I. F. transformer.
   Primary of first I. F. transformer.
   Adjusting the circuits to obtain maximum reading on the output meter, reducing the output of the test oscillator as required.

Radio Frequency Adjustments

The alignment of the radio frequency circuits of the various ranges in these receivers should be very carefully made and in the order specified.

Alignment of Short Wave Range (Also Referred to as "C" Band)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "C" range position, and set the test oscillator's frequency and the receiver's tuning dial to 16 megacycles.
2. Adjust the oscillator's "C" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "C" band high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Adjust the antenna's "C" band high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Aircraft, Amateur, and Police Range (Also Referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the "B" range position, and set the test oscillator's frequency and the receiver's tuning dial to 5 megacycles.
2. Adjust the oscillator's "B" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "B" band high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Adjust the antenna's "B" band high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
5. Set the test oscillator's frequency and the receiver's tuning dial to 1.8 megacycles.
6. Adjust the oscillator's "B" band low frequency aligner (series aligner), and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and the receiver's tuning dial to 5 megacycles and repeat operations Nos. 2, 3 and 4.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Operate the Range Switch to the "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the oscillator's "A" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "A" band high frequency aligner for maximum output.
4. Adjust the antenna's "A" band high frequency aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
6. Adjust the oscillator's "A" band low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2, 3 and 4.

Wave Trap Adjustment

In adjusting the wave trap circuit, the "Signal Admission Control" should be set for the most sensitive position (shaft rotated in the most counter-clockwise direction). Set the Range Switch of the receiver to the "A" range position and the tuning dial to 1000 kilocycles. Connect a 200-micro-microfarad capacitor in series with the output terminal of the modulated test oscillator and the antenna binding post on the receiver, and the ground terminal of the test oscillator to the ground binding post on the receiver. Then, with the modulated test oscillator set at the frequency of the intermediate amplifier, 465 kilocycles, supply a fairly strong signal to the receiver and adjust the wave trap aligner until a minimum indication is obtained on the output meter.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: O-2.5, O-10, O-100, O-250, O-500, O-1000 volts except when an asterisk appears after any given voltage value, in which case the 250 volt scale was used.

ALIGNMENT DATA

All alignment adjustments are accurately made at the factory on these receivers, and ordinarily no readjustments are necessary. However, should it become necessary to make any readjustments, the procedure given in these instructions should be carefully followed. The preferred method of aligning these receivers is by the use of a suitable cathode ray oscillograph and frequency modulator unit in conjunction with the standard signal generator.

To accurately align circuits in these receivers, it is necessary to use a high grade signal generator capable of being modulated 30% and having an output voltage of at least 100,000 microvolts; it will also be necessary to have this output voltage controlled so that only a few microvolts may be fed into the receiver. In conjunction with the signal generator, a sensitive output meter should be used for determining the maximum signal voltage developed across the voice coil of the loud speaker. In addition to this equipment, it will be necessary when making a final adjustment of the "Discriminator" tuned circuit to use a milliammeter having a range of 0 to 10 milliamperes connected in series with the cathode of the No. 6J5 oscillator control tube by means of an adaptor plug inserted between the tube and its socket. The leads to the meter should not be longer than 15", and should be shunted at the socket connections by a capacitor of not less than 0.25 Mfd.

In order to make the aligning adjustments in an easy and satisfactory manner, it is recommended that the Stromberg-Carlson P-27657 and P-27658 aligning tools be used.

Before proceeding with the alignment of any circuits in these receivers, except when specifically directed, be sure that the "Signal Admission Control" is set for the maximum sensitivity position, that the Fidelity Control knob is set for the "Normal" position and that the "Manual-Electric" control knob is set to the "Off" position. The "Off-On-Bass" control should also be set for the "Normal" position. In making any alignment adjustments always adjust the test oscillator's output voltage to the minimum value where a good alignment may still be obtained, except when specifically directed in these instructions. Figures Nos. 1 and 2, show the location of all the aligning capacitors or adjustments for this receiver. It will not be necessary to remove the chassis in this receiver from its cabinet in order to make any alignment adjustments. The alignment adjustments for the Intermediate Frequency circuits are accessible from the rear of the receiver, and the adjustments for the Radio Frequency circuits are accessible through the apertures located in the bottom metal base plate of the chassis. These apertures are easily accessible through the bottom of the cabinet shelf. Never align any of these receivers without having the metal base plate fastened to the chassis base.

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Rapid Station Selector" knob in a clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

Intermediate Frequency Adjustments

The intermediate frequency used in these receivers is 465 kilocycles. Because of the necessity of obtaining the proper shape of resonance curve of these stages in a high fidelity receiver, it is recommended that unless it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason

Alignment, Part 2
Tuner, Parts

STROMBERG-CARLSON TEL. MFG. CO.

it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed.

1. Operate the Range Switch of the receiver to the Standard Broadcast range position and set the tuning dial to its extreme low frequency position. Set the Fidelity control knob to its "Normal" position, the "Manual-Electric" control knob to the "Manual" position, and the "Off-On-Bass" control knob to its normal position.

   CAUTION: Never attempt to align the R. F. or I. F. circuits of this receiver with the Fidelity control knob set at any position other than the "Normal" position and the "Manual-Electric" control knob set at the "Electric" position unless specifically directed in the following paragraphs. Also, do not make any aligning adjustments of the R. F., I. F., or "Discriminator" circuits with the A. F. C. switch (which is located on rear of the chassis base) set at the "set-up" position. See Fig. 5.
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6A8 modulator-oscillator tube, a modulated signal of 465 kilocycles from the signal generator, using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6A8 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or the ground binding post.
3. Now, noting from Fig. 1, the alignment adjustments for the First and Second I. F. transformers, align the I. F. circuits in the following order:

   Adjust the Second I. F. transformer primary circuit for maximum output.

   Adjust the Second I. F. transformer secondary circuit for maximum output.

   Adjust the First I. F. transformer primary circuit for maximum output.

   Adjust the First I. F. transformer secondary circuit for maximum output.

   Carefully make all of the above adjustments, watching carefully the output meter so that the peak reading is obtained for each adjustment. As each adjustment is made reduce the output of the test oscillator as required.
4. To adjust the Discriminator circuit proceed as follows:

   Check the position of the "Manual-Electric" control knob which should be set to the "Manual" position. CAUTION: Before adjusting this circuit be sure that the I. F. amplifier is tuned exactly to 465 kilocycles. With the signal generator still set at a frequency of 465 kilocycles, adjust the signal generator's output control so that a signal of 50,000 to 100,000 microvolts is fed into the No. 6A8 modulator-oscillator tube. Now, observe the reading of the milliammeter which is connected in series with the cathode of the No. 6J5 oscillator control tube, and rotate the "Manual-Electric" control knob to the "Electric" position, observing whether there is any difference in the reading of the milliammeter. When this circuit is correctly adjusted, there should be no difference in the reading of the milliammeter when the "Manual-Electric" control knob is rotated from the "Manual" to the "Electric" position. If there is any difference in the milliammeter reading while rotating this control knob from the "Manual" to the "Electric" position and vice versa, adjust the "Discriminator" circuit by means of the screw adjustment located on the top of the Discriminator transformer until the meter reading has the same value regardless of whether the "Manual-Electric" control knob is rotated to the "Manual" or "Electric" position. When this condition is obtained, the Discriminator circuit is properly adjusted.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, the "Manual-Electric" control knob should be rotated to the "Manual" position, the Fidelity Control knob should be set for "Normal" operation, and the "Off-On-Bass" control knob should also be set for "Normal" operation.

Alignment of Short Wave Range (Also Referred to as "C" Band)

In aligning the radio frequency circuits for this range, replace the 0.1-microfarad capacitor which was placed in series with the test oscillator's output lead for the I. F. alignments, with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post located on the rear of the receiver chassis. The ground terminal (or low side) of the test oscillator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "C" range position, and set the test oscillator's frequency and the receiver's tuning dial to 18 megacycles.
2. Adjust the oscillator's "C" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "C" band high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Adjust the antenna's "C" band high frequency aligner for maximum output, at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.

Alignment of Medium Wave Range (Also Referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminal of the test oscillator as was used for aligning the short-wave range.

1. Operate the Range Switch on the receiver chassis to the "B" range position, and set the test oscillator's frequency and the receiver's tuning dial to 5 megacycles.
2. Adjust the oscillator's "B" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "B" band high frequency aligner for maximum output and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
4. Adjust the antenna's "B" band high frequency aligner for maximum output, and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
5. Set the test oscillator's frequency and the receiver's tuning dial to 1.8 megacycles.
6. Adjust the oscillator's "B" band low frequency aligner (series aligner), and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and the receiver's tuning dial to 5 megacycles and repeat operations Nos. 2, 3 and 4.

Alignment of Standard Broadcast Range (Also Referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm carbon type resistor in series with the test oscillator's output lead with a 200-micro-microfarad capacitor and align these circuits as follows:

1. Operate the Range Switch to the "A" range position and set the test oscillator's frequency and the receiver's tuning dial to 1.5 megacycles.
2. Adjust the oscillator's "A" band high frequency aligner for maximum output.
3. Adjust the R. F. interstage "A" band high frequency aligner for maximum output.
4. Adjust the antenna's "A" band high frequency aligner for maximum output.
5. Set the test oscillator's frequency and the receiver's tuning dial to 0.6 megacycles.
6. Adjust the oscillator's "A" band low frequency aligner (series aligner) for maximum output, and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum output is obtained.
7. Reset both the test oscillator's frequency and receiver's tuning dial to 1.5 megacycles and repeat operations Nos. 2, 3 and 4.

PROCEDURE FOR OBTAINING REPRODUCTION FROM PHONOGRAPH RECORDS

A socket having three contacts is provided on the rear of the chassis base of the No. 260-L Receiver, and is wired to the "Off-On-Bass-Phonograph" switch assembly located on the front of the receiver. A three prong plug is also inserted in the socket so that if at any time it is desired to use an electric pick-up and phonograph unit in conjunction with this receiver, it may readily be accomplished.

In order to obtain the best quality of phonograph reproduction when using an electric pick-up and phonograph unit with this receiver, a Stromberg-Carlson No. 10 Record Player is recommended. This record player is equipped with a correctly designed single record playing motor unit, and uses a crystal type pick-up in conjunction with a specially equalized circuit. To attach this instrument to a No. 260-L Receiver, it is only necessary to remove the three-prong plug furnished with the receiver and insert the three-prong plug which comes with the unit into the three-prong socket located on the rear of the chassis base. Then, the power supply plug of the phonograph unit should be inserted into a suitable power supply receptacle, and the unit will be ready for use.

If the Stromberg-Carlson No. 10 Record Player is not used and the electric pick-up to be used is of the high impedance type, it will be necessary to connect a low capacity shielded cable between the three-prong plug furnished with the receiver and the pick-up. This shielded cable should be of the low capacity type, in order to prevent the excessive cutting of high frequencies which is caused when a shielded cable having high capacity is used. The length of the shielded cable used should be kept as short as possible.

If a pick-up of the low impedance type is used, it will be necessary to connect a "matching transformer" between the three-prong plug and the pick-up. The transformer should be located as near to the receiver as possible, in which case it will not be necessary to use a shielded cable.

NORMAL VOLTAGE READINGS

The various values of voltages listed in the following table are obtained by measuring between the various tube socket contacts and the chassis base, with the tubes in their respective sockets. The receiver is, therefore, in operation when the measurements are made. Figure 1, shows the terminal layout of the sockets with the proper terminal numbers.

Tube	Circuit	Cap	*Terminals of Sockets* 1	2	3	4	5	6	7	8	*Heater Voltages Between Heater Terminals* Socket Terminal Numbers	Volts

A. C. voltages are indicated by italics. Receiver tuned to 1000 kc., no signal.

Voltages are given for a line voltage of 120 volts, and allowance should be made for differences when the line voltage is higher or lower. A meter having a resistance of 1000 ohms per volt should be used for measuring the D. C. Voltages. Voltage values shown are those obtained on the lowest possible scale of a meter having the following ranges: 0-2.5, 0-10, 0-100, 0-250, 0-500, 0-1000 volts except when an asterisk appears after any given voltage value in which case the 250 volt scale was used.

ALIGNMENT DATA

Dial Adjustment

Before aligning the circuits of these receivers, the tuning dial must be properly aligned to "track" with the gang tuning capacitor. To check whether the dial is set correctly with respect to the gang tuning capacitor, rotate the "Rapid Station Selector" knob in a counter-clockwise direction so that the gang tuning capacitor is set to its maximum capacity position. Then, with the receiver turned "on", the illuminated dial indicator line should be exactly centered over the dial alignment lines (black lines) which are located at the extreme low frequency end of each scale on the dial. If these lines do not center over the illuminated dial indicator line, loosen the two set screws located on the hub of the dial. Then, rotate the dial so that these alignment lines are centered over the illuminated dial indicator line. The two set screws of the dial hub should then be securely tightened.

Intermediate Frequency and A. F. C. Circuit Adjustments

The intermediate frequency system employed in these receivers has a complex circuit arrangement. Because of the necessity of obtaining the proper shape of resonance curve of these stages in a high fidelity receiver, it is recommended that unless it is absolutely essential, these I. F. adjustments be untouched. In the factory these adjustments are made using a visual system which allows the operator to see the exact shape of the resonance curve. For this reason it is best to have these adjustments made at the factory. However, in the case where this cannot be done, the following procedure should be followed:

1. Operate the Range Switch of the receiver to the "A" range position, and set the tuning dial to its extreme low frequency position. Set the Fidelity Control to its "Normal" position, the Automatic Frequency control knob to the "Off" position and the "Off-On-Bass-Phonograph" control knob to its "Normal" position. **Never attempt to align the R. F. or I. F. circuits of these receivers with the Fidelity Control knob set at any position other than the "Normal Fidelity" position, and the Automatic Frequency Control knob set at the "On" position unless specifically directed in the following paragraphs.**
2. Apply between the chassis base (or ground binding post) of the receiver and the grid of the No. 6K7 tube used in the second I. F. amplifier, a modulated signal of 465 kilocycles from the signal generator, using a 0.1 mfd. capacitor in series with the connection between the output terminal of the signal generator and the grid of the No. 6K7 tube. Do not remove the chassis grid lead connecting to this tube. The ground (or low side) terminal of the signal generator should be connected to either the chassis base or ground binding post terminal.
3. Now, noting from Figure 1, the alignment adjustments for the I. F. circuits proceed in the following order:

   Adjust the third I. F. transformer primary circuit for maximum output.

   Adjust the third I. F. transformer secondary circuit for maximum output.
4. Remove the lead connecting the signal generator (through the 0.1 mfd. capacitor) to the grid of the No. 6K7 tube of the second I. F. amplifier and connect this lead to the grid of the No. 6K7 tube of the first I. F. amplifier; then align in the following order:

   Adjust the second I. F. transformer secondary circuit for maximum output.

   Adjust the second I. F. transformer primary circuit for maximum output.
5. Remove the signal generator lead connecting to the grid of the No. 6K7 tube of the first I. F. amplifier and connect it to the grid of the No. 6A8 modulator tube; then align in the following order:

   Adjust the first I. F. transformer secondary circuit for maximum output.

   Adjust the first I. F. primary circuit for maximum output.
6. Check all the above adjustments again with the signal generator lead connected to the grid of the No. 6A8 modulator tube and in the order as given above.

Carefully make all the above adjustments, carefully watching the output meter and reduce the output of the test oscillator as required.

Adjustment of the Discriminator Tuned Circuits

To properly adjust the tuned circuits of the discriminator transformer, check the position of the A. F. C. Control knob which should be set to the "off" position. **Before making this circuit adjustment be sure that the I. F. amplifier and signal generator are exactly in resonance at 465 kilocycles.** Connect a high resistance voltmeter having a resistance of at least 1000 ohms per volt across the junction of the resistors R-37, R-38 and the chassis base. It is preferable to use the 500 volt scale of this meter in order that the load imposed on the discriminator circuit will not be too great. The D. C. milliammeter previously mentioned should be connected in series with the cathode of the No. 6J7 oscillator control tube exactly as described in the second paragraph of the Alignment Data. The signal generator should remain connected to the grid of the No. 6A8 modulator tube the same way as connected when making the aligning adjustments of the I. F. Amplifier circuits. The signal generator's output control should be adjusted so that a signal of 10,000 microvolts is fed into the modulator tube. Now, slightly detune the secondary circuit of the Discriminator transformer so that a fair voltage indication is obtained on the high resistance voltmeter connected across the junction of the resistors R-37, R-38, and the chassis base, and then adjust the primary circuit of the Discriminator transformer until a maximum reading is obtained on the voltmeter. Now, again adjust the secondary circuit of the Discriminator transformer so that zero reading is obtained on the voltmeter. Care should be taken that the meter does not read below zero.

CAUTION: In order to make sure that this adjustment of the secondary circuit of the Discriminator transformer has been correctly made, the adjusting screw should be turned gradually so that the indicator of the voltmeter will first return to zero, and then while continuing to turn this screw in the same direction, will go slightly below the zero mark, after which the screw should be turned in the opposite direction until the indicator is again brought back to the zero mark. If the above described condition cannot be obtained, this adjusting screw adjustment for the secondary circuit of the Discriminator transformer has been rotated in the wrong direction, and it will be necessary to carefully turn it in the opposite direction. After this adjustment has been made, it will not be necessary to use the voltmeter any more and it can be removed from the receiver circuit.

When the above adjustments have been carefully made, the milliammeter connected in the cathode circuit of the No. 6J7 oscillator control tube should be observed, and if the tuned circuits of the discriminator transformer are correctly adjusted there should be no difference in the reading of this milliammeter when the A. F. C. control knob is rotated from the "off" to the "on" position. If the above condition does not exist, the secondary circuit of the Discriminator transformer should be readjusted until the milliammeter has the same value regardless of whether the A. F. C. control knob is rotated to the "on" or "off" position.

Radio Frequency Adjustments

The alignment of the radio frequency circuits in these receivers should be very carefully made and in the order specified.

When making any aligning adjustments of these circuits, the A. F. C. Control knob should be rotated to the "off" position, the Fidelity Control knob should be set for "Normal" operation, and the "Off-On-Bass-Phonograph" Control knob should also be set for "Normal" operation.

Alignment of Ultra-Short Wave Range (Also referred to as "E" Band)

In order to align the circuits of this range, it is desirable to have a signal generator whose high frequency range will go to 60 megacycles. Such equipment, however, is rare and costly, and in most cases it will be necessary to make use of a signal generator whose high frequency range does not extend beyond 20 megacycles, using harmonics of 20 megacycles for aligning this range on 60 megacycles.

In aligning the radio frequency circuits for this range, replace the 0.1 mfd. capacitor which was placed in series with the signal generator's output lead for the I. F. alignment with a 400-ohm carbon type resistor. This lead should then be connected to the antenna binding post marked "U. H. A." located on the rear of the receiver chassis. The ground terminal (or low side) of the signal generator should be connected to the ground binding post on the receiver.

1. Operate the Range Switch on the receiver chassis to the "E" range position and set the signal generator's frequency and the receiver's tuning dial to 60 megacycles.
2. Adjust the aligning capacitor C-46 until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 20 megacycles and adjust the "E" range trimming loop, L-54, until maximum voltage output is obtained on the output meter. The adjustment of this loop is obtained by distorting its normally circular shape until it offers the correct inductive effect. If the oscillator does not track with the tuning dial scale at this frequency, it will be necessary to also adjust the oscillator's tuning loop.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 60 megacycles and repeat operation No. 2.

Alignment of Short-Wave Range (Also referred to as "D" Band)

In aligning the radio frequency circuits for this range use the same artificial antenna (400-ohm carbon type resistor) in series with the output terminals of the signal generator as was used for aligning the Ultra-Short Wave Range. Connect this lead to the antenna binding post marked "A" located on the rear of the receiver chassis, and align as follows:

1. Operate the Range Switch on the receiver chassis to the "D" range position and set the signal generator's frequency and the receiver's tuning dial to 20 megacycles.
2. Adjust aligning capacitors C-45, C-22, and C-8 respectively; and at the same time rotate the gang tuning capacitor slightly back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 11 megacycles and adjust aligning capacitors C-40, C-25, and C-12 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 20 megacycles and repeat operation No. 2.

Alignment of Short-Wave Range (Also referred to as "C" Band)

In aligning the radio frequency circuits for this range use the same artificial antenna and binding post on the receiver chassis as was used for aligning the "D" range.

1. Operate the Range Switch on the receiver chassis to the "C" range position and set the signal generator's frequency and the receiver's tuning dial to 10 megacycles.
2. Adjust the aligning capacitors C-44, C-21, and C-7 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 5 megacycles and adjust the aligning capacitors C-39, C-23, and C-11 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 10 megacycles and repeat operation No. 2.

Alignment of Aircraft Range (Also referred to as "B" Band)

In aligning the radio frequency circuits for this range, use the same artificial antenna and antenna binding post as was used for aligning the "C" range, and align this range as follows:

1. Operate the Range Switch on the receiver chassis to the "B" range position and set the signal generator's frequency and the receiver's tuning dial to 4.5 megacycles.
2. Adjust the aligning capacitors C-43, C-20, and C-6 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 1.8 megacycles and adjust the aligning capacitor C-38 and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 4.5 megacycles and repeat operation No. 2.

Alignment of Standard Broadcast Range (Also referred to as "A" Band)

In aligning the radio frequency circuits for this range, replace the 400-ohm resistor in series with the signal generator's output with a 200-micro-microfarad capacitor and align this range as follows:

1. Operate the Range Switch to the "A" range position and set the signal generator's frequency and the receiver's tuning dial to 1.5 megacycles (1500 kilocycles).
2. Adjust the aligning capacitors C-42, C-19, C4, and C-5 respectively; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
3. Set the signal generator's frequency and the receiver's tuning dial to 0.6 megacycles (600 kilocycles) and adjust the aligning capacitor C-37; and at the same time rotate the gang tuning capacitor back and forth through resonance until maximum voltage output is obtained on the output meter.
4. Reset both the signal generator's frequency and the receiver's tuning dial to 1.5 megacycles and repeat operation No. 2.

Adjustment of 10 Kilocycle Audio Cut-Off Filter

The adjustment of this filter is correctly made at the factory and no additional adjustment is required.

Instructions for Setting Up the A. F. C. Flash Tuning Unit

1. Remove the flash tuner lamp unit escutcheon plate by removing the four screws.
2. Remove the lists of station letters from the P-28420 package assembly which is tacked inside of the cabinet.
3. Remove the seven paper squares on which are printed the words "Tone", "Beauty", "Value", "Action", "Flash", "Tuning", and "Radio" from the square frames located on the rear side of the lamp unit escutcheon plate.
4. Remove the station letters of the seven stations which it is desired to set up in the flash tuning unit from the list of stations. It will be noted that the letters of the stations are printed on partly cut squares to facilitate ease in removing the desired letters. Insert one of these seven station letters into each frame of the flash tuner lamp unit. The recommended method of inserting these station letters into the frames of the escutcheon plate is to arrange them according to the frequency of the stations as follows:

   Looking at the front of the escutcheon plate the station having the highest frequency should appear in the top right-hand frame, and then in successive order according to frequency the remaining station letters should be inserted into the other frames; the top left-hand frame containing the station letters of the station having the lowest frequency. In inserting these letters into the frames be sure to have the letters located between two pieces of transparent material.
5. Fasten the escutcheon plate again to the lamp unit by means of the four screws. The receiver is now ready to be operated and the flash tuning unit contactors located on the rear of the chassis base adjusted for the seven favorite stations.
6. Rotate the "On-Off-Bass-Phonograph" Control knob from its complete counter-clockwise position, slightly clockwise from this position which turns the set "on" (indicated by illumination of the dial). Allow the receiver to reach operating temperature (about 15 minutes) before proceeding with setting up the flash tuning mechanism. Check the position of the Automatic Frequency Control knob which should be rotated to the "Off" position, and set the Fidelity Control knob to the "Normal" position. Now carefully tune in the desired station having the highest frequency, watching the tuning indicator so that the receiver will be exactly tuned to this station.
7. After carefully tuning in the desired station rotate the A. F. C. Control knob to the "On" position. Now, noting from Figure 3, the sketch which shows the contactor clamping frame and knurled nut, hold the clamping frame with one hand and loosen the knurled nut with the other hand. Then move the contactor, numbered 2, so that its point is engaged between the two small rollers of the switching mechanism as also shown in Figure 3. When the point is properly engaged between the rollers, the lamp of the lamp unit which is located behind the station letters of the station being tuned in will light. When this condition is obtained, retighten the large knurled nut and at the same time securely hold the gang tuning capacitor and the contactors from rotating by means of the extended portion of the contactor clamping frame. **It is extremely important to keep the gang tuning capacitor and the contactors from rotating when tightening the large knurled nut.**
8. Now rotate the A. F. C. Control knob to the "off" position and note whether the tuning has been shifted by watching the tuning indicator. If a change is noted it will be necessary to repeat operation No. 7.
9. When no change is noticed after performing the above operations Nos. 7 and 8, the remaining six favorite stations should be set up in the same manner.

   With the A. F. C. flash tuning unit in operation, the receiver will be automatically kept in tune with any one of the seven favorite stations as long as the station is operating or provided it has no unusual fading characteristics. If a distant station which is very weak is set up in the flash tuning unit, it will be found that the Automatic Frequency Control will not hold this station if a strong signal is present in either adjacent channel. This same phenomenon will occur if two stations in adjacent channels are almost of equal signal strength with the weakest signal fading slightly; with this condition the strong signal will have a tendency to "pull in" when the receiver is tuned to the station which is slightly weaker and fading.

The DQ-69 is a console model; the CQ-69 is a table model. The antenna should be as high as possible and about 100 feet long. A good ground is essential for good reception. The blue wire from the set is the antenna lead. If the set is to be operated on 110 volts continuously, the vibrator should be removed.

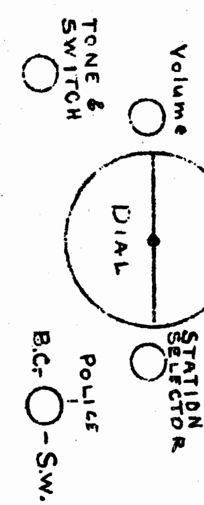
6T7G ... . .5 v.
6L5G .... 5 v.
Voltages when set is on AC are higher.

Knob arrangement



MODELS CQ-69 and DQ-69

Model CQ-69 (table model) and DQ-69 (Console) may be operated on either 6 volts DC or 110 volts AC. A separate cord is provided for each voltage. A nonsynchronous vibrator in conjunction with a type 6ZY5G rectifier furnishes high voltage. The vibrator should be removed if the set is to be operated on 110 volts continuously.

--- ALIGNMENT PROCEDURE ---

Turn dial to closed gang position to make certain that the dial needle coincides with the end of the scale. Turn dial to about midpoint and adjust the I.F. coils to 456 KC.
Switch to shortwave band, set dial needle to 15 MC and adjust bottom trimmers in antenna and oscillator coils to maximum output.
Switch to police band (middle band) set dial at 5 MC and adjust the second trimmers from the bottom to maximum output.
Switch to broadcast, set dial at 1400 KC and adjust the third trimmers from the bottom. Then adjust the padder located on the front section of the gang condenser. Turn to 600 KC and adjust the top trimmer in the oscillator coil. This is the series tracking condenser.

The type 6A8G tube has been found to give better oscillator performance then the 6D8G and is used in present production. The switch which turns the tuning eye and dialites off and on is located on the back of the panel.

TRANSFORMER CORP. OF AMER.

SERVICE NOTES FOR MODELS TC1 AND TC2

The Clarion TC-1 TC2 is a 7 tube all-wave super-heterodyne receiver, covering broadcast frequencies 550-1520 kilocycles and short-wave frequencies 1.5-4 megacycles, 3.6-10 megacycles, 8-10 megacycles.

Other outstanding features of this receiver are:—78 triple grid super-control tubes in the R. F. first detector and I. F. stages; 37 oscillator; 75 double diode triode, operating as a delayed AVC, second detector and first audio; and the 42 super-power amplifier, delivering 3 watts of undistorted output to the speaker.

R. F. and I. F. ALIGNMENT. The trimmer on the tuning condensers and the intermediate stages are very accurately adjusted before the receiver leaves the factory and should need little or no attention. To check adjustments the following procedure should be followed:

The action of the automatic volume control will defeat the purpose of an output meter. To overcome this, it will become necessary to reduce the coupling between the oscillator and the receiver so that only a small reading is obtained on the output meter with the volume control set for maximum volume. This will allow the output meter to work correctly. Adjust the test oscillator to 262 kilocycles and couple to the control grid of No. 2 tube and adjust trimmers on I. F. stage for maximum reading on the output meter.

R. F. ALIGNMENT. Couple oscillator to the antenna (reduce coupling as outlined in I. F. adjustment). Set pointer on tuning chart to 1400 kilocycles with wave band control switch in broadcast position. Adjust test oscillator to 1400 kilocycles. Adjust trimmers on No. 1 and 2 section of tuning condenser for maximum reading. ~~The trimmer of No. 3 section of~~ the tuning condenser should be set for minimum capacity, and the high frequency trimmer on back of chassis (left viewing chassis from back) should be adjusted for maximum reading. This operation should be repeated at 600 kilocycles and adjusting only the low frequency trimmer on back of chassis (right viewing chassis from back) for maximum reading. No adjustments are necessary on the short-wave band. All the coils are correctly matched so that they will be in perfect alignment if all the above adjustments are correctly made.

GENERAL DESCRIPTION

The Model 224 is an eight tube direct current superheterodyne receiver whose circuit consists of a stage of radio frequency amplification, an oscillator, a stage of intermediate frequency amplification, a second detector, a driver and a push-pull stage of class B audio amplification.

The receiver is designed to operate on the standard broadcast band extending from 550 to 1500 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view is shown in Figure #1 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENTS - 175 K.C.

1. Set volume control on full.
2. Set test oscillator to 175 K.C. and apply test signal to grid of 39 I.F. tube through a .5 mfd. blocking condenser.
3. Adjust the two trimmers on top of second I.F. transformer to maximum output reducing output of test oscillator as required.
4. Apply test signal to grid of 39 first detector tube and adjust the two trimmers on top of first I.F. transformer to maximum output.
5. Repeat above operations for accuracy.

OSCILLATOR & R.F. ADJUSTMENTS

1. Set test oscillator and dial scale to 1400 K.C.
2. With test signal still applied to the grid of the first detector, adjust oscillator trim condenser A to maximum output.
3. Apply test signal to antenna lead of the set and adjust trimmer B and the antenna adjustment screw to maximum output.
4. Set test oscillator and dial scale to 600 K.C. and adjust oscillator lagging condenser on top of oscillator coil to maximum output.
5. Return to 1400 K.C. setting and readjust A, B and the antenna adjustment screw as the adjustment of the oscillator lagging condenser may have altered these settings.
6. Check the sensitivity and calibration at several different positions of the dial scale.

For Schematics, see Index

GENERAL DESCRIPTION

The Model 226 is an eight-tube superheterodyne battery receiver whose circuit comprises one stage of radio frequency amplification, an oscillator, a first detector, an audio driver, and a stage of push-pull class B audio amplification.

The receiver is designed to operate on the standard broadcast band extending from 550 to 1500 K.C.

LINE-UP CAPACITOR ADJUSTMENTS

To align the chassis, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A. V. C. to function, making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the chassis, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. A top view of the chassis is shown in Fig. #1 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENTS (175 K.C.)

1. Connect the receiver to the batteries as shown in Fig. #1.
2. Set volume control on full and set test oscillator to 175 K.C.
3. Apply test signal to the grid of the 234 I.F. tube and adjust the two trimmers on top of the second I.F. transformer to maximum output reducing output of test oscillator as required.
4. Apply test signal to grid of the 232 first detector and adjust the two trimmers on top of the first I.F. transformer to maximum output.
5. Recheck the above two operations for accuracy.

OSC. & R.F. ADJUSTMENTS

1. Set test oscillator and dial scale to 1400 K.C.
2. With test signal still applied to the grid of the first detector, adjust trimmer A on top of condenser gang to maximum output.
3. Apply test signal to antenna lead and adjust trimmer B and the antenna adjustment screw to maximum output.
4. Set test oscillator and dial scale to 600 K.C. and adjust oscillator lagging condenser on top of oscillator coil to maximum output.
5. Return to 1400 K.C. setting and readjust A and B antenna trimmer screw as the adjustment of the oscillator lagging condenser may have altered the setting of these trimmers.

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes	1 #6A7, 1 #6D6, 1 #75, 1 #41 - Total 4
Total Battery Current (6 volt battery)	2.6 Amps.
Battery Required	6 Volt Storage Battery
Maximum Output	0.6 Watts
Maximum Undistorted Output	.25 Watts
Tuning Ranges	540 to 1725 KC., 2000 to 6800 KC.
Line-Up Frequencies	465 KC. I.F., 1600 KC., 600 KC., 6000 KC.

GENERAL DESCRIPTION

This model is a four tube, two band, superheterodyne receiver designed to be operated with only a six-volt storage battery. The receiver employs a type #6A7 tube as a combined first detector-oscillator, a type #6D6 tube as an intermediate frequency amplifier, a type #75 tube as a combined second detector, A.V.C. first audio amplifier, and a type #41 tube as an audio output amplifier. The power supply for this model is secured from a six volt storage battery. The plate voltage is secured by the use of a combined vibrator and mechanical rectifier.

SPEAKER ADJUSTMENT

This speaker has been carefully adjusted at the factory and should not require any further attention, as this design has been found to be very stable in maintaining its adjustment. However, if for any reason an adjustment is needed, it may be done by turning the screw, located nearer the speaker magnet, in either direction. Do not touch the other screw as this should always remain tight.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align this receiver it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making proper alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal. Before attempting to align the chassis, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and the various alignment condensers. Top and bottom views of the chassis are shown in figures #1 and #2 and should be carefully studied before the actual work is started.

I.F. ADJUSTMENTS (465 KC.)

1. Connect the receiver to the storage battery by connecting the red lead to the positive terminal and the black lead to the negative terminal of the battery.
2. Set the volume control to the maximum position, the tone control to the treble position, the wave change switch to the broadcast band position and the dial indicator to approximately 600 KC.
3. Set the test oscillator to 465 KC. and apply the test signal to the grid of the type #6D6 I.F. amplifier tube thru a .5 mfd. condenser.
4. Adjust trimmer condenser #15 and #20 to maximum output.
5. Apply the test signal to the grid of the type #6A7 first detector-oscillator tube and adjust trimmer condensers #12 and #13 to maximum output.
6. Apply the test signal to the antenna lead of the receiver and adjust the trap coil trimmer #3 to minimum output.

SHORT-WAVE BAND ADJUSTMENTS

1. Set the wave change switch to the short wave band position.
2. Set the test oscillator and dial indicator to 6000 KC. and adjust the short-wave oscillator trimmer condenser, #7, to maximum output.
3. Adjust the short wave antenna trimmer #5 to maximum output.
4. Check the receiver over the shortwave band for sensitivity and calibration.

GENERAL DESCRIPTION

These models are six-tube, three band, battery-operated, superheterodyne receivers whose circuits employ a type 1C6 tube as a combined first detector-oscillator, two type 1A4 tubes as intermediate frequency amplifiers, a type 1B5 as a combined second detector - A.V.C. - first audio amplifier, a type 30 as an audio frequency amplifier, and a type 1J6G as a power output amplifier. This receiver is equipped with a permanent magnet dynamic speaker.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the receiver, it is essential to use a high grade modulated test oscillator and a sensitive output meter. The R.F. signal fed into the receiver must be relatively weak or it will cause the A.V.C. to function making correct alignment difficult. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the location of the tubes and the various alignment condensers. The top and bottom view of the chassis are shown in Figure #1 and #2 and should be carefully studied before the actual work is started.

1. Connect the receiver to the batteries by plugging the "B" battery plugs and "C" battery plugs in their respective batteries. Connect the wire coming from the rear of the receiver to the terminal marked for the type of "A" supply you plan on using. Connect the red "A" battery lead to the positive terminal of the "A" battery and the black lead to the negative terminal of the "A" battery.

2. Set the volume control to the maximum position, the tone control to the treble position, the wave change switch to the broadcast band and the dial indicator to approximately 600 KC.

3. Set the test oscillator to 465 KC. and apply the test signal to the grid of the type 1A4 second I.F. tube through a .5 mfd. blocking condenser and adjust I.F. trimmer #36 to maximum output.

4. Apply the test signal to the grid of the type 1A4 first I.F. tube and adjust I.F. trimmers #28 and #30 to maximum output.

5. Apply the test signal to the grid of the type 1C6 first detector-oscillator tube and adjust I.F. trimmer condensers #22 and #24 to maximum output.

ADJUSTMENT OF BROADCAST BAND

1. Set the test oscillator and dial indicator to 1600 KC.

2. Apply the test signal to the antenna terminal of the receiver through a .0002 mfd. condenser and adjust the broadcast oscillator trimmer condenser #14 to maximum output.

3. Adjust the broadcast band preselector trimmer condensers #7 and #4 to maximum output.

4. Set the test oscillator and dial indicator to 600 KC. and adjust the broadcast oscillator series condenser #68 to maximum output at the same time rocking the variable condenser.

5. Return both the test oscillator and dial indicator to 1600 KC. and check the adjustment of trimmer condenser #14, #7, and #4.

ADJUSTMENT OF GREEN BAND

1. Set the wave change switch to the green band position.

2. Set the test oscillator and dial indicator to 6000 KC. and adjust the green band oscillator trimmer condenser #13 to maximum output.

3. Adjust the green band preselector trimmer condenser #3 to maximum output.

4. Check the receiver over the green band for sensitivity and calibration.

ADJUSTMENT OF RED BAND

1. Set the wave change switch in the red band position.

2. Set the test oscillator and dial indicator to 14000 KC. and adjust the red band oscillator trimmer condenser #12 to maximum output.

3. Adjust the red band preselector trimmer condenser #2 to maximum output.

4. Check the receiver over the red band for sensitivity and calibration.

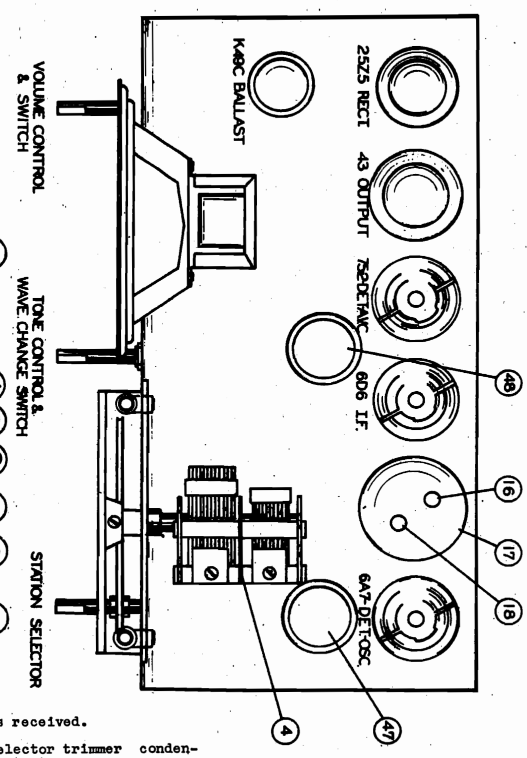
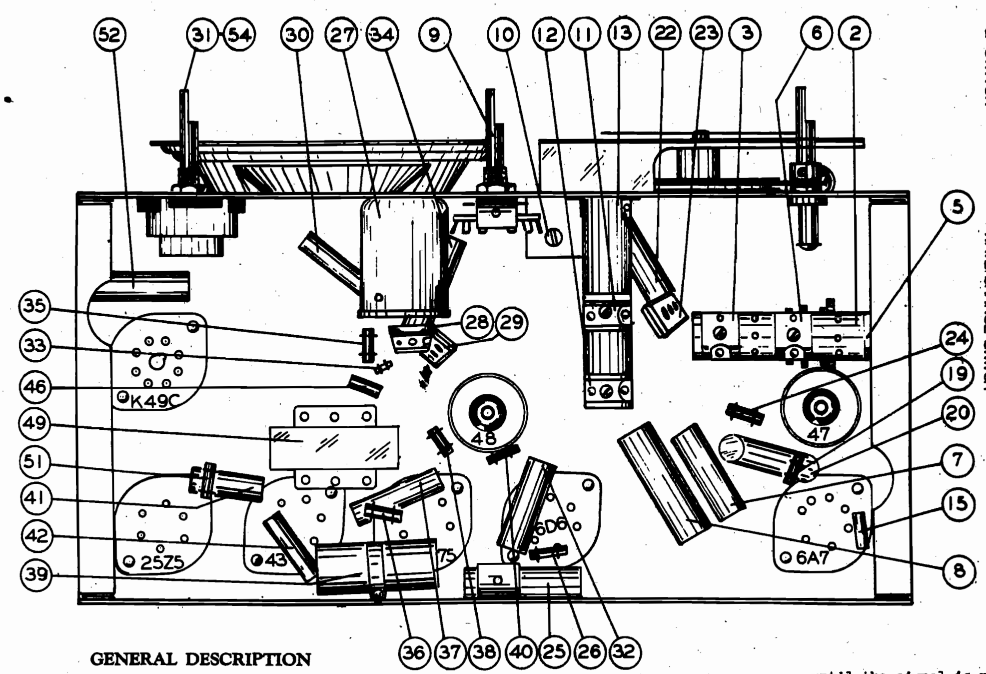
Power Supply Characteristics ---- 105-125 volts D.C. or 105-125 volts, 50-60 cycle A.C.
Power Consumption ---------- 47 Watts
Maximum Output ---------- 1.0 Watt
Maximum Undistorted Output ---------- 0.75 Watt
Tuning Ranges ---------- (Broadcast Band - 540 to 1720 KC.) (Short-wave Band - 2100 to 7200 KC.)
Line-Up Frequencies ---------- I.F. 465 KC., 1600 KC., 600 KC., 6000 KC.





GENERAL DESCRIPTION

This model is a six-tube, two-band, A.C.-D.C. superheterodyne receiver. A type 6A7 tube is used as a combined first detector-oscillator, a type 6D6 tube as an intermediate frequency amplifier, a type 75 tube as a second detector and automatic volume control and first audio frequency amplifier, a type 43 as an output amplifier, a type 25Z5 as a rectifier, and a type K49C as a ballast tube.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment.

A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figs. #1 and #2 and should be carefully studied before the actual work is started.

ADJUSTMENT OF I.F. (465 KC.)

1. Set the volume control to maximum position and tone control to treble position.

2. Connect the output meter to the terminals of the voice coil.

3. Set the test oscillator to 465 KC. and apply the test signal to the grid of the type 6D6 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmer condenser #28 to maximum output.

5. Apply the test signal to the grid of the type 6A7 first detector-oscillator tube and adjust trimmer condensers #16 and #18 to maximum output.

6. Connect the test oscillator to the antenna of the receiver and with a strong input signal, adjust wave trap trimmer condenser #5 to minimum output.

BROADCAST BAND ADJUSTMENT

1. Set the test oscillator and dial indicator to 1600 KC.

2. Apply the test signal to the antenna of the receiver through a .0002 mfd condenser.

3. Adjust oscillator trimmer condenser #11 until the signal is received.

4. Adjust the preselector trimmer condenser #6 to maximum output.

5. Set test oscillator and dial indicator to 600 KC., and adjust the oscillator series condenser #10 until the signal is received. Tune the receiver to a slightly lower frequency and readjust trimmer #10 to maximum output. If the sensitivity increases, continue this procedure in the same direction until maximum sensitivity is reached. If the sensitivity decreases, try this procedure at slightly higher frequencies until maximum sensitivity is reached.

6. Return test oscillator and dial indicator to 1600 KC. and check adjustment of the oscillator and preselector trimmer condensers.

ADJUSTMENT OF SHORT-WAVE BAND

1. Set the wave-change switch to the short-wave band position.
2. Set the test oscillator and dial indicator to 6000 KC. and adjust the oscillator trimmer condenser #12 until the signal is received.
3. Adjust the preselector trimmer condenser #3 to maximum output.

4. Check the sensitivity and calibration over scale.

GENERAL DESCRIPTION

The Model 680 is a thirteen-tube, four-band, high fidelity superheterodyne, employing all-metal tubes, with the exception of the rectifiers. This model is built in two units, namely, the receiver proper and the class A.-B.1 amplifier, both of which are provided with an independent power supply. Among the refinements and features incorporated are high fidelity, bass and treble control, delay and a triple automatic volume control system. The second A.V.C. operates in the usual manner and controls the first I.F. amplifier tube. The third A.V.C., which controls the second I.F. amplifier tube, is designed to give proper tuning meter indications under all conditions. The FIRST A.V.C. controls the R.F. and first detector and does not start to function until a comparatively strong signal is received, thus the highest possible sensitivity is maintained at low signal level. Due to the fact that the first A.V.C. voltage is essentially flat ± 30 KC. from resonance, greater first A.V.C. voltage is supplied if the receiver is used in the presence of a strong off-side signal, thereby preventing cross-talk, R.F. and modulation overload on the desired signal. The delay system, which prevents between-station noise, automatically becomes inactive when a signal is received.

A type 6K7 tube is used as an R.F. amplifier, a type 6A8 as a first detector, a type 6C5 as an oscillator, two 6K7's as I.F. amplifiers, a type 6H6 as a second detector and second and third A.V.C., a type 6K7 as a first A.V.C. amplifier, a type 6F5 as an audio amplifier, two type 6L6's in the output stage, a type 5Y3 as a rectifier in the main chassis and a type 5Z3 as a rectifier in the power amplifier chassis

REMOVING INDIVIDUAL COIL
AND SWITCH SECTIONS OF CENTROMATIC UNIT

If a component part located underneath the switch and coil assemblies of the "CentrOmatic" unit has to be replaced or a section of the unit has to be removed for inspection, each section can easily be removed separately. To do this, proceed with care as follows:

1. Remove the two screws which fasten the mounting plate of the wave-change switch shaft to the chassis frame. Pull switch shaft straight out.
2. Unsolder the stator and rotor leads from the gang condenser.
3. The fastening screws for the switch sections are located on top of the "CentrOmatic" unit and are indicated by X, Y and Z in Figure #1. Remove the corresponding screws.
4. Each individual section can then be pulled out straight.

NOTE: On the R.F. section, the plate lead from the 6K7 socket will have to be unsoldered from the switch terminal before the section can be removed.

On the oscillator section, the plate lead to the 6C5 socket and the plate supply lead will have to be unsoldered from the switch terminal before the section can be removed.

5. After repairs have been made, resolder the plate leads mentioned above and replace the section, being careful to observe that the slotted holes in the switch bracket line up with the round guide pins on the base plate of the "CentrOmatic" unit. This is IMPORTANT as the switch shaft cannot be inserted if the switch brackets do not line up.
6. Replace the section fastening screws.
7. Resolder the stator and rotor leads on gang condenser.
8. Replace the switch shaft and the mounting fastening screws. When inserting the switch shaft, be careful that all the switch discs are in the same position, otherwise the switch shaft will not slide in. NEVER force the shaft into the switch discs. If shaft does not slide in freely, examine the position of the slot in each switch disc.

LINE-UP CAPACITOR ADJUSTMENTS

To align the circuits of this receiver, it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied with absence from overload when the individual circuits of the receiver are brought into alignment. A conventional output meter can be connected across the terminals of the speaker voice coil to indicate when the circuits are aligned. The sensitivity of the output meter must be sufficient to give satisfactory reading with a low input signal.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, the location of the tubes and various alignment condensers. Top and bottom views of the chassis are shown in Figures #1 and #2 and should be carefully studied before the actual work is started.

It is recommended that no attempt be made to align this receiver unless it is definitely known that it is necessary and then only if high grade equipment is available, preferably a cathode ray oscillograph.

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control at maximum, the tone control on bass, the wave-change switch on broadcast, the dial indicator at approximately 600 KC., and the HIGH FIDELITY CONTROL AT MINIMUM (COUNTER-CLOCKWISE).
2. Connect output meter across voice coil of speaker.
3. Set test oscillator at 465 KC., and connect to the grid of the second I.F. tube (6K7) through a .5 mfd. blocking condenser.
4. Adjust trimmer #74 for maximum output.
5. Connect the test oscillator (through same blocking condenser) to the grid of the first I.F. tube (6K7), and adjust trimmers #61 and #62 for maximum output, reducing the oscillator output as required.
6. Connect the test oscillator (through same blocking condenser) to the grid of the first detector and adjust trimmers #51 and #52 for maximum output.
7. Adjust trimmer #81 which controls the tuning meter circuit, for a sharp dip in the output. This dip in the output will occur simultaneously with the tuning meter deflection. This adjustment should be made very accurately to a minimum reading.

ADJUSTMENT OF GREEN BAND

1. Set wave-change switch to Green Band position.
2. Set test oscillator and dial indicator to 350 KC.
3. Apply test signal to antenna terminal of the chassis through a .0002 mfd. series condenser and adjust #35, #21, and #6 for maximum output.
4. Set test oscillator and dial indicator to 165 KC., and adjust #36 for maximum output, at the same time rocking the variable tuning condenser.
5. Return to 350 KC. setting with both test oscillator and dial indicator, and repeat adjustment of #35, #21 and #6 for accuracy.

ADJUSTMENT OF BROADCAST BAND

1. Set wave-change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1400 KC., and adjust #38, #24 and #8 for maximum output.
3. Set test oscillator and dial indicator to 600 KC., and adjust #39 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 1400 KC. setting and make readjustment of #38, #24 and #8.

ADJUSTMENT OF BLUE BAND

NOTE: In adjusting the Blue and Red Bands, a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave-change switch to Blue Band position.
2. Set test oscillator and dial indicator to 5000 KC., and adjust #42, #26 and #10 for maximum output.
3. Set test oscillator and dial indicator to 2000 KC., and adjust #43 for maximum output, at the same time rocking the variable tuning condenser.

ADJUSTMENT OF RED BAND

1. Set wave-change switch to Red Band position.
2. Set test oscillator and dial indicator to 17000 KC., and adjust #45, #29 and #13 for maximum output.
3. Set test oscillator and dial indicator to 6500 KC., and adjust #47 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #45, #29 and #13.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents, making the condenser appear to be defective. If left in this position too long the condenser may be injured.

WARNING: On the first A.V.C. transformer, Diagram #119, are two trimmer condensers which should, under no conditions, be adjusted excepting when the entire transformer has been replaced. The first production lot of this model was shipped with these two trimmers accessible, but on all future shipments these will be covered with a strip of fish paper.

The adjustment of this transformer is very critical, requiring the use of a very sensitive micro-ammeter and after the adjustments have been made at the factory, no further adjustment will be necessary.

Should it become necessary to replace this A.V.C. transformer, communicate with the Radio Service Department of the United American Bosch Corporation, Springfield, Massachusetts.

TUBE SOCKET VOLTAGES

Tube	Function	H	P	S	SU	GA	GO	K
6K7G	R-F Amp.	6	230	55	4.0	-	-	4.0
6A8G	Osc. Mod.	6	230	55	-	120	0	4.0
6K7G	I-F Amp.	6	230	55	2.7	-	-	2.7
6Q7G	Det. Aud.	6	125	-	-	-	-	11.0
6F6G	Output	6	220	230	-	-	-	0
6X5G	Rectifier	6	-	-	-	-	-	230

All readings taken from tube socket contacts to ground with 1000 ohm per volt voltmeter.

Aligning I-F Stages at 262 K.C.

Set signal generator to 262 K.C. and connect signal lead to grid cap of 6A8G tube, through a .1 mfd. condenser. Adjust trimmers on both I-F coils located on under side of chassis sub-panel. Repeat adjustments until maximum output is obtained, using a weak signal.

Aligning R-F Stages

Set signal generator to 1530 K.C. and connect signal lead to antenna terminal of receiver through a .0002 mfd. mica condenser. Adjust oscillator trimmer on middle section of condenser gang. Set signal generator at 1400 K.C. and turn condenser gang until this signal is tuned in. Adjust the other two sections of condenser gang. Set signal generator to 600 K.C. and turn condenser plates until this signal is tuned in. Adjust antenna compensating condenser (located near antenna connector) while rocking the condenser gang plates back and forth until maximum output is obtained. Repeat adjustments made at 1400 K.C.

R.F. ALIGNMENT ON NEXT PAGE

CIRCUIT ALIGNMENT

1. Peaking I-F Stages at 262 K.C.

(a) Connect the signal lead of the signal generator to the grid cap of the 6J7 tube, through a .1 mfd. condenser. Do not remove grid clip from tube. Connect the ground lead of the signal generator to the receiver case.

(b) Connect output meter from tone control jack to receiver case.

(c) Turn condenser gang plates to approximately 1000 K.C. and volume control on full.

(d) Adjust screws "A" and "C", located on the top of each I-F transformer, for maximum output. (See Parts Layout.)

(e) Adjust screw "B" (third I-F adjustment) on bottom of chassis, accessible through hole provided in bottom cover of receiver. DO NOT REMOVE BOTTOM COVER OF RECEIVER FOR THIS ADJUSTMENT.

(f) Repeat (d) and (e) until no further increase in output can be obtained.

Note: In order not to actuate the A.V.C. circuit, always use the lowest output from the signal generator, which will give a readable indication on the output meter.

Socket, Trimmers
Chassis, Alignment

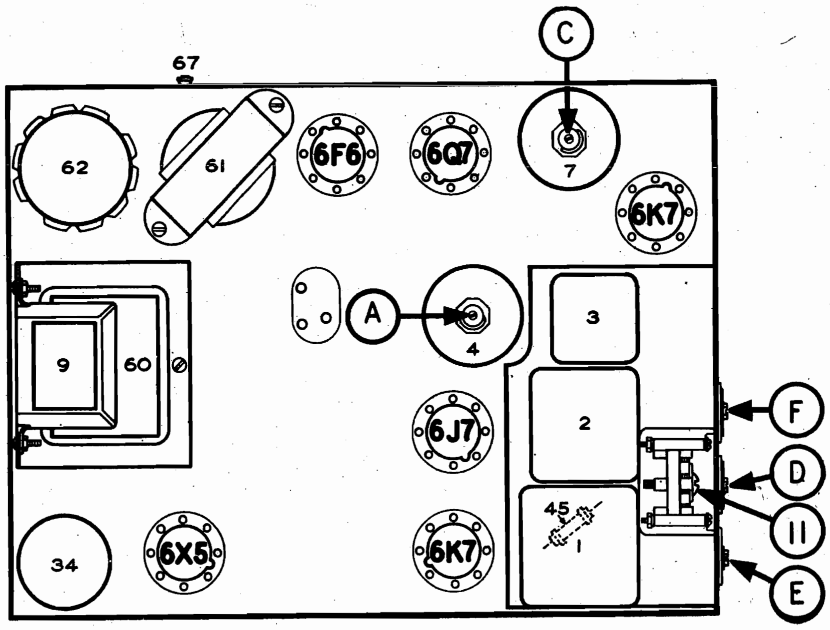

FIG. 3--PARTS LAYOUT--Top View

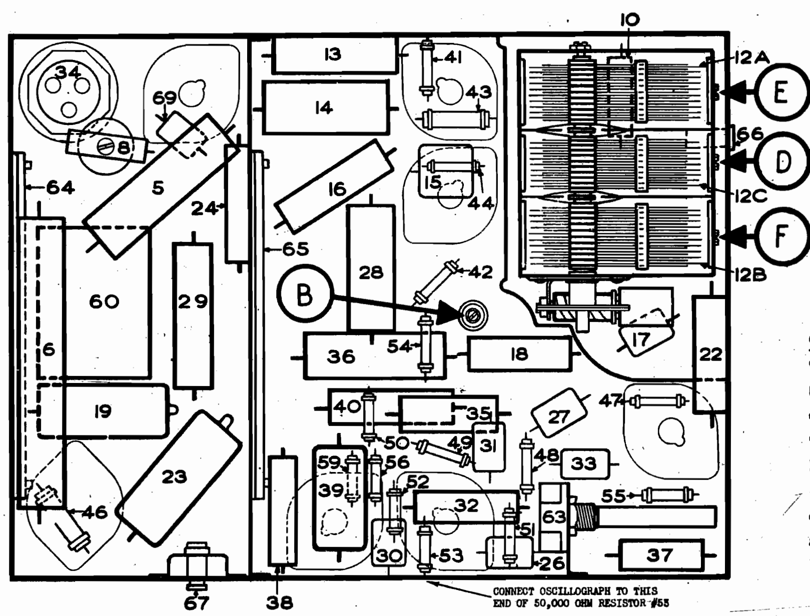

FIG. 4--PARTS LAYOUT--Bottom View

I.F. ALIGNMENT ON PRECEDING PAGE

2. Aligning at 1530 Kilocycles

(a) Leave signal lead of signal generator connected to grid cap of 6J7 tube. Turn condenser gang plates all the way out of mesh and against high frequency stop.

(b) Set signal generator to exactly 1530 kilocycles and remove small plate on side of chassis covering trimmer screws.

(c) Adjust trimmer "D" on condenser gang carefully until generator signal is tuned in with maximum output.

3. Aligning at 1400 Kilocycles

(a) Connect generator signal lead to antenna connection of receiver THROUGH A .0002 MFD. MICA CONDENSER.

(b) Set signal generator carefully to 1400 kilocycles and turn condenser plates until this signal is tuned in with maximum output

(c) Adjust trimmers "E" and "F" for maximum output. Do not disturb the adjustment of trimmer "D" set at 1530 K.C.

4. Aligning at 600 Kilocycles

(a) Set signal generator to 600 kilocycles and turn condenser plates until signal is tuned in.

(b) Remove small button plug on control side of receiver. Adjust Delco Syncro-Tuning condenser (Illus. #11), while rocking tuning condenser plates back and forth slightly until maximum output is obtained.

(c) Repeat adjustments of trimmers "E" and "F" at 1400 kilocycles as covered in paragraphs (b) and (c) under "Aligning at 1400 Kilocycles".

UNITED MOTORS SERVICE

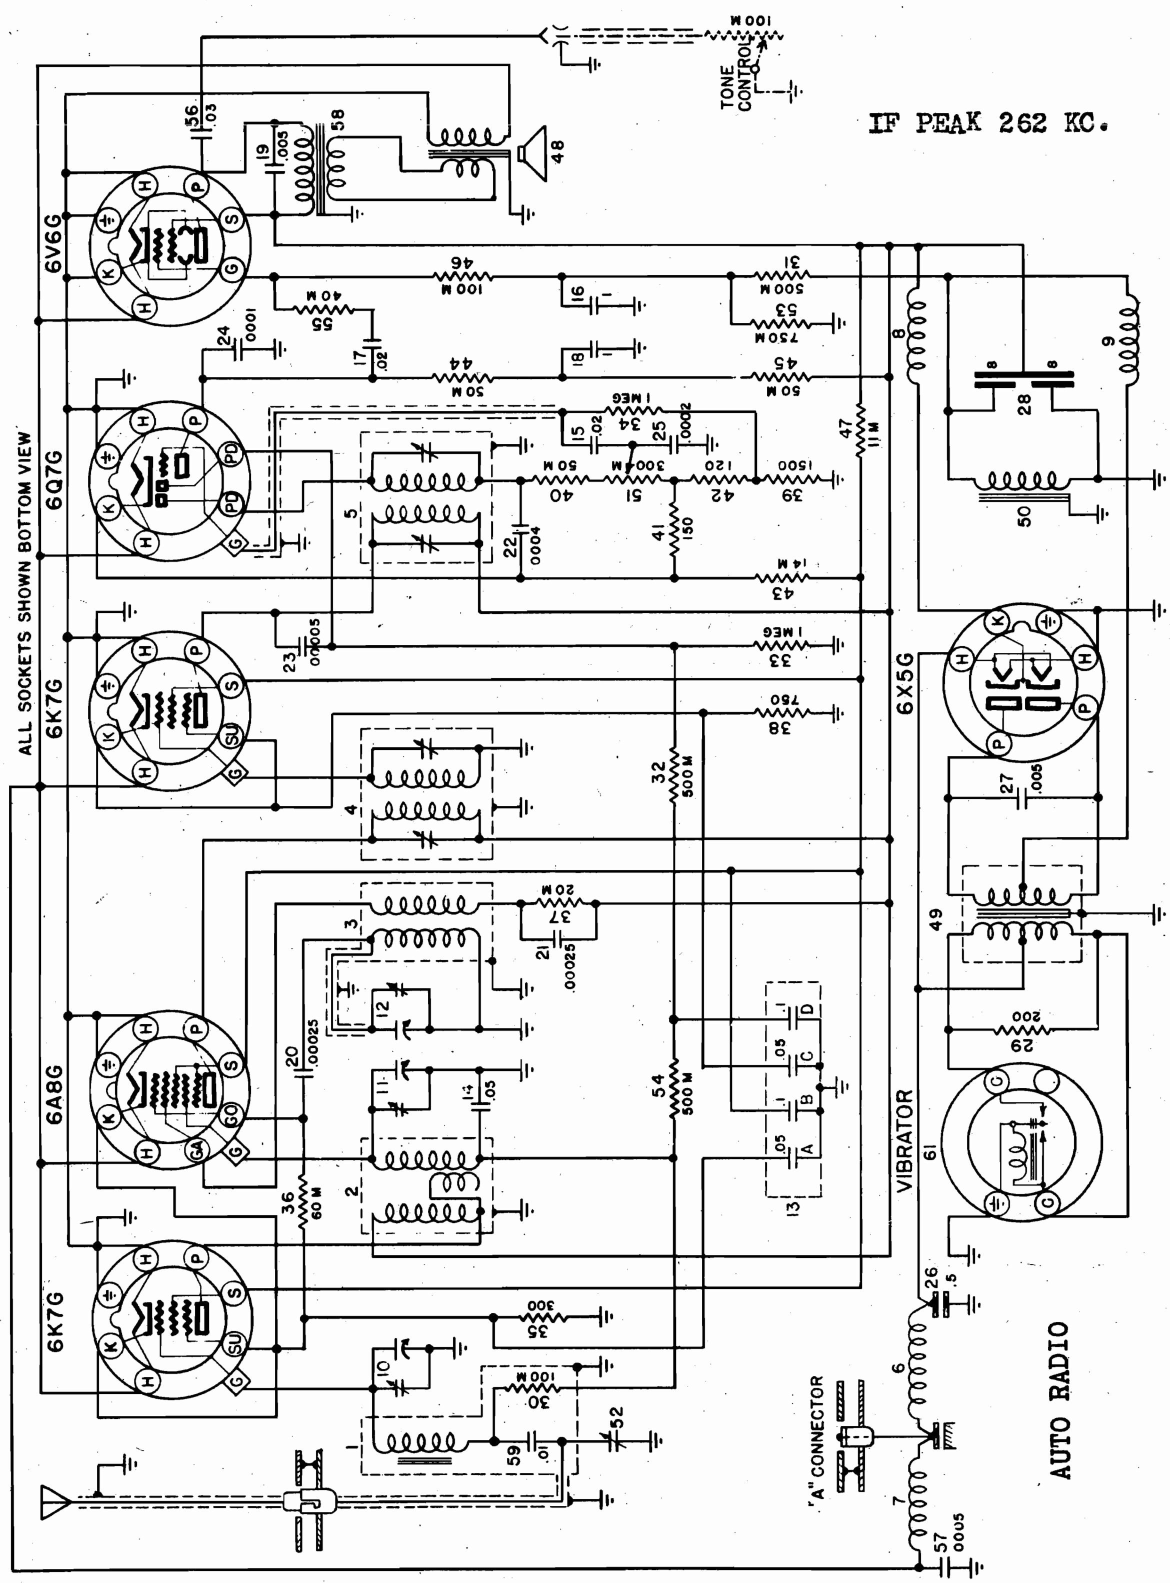
MODEL R-641 Delco
Schematic



The Delco Model R-641 is a six tube, single unit auto radio, with variable tone control, non-synchronous vibrator and type 6V6G "Beam" Power Tube.

Delco Model R-641

Date: 7-1-37

OSCILLOGRAPH CONNECTIONS

In making tests with the Cathode Ray Oscillograph, connect to black lead of 2nd I-F coil (Illus. #5) and to chassis ground.

MODEL R-641 Delco
Socket, Trimmers
Chassis, Alignment
Voltage

UNITED MOTORS SERVICE

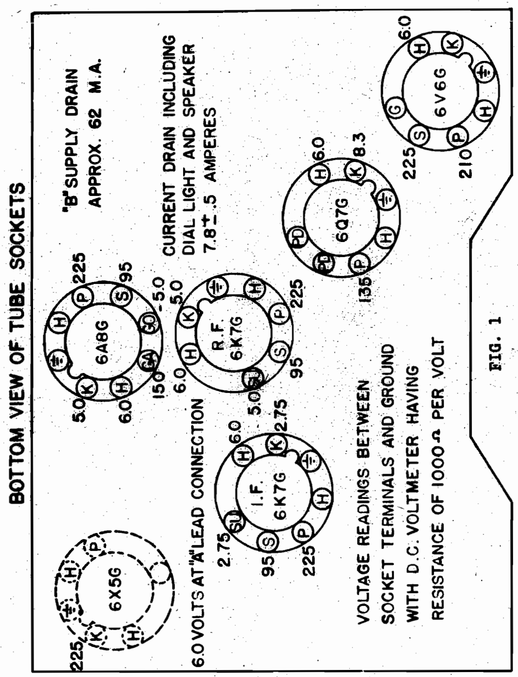


FIG. 1

(Bottom View of Chassis)

In order to prevent the A.V.C. circuit from affecting the alignment adjustments, the lowest Signal Generator output should be used, which will give a readable indication on the output meter.

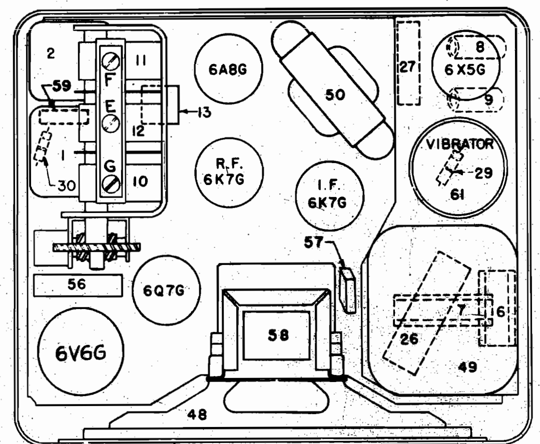

FIG. 3--PARTS LAYOUT--Top View

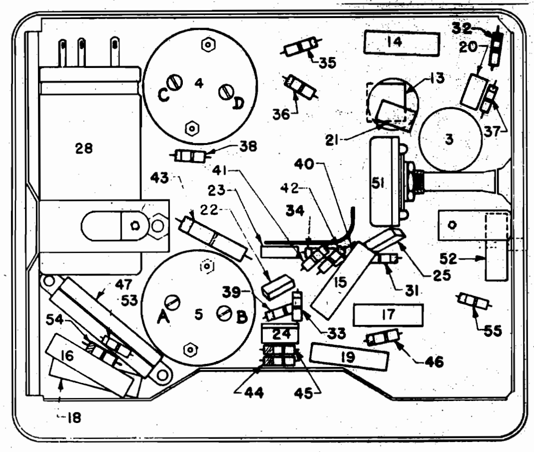

FIG. 4--PARTS LAYOUT--Bottom View

All voltage measurements made with a voltmeter having a resistance of 1000 ohms per volt.

Delco Model R-641

Date: 7-1-37

Checking I-F Band Spread

The Model 165 Cathode Ray Oscillograph should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustment of the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Complete information concerning this check with the Oscillograph, is given in the Oscillograph Manual, included with each instrument.

1. Peaking I-F Stages at 262 Kilocycles

(a) Connect the ground lead of the Signal Generator to the chassis case. Connect the signal lead of the Signal Generator to the grid cap of the 6A8G tube, through a .1 mfd. condenser, leaving the tube's grid clip in place.

(b) Connect output meter from plate of 6V6G tube to ground.

(c) Set Signal Generator to exactly 262 kilocycles and turn volume control on full.

(d) Turn condenser gang to a position where no squeals or beat notes can be noticed, also so that when the tuning condenser is rotated within narrow limits there is no appreciable change in output.

(e) Adjust trimmers A-B-C-D on the top of the I-F coils (Illus. 4 & 5) carefully for maximum output.

(f) Repeat adjustments of I-F trimmers A-B-C-D with as low an output from the Signal Generator as possible, for more accurate alignment.

2. Aligning at 1530 Kilocycles

(a) Leave Signal Generator leads connected the same as for I-F adjustments.
(b) Turn tuning condenser plates all the way out and against high frequency stop.

(c) Set Signal Generator to exactly 1530 kilocycles and adjust oscillator trimmer "E" on middle section of condenser gang carefully for maximum output.

3. Aligning at 1400 Kilocycles

(a) Remove signal lead of Signal Generator from grid cap of 6A8G tube and connect to antenna terminal of receiver through a .0002 mfd. mica condenser.

(b) Set the Signal Generator to 1400 kilocycles and tune the receiver to this signal.

(c) Adjust the parallel trimmers "F" and "G" of the condenser gang carefully for maximum output. Do not disturb the 1530 kilocycle adjustment of the middle section of the condenser gang.

4. Aligning at 600 Kilocycles

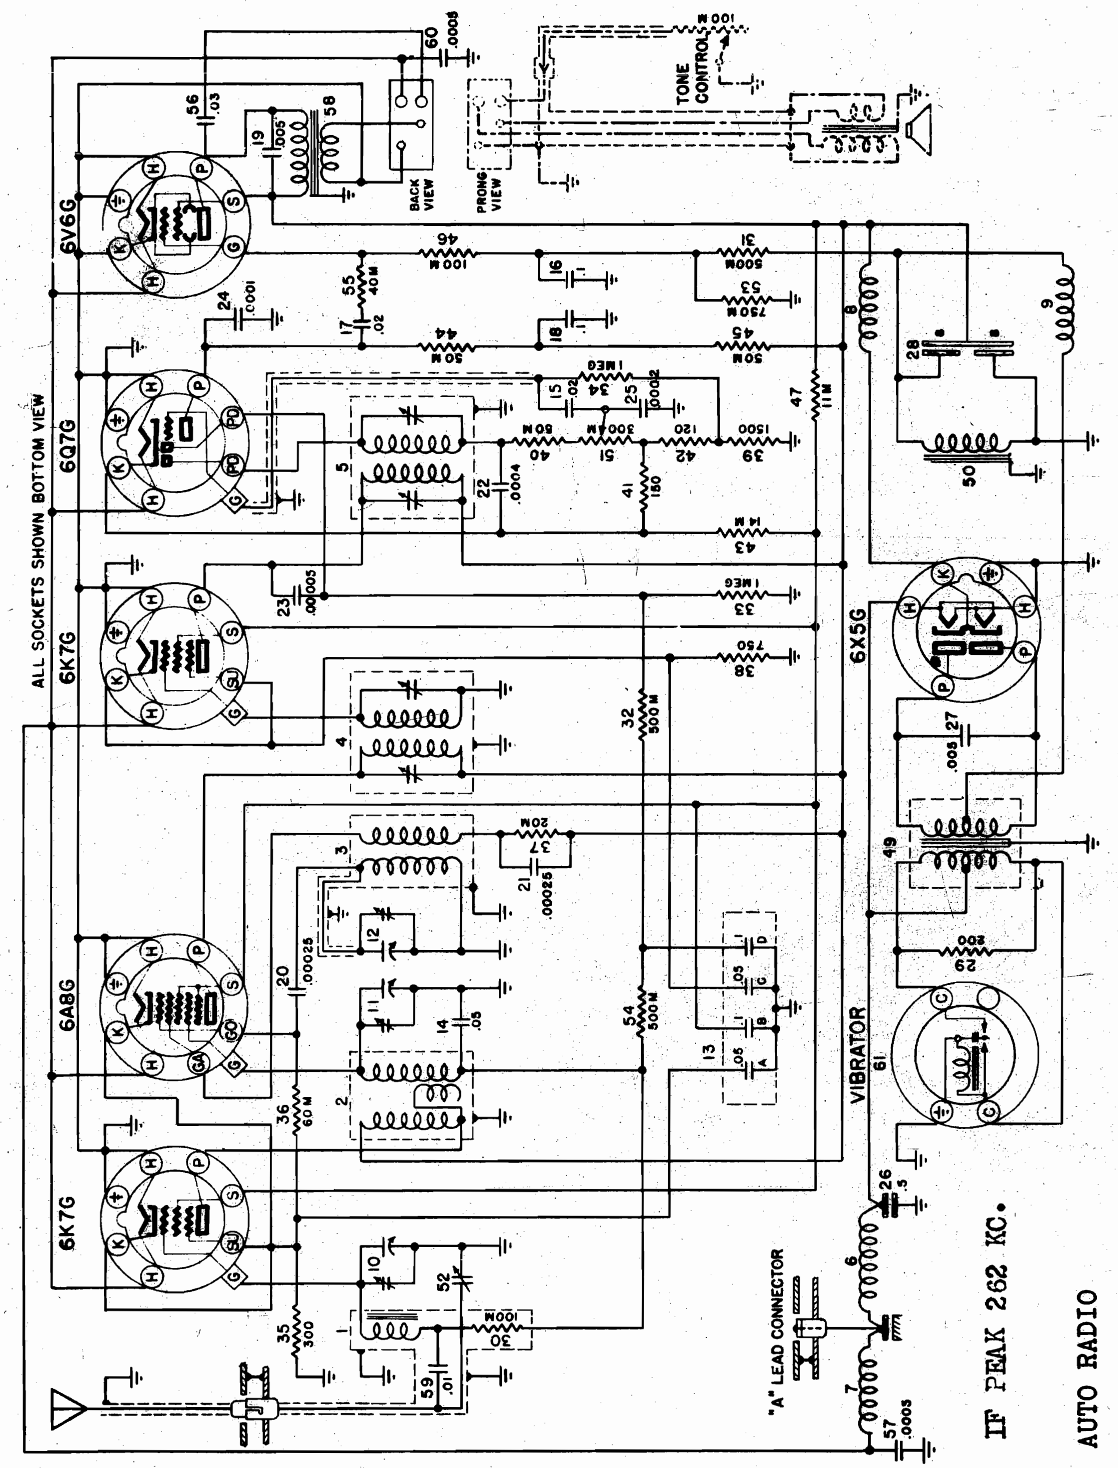
(a) Set Signal Generator to approximately 600 kilocycles and turn condenser gang plates until this signal is tuned in with maximum output.

(b) Adjust Delco Syncro-Tuning condenser (Illus. 52) located on side of chassis near antenna connector, rocking gang condenser plates back and forth through the signal until maximum output is obtained. (It will be necessary to readjust this condenser to the car antenna upon installation of the set.)

(c) Repeat adjustments made under--"Aligning at 1400 K.C.".

MODEL R-643 Delco
Schematic

UNITED MOTORS SERVICE



The Delco Model R-643 is a six tube, external speaker auto radio, with variable tone control, non-synchronous vibrator and type 6V6G "Beam" Power Tube.

Delco Model R-643

Date: 6-25-37

Checking I-F Band Spread

The Model 165 Cathode Ray Oscillograph should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustment of the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Complete information concerning this check with the Oscillograph, is given in the Oscillograph Manual, included with each instrument.

1. **Peaking I-F Stages at 262 Kilocycles**

   (a) Connect the ground lead of the Signal Generator to the chassis case. Connect the signal lead of the Signal Generator to the grid cap of the 6A8G tube, through a .1 mfd. condenser, leaving the tube's grid clip in place.

   (b) Connect output meter from plate of 6V6G tube to ground.

   (c) Set Signal Generator to exactly 262 kilocycles and turn volume control on full.

   (d) Turn condenser gang to a position where no squeals or beat notes can be noticed, also so that when the tuning condenser is rotated within narrow limits there is no appreciable change in output.

   (e) Adjust trimmers A-B-C-D on the top of the I-F coils (Illus. 4 & 5) carefully for maximum output.

   (f) Repeat adjustments of I-F trimmers A-B-C-D with as low an output from the Signal Generator as possible, for more accurate alignment.

2. **Aligning at 1530 Kilocycles**

   (a) Leave Signal Generator leads connected the same as for I-F adjustments.
   (b) Turn tuning condenser plates all the way out and against high frequency stop.

   (c) Set Signal Generator to exactly 1530 kilocycles and adjust oscillator trimmer "E" on middle section of condenser gang carefully for maximum output.

3. **Aligning at 1400 Kilocycles**

   (a) Remove signal lead of Signal Generator from grid cap of 6A8G tube and connect to antenna terminal of receiver through a .0002 mfd. mica condenser.

   (b) Set the Signal Generator to 1400 kilocycles and tune the receiver to this signal.

   (c) Adjust the parallel trimmers "F" and "G" of the condenser gang carefully for maximum output. Do not disturb the 1530 kilocycle adjustment of the middle section of the condenser gang.

4. **Aligning at 600 Kilocycles**

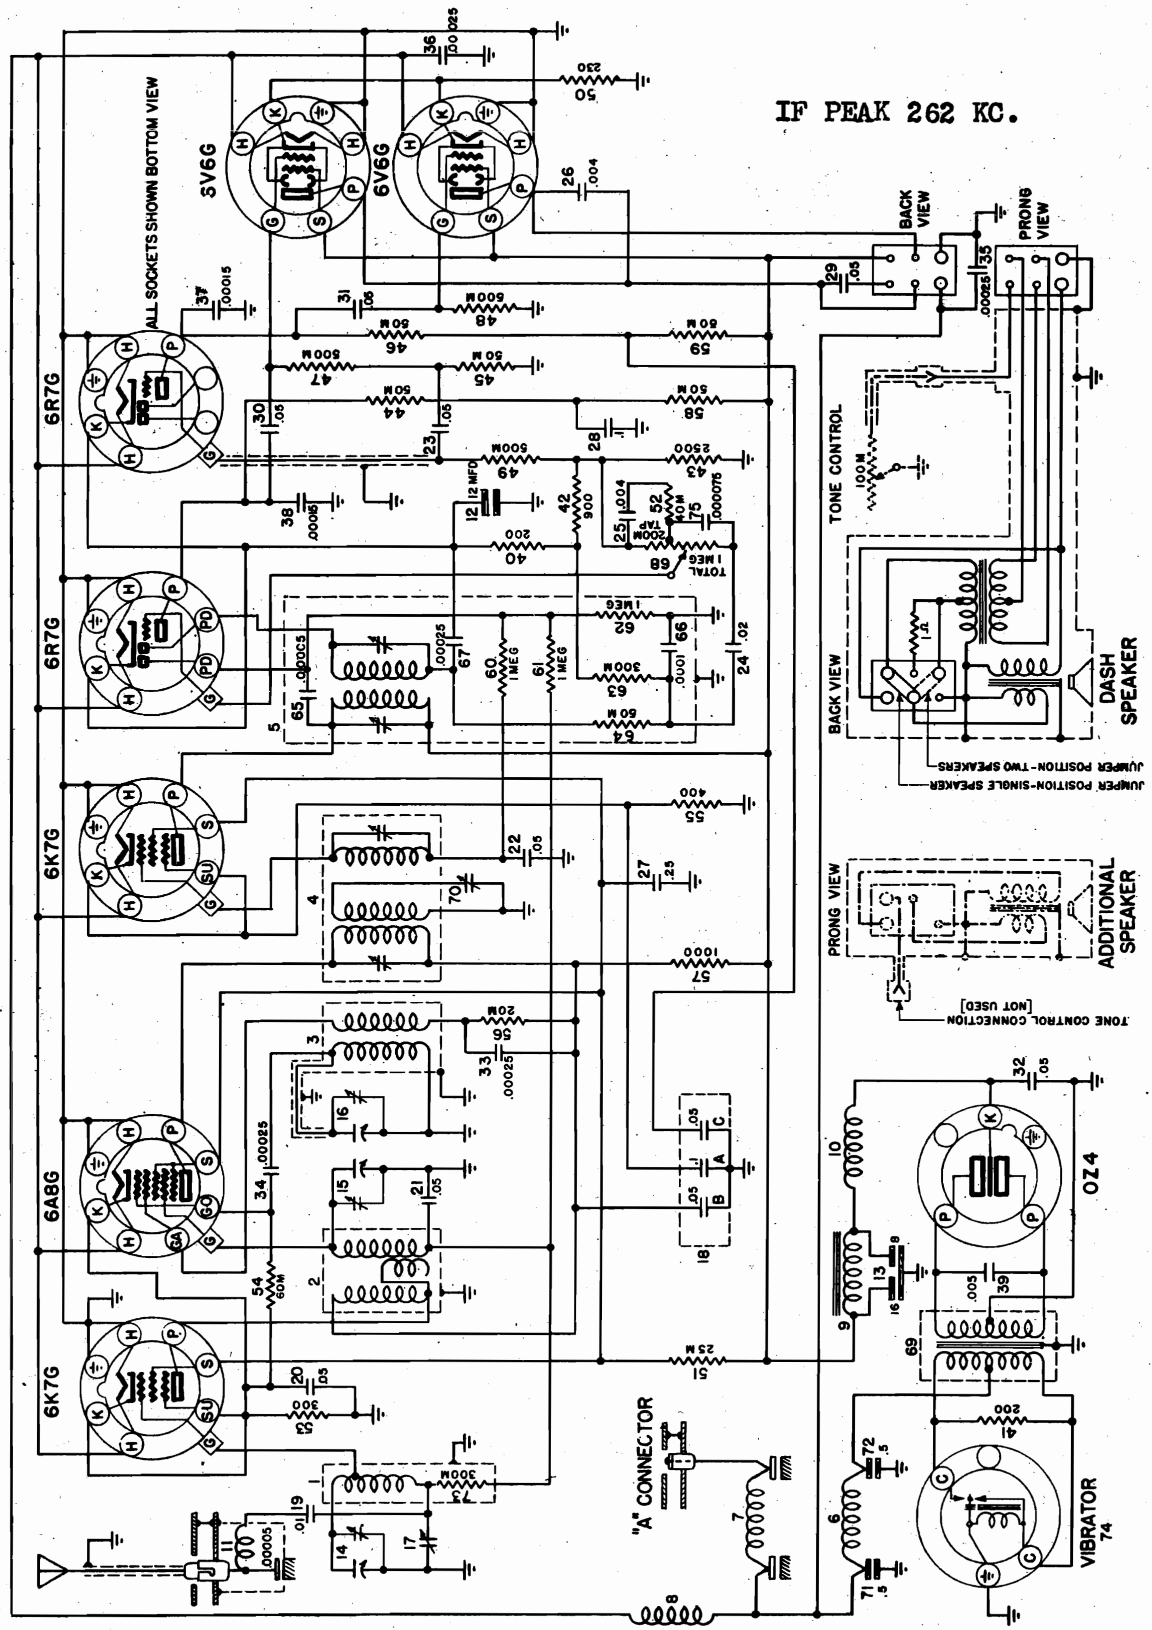
   (a) Set Signal Generator to approximately 600 kilocycles and turn condenser gang plates until this signal is tuned in with maximum output.

   (b) Adjust Delco Syncro-Tuning condenser (Illus. 52) located on side of chassis near antenna connector, rocking gang condenser plates back and forth through the signal until maximum output is obtained. (It will be necessary to readjust this condenser to the car antenna upon installation of the set.)

   (c) Repeat adjustments made under--"Aligning at 1400 KC.

MODEL R-644 Delco
Schematic

UNITED MOTORS SERVICE



An extra socket is provided on the dash speaker for plugging in an additional speaker for two speaker operation.

AUTO RADIO

Delco Model R-644

Date: 6-11-37

The Delco Model R-644 is an 8 tube, dash speaker auto radio, with bass compensation, octal base tubes and tone control. Two of the new 6V6G "Beam" power tubes are used in the output stage.

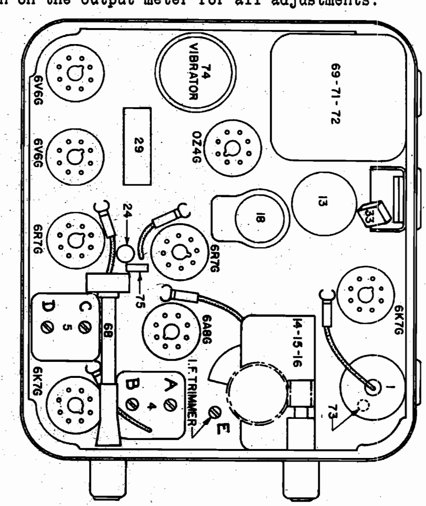

FIG. 3--PARTS LAYOUT--Top View

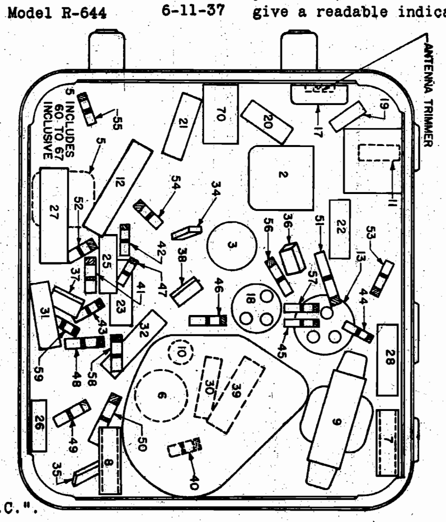

FIG. 4--PARTS LAYOUT--Bottom View

Checking I-F Band Spread

The Model 165 Cathode Ray Oscillograph should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustments to the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Complete information concerning this check with the Oscillograph, is given in the Oscillograph Manual, included with each instrument. In connecting the Oscillograph to the R-644, connect to white lead from bottom of 2nd I-F Coil (Illus. #5) and to chassis frame.

1. Peaking I-F Stages at 262 Kilocycles

(a) Connect the ground lead of the Signal Generator to the chassis case. Connect the signal lead of the Signal Generator to the grid cap of the 6A8G tube, through a .1 mfd. condenser, leaving the tube's grid clip in place.

(b) Connect output meter across plates of 6V6G output tubes. (If an A.C. meter is available having a full scale range of 4 volts or less, it can be connected directly across the voice coil connection on the speaker socket provided on the dash speaker for an additional speaker.)

(c) Set Signal Generator to exactly 262 kilocycles and turn volume control on full.

(d) Turn condenser gang to a position where no squeals or beat notes can be noticed, also so that when the tuning condenser is rotated within narrow limits there is no appreciable change in output.

(e) Adjust trimmers A-B-C-D on the top of the I-F coils (Illus. 4 & 5) carefully for maximum output.

(f) Adjust I-F trimmer "E" located on chassis sub-panel carefully for maximum output.

(g) Repeat adjustments of I-F trimmers A-B-C-D-E with as low an output from the Signal Generator as possible, for more accurate alignment.

2. Aligning at 1530 Kilocycles

(a) Leave Signal Generator leads connected the same as for I-F adjustments.

(b) Turn tuning condenser plates all the way out and against high frequency stop.

(c) Set Signal Generator to exactly 1530 kilocycles and adjust oscillator trimmer on middle section of condenser gang carefully for maximum output.

3. Aligning at 1400 Kilocycles

(a) Remove signal lead of Signal Generator from grid cap of 6A8G tube and connect to antenna terminal of receiver through a .0002 mfd. mica condenser.

(b) Set the Signal Generator to 1400 kilocycles and tune the receiver to this signal.

(c) Adjust the parallel trimmers on the top and bottom sections of the condenser gang carefully for maximum output. Do not disturb the 1530 kilocycle adjustment of the middle section of the condenser gang.

4. Aligning at 600 Kilocycles

(a) Set Signal Generator to approximately 600 kilocycles and turn condenser gang plates until this signal is tuned in with maximum output.

(b) Adjust Delco Syncro-Tuning condenser (Illus. #17) located on side of chassis near antenna connector, rocking gang condenser plates back and forth through the signal until maximum output is obtained. (It will be necessary to readjust this condenser to the car antenna upon installation of the set.) (c) Repeat adjustments "Aligning at 1400 K.C.".

MODELS R1116,R1117 Delco Alignment,Notes

UNITED MOTORS SERVICE

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties in adjusting the short wave circuits.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The dial pointer should be on the white horizontal line below 530 K.C. on the dial. This check should be made before attempting any trimmer adjustments.

1. Peaking I-F Stages at 456 Kilocycles

(a) Connect the signal lead of the test oscillator to the grid cap of the 6A8G tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the test oscillator to the receiver chassis.

(c) Place the test oscillator in operation at 456 K.C.

(d) Change the band switch to the broadcast position (fully clockwise).

(e) Set the receiver dial pointer to any position where it has no tuning effect on the I-F signal from the oscillator.

(f) Turn the receiver volume control to the maximum position.

(g) Adjust the four I-F trimmers A, B, C & D on the two I-F coils Illus. 30 and 56 (Fig. 2) carefully for maximum output in the following sequence--A-B-C-D. Then repeat the four trimmer adjustments During alignment, maintain as low a signal output from the test oscillator as is consistent with obtaining at least half scale indication on the output meter.

2. Aligning at 1500 Kilocyles (Broadcast Band)

(a) Connect the signal lead of the test oscillator to the antenna terminal on the chassis through a 400 or 500 ohm carbon resistor. Leave test oscillator ground lead connected to the receiver chassis.

(b) Place test oscillator in operation at 1500 K.C.

(c) Turn dial pointer to 1500 K.C. setting.

(d) Adjust the Broadcast Band oscillator parallel condenser, Illus. 36 (Fig. 4) to maximum output.

(e) Adjust the Broadcast Band detector parallel trimmer, Illus. 33 (Fig. 2) to maximum output.

(f) Adjust the Broadcast Band antenna parallel trimmer, Illus. "E" (Fig. 2) to maximum output.

3. Aligning at 600 Kilocycles (Broadcast Band)

(a) Place test oscillator in operation at 600 K.C.

(b) Tune in the 600 K.C. test oscillator with the receiver dial for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the Broadcast Band oscillator tracking condenser, Illus. 17 (Fig. 2) while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under paragraph #2 "Aligning at 1500 Kilocycles" for accurate adjustments.

4. Adjusting the Wave Trap

(a) Place test oscillator in operation at 456 K.C. but leave it connected to the antenna terminal through a carbon resistor.

(b) Set the receiver dial pointer to any position where it has no tuning effect on the 456 K.C. signal.

(c) Adjust the wave trap trimmer, Illus. 16 (Fig. 2) for MINIMUM output, increasing the oscillator output as necessary to obtain a clearly defined point of minimum output.

5. Aligning at 5 Megacycles (5000 K.C. Police Band)

(a) Place test oscillator in operation at 5 megacycles.

(b) Turn dial pointer to 5 megacycles and turn band change switch to the Police Band (center position).

(c) Adjust the Police Band oscillator parallel trimmer, Illus. 37 (Fig. 4) for maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out (less capacity).

(d) Adjust the Police Band antenna parallel trimmer, Illus. 34 (Fig. 2) to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dail until maximum output meter deflection is secured.

Aligning at 16 Megacycles (16000 KC Foreign Band)

(a) Place the test oscillator in operation at 16 megacycles.

(b) Turn dial pointer to 16 megacycles and turn band change switch to the Foreign Band (fully counter-clockwise).

(c) Adjust the Foreign Band oscillator parallel trimmer, Illus. 38 (Fig. 3) to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 megacycles. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 M.C. and adjust the trimmer, Illus. 38, to the proper peak with the trimmer screw farther out (less capacity).

(d) Adjust the Foreign Band antenna trimmer, Illus. 35 (Fig. 2) to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

(e) Check the adjustment by tuning the receiver to the image at about 15.1 M.C. The image should be much weaker than the 16 M.C. signal. If the image is equal to or stronger than the 16 M.C. signal, trimmer Illus. 35 is not at the proper peak. Turn the trimmer in a turn or so, then readjust as above.

NOTES ON TUBE SOCKET VOLTAGES

A bottom view of the receiver chassis is shown in Fig. 1 (Circuit Diagram) on which the voltages at each of the tube socket contacts are indicated. These readings were made with a D.C. voltmeter having a resistance of 1000 ohms per volt.

NOTE A: The grid bias for the 6F5G is--1.5 volts measured across resistor 29.

NOTE B: The grid bias for the 6A8G, 6K7G, and the anode voltage of the A.V.C. section of the 6H6 is--3.5 volts measured across resistors 29 and 54.

NOTE C: The grid bias for the 6F6 output tube is--19.5 volts measured across resistors 29, 54 and 27.

NOTE D: Target voltage for the 6G5 tuning eye is 255 volts.-DELCO MODEL R-1117

Alignment, Notes

UNITED MOTORS SERVICE

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will cause difficulties in adjusting the short wave circuits.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The slow moving dial pointer should then coincide with the low frequency end of the dial scale. This check should be made before attempting any trimmer adjustments.

1. Peaking I-F Stages at 456 Kilocycles

(a) Connect the signal lead of the test oscillator to the grid cap of the 6A8 tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the test oscillator to the receiver chassis.

(c) Place the test oscillator in operation at 456 KC.

(d) Change the band switch to the broadcast position (fully clockwise)

(e) Set the receiver dial pointer to any position where it has no tuning effect on the I-F signal from the oscillator.

(f) Turn the receiver volume control to the maximum position.

(g) Adjust the four I-F trimmers A, B, C and D on the two I-F coils, Illus. #66 and #67 (Fig. 2) carefully for maximum output in the following sequence--A-B-C-D. Then repeat the four trimmer adjustments. During alignment, maintain as low a signal output from the test oscillator as is consistent with obtaining at least half scale indication on the output meter.

2. Adjusting the Wave Trap

(a) Leave test oscillator in operation at 456 KC, but connect the oscillator output to the "A" and "G" terminals of the receiver with a 400 or 500 ohm carbon resistor in series with the "A" terminal and the oscillator signal lead.

(b) Set the receiver dial pointer to any position where it has no tuning effect on the 456 KC signal.

(c) Adjust the wave trap trimmer, Illus. #26 (Fig. 3) for MINIMUM output, increasing the oscillator output as necessary to obtain a clearly defined point of minimum output. If some particular station with a frequency near 456 KC causes code interference, it may be desirable to adjust the wavetrap on the actual frequency of the interfering station.

3. Aligning at 1500 Kilocycles (Broadcast Band)

(a) Leave the signal lead of the test oscillator connected to the antenna terminal on the chassis through a 400 or 500 ohm carbon resistor. Leave test oscillator ground lead connected to the receiver chassis.

(b) Place test oscillator in operation at 1500 KC.

(c) Turn receiver dial pointer to 1500 KC setting.

(d) Adjust the Broadcast Band oscillator parallel trimmer, Illus. #57A (Fig. 3) to maximum output.

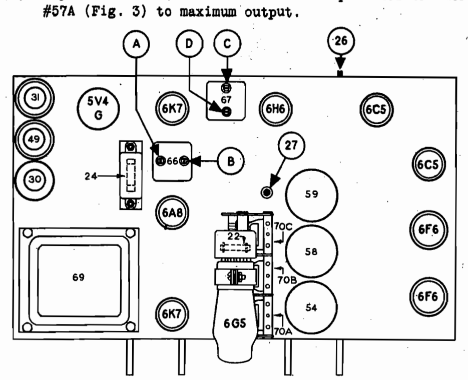

FIG. 2--PARTS LAYOUT--Top View

Delco Model R-1118
Date: 9-16-36

(e) Adjust the Broadcast Band detector parallel trimmer, Illus. #56A (Fig. 3) to maximum output.

(f) Adjust the Broadcast Band antenna parallel trimmer, Illus. #55A (Fig. 3) to maximum output.

4. Aligning at 600 Kilocycles (Broadcast Band)

(a) Place test oscillator in operation at 600 KC.

(b) Tune in the 600 KC test oscillator signal with the receiver dial for maximum output. (This point does not have to be exactly at the 600 KC dial setting.)

(c) Adjust the Broadcast Band oscillator tracking condenser, Illus. #27 (Fig. 3) while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under paragraph #3 "Aligning at 1500 Kilocycles" for accurate adjustment.

5. Aligning at 5 Megacycles (5000 KC--Police Band)

(a) Place test oscillator in operation at 5 megacycles.

(b) Turn dial pointer to 5 megacycles and turn band change switch to the Police Band (center position).

(c) Adjust the Police Band oscillator parallel trimmer, Illus. #46 (Fig. 3) for maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out, (less capacity).

(d) Adjust the Police Band antenna parallel trimmer, Illus. #44 (Fig. 3) to maximum output.

(e) Adjust the Police Band detector trimmer, Illus. #45 (Fig. 3) to maximum output.

(f) Then try to increase the output by detuning the detector trimmer, Illus. #45, slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

6. Aligning at 16 Megacycles (16,000 KC--Foreign Band)

(a) Be sure that the "D" terminal is connected to the "G" terminal on the antenna terminal strip.

(b) Place the test oscillator in operation at 16 megacycles.

(c) Turn dial pointer to 16 megacycles and turn band change switch to the Foreign Band (fully counter-clockwise).

(d) Adjust the Foreign Band oscillator parallel trimmer, Illus. #57B (Fig. 3) to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 megacycles. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 MC and adjust the trimmer, Illus. #57B, to the proper peak with the trimmer screw farther out (less capacity).

(e) Adjust the Foreign Band antenna trimmer, Illus. #55B (Fig. 3) to maximum output.

(f) Adjust the Foreign Band detector trimmer, Illus. #56B (Fig. 3) to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

(g) Check the adjustment by tuning the receiver to the image at about 15.1 MC. The image should be much weaker than the 16 MC signal. If the image is equal to or stronger than the 16 MC signal, trimmer Illus. #56B is not at the proper peak. Turn the trimmer IN a turn or so, then readjust as above.

GENERAL: The Delco Model R-1118 is a ten tube, three band, all wave receiver with A.V.C., continuously variable tone control and automatic bass compensation. The receiver is equipped with a band spread dial and a "Robot Eye" tuning indicator. The complete tube complement is as follows: two type 6K7, R-F and I-F Amplifiers; one type 6A8, Detector-Oscillator; one type 6H6, 2nd Detector and A.V.C.; two type 6C5, 1st and 2nd A-F Amplifiers; two type 6F6 in the Output Stage; one type 5V4G Rectifier and one type 6G5 Tuning Indicator.

The frequency ranges on the three bands covered are: American Broadcast Band (yellow) 527 to 1750 KC; Police and Amateur Band (green) 1720 to 5600 KC; and the Foreign Short Wave Band (red) 5.5 to 18 MC.

Delco Model R-1127 Date: 8-2-37

Voltage measurements (except heaters) made with 1000 ohm per volt D.C. voltmeter from tube socket contacts to ground.

* A.C. voltage--290 volts.....Target voltage tuning eye.....230 volts.

Note A: The bias on the control grids of the 6A8G, 6U7G and 6U5 tubes is -2.3 volts measured across resistor 36.

Note B: The bias on the control grid of the 6Q7G is -4 volts measured across resistors 36 and 37.

Note C: The bias on the control grid of the 6K6G is -14 volts measured across resistors 36, 37 and 38.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The dial pointer should now be on the black horizontal line below 530 K.C. on the dial. This check should be made before attempting any trimmer adjustments.

1. Peaking I-F Stages at 465 K.C.

(a) Connect the signal lead of the signal generator to the grid cap of the 6A8G tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the signal generator to the receiver chassis.

(c) Place the signal generator in operation at 465 K.C.

(d) Turn the range switch to the broadcast position (fully clockwise).

(e) Set the receiver dial pointer to about the 1000 K.C. point BETWEEN STATIONS.

(f) Turn the receiver volume control to the maximum position.

(g) Adjust the four I-F trimmers, A, B, C and D on the two I-F coils, (Fig. 3), carefully for maximum output in the following sequence A-B-C-D. Then repeat the four trimmer adjustments.

2. Adjusting the Wave Trap

(a) Connect the signal generator to the antenna terminal through a 400 or 500 ohm carbon resistor.

(b) Adjust the signal generator to 465 K.C.

(c) Turn the volume control on full.

(d) Set the dial pointer to about 1000 K.C. BETWEEN STATIONS.

(e) Adjust the wave trap trimmer, Illus. #1, (Fig. 3), for MINIMUM output, increasing the oscillator output as necessary to obtain a clearly defined point of minimum output.

3. Aligning at 16 M.C. (16,000 K.C. Foreign Wave Band)

(a) Turn the range switch to the Foreign Band position (extreme counter-clockwise).

(b) Set the dial pointer to 16 megacycles.

(c) Apply a 16 M.C. Signal to the A and G terminals of the receiver through a 400 or 500 ohm carbon resistor.

(d) Adjust the Foreign Band oscillator parallel trimmer, Illus. #53, (Fig. 3), to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 M.C. A repeat signal should be heard at this point. If none is present, even with greatly increased oscillator output, retune the receiver to 16 M.C. and readjust the trimmer, Illus. #53, (Fig. 3), the proper peak is the one with the trimmer screw farthest out (least capacity).

(e) Adjust the Foreign Band antenna trimmer, Illus. #50, (Fig. 2), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

(f) Check the adjustment by tuning the receiver to the image at about 15.1 M.C. The image should be much weaker than the 16 M.C. signal. If the image is equal to or stronger than the 16 M.C. signal, the trimmer, Illus. #50, is not at the proper peak. Turn the trimmer in a turn or so, then readjust as above.

4. Aligning at 5 M.C. (5,000 K.C. Police Band)

(a) Place the signal generator in operation at 5 M.C. and apply the signal to the A and G terminals of the receiver through a 400 or 500 ohm carbon resistor.

(b) Turn the dial pointer to 5 megacycles and the band change switch to the Police Band (center) position.

(c) Adjust the Police Band oscillator parallel trimmer, Illus. #54, (Fig. 3), for maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out (least capacity).

(d) Adjust the Police Band antenna parallel trimmer, Illus. #51, (Fig. 2), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

5. Aligning at 1500 K.C. (Broadcast Band)

(a) Place the signal generator in operation at 1500 K.C. and apply a 1500 K.C. signal to the A and G terminal of the receiver through a 400 or 500 ohm carbon resistor.

(b) Turn the range switch to the Broadcast position (fully clockwise) and set the dial pointer to 1500 K.C.

(c) Adjust the Broadcast Band oscillator parallel trimmer, Illus. #55, (Fig. 3), to maximum output.

(d) Adjust the Broadcast Band antenna parallel trimmer, Illus. #52, (Fig. 2), to maximum output.

6. Aligning at 600 K.C. (Broadcast Band)

(a) Leave the signal generator connected as above but readjust to 600 K.C.

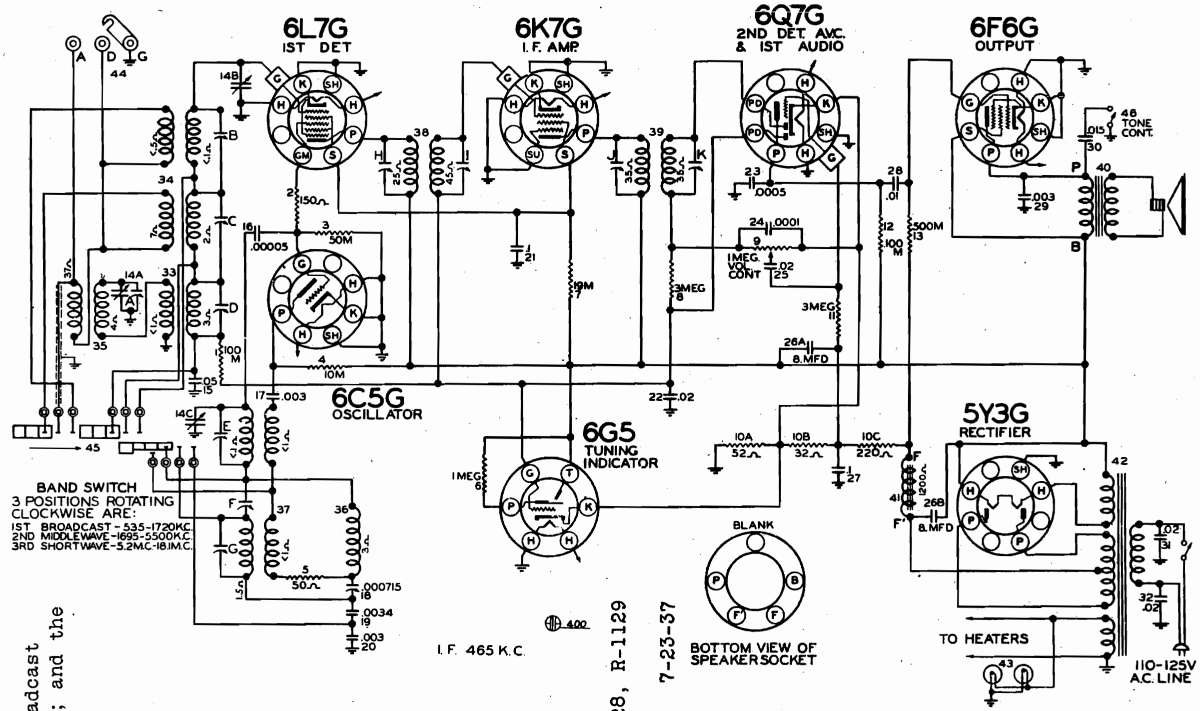
(b) Tune in the 600 K.C. Signal generator signal with the receiver dial for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the Broadcast Band oscillator tracking condenser, Illus. #8, (Fig. 3), while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under paragraph 5, "Aligning at 1500 Kilocycles" for accurate adjustments.

MODELS R1128,R1129 Delco Schematic,Socket Trimmers,Chassis

UNITED MOTORS SERVICE



The frequency ranges on the three bands covered are: American Broadcast Band, 535 to 1720 K.C.; Police and Amateur Band, 1695 to 5500 K.C.; and the Foreign Short Wave Band, 5.2 to 18.1 M.C.

Models R-1128, R-1129

Date: 7-23-37

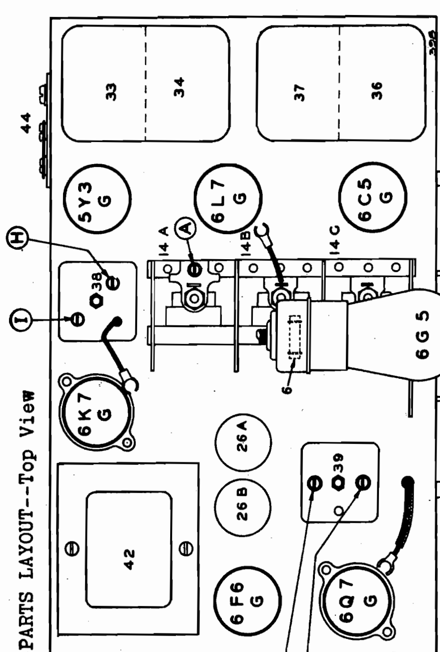


FIG. 3--PARTS LAYOUT--Top View

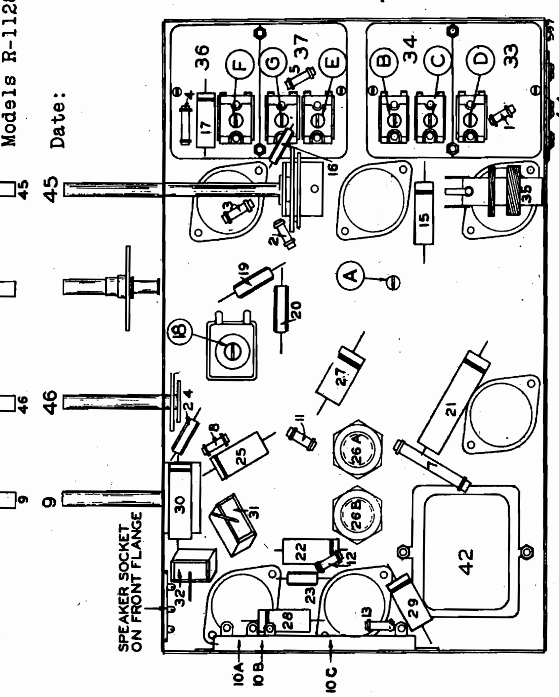

FIG. 4--PARTS LAYOUT--Bottom View

The Delco Models R-1128 (Table) and R-1129 (Console) are seven tube, three band receivers with A.V.C., tone control and Robot Eye tuning indicators. Both of these models employ the same chassis and use octal base glass type tubes.

MODELS R1128,R1129 Delco
Voltage,Alignment

UNITED MOTORS SERVICE

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.), as high frequency disturbances will cause difficulties in adjusting the short wave circuits.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The dial pointer should be on the horizontal line below 550 K.C. on the dial. This check should be made before attempting any trimmer adjustments.

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the Signal Generator to the receiver chassis.

(b) Connect the signal lead of the Signal Generator to the grid cap of the 6L7G tube through a .1 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(c) Place the Signal Generator in operation at 465 K.C.

(d) Change the band switch to the broadcast position (fully counter-clockwise).

(e) Set the receiver dial pointer to any position where it has no tuning effect on the I-F signal from the Signal Generator.

(f) Turn the receiver volume control to the maximum position.

(g) Adjust the four I-F trimmers, H, I, J, K on coils Illus. 38 and 39 (Fig. 3) carefully for maximum output in the following sequence: K, J, I, H. Then repeat the four trimmer adjustments. During alignment, maintain as low a signal output from the signal generator as is consistent with obtaining at least half scale indication on the output meter.

2. Aligning at 1720 and 1550 Kilocycles (Broadcast Band)

(a) Connect the signal lead of the Signal Generator to the antenna terminal on the chassis through a .0002 mica condenser. Leave signal generator ground lead connected to the receiver chassis.

(b) Place Signal Generator in operation at 1720 K.C.

(c) Turn dial pointer to 1720 K.C. setting (gang condenser open).

(d) Adjust the oscillator trimmer condenser "F", Illus. 36 (Fig. 4) to maximum output.

(e) Place Signal Generator in operation at 1550 K.C.

(f) Turn dial pointer until 1550 K.C. signal is tuned in with maximum output.

(g) Adjust the detector parallel trimmer condenser "D", Illus. 33 (Fig. 4) to maximum output.

(h) Adjust the pre-selector parallel trimmer condenser "A", Illus. 14A (Fig. 3) to maximum output.

3. Aligning at 600 Kilocycles (Broadcast Band)

(a) Place Signal Generator in operation at 600 K.C.

(b) Tune in the 600 K.C. signal with the receiver dial for maximum output.

(c) Adjust the oscillator tracking condenser, Illus. 18 (Fig. 4) while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under paragraph #2 "Aligning at 1720 and 1550 Kilocycles" for accurate adjustments.

4. Aligning at 17 Megacycles (Foreign Band)

(a) Place the Signal Generator in operation at 17 megacycles.

(b) Turn dial pointer to 17 megacycles and turn band change switch to the Foreign Band (fully clockwise).

(c) Adjust the oscillator parallel trimmer condenser "E", Illus. 37 (Fig. 4) to maximum output.

(d) Adjust the antenna trimmer condenser "B", Illus. 34, (Fig. 4) to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

(e) Check the adjustment by tuning the receiver to the image at about 16.1 M.C. The image should be much weaker than the 17 M.C. signal. If the image is equal to or stronger than the 17 M.C. signal, trimmer "E", Illus. 37, is not at the proper peak. Turn the trimmer out a turn or so, then readjust as above.

5. Aligning at 5 Megacycles (5000 K.C. Police Band)

(a) Place Signal Generator in operation at 5 megacycles.

(b) Turn dial pointer to 5 megacycles and turn band change switch to the Police Band (center position).

(c) Adjust the oscillator parallel trimmer condenser "G", Illus. 37 (Fig. 4) for maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out (less capacity).

(d) Adjust the antenna trimmer condenser "C", Illus. 34 (Fig. 4) to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

Voltage measurements (except heaters) made with 1000 ohm per volt D.C. voltmeter from tube socket contacts to ground.

Note A: The bias on the control grids of the 6L7G, 6K7 and 6U5 tubes is -2.5 volts measured across resistors 53 and 54.

Note B: The bias on the control grid of the 6F5 tube is -1.2 volts measured across resistor 53.

Note C: The bias on the control grid of the 6V6G tube is -14 volts measured across resistors 53, 54 and 55.

The frequency ranges on the three bands covered are: American Broadcast Band 540 to 1720 K.C., Police and Amateur Band 1.7 to 5.6 M.C., and the Foreign Short Wave Band 5.5 to 18 M.C.

MODEL R1130 Delco
Trimmers, Alignment

UNITED MOTORS SERVICE

Delco Model R-1130

Date: 8-4-37

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will make it difficult to adjust the short wave circuits.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The dial pointer should be on the 510 K.C. line on the dial. This check should be made before attempting any trimmer adjustments. Alignment of the chassis MUST be in the following order:

1. Peaking I-F Stages at 465 K.C.

(a) Connect the signal lead of the signal generator to the grid cap of the 6L7G tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the signal generator to the receiver chassis.

(c) Place the signal generator in operation at 465 K.C.

(d) Set the receiver band switch to the broadcast position (fully clockwise).

(e) Set the dial pointer at about the 1000 K.C. BETWEEN STATIONS.

(f) Turn the volume control full on (to extreme clockwise position).

(g) Adjust the four I-F trimmers, A, B, C and D on the two I-F coils Illus. #62 and 63, carefully for maximum output in the following sequence--A-B-C-D. Then repeat the four trimmer adjustments.

2. Adjusting the Wave Trap

(a) Place the signal generator in operation at 465 K.C. and connect it to the receiver "A" terminal with a 400 or 500 ohm carbon resistor in series. (Leave the "D" and "G" terminals connected together during the complete alignment.) Connect the ground lead of the signal generator to the "G" terminal.

(b) With the volume control full on and the range switch in the broadcast position, tune the set to about 1000 K.C., BETWEEN STATIONS.

(c) Adjust the wave trap trimmer, Illus. #1, (Fig. 2), for MINIMUM output, increasing the signal generator output as necessary to obtain a clearly defined point of minimum output.

3. Aligning at 16 M.C. (16,000 K.C. Foreign Band)

(a) Place the signal generator in operation at 16 M.C. leaving it connected to the "A" terminal of the set through a 400 or 500 ohm carbon resistor, and with the ground lead connected to the "G" terminal as above.

(b) With the volume control full on, turn the range switch to the Foreign Band position (fully counter-clockwise) and tune the receiver dial pointer to 16 M.C.

(c) Adjust the Foreign Band oscillator parallel trimmer, Illus. #17, (Fig. 3), to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 M.C. A repeat signal should be heard at this point. If none is present, even with greatly increased signal generator output, retune the receiver to 16 M.C. and adjust the trimmer, Illus. #17, to the proper peak with the trimmer screw farther out (least capacity).

(d) Adjust the Foreign Band antenna trimmer, Illus. #5, (Fig. 2), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

(e) Check the adjustment by tuning the receiver to the image at about 15.1 M.C. The image should be much weaker than the 16 M.C. signal. If the image is equal to or stronger than the 16 M.C. signal, the trimmer, Illus. #5, is not at the proper peak. Turn the trimmer in a turn or so, then readjust as above.

4. Aligning at 5 M.C. (5,000 K.C. Police Band)

(a) Place the signal generator in operation at 5 M.C. leaving it connected to the "A" terminal of the set through a 400 or 500 ohm carbon resistor.

(b) With the volume control full on turn the range switch to the Police and Amateur Band position (center position), and tune the receiver dial pointer to 5 M.C.

(c) Adjust the oscillator parallel trimmer, Illus. #18, (Fig. 3), to maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out (least capacity).

(d) Adjust the antenna parallel trimmer, Illus. #6, (Fig. 2), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

5. Aligning at 1500 K.C. (Broadcast Band)

(a) Place the signal generator in operation at 1500 K.C. leaving it connected to the "A" terminal of the set through a 400 or 500 ohm carbon resistor.

(b) With the volume control full on turn the range switch to the Broadcast position (fully clockwise) and tune the receiver dial pointer to 1500 K.C.

(c) Adjust the oscillator parallel condenser, Illus. #19, (Fig. 3), to maximum output.

(d) Adjust the preselector trimmer, Illus. E, (Fig. 2), to maximum output.

(e) Adjust the antenna parallel trimmer, Illus. #7, (Fig. 2) to maximum output.

6. Aligning at 600 K.C. (Broadcast Band)

(a) Place the signal generator in operation at 600 kilocycles leaving it connected to the "A" terminal of the receiver through a 400 or 500 ohm carbon resistor.

(b) With the volume control full on and the range switch in the Broadcast Band position, tune the receiver to the 600 K.C. signal generator signal for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the oscillator tracking condenser, Illus. #22, (Fig. 2), while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under paragraph 5, "Aligning at 1500 Kilocycles" for accurate adjustments.

Tuning eye target voltage.....260 volts.

Voltage measurements made with a 100 ohm per volt DC voltmeter from tube socket contacts to ground. Plate voltage reading on 6F5 tube should be made on highest voltage scale.

Delco Model R-1131

Date: 9-14-37

The Delco Model R-1131 is a nine tube, three band, all wave receiver with A.V.C., "Robot" tuning eye, automatic bass compensation, tone control and permeability tuned--iron core I-F transformers. Seven of the tubes in this receiver are of the metal type, and two are of the glass type. The tube complement is as follows: 6K7 R-F Amplifier, 6L7 Modulator, 6C5 Oscillator, 6K7 I-F Amplifier, 6H6 2nd Detector and A.V.C., 6F5 Audio Amplifier, 6L6 Audio Output, 5Y3G Rectifier and a type 6U5 Tuning Eye.

MODEL R1131 Delco
Trimmers, Alignment

UNITED MOTORS SERVICE

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will make it difficult to adjust the short wave circuits.

DIAL SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. The dial pointer should be set on the 500 KC line on the dial, by loosening the clip at the point where the pointer slide is attached to the drive cord, and moving the pointer to the correct position. This check should be made before attempting any trimmer adjustments.

Alignment of the chassis MUST be in the following order:

1st	Intermediate Frequency	4th	Broadcast Band (600 KC)
2nd	Wave Trap	5th	Police and Amateur Band
3rd	Broadcast Band (1500 KC)	6th	Short Wave Band

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the signal lead of the signal generator to the grid cap of the 6L7 tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the signal generator to the receiver chassis.

(c) Place the signal generator in operation at 465 KC.

(d) Set the receiver band switch to the broadcast position (counter clockwise).

(e) Set the dial pointer at any point where it does not affect the signal.

(f) Turn the volume control full on (to extreme clockwise position).

(g) Adjust the four I-F trimmers A, B, C and D on the two I-F coils, Illus. 83 and 84, Fig. 2, carefully for maximum output in the following sequence--A, B, C and D. Then repeat the four trimmer adjustments. During alignment, maintain as low a signal output from the signal generator as is consistent with obtaining at least half scale indication on the output meter.

2. Adjusting the Wave Trap

(a) Place the signal generator in operation at 465 KC and connect it to the receiver A terminal with a 400 or 500 ohm carbon resistor in series. (Leave the D and G terminals connected together during the complete alignment.) Connect the ground lead of the signal generator to the G terminal.

(b) With the volume control full on and the range switch in the broadcast position, tune the set to about 1000 KC, BETWEEN STATIONS.

(c) Adjust the wave trap trimmer, Illus. E, Fig. 3, for MINIMUM output, increasing the signal generator output as necessary to obtain a clearly defined point of minimum output.

3. Aligning at 1500 Kiocycles (Broadcast Band)

(a) Place the signal generator in operation at 1500 kilocycles leaving it connected to the A terminal of the set through a 400 or 500 ohm resistor.

(b) With the volume control full on turn the range switch to the broadcast position (counter clockwise) and tune the receiver dial pointer to 1500 KC.

(c) Adjust the oscillator trimmer condenser, Illus. 25, Fig. 3, to maximum output.

(d) Adjust the antenna trimmer, Illus. 16, Fig. 3, to maximum output.

(e) Adjust the detector trimmer, Illus. 21, Fig. 3, to maximum output.

4. Aligning at 600 Kilocycles (Broadcast Band)

(a) Place the signal generator in operation at 600 kilocycles leaving it connected to the A terminal of the receiver through a 400 or 500 ohm carbon resistor.

(b) With the volume control full on and the range switch in the Broadcast Band position, tune the receiver to the 600 KC signal generator signal for maximum output. (This point does not have to be exactly at the 600 KC dial setting.)

(c) Adjust the oscillator tracking condenser, Illus. 26, Fig. 3, while rocking the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under "Aligning at 1500 Kilocycles" for accurate adjustments.

5. Aligning at 5 Megacycles (5000 KC Police Band)

(a) Place the signal generator in operation at 5 megacycles leaving it connected to the A terminal of the set through a 400 or 500 ohm carbon resistor.

(b) With the volume control full on turn the range switch to the Police and Amateur Band position (center position), and tune the receiver dial pointer to 5 megacycles.

(c) Adjust the oscillator parallel trimmer, Illus. 28, Fig. 3, to maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out (least capacity).

(d) Adjust the antenna parallel trimmer, Illus. 15, Fig. 3, to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

(e) Adjust the detector parallel trimmer, Illus. 20, Fig. 3, to maximum output. Try to increase output by rocking the dial through resonance and retuning the trimmer until maximum output is obtained.

6. Aligning at 16 Megacycles (16,000 KC Foreign Band)

(a) Place the signal generator in operation at 16 megacycles leaving it connected to the A terminal of the set through a 400 or 500 carbon resistor, and with the ground lead connected to the G terminal as above.

(b) With the volume control full on, turn the range switch to the foreign band position (fully clockwise) and tune the receiver dial pointer to 16 megacycles.

(c) Adjust the oscillator parallel trimmer, Illus. 30, Fig. 3, to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 megacycles. A repeat signal should be heard at this point. If none is present even with greatly increased signal generator output, retune the receiver to 16 MC and adjust the trimmer, Illus. 30, to the proper peak with the trimmer screw farther out.

(d) Adjust the antenna trimmer, Illus. 14, Fig. 3, to maximum output. Then try to increase output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is secured.

Check the adjustment by tuning the receiver to the image at about 15.1 MC; the image should be much weaker than the 16 MC signal. If the image is equal to or stronger than the 16 MC signal, trimmer No. 14 is not at the proper peak. Turn the trimmer in a turn or so, then readjust as above.

(e) Adjust the parallel trimmer, Illus. 19, Fig. 3, to maximum output. Then try to increase output by detuning trimmer slightly and retuning the dial until a maximum output meter deflection is obtained. Check adjustment by tuning in image as described in the last paragraph under (d).

UNITED MOTORS SERVICE

The Delco Model R-1132 is a twelve tube, three band, all wave receiver with the entirely new and different "Delcomatic Tuner". Other features which this receiver embodies are A.V.C., "Robot" tuning eye, A.F.C., automatic bass compensation, tone control and permeability tuned--iron core I-F transformers. Ten of the tubes in this receiver are of the metal type, and two are of the glass type. The tube complement is as follows: One type 6K7 R-F amplifier, one type 6L7 modulator, one type 6C5 oscillator, one type 6K7 1st I-F amplifier, one type 6K7 2nd I-F amplifier, one type 6H6 second detector, A.V.C., and discriminator, one type 6C5 1st audio, two type 6V6 audio output, one type 5U4G rectifier, and one type 6U5 tuning eye.

Rectifier tube output voltage measured from filament contacts to ground... 355 volts D.C.

Tuning eye target voltage...290 volts.

NOTE "A": The grid bias for the 6L7 Modulator, 6K7 R-F, 6K7 1st I-F and 6K7 2nd I-F tubes is -3.5 volts, measured across resistor #97.

Delco Model R-1132

Date: 10-1-37

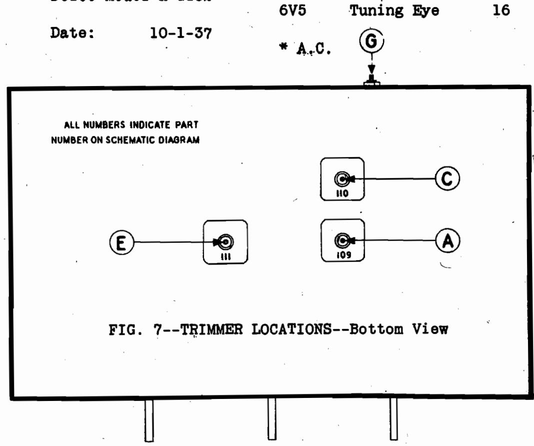

FIG. 7--TRIMMER LOCATIONS--Bottom View

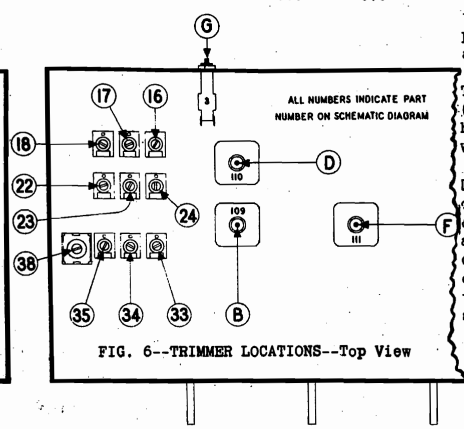

FIG. 6--TRIMMER LOCATIONS--Top View

INSTALLING THE DIAL DRIVE CORD

Before starting to thread the dial drive cord, see that the gang condenser is fully meshed, (plates fully closed). Insert one end of the cord through the upper eyelet on Drum "A" and knot it on the inside of the drum. Thread the cable over pulley "B" to the lower side of pulley "C", returning over pulley "C" to the upper side of pulley "D", thence to the rear of pulley "E". Lead the cord under pulley "E" and up to the front of drum "A". Wind two complete turns around drum "A", thread the cord through the lower eyelet on the drum and tie the end to the tension spring. Adjust the length of the cord so that the tension will be maintained on the cord when the spring is fastened to the small clip on the inside of the drum. Set the dial pointer to the last division on the left of the broadcast band scale, and clip the cord to the pointer slider.

INSTALLING THE BAND INDICATOR CORD

Before starting to thread the band indicator cord, tie a knot loosely in one end of the cord so that the tension spring may be connected to it. Tie a full knot about 3 inches from the knotted end of the cord. Place the range switch in the short wave position.

To thread the cord, take the end which has not been knotted, and wind one complete turn around drum "F", winding the turn from front to back. The cord should pass under the small metal pin which spans the drum. Loop the cord around the pin and wind one more complete turn around the drum. Run the knotted end of cord under pulley "H" to the lower side of pulley "I" and make one complete turn around "I". Insert the knot which has been tied 3 inches from the end of the cord into the slot in the pulley "I", and adjust the position of the dial scale so that the end of the pointer comes opposite the horizontal line across the dial scale, when the cord between the pulley "I" and "H" is fairly taut. Run the free end of the cord under pulley "G" and tie it to the tension spring. Adjust the lengths so that the tension will be maintained when the free end of the spring is connected to the knot at the other end of the cord. If the scale is not in exact alignment with the pointer, loosen the set screw which holds pulley "I" to the range switch shaft and adjust for correct position.

CIRCUIT ALIGNMENT

Individual coils and trimmer condensers are provided for each band, so that each circuit can be adjusted to give maximum efficiency on every tuning range. If realignment is found necessary, the circuits can be properly adjusted only with the use of a calibrated signal generator and an output meter.

The receiver should be aligned in a location free from local interference (interference caused by motors, flashers, automobile ignition, etc.) as high frequency disturbances will make it difficult to adjust the short wave circuits.

DIAL AND CAM SETTING CHECK: Turn the tuning knob until the rotor plates of the condenser gang are fully meshed. If the condenser will not close completely, proceed to loosen the set screws on the brass dial drive gear at the left side of the receiver and also the set screw on the flexible coupler on the gang condenser shaft. Then press the gang condenser plates closed and set the dial pointer to the 500 K.C. line on the dial scale by turning the cord drive drum on the left side of the mechanism. This check should be made before attempting any trimmer adjustments.

Alignment of the chassis MUST be in the following manner:

1st - Intermediate frequency
2nd - Wave trap
3rd - Broadcast band (1500 K.C.)
4th - Broadcast band (600 K.C.)
5th - A.F.C. alignment
6th - Police and amateur band
7th - Short wave band

UNITED MOTORS SERVICE

MODEL R1132 Delco Alignment

1. Peaking I-F Stages at 465 Kilocycles Delco Model R-1132 Date: 10-1-37

(a) Connect the signal lead of the signal generator to the grid cap of the 6L7 tube through a .1 or .25 mfd. condenser. DO NOT REMOVE THE GRID CLIP FROM THE TUBE.

(b) Connect the ground lead of the signal generator to the receiver chassis and leave it connected throughout the entire alignment procedure.

(c) Place the signal generator in operation at 465 K.C.

(d) Set the receiver band switch to the broadcast position (counter clockwise).

(e) Set the A.F.C. switch to the MANUAL TUNING POSITION (center position).

(f) Set the dial pointer at any point where it does not affect the signal.

(g) Turn the volume control full on (to extreme clockwise position).

(h) Adjust the six trimmers A, B, C, D, E and F on the three I-F coils, Illus. 109, 110 and 111 (Figs. 6 & 7), carefully for maximum output in the sequence given. Then repeat the six trimmer adjustments. During alignment, maintain as low a signal output from the signal generator as is consistent with obtaining at least half scale indication on the output meter.

2. Adjusting the Wave Trap

(a) Place the signal generator in operation at 465 K.C. and connect it to the receiver A terminal with a .0002 mfd. mica condenser in series. (Leave the D and G terminals connected together during the complete alignment.)

(b) With the volume control full on, the range switch in the broad cast position, and the A.F.C. switch in the manual (center) position tune the set to about 1000 K.C. BETWEEN STATIONS.

(c) Adjust the wave trap trimmer, Illus. G, (Fig. 6,) for MINIMUM output, increasing the signal generator output as necessary to obtain a clearly defined point of minimum output.

3. Aligning at 1500 Kilocycles (Broadcast Band)

(a) Place the signal generator in operation at 1500 kilocycles leaving it connected to the A terminal of the set through the .0002 mfd. mica condenser.

(b) With the volume control full on turn the range switch to the broadcast position (counter-clockwise) and tune the receiver dial pointer to 1500 K.C. BE SURE THAT A.F.C. SWITCH IS IN THE MANUAL (CENTER) POSITION.

(c) Adjust the oscillator parallel trimmer condenser, Illus. 35, (Fig. 6) to maximum output.

(d) Adjust the antenna parallel trimmer, Illus. 18, (Fig 6) to maximum output.

(e) Adjust the detector parallel trimmer, Illus. 22, (Fig. 6) to maximum output.

4. Aligning at 600 Kilocycles (Broadcast Band)

(a) Place the signal generator in operation at 600 kilocycles leaving it connected to the A terminal of the receiver through a .0002 mfd. mica condenser.

(b) With the volume control full on, the range switch in the broadcast position, and the A.F.C. switch in the manual (center) position, tune the receiver to the 600 K.C. signal for maximum output. (This point does not have to be exactly at the 600 K.C. dial setting.)

(c) Adjust the oscillator tracking condenser, Illus. 38, (Fig. 6) while "rocking" the tuning condenser plates back and forth through resonance until no further increase in output can be obtained.

(d) Repeat operations under "Aligning at 1500 Kilocycles" for accurate adjustments.

5. Automatic Frequency Control Alignment (A.F.C.)

(a) Place the signal generator in operation at 465 K.C. and couple it loosely to the 6L7 grid (connect the oscillator signal lead to the insulation on the grid lead of the 6L7). Switch off the modulation of the signal generator.

(b) Leave the A.F.C. switch in the manual (non A.F.C. or center) position.

(c) Connect the antenna A post to an outside aerial.

(d) Tune in a strong local station in the region of 1000 K.C. or lower (avoid stations around 930 K.C. which might beat with the second harmonic of the signal generator).

(e) Tune the receiver to zero beat (UNTIL AUDIO WHISTLE VANISHES COMPLETELY). (Tuning to either side of zero beat will cause the whistle to be heard.)

(f) NOW TURN THE A.F.C. SWITCH INTO THE A.F.C. POSITION (MAXIMUM CLOCKWISE POSITION).

(g) If the A.F.C. system is out of alignment, the beat note or whistle will again appear. If the beat note is heard adjust the discriminator trimmer, Illus. F, (Fig. 6), until zero beat is again obtained.

(h) If the above procedure has been followed correctly, opening or closing the A.F.C. switch will have no effect on zero beat.

5A. Alternate Method of A.F.C. Alignment

(Two Signal Generators Necessary)

(a) Connect one of the signal generators to the antenna A terminal and place it in operation at 1000 K.C. The 1000 K.C. signal should be unmodulated and its output should be rather high.

(b) Now proceed to connect the other generator as described in the previous method and place it in operation at 465 K.C. (unmodulated).

(c) The remaining procedure is the same as in e, f, g and h of the previous method of A.F.C. alignment.

NOTE: This method is preferable to the first as both signals being unmodulated, the zero beat setting is more easily distinguished.

6. Aligning at 5 Megacycles (5000 K.C. Police Band)

(a) Place the signal generator in operation at 5 megacycles leaving it connected to the A terminal of the set through .0002 mfd. mica condenser.

(b) With the volume control full on turn the range switch to the Police and Amateur Band position (center position). Then tune the receiver dial pointer to 5 megacycles.

(c) Adjust the oscillator parallel trimmer, Illus. 34, (Fig. 6), to maximum output. If there are two peaks, the proper one is with the trimmer screw farthest out. (Least capacity.)

(d) Adjust the antenna parallel trimmer, Illus. 17, (Fig. 6), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the receiver dial. If this causes the output to go down, detune the trimmer in the opposite direction. Continue detuning the trimmer and retuning the receiver dial until maximum output meter deflection is secured.

(e) Adjust the detector parallel trimmer, Illus. 23, (Fig. 6), to maximum output. Try to increase output by rocking the dial through resonance and retuning the trimmer until maximum output is obtained

7. Aligning at 16 Megacycles (16,000 K.C. Foreign Band)

(a) Place the signal generator in operation at 16 megacycles leaving it connected to the A terminal of the set through a .0002 mfd. mica condenser.

(b) With the volume control full on, tune the range switch to the Foreign Band position (fully clockwise), and tune the receiver dial pointer to 16 megacycles.

(c) Adjust the oscillator parallel trimmer, Illus. 33, (Fig. 6), to maximum output. Check to see if it has been adjusted to the proper peak by tuning the receiver to approximately 15.1 megacycles. A repeat signal should be heard at this point. If none is present even with greatly increased signal generator output, retune the receiver to 16 M.C. and adjust the trimmer, Illus. 33, to the proper peak with the trimmer screw farther out.

(d) Adjust both the antenna trimmer, Illus. 16, (Fig. 6), and the detector parallel trimmer, Illus. 24, (Fig. 6), to maximum output. Then try to increase the output by detuning the trimmer slightly and retuning the dial until a maximum output meter deflection is obtained.

Check the adjustment by tuning the receiver to the image at about 15.1 M.C., the image should be much weaker than the 16 M.C. signal. If the image is equal to or stronger than the 16 M.C. signal, trimmers #16 and #24 are not at the proper peak. Turn the trimmer in a turn or so, then readjust as above.

MODEL R1132 Delco "Delcomatic" Tuner Adjustments, Notes

UNITED MOTORS SERVICE

OPERATION OF DELCOMATIC TUNER

The "Delcomatic Tuner" is a mechanical device which has for its prime purpose the accurate, noiseless and speedy tuning of a station, by the mere push of a button. This function is performed in the following manner:

As the push button on the keyboard is depressed, a pawl arm at the rear of the tuner comes forward and rests against a circular cam. It will be noted that these cams have two different heights (that is, a high and a low side). The purpose of the two different levels will be self-evident as this explanation progresses.

Projecting from the rear of the unit is a set of switches which are motivated by a Bakelite cam arm. This arm is in turn operated by the movement of the pawls. Therefore, it is readily seen that the position of the pawl arm will control the setting of the electrical contacts of the switches in question.

Also located directly above the tuning shaft will be found an auxiliary pair of contacts known as the power contacts.

Before any button is depressed or with the tuner in the manual tuning position, all contact switches are in the position shown in Figure 1.

Now as a button is depressed, the power contacts will automatically be closed and the pawl arm will come forward to rest either upon the high or the low side of the cam, depending upon its position. This will move the Bakelite switch arm to the position shown in Figures 2 or 3. (See Note below.) In either of these positions, the reversing contact will be closed (this contact governs the direction of travel of the tuner in order that the pointer may travel directly to the station). Also, with the Bakelite arm in this position, the starting contacts will close, supplying power to start the motor.

The mute contacts will be closed in order that no noise or signal may come through the speaker until the station is properly tuned in.

Lastly, the A.F.C. contacts are also closed, at the same time, and this serves to remove A.F.C. until the station is tuned in, thus eliminating the possibility of "grasping" the wrong station before the tuner comes to rest.
Now the motor proceeds to drive the mechanism to the proper position for the desired station and as it comes to rest, the following events will occur.

First, the pawl arm will fall into a notch in the circular cam. This in turn causes the Bakelite cam arm to set the rear contact switches in a new position. The starting contacts are now open and the motor power supply is off; also, the mechanism is at rest.

NOTE: IN CHECKING THESE POSITIONS BE SURE TO TURN THE POWER OFF.

The A.F.C. and mute contacts are both open, thus allowing the signal to come through the receiver and also allowing the A.F.C. to function, which in turn puts the finishing touches on a perfectly tuned-in program. This position of the switch showing the station tuned in is shown in Figure 4.

Thus we have completed one entire cycle from push button to the completely tuned program, utilizing the Delcomatic Tuner.

There remain, however, two mechanical features which may be of interest to the service man. One of these is a small star gear on the tuning shaft. When changing from automatic tuning to manual tuning, the button is released by merely turning the tuning knob. This is accomplished by the star gear in question, which pushes the kick-out bar, thus releasing the button.

The second feature mentioned is the friction drive of the tuning mechanism. The rubber ring on the end of the motor shaft engages a metal drive disc on the tuning shaft which serves to drive the mechanism when in the manual tuning position.

Should slippage between these parts occur, due to wear, it is possible to increase the contact pressure by loosening the set screw of the drive disc on the motor shaft. When this is done, then push the rubber wheel to a closer contact and retighten the set screw.

NOTE: DO NOT ATTEMPT TO OPERATE DELCOMATIC TUNER ON ANY VOLTAGE LOWER THAN 105 VOLTS A.C.

SERVICING DELCOMATIC TUNER

1. Be sure the principle of operation, both electrically and mechanically is understood before attempting to service the Delcomatic Tuner.

2. Do not attempt to operate Delcomatic Tuner on any voltage lower than 105 volts A.C.

3. In case of trouble, first check switch contact positions with A.C. power off, against Figures 1 to 4 to see that they correspond to those illustrated. If switch contact springs do not correspond to those illustrated, adjust complete switch assembly by loosening the two screws in the switch support bracket and moving entire switch assembly so that their respective contact positions line up with those as illustrated. Tighten screws in support bracket firmly after proper switch adjustment has been made. If satisfactory operation of switch cannot be obtained by this adjustment, certain of the switch contact springs may be out of adjustment! In this case, if adjustment is required to more than one spring (except reversing contacts) or if a spring is badly out of adjustment, complete replacement of the switch assembly should be made.

4. A clutch is provided on the main cam assembly shaft to absorb the shock from the motor when the pawls drop down into the cam slots. Clutch action is obtained by the pressure of a small horseshoe shaped spring against the #1212590 Driven Gear and Bushing. If this clutch slips it will be necessary to remove any oil or grease with carbon tetrachloride, which may have entered the clutch. If, after cleaning any oil or grease from between the gear and spring, the clutch continues to slip, it will then be necessary to replace the spring, Part #1212616.

5. If motor runs slow and line voltage is over 105 volts, check all mechanical parts to see that they turn freely with power off.

6. If motor does not operate, check to see that switch on front of chassis is in A.F.C. position. Also, when button is depressed, the motor power contacts above tuning shaft and starting contacts on switch behind tuner should be checked to see that they are closed. One set of reversing contacts, depending on whether pawl is on high or low side of cam, should also be closed.

7. It should be noted that when Delcomatic Tuner is in the process of tuning a station, that the "mute" contacts short the control grids of the 6V6 output tubes together. Also, that the "A.F.C." contacts are closed, causing the A.F.C. circuit to be inoperative until station pawl drops in cam slot.

Delco Model R-1132 Date: 10-1-37

"SETTING UP" THE DELCOMATIC TUNER

1. Remove the knob on tuning control shaft which is the control in the upper right hand corner of the receiver panel. This knob may be removed by simply pulling it away from the panel. As this knob is removed another knob on the same shaft, partly hidden behind the panel face, will appear.

2. Grasp this knob and pull it out as far as it will go and at the same time "rocking" it so that the gears in the mechanism at the rear will mesh properly.

3. The knob should now be rotated to the right (clockwise) as far as it will go. BE SURE THAT THE KNOB IS TURNED ALL THE WAY UNTIL IT REACHES A DEFINITE STOP.

4. Push any button which you wish to set to a particular station. Be sure the button is pushed all the way in.

5. Grasp the small tuning control knob again and tune the receiver to the desired station. TUNE CAREFULLY MAKING USE OF THE "ROBOT EYE" TO BE SURE THAT YOU ARE CORRECTLY TUNED TO THE STATION IN QUESTION.

6. Push in the next button you wish to set. You will notice that as the second button is pushed in the first one will be released. Now tune in the next station that you wish to set up, again making use of the "robot eye" to be sure that you are correctly tuned to the station.

7. Repeat above operations until all buttons have been set to stations.

8. In order to release the last button, which now remains depressed, grasp the knob on the tuning control shaft and push it back into the cabinet as far as it will go and then pull it out again. Do not forget to "rock" the control when pulling it out in order that its gears may mesh properly.

9. Turn the knob to the LEFT until you reach a definite stop. A firm pressure must be applied, otherwise you will not lock all of the internal controls.

10. Push the small tuning knob back into the cabinet again and put on the large knob that was originally pulled off of this shaft at the start of operations.

11. The "automatic tuner" is now ready for operation and will tune to any station that you have previously selected by merely pushing the button for which that station was set. Labels bearing the names of all stations are supplied with the receiver for use in labeling the push bottons. To label the push buttons you must first remove the cap of the push button. The cap should be pulled off by pulling on the top end which has a small hump that holds the cap on. Then remove the white cardboard tab and insert the label for the station to which the button was set. In replacing the cap start at the bottom and press on the top.

12. YOU DO NOT NEED TO ADJUST THE DELCOMATIC TUNER AGAIN UNLESS YOU DESIRE TO SET ANY ONE OF THE BUTTONS TO A DIFFERENT STATION.

13. If you should desire to again tune manually, merely turn the A.F.C. control knob (lower center knob) to the center or standard position. This will release the automatic tuning mechanism completely.

14. WHEN USING DELCOMATIC TUNING THE A.F.C. CONTROL KNOB MUST BE TURNED TO THE EXTREME RIGHT HAND POSITION.

15. It is not advisable to set up the "automatic tuner" for operation on the Short Wave or Police band. However, the "tuner" may be set up for stations on the police band but extremely accurate tuning such as is obtained on the broadcast band cannot be expected. In this case the automatic tuner will only serve to give the approximate location of the station.

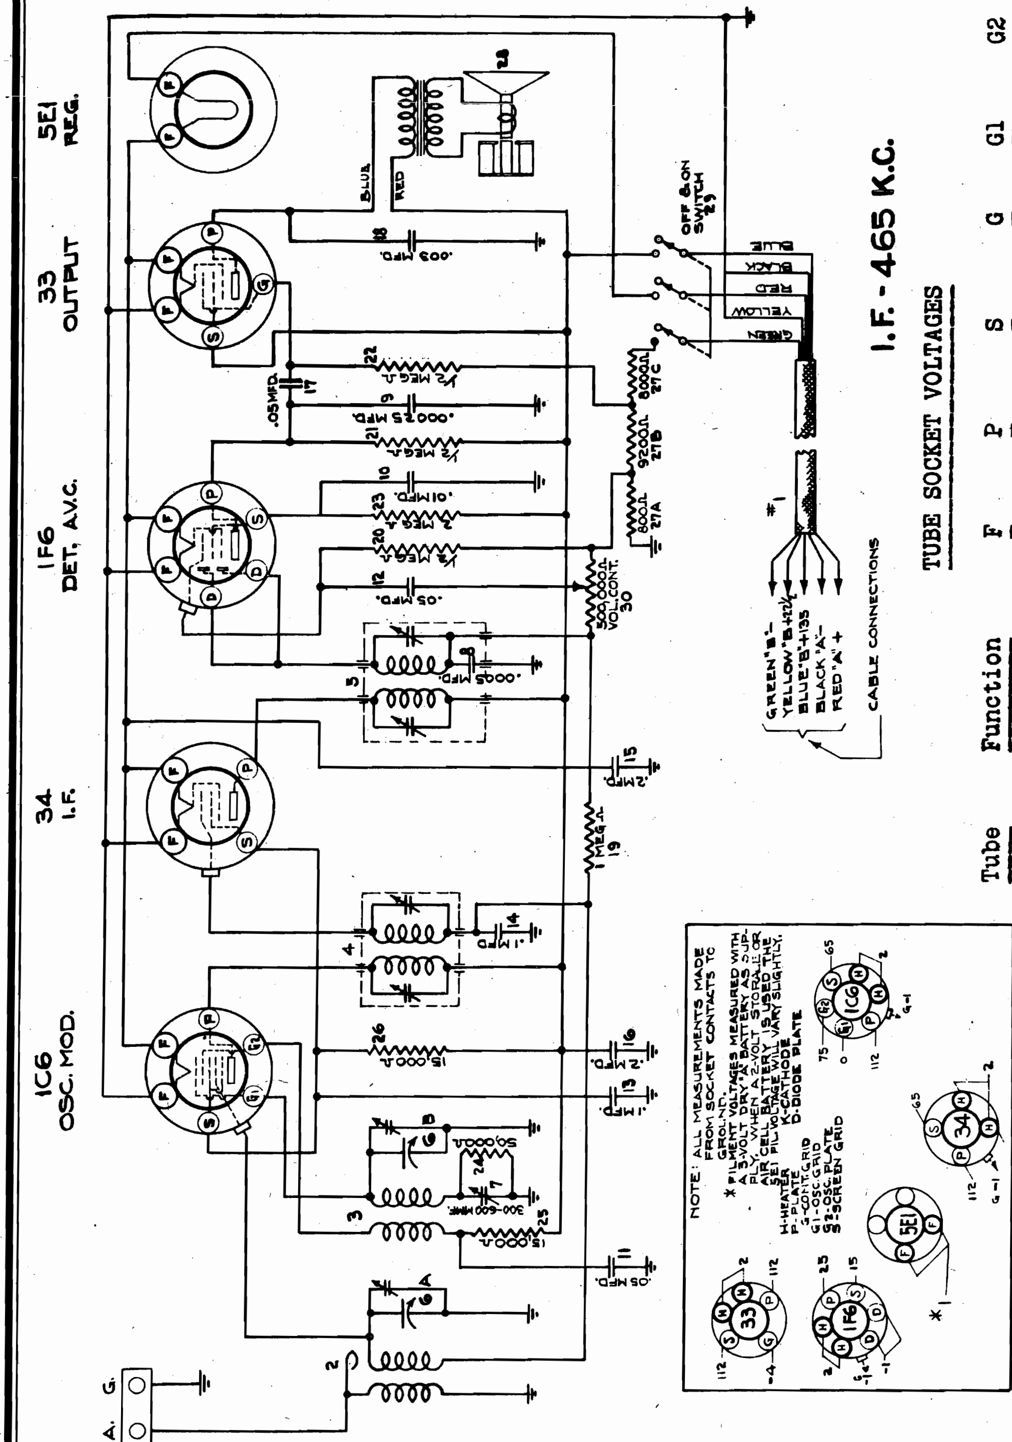
Socket, Notes



I.F. - 465 K.C.

TUBE SOCKET VOLTAGES

Tube	Function	F	P	S	G	G1	G2
1C6	Osc-Mod.	2	112	65	-1	0	75
34	I-F	2	112	65	-1	-	-
1F6	Det.1st A-F	2	25	15	-1	-	-
33	Output	2	112	112	-4	-	-
5E1	Regulator	1	-	-	-	-	-

Readings taken on 3 volt battery from tube socket contacts to ground, with a 1000 ohm per volt meter. 5E1 voltage Regulator filament voltage will vary depending on input voltage to receiver.

Delco Model R-2050

Date: 9-3-36

The Delco Model R-2050 is a five tube, two volt, two band, battery operated receiver with A.V.C. and a voltage regulator. The tubes use are: 1C6 Oscillator-Modulator, 34 I-F Amplifier, 1F6 Diode Detector--A.V.C. and 1st A-F Amplifier, 33 Power Output and a 5E1 Voltage Regulator.

The band coverage of the R-2050 receiver is from 540 to 1720 kilocycles.

The receiver is designed to be operated from 3-45 volt "B" batteries and either a 3 volt dry "A" battery, a 2 volt wet storage battery, or an "Aircell" battery.

MODEL R2050 Delco
Socket, Trimmers
Chassis, Alignment

UNITED MOTORS SERVICE

1. Peaking I-F Stages at 465 Kilocycles

(A) Connect the ground lead of the test oscillator to the chassis frame. Connect the other lead to the grid cap of the 1C6 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(B) Set the test oscillator to exactly 465 kilocycles.

(C) Turn the volume control of the receiver on full.

(D) Peak each of the trimmers on the second I-F coil, Illus. #5 on Fig. 1

(E) Peak each of the trimmers on the first I-F coil, Illus. #4 on Fig. 1

(F) In order to assure accurate settings of the I-F trimmers the above adjustments should be repeated using the lowest test oscillator output that will give a reasonable output scale deflection.

2. Aligning R-F Circuits

(A) Remove the test oscillator lead from the grid of the 1C6 tube and connect it to the receiver "Ant." terminal through a .00025 mfd. series condenser.

(B) Check to see that the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the gang condenser until they are completely out of mesh, at which point the dial pointer should be at the high frequency end of the dial calibration.

(C) Set the test oscillator frequency and receiver dial to exactly 1720 kilocycles.

(D) Adjust the trimmer mounted on top of the "Osc." section of the gang condenser, Ilus. #6B on Fig. 1, to bring in the 1720 kilocycle test oscillator signal to maximum output.

(E) Set the test oscillator frequency and the receiver dial to exactly 1400 kilocycles.

(F) Adjust trimmer on top of the "Ant." section of the gang condenser, Illus. #6A on Fig. 1, for maximum output.

(G) Set receiver dial at approximately 600 kilocycles, leave the test oscillator connected to the antenna and ground terminals of the receiver.

(H) Set test oscillator frequency to 600 kilocycles.

(I) Adjust the 600 kilocycle oscillator padder condenser accessible through the hole in the top of the chassis adjacent to the gang condenser, while rocking the tuning condenser back and forth for maximum 600 kilocycle signal response.

Connect the set cable wires exactly as indicated on the cable markers. Remove the tubes from their sockets when hooking up batteries and recheck all connections before placing the tubes back in their sockets. The battery connections are as follows:

BATTERY CONNECTIONS

Connection	Lead Color
B -	Green
B + 22½ V.	Yellow
B + 135 V.	Blue
A -	Black
A +	Red

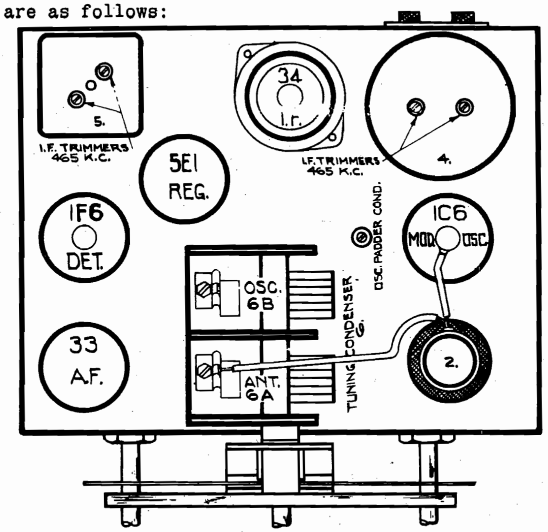


FIG. 2--PARTS LAYOUT--Top View

Delco Model R-2050

Date: 9-3-36

VOLTAGE REGULATOR

The 5E1 Voltage Regulator is used to maintain the filament voltage on the remaining tubes at the correct value of approximately 2 volts in order to adapt the receiver to operation on a 3 volt dry "A" battery and to take care of the normal charge to discharge battery voltage variations.

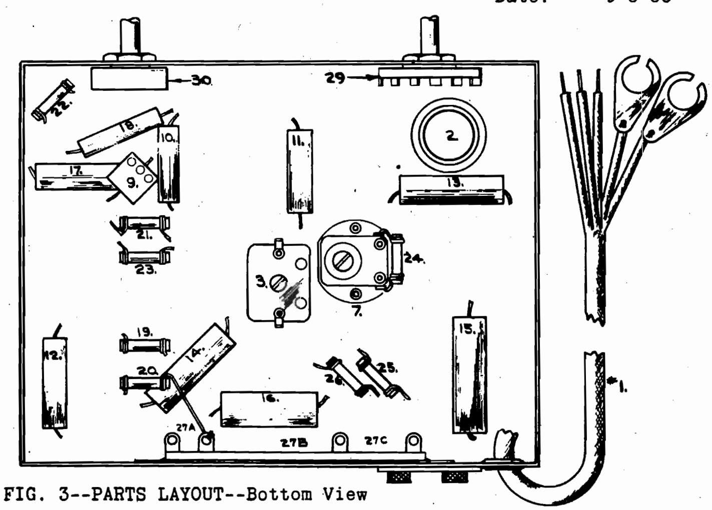

FIG. 3--PARTS LAYOUT--Bottom View

UNITED MOTORS SERVICE

Delco Model R-2055

Date: 7-29-37

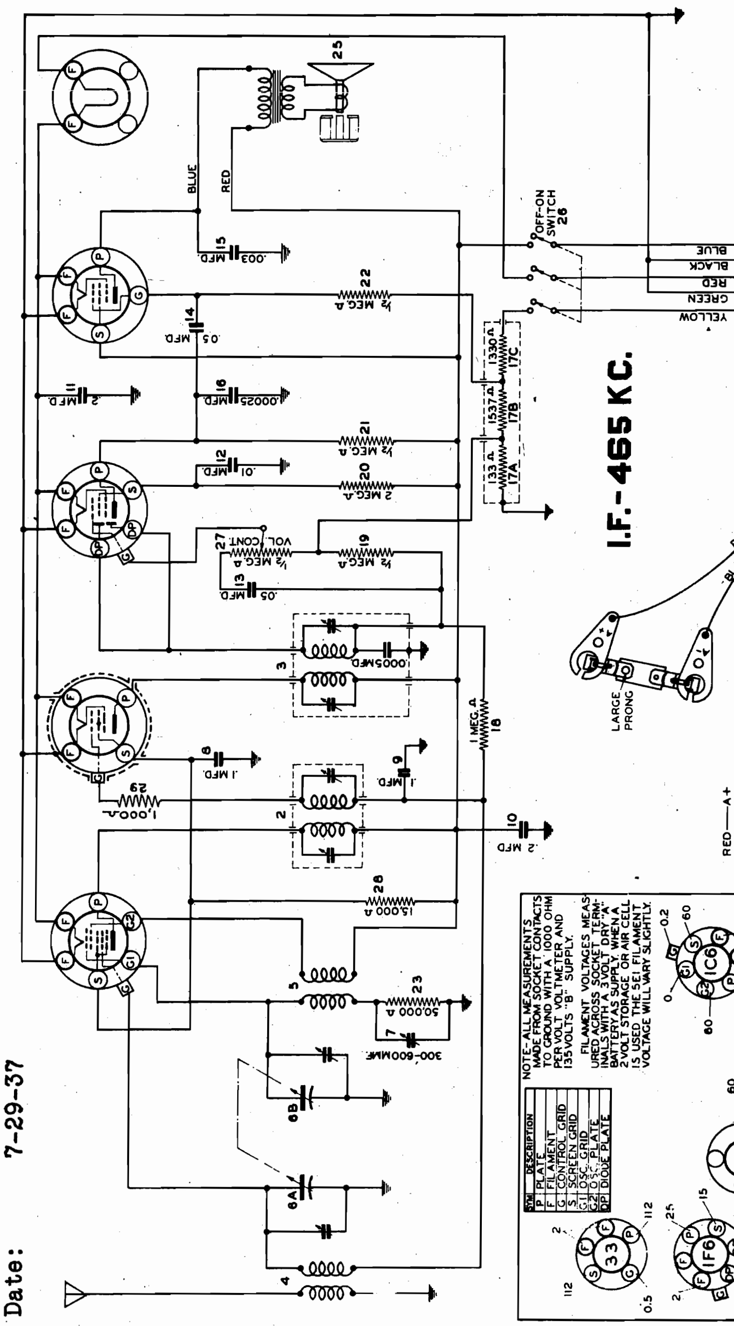

FIG. 1
CIRCUIT DIAGRAM AND VOLTAGE CHART

CIRCUIT CHANGE

Part #1210432 I-F Coil Assembly (Illus. #2) used on the first production of R-2050 sets, was replaced by Part #1212305 I-F Coil Assembly in order to correct a tendency of the I-F stages to oscillate. All service replacements of #1210432 I-F Coils should be made with the new coil #1212305. This coil has a 1000 ohm resistor mounted on the shield can, connected in series with the 34 tube grid.

BATTERY CONNECTIONS

PLUG-IN TYPE CONNECTORS ARE ATTACHED TO ENDS OF SET BATTERY CABLE LEADS--INSERT THESE PLUGS INTO THE PROPER TERMINAL ON TOP OF BATTERIES AND ALL BATTERY CONNECTIONS WILL BE CORRECTLY MADE. IF BATTERIES USED HAVE SCREW TYPE OR FAHNESTOCK TERMINALS REMOVE PLUGS FROM CABLE AND CONNECT WIRES IN ACCORDANCE WITH COLOR CODE.

Connect the set cable wires exactly as indicated on the cable markers. Remove the tubes from their sockets when hooking up batteries and recheck all connections before placing the tubes back in their sockets. The battery connections are as follows:

Lead Color	Connection
Green	B+ 22½
Yellow	B-
Blue	B+ 135
Black	A-
Red	A+

SENSITIVITY CONTROL

The sensitivity control is a potentiometer connected across the terminals on the antenna and ground terminal strip on the rear of the chassis. The movable arm is connected to the antenna coil. It is used to vary the strength of the signal in order to prevent overloading the R-F amplifier in view of the low plate voltage used.

GROUND CIRCUIT

DO NOT ground the chassis except through the use of the "GND" terminal on the terminal strip located on the rear of the chassis. This terminal connects to the chassis frame through a series condenser in order to prevent a short circuit when operating the receiver on a 32 volt system with the positive side grounded.

Models R-3208 & R-3209 Date: 8-5-36

1. Peaking I-F Stages at 450 Kilocycles
   - (a) Connect the antenna of the signal generator to the control grid connection on top of the 6A7 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.
   - (b) Connect the ground terminal of the signal generator to the ground terminal of the receiver.
   - (c) Set the signal generator to exactly 450 kilocycles.
   - (d) Rotate the receiver tuning condenser until the rotor plates are completely out of mesh.
   - (e) Turn the band selector switch to the Red Band. (First position on left)
   - (f) Adjust the line voltage to 32 volts.
   - (g) Turn the volume control and sensitivity control knobs all the way to the right.
   - (h) With the signal generator set to the lowest usable output level, adjust the I-F trimmer condensers for maximum signal output.

   NOTE: The I-F trimmers are located on top of the I-F coils, Fig. 2, and may be adjusted with an insulated screw driver. Always make the adjustments very carefully, going over them several times to insure that the final setting is at resonant frequency.

2. Aligning R-F Circuits Blue Band (148-400 K.C.)
   - (a) Turn the band selector switch to the first position on the right. (Blue Band)
   - (b) Rotate the receiver tuning condenser until the rotor plates are completely IN MESH and adjust the dial pointer, if necessary, so that it is exactly horizontal.
   - (c) Connect the antenna terminal of the signal generator to terminal on the rear of the receiver through a .00025 mfd. mica series condenser.
   - (d) Set the signal generator to 400 kilocycles.
   - (e) Rotate the station selector until the rotor plates are completely OUT OF MESH.
   - (f) Adjust the Blue Band "Osc." parallel trimmer (Fig. 2), for maximum output.

   NOTE: If electrical interference causes an excessive reading on the output meter, making alignment difficult, it can be reduced by connecting a 5 to 10 mfd. paper condenser between the ground terminal of the receiver and the chassis frame.

   - (g) Adjust the Blue Band "R-F" parallel trimmer, (Fig. 2), for maximum output.
   - (h) Adjust the Blue Band "Ant" parallel trimmer, (Fig. 2), for maximum output.
   - (i) Repeat operations (f), (g) and (h) until no further improvement in output can be obtained.
   - (j) Set the signal generator to 150 kilocycles.
   - (k) Tune in the 150 kilocycle signal with the station selector in the region of 15 on the dial (Blue Band), for maximum reading on the output meter.
   - (l) Adjust the Blue Band oscillator series trimmer, (Illus. #31B, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.
   - (m) Repeat operations (f), (g) and (h) for more accurate adjustments.

3. Aligning R-F Circuits - Yellow Band (540-1600 K.C.)
   - (a) Turn the band selector switch to the second position from the right. (Yellow Band)
   - (b) Set the signal generator to 1400 kilocycles.
   - (c) Rotate the station selector until the pointer points to 140. (Yellow Band)
   - (d) Adjust the Yellow Band "Osc." parallel trimmer, (Fig. 2), for maximum signal output.
   - (e) Adjust the Yellow Band "R-F" parallel trimmer, (Fig. 2), for maximum signal output.
   - (f) Adjust the Yellow Band "Ant" parallel trimmer, (Fig. 2), for maximum signal output.
   - (g) Repeat operations (d), (e) and (f).
   - (h) Set the signal generator to 600 kilocycles.
   - (i) Tune in the 600 kilocycle signal with the station selector in the région of 60 on the dial (Yellow Band), for maximum reading on the output meter.
   - (j) Adjust the Yellow Band oscillator series trimmer, (Illus. #31A, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.
   - (k) Repeat operations (d), (e) and (f) for more accurate adjustments.

4. Aligning R-F Circuits - Green Band (1590-4500 K.C.)
   - (a) Turn the band selector switch to the second position from the left. (Green Band)
   - (b) Set the signal generator to 4000 kilocycles.
   - (c) Rotate the station selector until the pointer points to 4.0. (Green Band)
   - (d) Adjust the Green Band "Osc." parallel trimmer, (Fig. 2), for maximum signal output.
   - (e) Adjust the Green Band "R-F" parallel trimmer, (Fig. 2), for maximum signal output.
   - (f) Adjust the Green Band "Ant." parallel trimmer, (Fig. 2), for maximum signal output.
   - (g) Repeat operations (d), (e) and (f).
   - (h) Set the signal generator to 1700 kilocycles.
   - (i) Tune in the 1700 kilocycle signal with the station selector in the region of 1.7 on the dial (Green Band), for maximum reading on the output meter.
   - (j) Adjust the Green Band oscillator series trimmer (Illus. #30B, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.
   - (k) Repeat operations (d), (e) and (f) for more accurate adjustments.

5. Aligning R-F Circuits - Red Band (5,900-15,300 K.C.)
   - (a) Replace the .00025 series condenser in the output lead from the signal generator with a 400 ohm, carbon resistor.
   - (b) Turn the band selector switch to the first position on the left. (Red Band)
   - (c) Set the signal generator to 15 megacycles. (15,000 K.C.)
   - (d) Rotate the station selector until the pointer points to 15. (Red Band)
   - (e) Adjust the Red Band "Osc." parallel trimmer, (Fig. 2), for maximum signal output.
   - (f) Adjust the Red Band "R-F" parallel trimmer, (Fig. 2), for maximum signal output.
   - (g) Adjust the Red Band "Ant." parallel trimmer, (Fig. 2), for maximum signal output.
   - (h) Repeat operations (e), (f) and (g).
   - (i) Set the signal generator to 6 megacycles. (6000 K.C.)
   - (j) Tune in the 6 megacycle signal with the station selector in the region of 6.0 on the dial (Red Band) for maximum reading on the output meter.
   - (k) Adjust the Red Band oscillator series trimmer (Illus. #30A, Fig. 2) while rocking the condenser gang plates back and forth slightly, until no further increase in output can be obtained.
   - (l) Repeat operations (e), (f) and (g) for more accurate adjustments.

GENERAL: The Delco Models R-3208 (table model) and R-3209 (console model) employ the same chassis which is a nine tube, 32 volt, four band receiver. The tubes used are 6D6 R-F amplifier, 6A7 Oscillator-Modulator, 6D6 I-F Amplifier, 85 Detector and A-F Amplifier and four type 48 output tubes in push-pull parallel.

UNITED MOTORS SERVICE

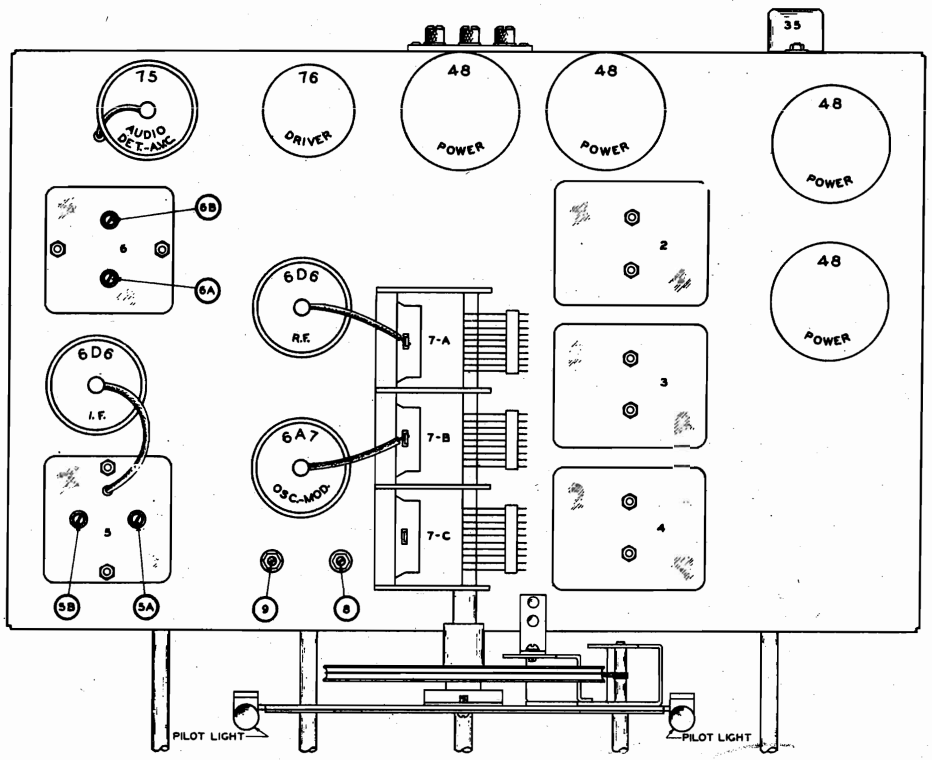

FIG. 2--PARTS LAYOUT--Top View

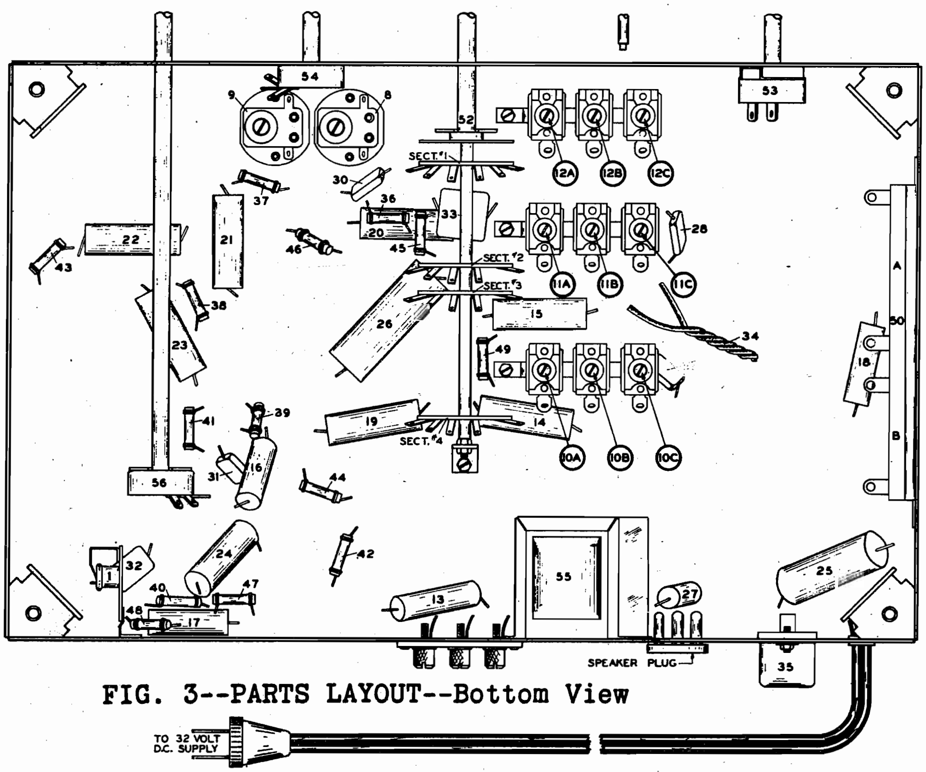

FIG. 3--PARTS LAYOUT--Bottom View

The Delco Model R-3212 is a nine tube, three band 32 volt operated superheterodyne receiver with AVC, tone control and an electro-dynamic speaker. The tubes used are: 6A7 Oscillator-Modulator, 6D6 R.F. Amplifier, 6D6 I.F. Amplifier, 75 Detector AVC and 1st Audio, 76 Driver, and four type 48 Output Tubes in push-pull parallel.

The frequency ranges on the bands covered are: American Broadcast Band 540-1720 kilocycles, Police and Amateur Band 2230 to 7500 kilocycles, and the Foreign Short Wave Band 7.15-18.5 megacycles.

TUBE SOCKET VOLTAGES

A bottom view of the chassis is shown in Fig. 1 (Circuit Diagram) on which the voltages to ground at each of the tube socket contacts are indicated.

MODEL R3212 Delco
Alignment

UNITED MOTORS SERVICE

Peaking I.F. Stages at 172 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a .5 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. The .5 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.

(b) Set the test oscillator on 172 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the I.F. trimmers on the 2nd I.F. coil, Illus. #9 on Fig. 2.

(e) Then peak each of the trimmers on the 1st I.F. coil, Illus. #8 on Fig. 2.

NOTE:
In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

Peaking Gang Condenser at 1530 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. (Do not use the .5 mfd. condenser that was required in aligning the I.F. stages.)

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on 1530 kilocycles.

(d) Adjust the trimmer for the oscillator section of the gang condenser (middle section) CAREFULLY for maximum output. Then adjust the trimmers for the "R.F." and "ANT." sections of the gang condenser also for maximum output.

Tracking Oscillator at 540 K.C.

(a) Turn the condenser plates until they are COMPLETELY IN MESH.

(b) Set test oscillator at 540 kilocycles. (Leave test oscillator leads connected to antenna and ground of receiver.)

(c) Adjust the oscillator tracking condenser (Illus. #24 on Fig. 3) located on the bottom of the chassis until the 540 K.C. signal is tuned in with maximum output.

Peaking Gang Condenser at 1400 K.C.

(a) Set the test oscillator at 1400 kilocycles.

(b) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output.

(c) Readjust the parallel trimmers for the "R.F." and "ANT." sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT DISTURB the setting of the "OSC." section of the gang condenser as this is adjusted at 1530 K.C. only, and any further adjustments at this point will affect both the tuning range of the receiver and the tracking of its circuits.

Adjusting Receiver to Car Antenna

NOTE: An antenna compensating condenser is provided in the antenna circuit of this receiver that must be adjusted to the particular car antenna the receiver is to be used on. The test oscillator cannot be used for this adjustment due to the fact that capacity of its output circuit will not match the wide range of antenna capacities being used. Therefore, it is necessary that the adjustment be made after the receiver is installed on the car and is done in the following manner:

(a) Tune the receiver to a weak broadcast station on the low frequency end of the dial 550 to 700 K.C.

(b) Adjust the antenna compensating condenser for maximum response from the broadcast station. This condenser is shown as Illus. #23 on Fig. 3 and is located immediately to the rear of the speaker plug on the side of the receiver.

PART NO. 1209525 FILTER ASSEMBLY

Part No. 1209525 Filter Assembly is part of the "B" supply filter circuit and choke, R.F. filter choke along with an .06 mfd. 600 volt condenser sealed in a separate container. In case any of the parts used in this assembly are found to be defective it will be necessary to replace the complete filter assembly. The power transformer is mounted on top of the container for the filter assembly and both of these units are covered by the transformer can which may be removed by taking out the self-tapping screws which hold the can to its lower lid on the base of the receiver.

CIRCUIT CHANGES

On the part #1210009 Condenser Block, it will be found on some receivers that the sections having a black lead (18C) and blue lead (18G) are not used. In using the service replacement stock of part #1210009 Condenser Blocks, simply cut off either or both of the blue or black leads close to the block if they are not found on the defective block removed from the receiver. A number of receivers used a small tubular .01 mfd. condenser in place of the .01 section (18G) on this Condenser Block. If this condenser becomes defective--replace with a part #1210080 condenser.

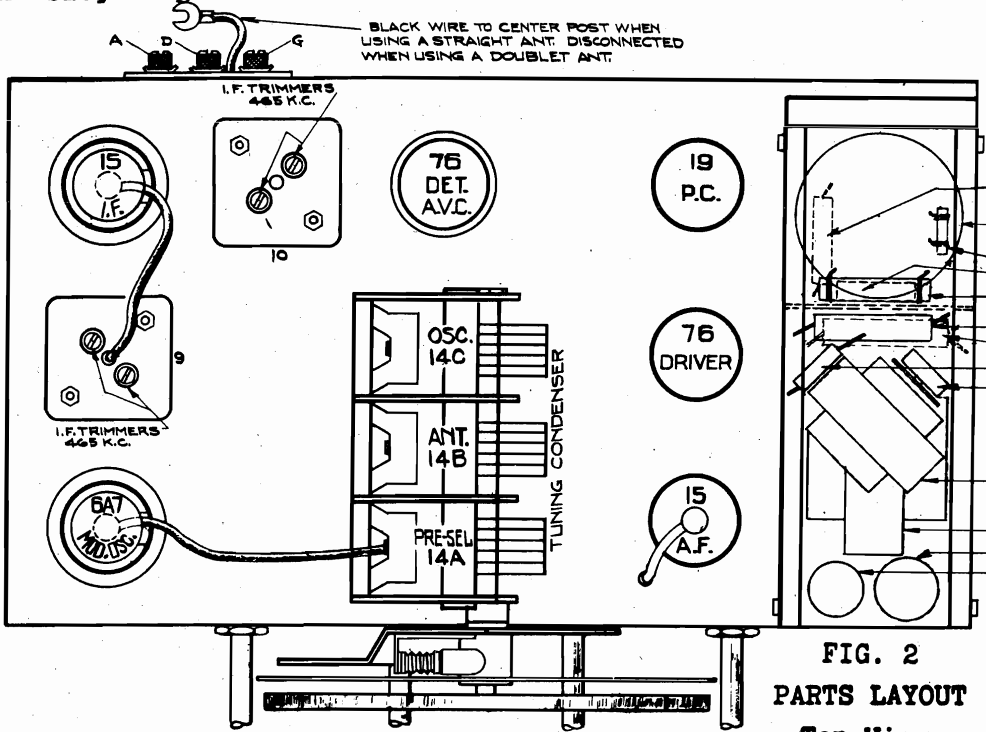

FIG. 2
PARTS LAYOUT
Top View

Delco Model R-6011 Date: 9-8-36

All R-6011 receivers incorporating the above changes can be identified by the letter "A" stamped on the rear of their chassis. The Circuit Diagram for these receivers is shown in Fig. 1A.

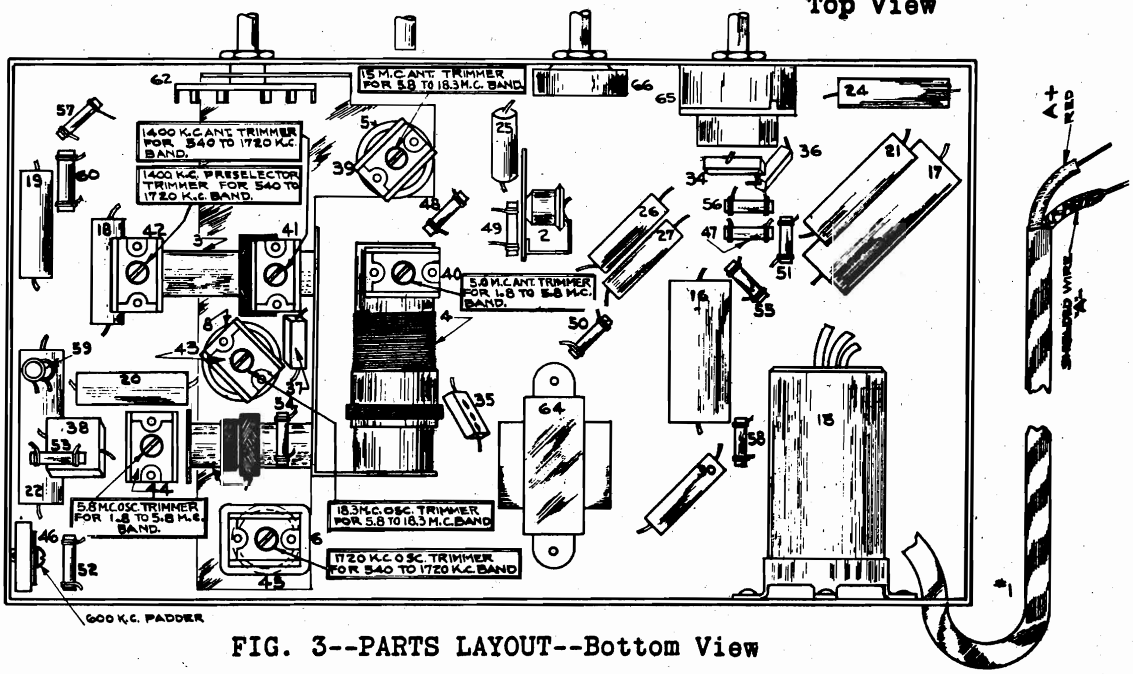

FIG. 3--PARTS LAYOUT--Bottom View

The following changes have been made in the Circuit Diagram of the R-6011 receiver as shown in Fig. 1.

CIRCUIT CHANGES

1. The .01 mfd. 1200-volt condenser, Illus. 32, connected across secondary of vibrator transformer was removed.

2. A 5000 ohm 1-watt resistor was added to the chassis and connected in series with condenser .01 mfd. Illus. #31.

3. A 150 ohm 1/3-watt resistor was added to the chassis and connected in the primary circuit of the vibrator transformer.

Change, Notes

UNITED MOTORS SERVICE

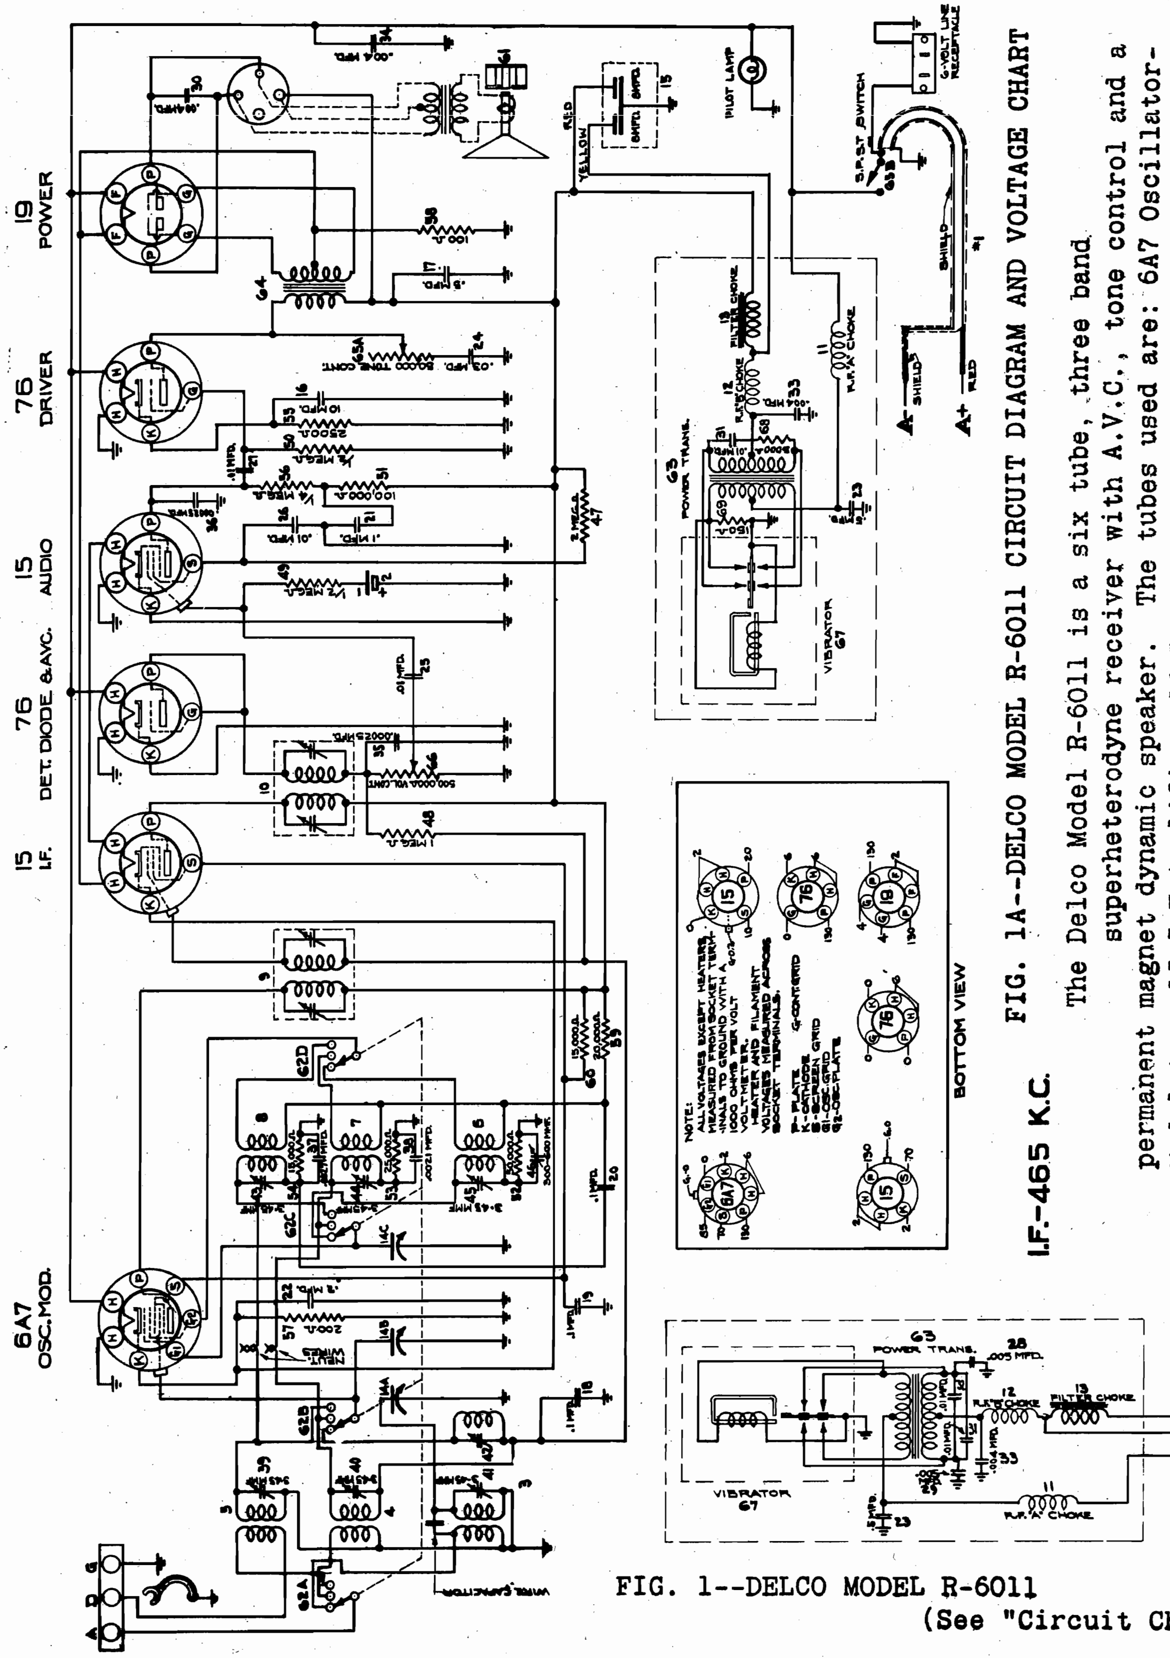

FIG. 1A--DELCO MODEL R-6011 CIRCUIT DIAGRAM AND VOLTAGE CHART

I.F.-465 K.C.

The Delco Model R-6011 is a six tube, three band superheterodyne receiver with A.V.C., tone control and a permanent magnet dynamic speaker. The tubes used are: 6A7 Oscillator-Modulator, 15 I-F Amplifier, 76 Detector and A.V.C., 15 1st Audio, 76 Driver and a Type 19 Output tube.

This receiver is designed to be operated from a six volt storage battery.

Delco Model R-6011

Date: 9-8-36

FIG. 1--DELCO MODEL R-6011

(See "Circuit Changes")

The frequency ranges on the bands covered are: American Broadcast Band (Yellow) 540 to 1720 kilocycles, Police and Amateur Band (Green) 1800 to 5800 kilocycles, and the Foreign Short Wave (Red) 5.8 to 18.3 megacycles.

MODEL R6011 Delco
Alignment, Voltage

UNITED MOTORS SERVICE

Delco Model R-6011

Date: 9-8-36

NOTE: A bottom view of the chassis is shown in Fig. 1 & 1A (Circuit Diagram) on which the voltages to ground at each of the tube socket contacts are indicated.

1. Peaking I-F Stages at 465 Kilocycles

   (a) Connect the ground lead of the test oscillator to the chassis frame. Connect the other lead to the grid cap of the 6A7 tube through a .1 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

   (b) Set the test oscillator to exactly 465 kilocycles.

   (c) Turn the volume control of the receiver on full.

   (d) Peak each of the trimmers on the 2nd I-F coil, Illus. #10 on Fig. 1.

   (e) Peak each of the trimmers on the 1st I-F coil, Illus. #9 on Fig. 1.

   (f) In order to assure accurate settings of the I-F trimmers the above adjustments should be repeated using the lowest test oscillator output that will give a reasonable output meter scale defection.

2. Aligning R.F. Circuits--Foreign Band (5.8-18.3 Megacycles)

   (a) Remove the test oscillator lead from the grid of the 6A7 tube and connect it to the receiver antenna terminal through a 400 ohm carbon resistor.

   (b) Check to see that the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the gang condenser until they are completely out of mesh, at which point the dial pointer should be at the high frequency end of the dial calibration.

   (c) Set the test oscillator frequency and receiver dial to exactly 18.3 megacycles.

   (d) Adjust the 18.3 megacycle oscillator trimmer, Illus. #43 on Fig. 2, to bring in the 18.3 megacycle test oscillator signal with maximum output. NOTE: When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.3 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.3 megacycles always check to see if the proper peak has been used. To do this leave test oscillator frequency at 18.3 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 17.3 megacycles Then vary the receiver dial slightly to the right and left of 17.3 megacycles, and if the fundamental peak was used in aligning at 18.3 megacycles the test oscillator signal will be heard at approximatey 17.3 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.3 megacycle oscillator trimmer must be properly readjusted.

   (f) Set the test oscillator frequency and the receiver dial to exactly 15 megacycles.

   (g) Adjust 15 megacycle antenna trimmer, Illus. #39 on Fig. 2, to maximum output.

3. Aligning R.F. Circuits--Police-Amateur Band (1.8-5.8 Megacycles)

   (a) Set test oscillator frequency and receiver dial to exactly 5.8 megacycles.

   (b) Adjust 5.8 megacycle oscillator trimmer, Illus. #44 on Fig. 2, to bring in 5.8 megacycle test oscillator signal with maximum output.

   (c) Set test oscillator frequency and receiver dial to exactly 5 megacycles.

   (d) Adjust 5 megacycle antenna trimmer, Illus. #40 on Fig. 2, for maximum output.

4. Aligning R.F. Circuits--American Broadcast Band (1720-540 Kilocycles)

   (a) Set test oscillator frequency and receiver dial to exactly 1720 kilocycles. Replace 400 ohm series resistor with a .00025 mfd. condenser.

   (b) Adjust 1720 kilocycle oscillator trimmer, Illus. #45 on Fig. 2, to bring in 1720 kilocycle test oscillator signal to maximum output.

   (c) Set test oscillator frequency and receiver dial to exactly 1400 kilocycles.

   (d) Adjust 1400 kilocycle antenna and preselector trimmers, Illus. #41 and #42 on Fig. 2, for maximum output.

   (e) Set receiver dial and test oscillator frequency to approximately 600 kilocycles, leaving the test oscillator connected to antenna and ground terminals of the receiver.

   (f) Adjust 600 kilocycle oscillator padder condenser, Illus. #46 on Fig. 2, rocking tuning condenser back and forth for maximum 600 kilocycle signal response.

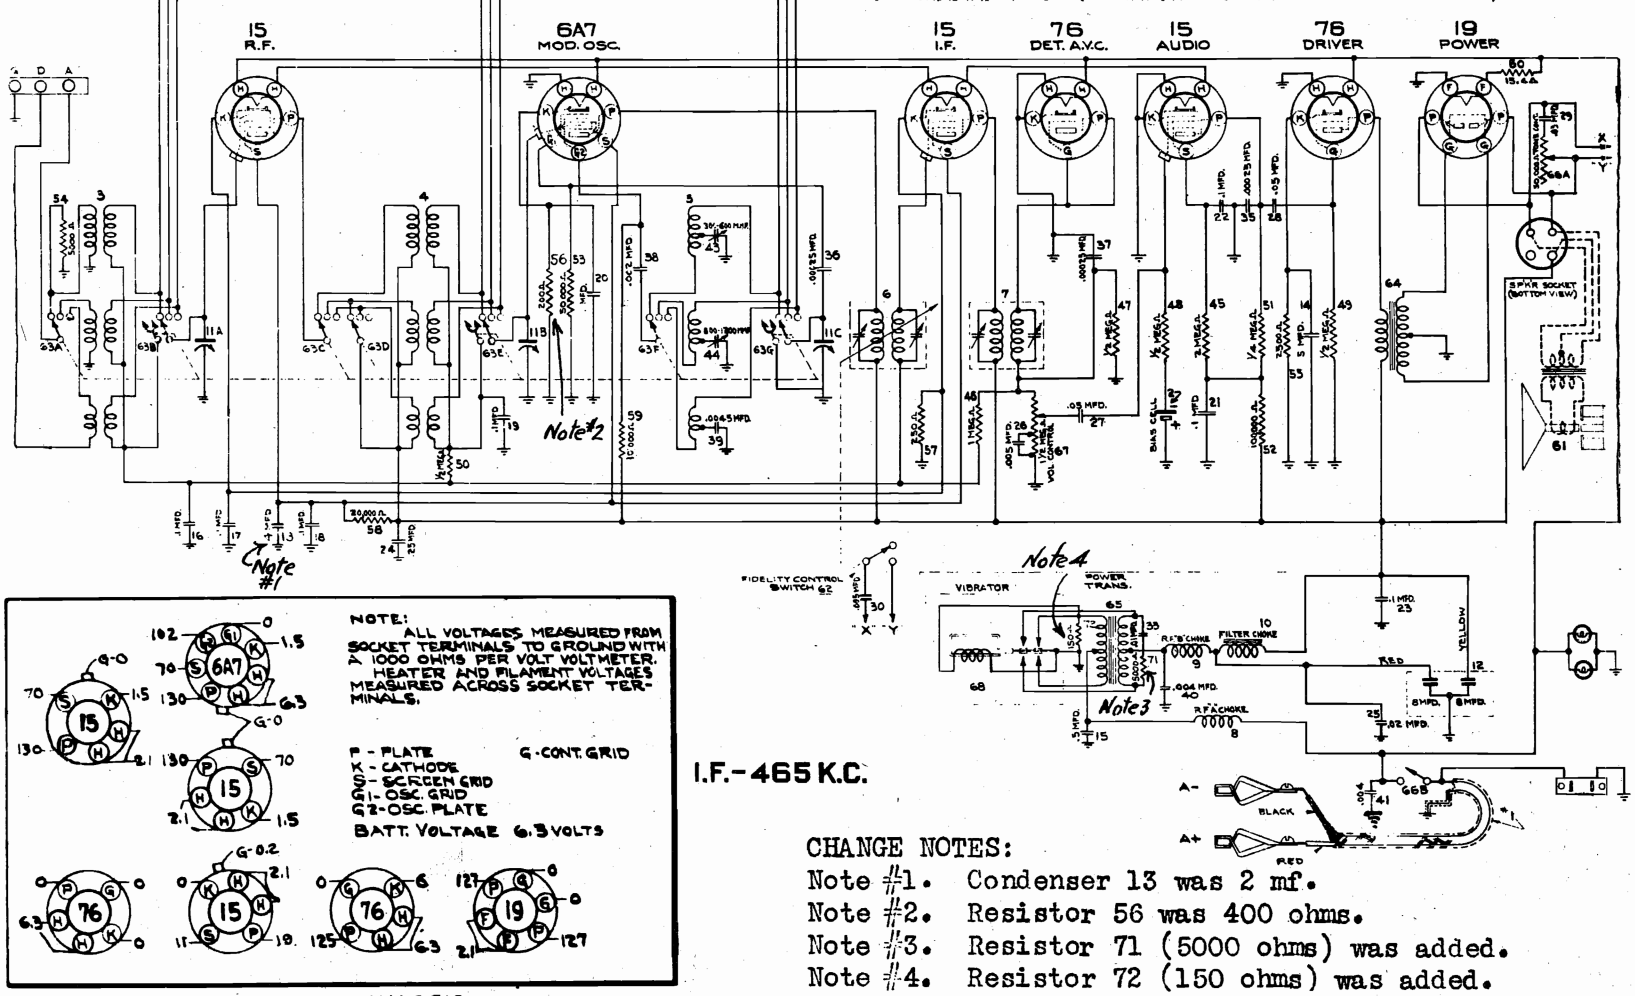
Changes

UNITED MOTORS SERVICE

FIG. 1A--DELCO MODEL R-6012 CIRCUIT DIAGRAM AND VOLTAGE CHART
(Chassis marked with letter "C" on rear)



BOTTOM VIEW OF CHASSIS.

CHANGE NOTES:

Note #1. Condenser 13 was 2 mf.
Note #2. Resistor 56 was 400 ohms.
Note #3. Resistor 71 (5000 ohms) was added.
Note #4. Resistor 72 (150 ohms) was added.

In early models, a .005-mf. condenser was connected between each end of the vibrator transformer secondary and ground. Both these condensers were removed in later models.
In early models, a .01 mf condenser was connected across the secondary of the vibrator transformer. This was removed in later models.
The receivers in which these changes have been made can be identified by the letter "A" stamped on the rear of the chassis.

Voltage, Alignment

CIRCUIT ALIGNMENT

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with or in the replacement of a defective coil. If realignment is found necessary the set can be properly adjusted only by using a calibrated test oscillator, or signal generator, and an output meter.

TUBE SOCKET VOLTAGES (See Chart on Fig. 1)

Readings taken from tube socket contacts to chassis ground (except filaments) with a 1000 ohm per volt D.C. meter.

Ampere drain--2.7 amps.

Delco Model R-6012

Date: 9-23-36

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect the other lead to the grid cap of the 6A7 tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Set test oscillator to exactly 465 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the trimmers on the 2nd I-F coil, Illus. #7 on Fig. 2.

(e) Peak each of the trimmers on the 1st I-F coil, Illus. #6 on Fig. 2.

(f) In order to assure accurate settings of the I-F trimmers, the above adjustments should be repeated using the lowest test oscillator output that will give a reasonable output meter scale deflection.

2. Aligning R-F Circuits--"Foreign" Band (5.65-20.25 Megacycles)

(a) Remove the test oscillator lead from the grid of the 6A7 tube and connect it to the receiver antenna terminal through a 400 ohm resistor.

(b) Check to see that the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the gang condenser until they are completely out of mesh, at which point the dial pointer should be at the high frequency end of the dial calibration.

(c) Set the test oscillator frequency and receiver dial to exactly 20.25 megacycles.

(d) Adjust the 20.25 megacycle oscillator, Illus. #42J on Fig. 3, to bring in the 20.25 megacycle test oscillator signal to maximum output. NOTE: When adjusting this trimmer, two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 20.25 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 20.25 megacycles, check to see if the proper peak has been used. To do this, leave the test oscillator frequency at 20.25 megacycles, increase the output of the test oscillator and tune the receiver dial to approximately 19.25 megacycles. Then vary the receiver dial slightly to the right and left of 19.25 megacycles, and if the fundamental peak was used in aligning at 20.25 megacycles, the test oscillator signal will be heard at approximately 19.25 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 19.25 megacycle oscillator trimmer must be properly readjusted.

(f) Set the test oscillator frequency and the receiver dial to exactly 18 megacycles.

(g) Adjust 18 megacycle antenna and R-F trimmers, Illus. #42C & 42F on Fig. 3, for maximum output.

3. Aligning R-F Circuits--"Police-Amateur" Band (1.58-5.75 Megacycles)

(a) Set test oscillator frequency and receiver dial to exactly 5.25 megacycles.

(b) Adjust 5.75 megacycle oscillator trimmer, Illus. #42H on Fig. 3, to bring in 5.75 megacycle test oscillator signal to maximum output.

(c) Set test oscillator frequency and receiver dial to exactly 5 megacycles.

(d) Adjust 5 megacycle antenna R-F trimmers, Illus. #42B & 42E on Fig. 3, for maximum output.

4. Aligning R-F Circuits--"American" Broadcast Band (1720-536 Kilocycles)

(a) Set test oscillator frequency and receiver dial to exactly 1720 kilocycles. Replace 400 ohm series resistor with .00025 condenser

(b) Adjust 1720 kilocycle oscillator trimmer, Illus. #42G on Fig. 3, to bring in 1720 kilocycle test oscillator signal to maximum output

(c) Set test oscillator frequency and receiver dial to exactly 1500 **kilocycles.**

(d) Adjust 1500 kilocycle antenna and R-F trimmers, Illus. #42A and #42D on Fig. 3, for maximum output.

(e) Set receiver dial and test oscillator frequency to approximately 600 kilocycles, leaving the test oscillator connected to antenna and ground terminals of the receiver.

(f) Adjust 600 kilocycle oscillator padder condenser, Illus. #43 on Fig. 3, rocking tuning condenser back and forth for maximum 600 kilocycle signal response.

SERVICE HINT--Vibrator Hash

In cases where a slight amount of vibrator hash or interference is noticeable on the R-6012, the reversing of the red and yellow leads on the dual 8 mfd. electrolytic condenser (Illus. #12) will usually eliminate the trouble. A letter "B" is stamped on the rear of all R-6012 chassis in which this change has been made in receiver production.

NOTES
1. I.F.-465 KC.
2. ⊗ INDICATES CAPACITY TOLERANCE ±3%
3. BAND SWITCH 57 SHOWN IN B.C. POSITION (REAR VIEW)

The Delco Model R-6015 is a six tube, three band, six volt battery operated superheterodyne receiver with A.V.C., tone control and a permanent magnet dynamic speaker. The tubes used are: 6D8G Oscillator-Modulator, 6S7G I-F Amplifier, 6L5G Detector and A V.C., 6S7G 1st Audio, 6L5G Driver and a type 19 output tube.

The frequency ranges on the bands covered are: American Broadcast Band 540-1720 kilocycles, Police and Amateur band 1.7-5.8 megacycles, and the Foreign Short Wave band 5.7-18.3 megacycles.

This receiver is designed to be operated from a six volt storage battery.

UNITED MOTORS SERVICE

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the signal generator to the chassis frame. Connect the other lead to the grid cap of the 6D8G tube through a .02 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Set the signal generator to exactly 465 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the trimmers on the 2nd I-F coil, Illus. #8 (Fig. 2).

(e) Peak each of the trimmers on the 1st I-F coil, Illus. #7 (Fig. 2).

(f) In order to assure accurate settings of the I-F trimmers the above adjustments should be repeated using the lowest signal generator output that will give a reasonable output meter scale deflection.

2. Aligning R-F Circuits--Foreign Band 5.7-18.3 Megacycles

(a) Remove the signal generator lead from the grid of the 6D8G tube and connect it to the receiver antenna terminal through a 400 ohm carbon resistor.

(b) Check to see that the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the gang condenser until they are completely in mesh, at which point the dial pointer should be at the low frequency end of the dial calibration.

(c) Set the signal generator frequency and receiver dial to exactly 18.3 megacycles.

(d) Adjust the 18.3 megacycle oscillator trimmer, Illus. #11 (Fig. 3) to bring in the 18.3 megacycle signal with maximum output. NOTE: When adjusting this trimmer two peaks, the fundamental and the image peak will be noticed. CARE MUST BE TAKEN THAT THE FUNDAMENTAL PEAK AND NOT THE IMAGE PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.3 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the first peak which is the fundamental and the proper one to use is tuned in. If the trimmer is screwed down beyond the point where the first peak is received, the incorrect image peak will be tuned in. After completing adjustment of the oscillator trimmer at 18.3 megacycles always check to see if the proper peak has been used. To do this leave signal generator frequency at 18.3 megacycles, increase the output of the signal generator and tune the receiver dial to approximately 17.3 megacycles. Then vary the receiver dial slightly to the right and left of 17.3 megacycles, and if the fundamental peak was used in aligning at 18.3 megacycles the test signal will be heard at approximately 17.3 megacycles on the receiver dial. If it is not possible to receive the signal, then the fundamental peak was not used and the 18.3 megacycle oscillator trimmer must be properly readjusted.

(e) Set the signal generator frequency and the receiver dial to exactly 15 megacycles.

(f) Ajust 15 megacycle antenna trimmer, Illus. #10 (Fig. 3) to maximum output.

3. Aligning R-F Circuits--Police-Amateur Band (1.7-5.8 Megacycles)

(a) Set signal generator frequency and receiver dial to exactly 5.8 megacycles.

(b) Adjust 5.8 megacycle oscillator trimmer, Illus. #11 (Fig. 3) to bring in 5.8 megacycle signal generator signal with maximum output.

(c) Set signal generator frequency and receiver dial to exactly 5 megacycles.

(d) Adjust 5 megacycle antenna trimmer, Illus. #10 (Fig. 3) for maximum output.

4. Aligning R-F Circuits--American Broadcast Band 1720-540 Kilocycles

(a) Replace 400 ohm series resistor with a .00025 mfd. condenser.

(b) Set signal generator frequency and receiver dial to exactly 1720 kilocycles.

(c) Adjust 1720 kilocycle oscillator trimmer, Illus. #11 (Fig. 3) to bring in 1720 kilocycle signal generator signal to maximum output.

(d) Set signal generator frequency and receiver dial to exactly 1400 kilocycles.

(e) Adjust 1400 kilocycle antenna trimmer, Illus. #12A (Fig. 2), for maximum output.

(f) Adjust 1400 kilocycle preselector trimmer, Illus. #10 (Fig. 3), for maximum output.

(g) Set receiver dial and signal generator frequency to approximately 600 kilocycles, leaving the signal generator connected to antenna and ground terminals of the receiver.

(h) Adjust 600 kilocycle oscillator padder condenser, Illus. #13 (Fig. 3), while rocking tuning condenser back and forth for maximum 600 kilocycle signal response.

*98 volts on sets above Serial No. 0383500.

Date: 11-1-36

Ampere drain of set at 6 volts is 5.8 amperes. Milliampere drain from "B" supply is approximately 55 M.A.

All readings were taken to the chassis frame with a 1000 ohm per volt meter.

The audio output of the detector circuit is coupled to the triode portion of the 6F7 tube for audio frequency amplification. The pentode section of this same tube is used as a radio frequency amplifier.

MODEL 405063,Early,Late
Alignment,Parts

UNITED MOTORS SERVICE

1. Peaking I-F Stages at 465 Kilocycles

(a) Connect the ground lead of the signal generator to the chassis frame. Connect the other lead to the grid cap of the 6A7 tube through a .1 mfd. series condenser. DO NOT REMOVE THE GRID CLIP.

(b) Set the signal generator to exactly 465 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak each of the trimmers on the 2nd I-F coil, Illus. #6A and 6B (Fig. 2).

(e) Peak each of the trimmers on the 1st I-F coil, Illus. #5A and 5B (Fig. 2).

(f) In order to assure accurate settings on the I-F trimmers the above adjustments should be repeated using the lowest signal generator output that will give a reasonable output meter scale deflection.

2. Aligning Circuits--Foreign Band 7.15-18.5 Megacycles

(a) Remove the signal generator lead from the grid of the 6A7 tube and connect it to the receiver antenna terminal through a 400 ohm carbon resistor.

(b) Check to see that the tuning dial has not slipped on the condenser gang shaft by turning the rotor plates of the gang condenser until they are completely in mesh, at which point the dial pointer should point to the last line at the low frequency end of the dial calibration.

(c) Turn band selector switch for operation on 18.5-7.15 megacycle band and set signal generator frequency and receiver dial to exactly 18.5 megacycles.

(d) Adjust the 18.5 megacycle oscillator trimmer, Illus. #12A (Fig. 3) for maximum 18.5 megacycle signal generator signal output. NOTE: When adjusting this trimmer two peaks may be noticed, in which case CARE MUST BE TAKEN THAT THE PROPER PEAK IS USED FOR ALIGNING THE RECEIVER AT 18.5 MEGACYCLES. Always back off the trimmer to minimum capacity, then screw down the trimmer (add capacity) until the second peak which is the proper one to use is tuned in.

(e) Set the signal generator frequency and the receiver dial to exactly 15 megacycles.

(f) Adjust 5 megacycle antenna trimmer, Illus. #10A (Fig. 3) for maximum output.

(g) Adjust 15 megacycle R-F trimmer, Illus. #11A (Fig. 3) for maximum output.

3. Aligning Circuits--Police-Amateur Band 2230-7500 Kilocycles

(a) Turn band selector switch for operation on 2230-7500 kilocycle band, set signal generator frequency and receiver dial to exactly 7.5 megacycles.

(b) Adjust 7.5 megacycle oscillator trimmer, Illus. #12B (Fig. 3) for maximum 7.5 megacycle signal output.

(c) Set signal generator frequency and receiver dial to exactly 6 megacycles.

(d) Adjust 6 megacycle antenna trimmer, Illus. #10B (Fig. 3) for maximum sensitivity.

(c) Adjust 6 megacycle R-F trimmer, Illus. #11B (Fig. 3) for maximum sensitivity.

(f) Set signal generator and receiver dial to approximately 2.5 megacycles--then while rocking gang condenser back and forth adjust 2.5 megacycle oscillator padder condenser, Illus. #9 (Fig. 2) for maximum sensitivity.

4. Aligning Circuits--American Broadcast Band 1720-540 K.C. Band

(a) Turn band selector for operation on 1720 to 540 kilocycle band, set signal generator frequency and receiver dial to exactly 1702 kilocycles. Replace 400 ohm series resistor in signal lead connected to antenna terminal with a .00025 mfd. condenser.

(b) Adjust 1720 kilocycle oscillator trimmer, Illus. #12C (Fig. 3) for maximum 1720 kilocycle signal generator signal output.

(c) Set signal generator frequency and receiver dial to exactly 1400 kilocycles.

(d) Adjust 1400 kilocycle antenna and R-F trimmers, Illus. #10C and 11C (Fig. 3) for maximum output.

(e) Set receiver dial and test oscillator frequency to approximately 600 kilocycles.

(f) Adjust 600 kilocycle oscillator padder condenser, Illus. #8 (Fig. 2) while rocking tuning condenser back and forth for maximum 600 kilocycle signal response.

All of the adjustable condensers are very accurately adjusted at the factory and should need no further adjustment unless tampered with in the field or a defective coil has been replaced. If realignment is found necessary, the set can be properly adjusted only by using a calibrated test signal oscillator or signal generator and an output meter.

CIRCUIT ALIGNMENT

If realignment is found necessary, the circuits can be adjusted only with the chassis in its case, using a calibrated test oscillator or signal generator and an output meter.

1. Aligning I-F Stages at 262 Kilocycles

(a) Connect the signal lead of the signal generator to the grid cap of the 6A7 tube through a .5 mfd. condenser, leaving the tube's grid clip in place.

(b) Connect the ground lead of the signal generator to the chassis frame.

(c) Connect the output meter to the plate prongs of the 42 type tubes.

(d) Set the signal generator to 262 kilocycles.

(e) Adjust the 2nd I-F trimmers (Illus. 9, Fig. 2) and then the 1st I-F trimmers (Illus. 8, Fig. 2) for maximum output. This operation should be repeated until no further increase in output is obtained.

2. Aligning at 1530 Kilocycles

(a) Disconnect the signal lead of the signal generator from the grid of the 6A7 tube and connect to the antenna terminal of the receiver.

(b) Turn the rotor plates of the gang condenser completely out of mesh and against the high frequency stop.

(c) Set the signal generator to 1530 kilocycles.

(d) Adjust the trimmer for the oscillator section of the gang condenser (middle section) CAREFULLY for maximum output. Then adjust the trimmer for the "R-F" and "ANT" sections of the gang condenser also for maximum output.

3. Aligning at 1400 Kilocycles

(a) Set the signal generator to 1400 kilocycles.

(b) Turn the condenser rotor plates until this signal is tuned in with maximum output.

(c) Readjust only the parallel trimmers for the "R-F" and ANT. sections of the gang condenser (Fig. 2) for maximum output.

4. Aligning at 600 Kilocycles

(a) Set the signal generator to 600 kilocycles.

(b) Turn the condenser rotor plates until this signal is tuned in with maximum output.

(c) Adjust the antenna compensating condenser (Illus. 16, Fig. 3) for maximum output.

(d) Retune the condenser plates for maximum output.

Repeat these operations alternately until no further improvement in output can be noted.

5. Realigning at 1400 Kilocycles

(a) Set the signal generator again to 1400 kilocycles.

(b) Turn the condenser rotor plates until this signal is tuned in with maximum output.

(c) Readjust the trimmer for the "ANT" section of the gang condenser CAREFULLY for maximum output.

6. Adjusting Receiver to Car Antenna

(a) Tune the receiver to a weak broadcast station on the low frequency end of the dial, 550 to 700 K.C.

(b) Adjust the antenna compensating condenser (Illus. 16, Fig. 3) for maximum response from the broadcast station.

VOLTAGE CHART

Tube	#1 Screen	#2 Plate	#3 Fil.	#4 Fil.	#5 Cathode	#6 Cond.	#7 Triode Plate
78	85	210	6.0	0	3.2	3.2	
6F7	85	210	0	6.0	3.2	0	90
78	85	210	6.0	0	3.2	3.2	
85	0	85	0	6.0	8.0	0	
41	210	205	6.0	0	16	0	
41	210	205	6.0	0	16	0	

Peaking I.F. Stages at 262 K.C.

The only way the I.F. stages can be peaked properly is with the use of an oscillator and output meter. Connect the output meter to the plate prongs of the 41 output tubes Make sure that the output meter is protected with a series condenser internally; if not, connect a 1/10 mfd. condenser in series with one of the output meter leads. The Dayrad #875 Universal Test Meter and Series #51 Volt-Ohmeter have this protective condenser included in them.

(a) Connect the output of the oscillator to the grid cap of the 6F7 tube (leave grid cap in place) and to the chassis ground.

(b) Turn the condenser gang until the plates are entirely out of mesh.

(c) Set the oscillator on 262 K.C. and feed this signal through the I.F. stages of the set.

(d) Peak the I.F. trimmer which is on the I.F. coil having only one adjusting screw first. Then peak the two condensers of the 2nd I.F. coil.

(e) Set the oscillator output at the lowest level that will give a reasonable scale deflection on the output meter. This should be less than half the maximum output available.

(f) Make all trimmer adjustments for maximum deflection on the output meter scale.

Peaking Gang Condenser at 1400 K.C.

(a) Connect the output of the oscillator to the antenna connection of the set and to the chassis ground.

(b) In order that the position of the condenser plates for 1400 K.C. may be accurately determined, a wood calibration block (painted red, part number 1208073) should be used. This block may be used also in peaking all of the U.M.S., B-O-P, and Chevrolet radios that use the "tubeless rectifier."

(c) Insert the RED block under the middle section of the gang condenser, so that the largest flat side rests on the chassis base and the square notch stops solidly against the stationary plate support bracket.

(d) Open the condenser plates until they stop solidly against the beveled edge of the block as shown in Fig. 1.

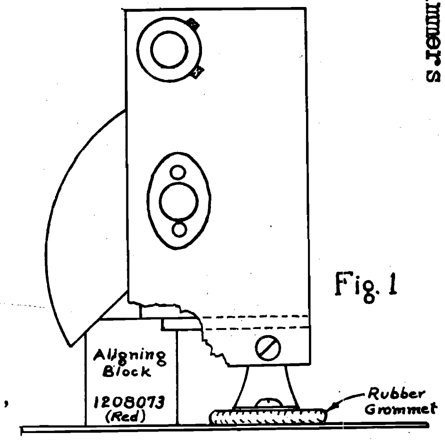

Fig. 1

(e) Peak the parallel trimmers on top of the condenser gang, the oscillator section first at 1400 K.C. for maximum deflection on the output meter.

(f) To insure sharp peaking of all trimmers reduce the oscillator output to the lowest level that will give a reasonable deflection on the output meter scale.

NOTE: Always use the red calibration block when aligning the parallel trimmers on the gang condenser. Do not rely on the logging of the dial to determine the 1400 K.C. setting. When the aligning procedure is completed the logging of the dial may be slightly off and should be re-set.

GENERAL: The model 600565 auto radio is a powerful, two unit type, six tube superheterodyne radio receiver with airplane dial.

VIBRATOR NOISE

Examination of the mechanical construction of the transformer vibrator assembly will show that the bottom plate of the vibrator case is riveted to the chassis. The transformer-vibrator assembly is fastened to the bottom plate with two Parker Kalon screws through each end of the lid. For complete elimination of vibrator noise it is necessary that the bottom plate of the vibrator assembly make a good contact with the vibrator case at all points. Placing screws on all four sides of the bottom plate would make the servicing of the vibrator rather difficult, consequently screws were placed in the ends only. The press fit of the bottom plate must be depended upon to eliminate the vibrator noise.

Do not change a vibrator that is noisy electrically before checking the grounding of the vibrator assembly to its bottom plate. Use a pair of pliers to bend the longest sides of the bottom plate inward just enough to insure a pressure contact with the vibrator assembly at all points.

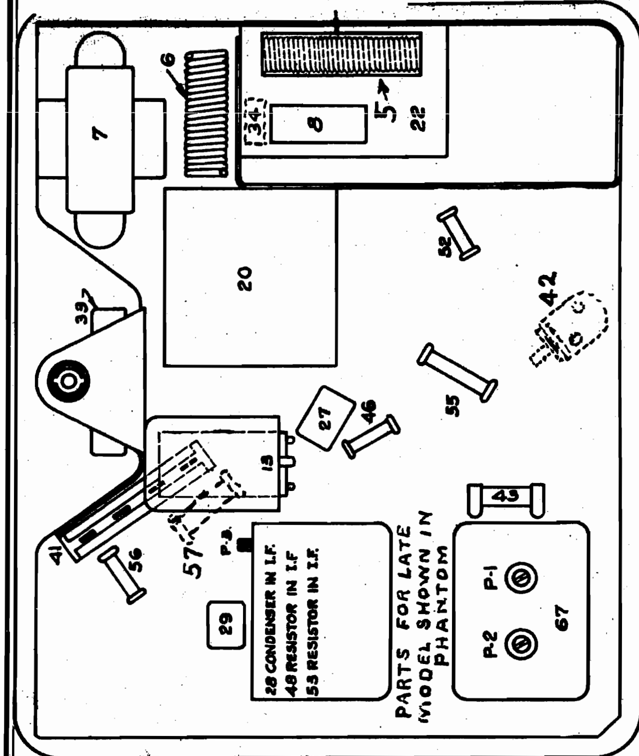

FIG.2 PARTS LAYOUT--Bottom View

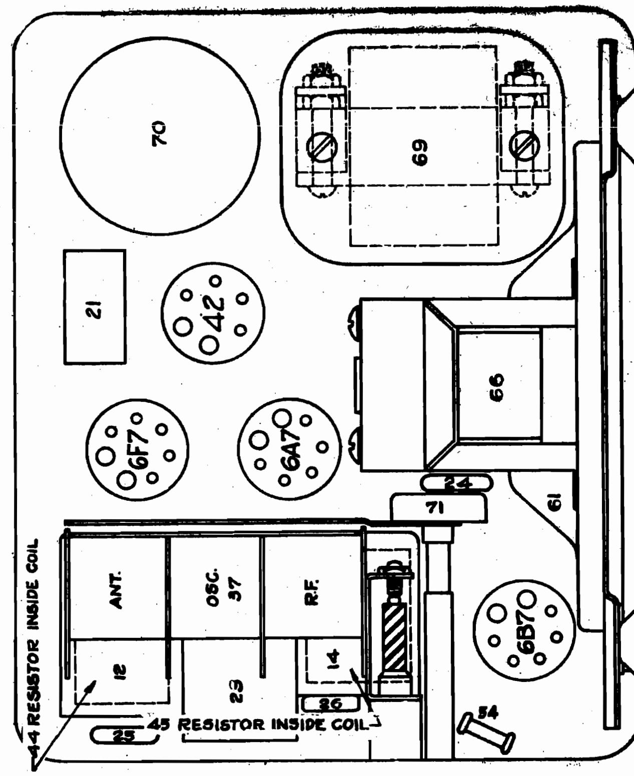

FIG. 3 PARTS LAYOUT--Top View

CIRCUIT CHANGES

Several changes were made in the receiver circuit starting at serial #1748809. It will be necessary to use Figures 1, 2 and 3 for receivers below serial #1748809 and to use Figures 1A, 2A and 3A for receivers above serial #1748809. PARTS SHOWN IN PHANTOM.

It will be noted on some receivers that the .008 mfd. section (Illus. 21C) of the part #1209048 Condenser Block has its lead cut off close to the block and a .008 mfd. tubular condenser connected from the plate of the 42 tube in its place. This change was made because it was found necessary to change the voltage rating of the .008 mfd. section of the condenser block after production started and a .008 mfd. tubular condenser was simply used until a new block could be manufactured. The tubular condenser used is part #1209212 and is located alongside of the power filter choke. All of the service replacement stock of #1209048 condenser blocks have a .008 mfd. section of a higher voltage rating and in installing these blocks in a receiver where the tubular condenser was used it will be necessary to either remove the tubular condenser or clip the lead off of the .008 section of the block.

The capacity of two sections of the part #1209050 Condenser Block (Illus. 23A to F) were changed at serial #1748809 along with several other circuit changes. The "D" section which was originally .04 mfd. was changed to .01 mfd. and the "E" section which was originally .01 mfd. was changed to .1 mfd. All of the service replacement stock of the part #1209050 Condenser Blocks are of the new type incorporating the above changes and should be used in the service replacement of all part #1209050 condenser blocks used below serial #1748809.

MODEL 601177,Early,Late
Chevrolet
Alignment

UNITED MOTORS SERVICE

Peaking I.F. Stages at 262 K.C.

(a) Connect the ground lead of the test oscillator to the chassis frame. Connect a 1 mfd. condenser in series with the other lead and connect this lead to the grid cap of the 6A7 tube, leaving the tube's grid clip in place. The 1 mfd. condenser is necessary to prevent the oscillator circuit of the receiver from affecting the I.F. adjustments.

(b) Set the test oscillator on 262 kilocycles.

(c) Turn the volume control of the receiver on full.

(d) Peak the I.F. trimmer P-3 for the 2nd I.F. coil shown on Figure 2.

(e) Then peak trimmers P-2 and P-1 of the first I.F. coil also shown on Figure 2.

(f) In order to insure accurate settings of the I.F. trimmers the above adjustments should be repeated using the lowest oscillator output that will give a reasonable output meter scale deflection. Make all adjustments for maximum output.

Peaking Gang Condenser at 1530 and 1400 K.C.

(a) Connect the output of the test oscillator to the antenna connection of the receiver and to the chassis ground. Do not use the 1 mfd. condenser that was required in aligning the I.F. stages.

(b) Turn the rotor plates of the gang condenser until they are COMPLETELY OUT OF MESH.

(c) Set the test oscillator on 1530 kilocycles.

(d) Adjust the oscillator section (middle section) of the gang condenser CAREFULLY for maximum output. Then adjust the trimmers for the "R.F." and "ANT" sections of the gang condenser.

(e) Set the test oscillator on 1400 kilocycles.

(f) Turn the condenser rotor plates until the 1400 K.C. signal from the test oscillator is tuned in with maximum output. (No calibration blocks should be used as the oscillator circuit is adjusted at 1530 K.C. on this set.)

(g) Readjust the parallel trimmers for the "R.F." and "ANT" sections of the gang condenser (shown on Fig. 2) for maximum output. DO NOT disturb the oscillator trimmer (middle section) as this is adjusted at 1530 K.C. only, and any further adjustments at this point will affect both the tuning range of the receiver and the tracking of its circuits.

CAUTION: Always use the lowest possible test oscillator output that will give a reasonable deflection of the output meter pointer, in order to prevent the A.V.C. from leveling out the output as the adjustments are made.

CIRCUIT ALIGNMENT

NOTE: BEFORE STARTING ALIGNMENT PROCEDURE, SEE THAT EITHER A JUMPER IS INSTALLED IN THE DUAL SPEAKER PLUG SOCKET (SEE CIRCUIT DIAGRAM) OR THE DUAL SPEAKER ITSELF IS CONNECTED. FAILURE TO DO THIS WILL RESULT IN AN OPEN CIRCUIT IN THE VOICE COIL.

1. Aligning I-F Stages at 260 Kilocycles

(a) Remove the top and bottom covers from the receiver case and place the receiver so that all adjustments are accessible. Connect the signal output of the signal generator to the control gid cap of the 6A7 tube through a .25 mfd. condenser (without disconnecting the grid lead) and connect the ground of the signal generator to the receiver chassis. Connect the Output Meter across the two plates of the 6A6 power tube for output indication. Tune the signal generator accurately to 260 KC. Adjust the four screws of the two I-F transformers, one on top and one on bottom of each transformer (Illus. #61 and 62, Figs. 2 & 3) for maximum output. Repeat these adjustments a second time for greater accuracy.

Checking I-F Band Spread

The Model 165 Cathode Ray Oscillograph should be used to check the I-F band spread after completing the "Alignment Procedure". Slight adjustments to the I-F stages may be found necessary in order to obtain a symmetrical selectivity curve. Complete information concerning this check with the Oscillograph, is given in the Oscillograph Manual, included with each instrument.

2. R-F Stage Alignment

The antenna and R-F coils used in these receivers contain adjustable iron cores, which require very careful adjustment at the factory. These adjustments are sealed and no further attempts to adjust them in service should be made unless they show evidence of being disturbed or tampered with. In any event where realignment is deemed necessary, the capacity adjustments should be made first in an effort to obtain normal sensitivity.

Two separate procedures are given for aligning the R-F circuits of these receivers and the procedure to be used will depend on whether the sealed iron core adjustments have been disturbed. The first procedure contains only capacity adjustments, while the second procedure contains both capacity and inductance adjustments.

The service replacement iron core antenna and R-F coils are pre-set at the factory and in most instances will require no further adjustment.

Properly align the tuning dial pointer to the gang tuning condenser by turning the receiver tuning control clockwise until all stops are reached at the high-frequency end of the dial, then rotate the tuning control counter-clockwise until all stops are reached at the low-frequency end of the dial.

IN THE FOLLOWING PARAGRAPHS WHEN ALIGNMENT IS MADE AT 600 K.C. THE DIAL POINTER ON THE CONTROL HEAD SHOULD BE SET TO THE CENTER OF THE "0" IN "60" WHEN LOOKING STRAIGHT INTO THE DIAL.

3. Aligning R-F Stages--Capacity Adjustments

(a) Connect the signal generator to the control grid cap of the 6A7 detector-oscillator tube through a .25 mfd. condenser. Adjust the signal generator to 1560 KC. Set the receiver tuning control to its mimimum capacity (full open) position. Adjust the oscillator parallel trimmer (Illus. 1-F, Fig. 2) for maximum output.

(b) Connect the signal generator to the antenna connection on the receiver through a .0005 mica condenser and adjust to 1400 KC. Tune the receiver to this signal and adjust the R-F and antenna trimmers (Illus. 1-D and 1-B, Fig. 2) on gang condenser for maximum output.

(c) Adjust signal generator to 600 KC and tune receiver to 600 KC. Adjust the oscillator series condenser (Illus. #2, Fig. 2) while rocking the gang tuning condenser back and forth through the signal, for maximum output.

(d) Adjust signal generator to 1400 KC and tune receiver to this signal. Readjust the oscillator, R-F, and antenna trimmers (Illus. #1-F, 1-D and 1-B, Fig. 2) for maximum output.

4. Aligning R-F Stages--Capacity and Inductance Adjustments

This procedure covers all R-F adjustments and should not be resorted to, unless the adjustments outlined in section "3" fail to restore normal sensitivity.

(a) Connect the signal generator to the control grid cap of the 6A7 tube through a .25 mfd. condenser. Adjust the signal generator to 1560 KC. Set the receiver tuning control to its minimum capacity (full open) position. Adjust the oscillator parallel trimmer (Illus. #1-F, Fig. 2) for maximum output.

(b) Adjust the signal generator to 600 KC and set the receiver dial to 600 KC. Adjust the oscillator series condenser (Illus. #2, Fig. 2) for maximum output.

(c) Adjust the signal generator to 1560 KC and set the receiver tuning to its minimum capacity (full open) position. Adjust the oscillator parallel trimmer (Illus. #1-F, Fig. 2) for maximum output.

(d) Connect signal generator to the antenna connector of the receiver through a .0005 mfd. mica condenser. Adjust the signal generator to 600 KC and tune the receiver to this signal. Adjust the magnetite core screws of the R-F and antenna coils (Illus. #35 and #32, Fig. 3) for maximum output.

(e) Adjust signal generator to 1400 KC and tune receiver to this signal. Adjust the oscillator, R-F and antenna trimmers (Illus. #1-F, 1-D and 1-B, Fig. 2) for maximum output.

(f) Adjust signal generator to 600 KC and tune the receiver to this signal. Adjust the R-F and antenna magnetite core screws (Illus. #35 and #32, Fig. 3) for maximum output.

(g) Adjust signal generator to 600 KC and tune receiver to 600 KC. Adjust the oscillator series condenser (Illus. #2, Fig. 2) while rocking the gang tuning condenser back and forth through the signal, for maximum output.

(h) Adjust signal generator to 1400 KC and tune receiver to this signal. Readjust the oscillator, R-F, and antenna trimmers (Illus. #1-F, 1-D and 1-B, Fig. 2) for maximum output.

GENERAL: The Pontiac Model 983526 is a seven tube, "dash" speaker receiver with a "Local-Distance" switch and tone control. The receiver was designed for operation in 1937 Pontiacs and is equipped with an instrument panel tuning control having a tone control in addition to the tuning and volume controls.

MODEL 983526 Pontiac
Socket, Trimmers
Chassis, Alignment

UNITED MOTORS SERVICE

CIRCUIT ALIGNMENT

Pontiac Model 983526

Aligning I-F Stages at 262 Kilocycles

IMPORTANT: The "Local-Distance" switch on the tuning control used with this receiver is used to control the alignment of the first I-F coil windings. It is important, therefore, in peaking the I-F stages, that the "Local-Distance" switch be placed in the "Distance" position.
Connect the signal lead of the signal generator to the grid cap of the 6A8G Translator Tube through a .1 mfd. condenser, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the chassis frame.

Turn "Local-Distance" switch on set to "DISTANCE" position. (If the receiver is aligned with the switch in the "Local" position, the "Local-Distance" switch will operate backwards.)

Connect the output meter across the plate prongs of the 6N7G tube.

Set the signal generator to exactly 262 kilocycles.

Adjust the trimmers on the I-F coils (Illus. 6 & 10, Fig. 3) for maximum output. These adjustments should be repeated several times.

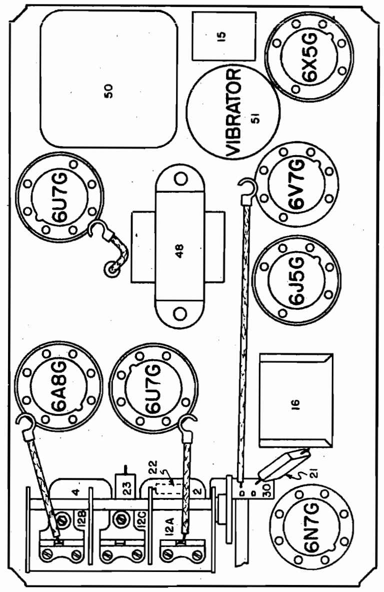

FIG. 2--PARTS LAYOUT--Top View

Aligning at 1530 Kilocycles

Leave the signal generator leads connected the same for aligning the I-F circuits. Turn the rotor plates of the gang condenser all the way out and against the high frequency stop. Set the signal generator to 1530 kilocycles. Adjust the parallel trimmer for the oscillator section of the condenser gang (Illus. 12C, Fig. 2) for maximum output. (It is very important that this frequency be set accurately as a slight mis-setting will cause the receiver to be out of track over the entire high frequency end of the dial.)

Aligning at 540 Kilocycles

Leave signal generator leads connected the same as before. Turn the rotor plates of the gang condenser all the way into mesh so that they rest against the low frequency stop. Set the signal generator to 540 K.C. Adjust the oscillator padding condenser (Illus. 29, Fig. 3) located on the under-side of the receiver sub-panel to maximum output.

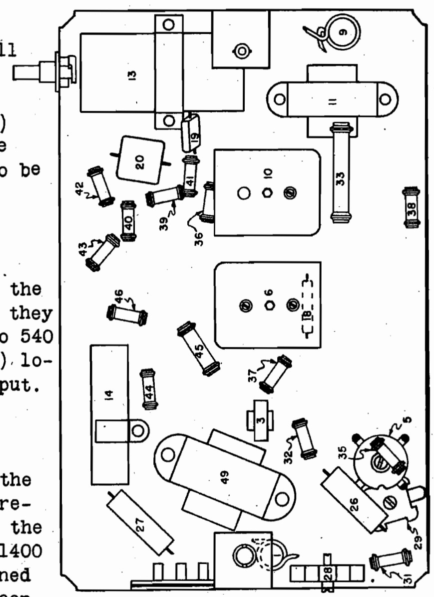

FIG. 3--PARTS LAYOUT--Bottom View

Aligning at 1400 Kilocycles

Remove the signal lead of the signal generator from the grid of the 6A8G Translator tube and connect to the antenna terminal of the receiver THROUGH A .0002 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used. Set the signal generator to 1400 K.C. Turn the condenser rotor plates until this frequency is tuned in with maximum output. Adjust the R-F parallel trimmer on the condenser gang (Illus. 12B, Fig. 2) and the antenna compensating condenser (Illus. 28, Fig. 3) located on the side of the receiver case for maximum output.

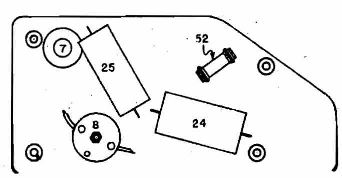

FIG. 4--PARTS LAYOUT--Vibrator Filter

Aligning at 600 Kilocycles

Set the signal generator on 600 K.C. Turn the condenser rotor plates until the signal from the signal generator is tuned in with maximum output. Maintain a low output signal from the signal generator and readjust the oscillator tracking condenser (Illus. 29, Fig. 3) while rocking the variable condenser gang tuning shaft back and forth through the signal. This operation should be continued until no further increase in output can be obtained.

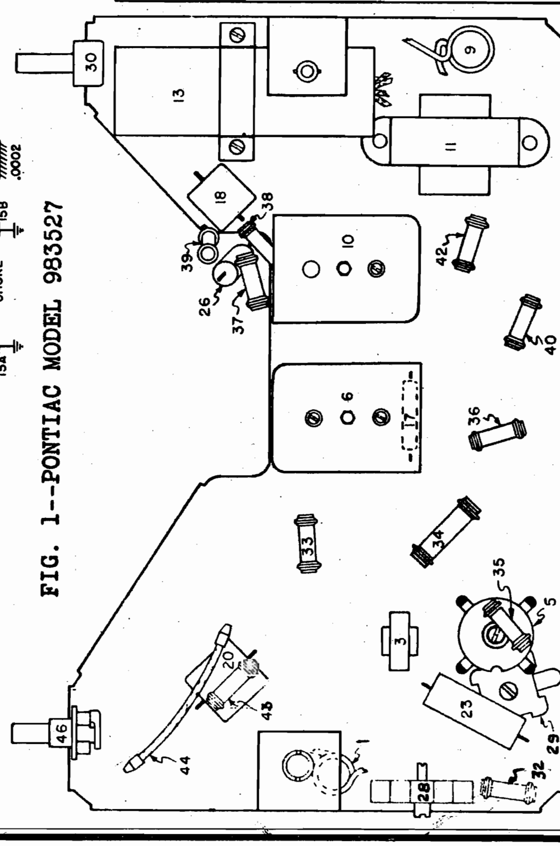

FIG. 3--PARTS LAYOUT--Bottom View

MODEL 983527 Pontiac
Alignment

UNITED MOTORS SERVICE

Pontiac 983527

1. Aligning I-F Stages at 262 Kilocycles

(a) Connect the signal lead of the signal generator to the grid cap of the 6A8G tube, through a .1 mfd. condenser, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the chassis frame.

(b) Connect the output meter from the plate of the 6F6G tube to ground.

(c) Place Local-Distance switch in "Distance" position.

(d) Set the signal generator at exactly 262KC.

(e) Adjust trimmers on the IF coils (6 and 10 FIG. 3) carefully for maximum output. Repeat adjustments several times.

2. Aligning at 1530 Kilocycles

(a) Leave the signal generator leads connected the same as for aligning the I-F circuits.

(b) Turn the rotor plates of the gang condenser all the way out and against the high frequency stop.

(c) Set the signal generator to 1530 kilocycles.

(d) Adjust the parallel trimmer for the oscillator section of the condenser gang (Illus. 12C, Fig. 2) for maximum output. It is very important that this frequency be set accurately as a slight missetting will cause the receiver to be out of track over the entire high frequency end of the dial.

3. Aligning at 540 Kilocycles

(a) Leave signal generator leads connected the same as before.

(b) Turn the rotor plates of the gang condenser all the way into mesh so that they rest against the low frequency stop.

(c) Set the signal generator to 540 K.C.

(d) Adjust the oscillator tracking condenser (Illus. 29, Fig. 3) located on the under-side of the receiver sub-panel to maximum output.

4. Aligning at 1400 Kilocycles

(a) Remove the signal lead of the signal generator from the grid of 6A8G tube and connect to the antenna terminal of the receiver THROUGH A .0002 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used.

(b) Set the signal generator to 1400 K.C.

(c) Turn the condenser rotor plates until this frequency is tuned in with maximum output.

(d) Adjust the R-F parallel trimmer on the condenser gang (Illus. 12B, Fig. 2) and the antenna compensating condenser, (Illus. 28, Fig. 3) located on the side of the receiver case for maximum output.

5. Aligning at 600 Kilocycles

The oscillator padding condenser was previously adjusted at 540 K.C.; however, it is necessary in most cases to repeak this condenser at 600 K.C. in order to make the receiver track properly and to secure full sensitivity

(a) Set the signal generator on 600 K.C.

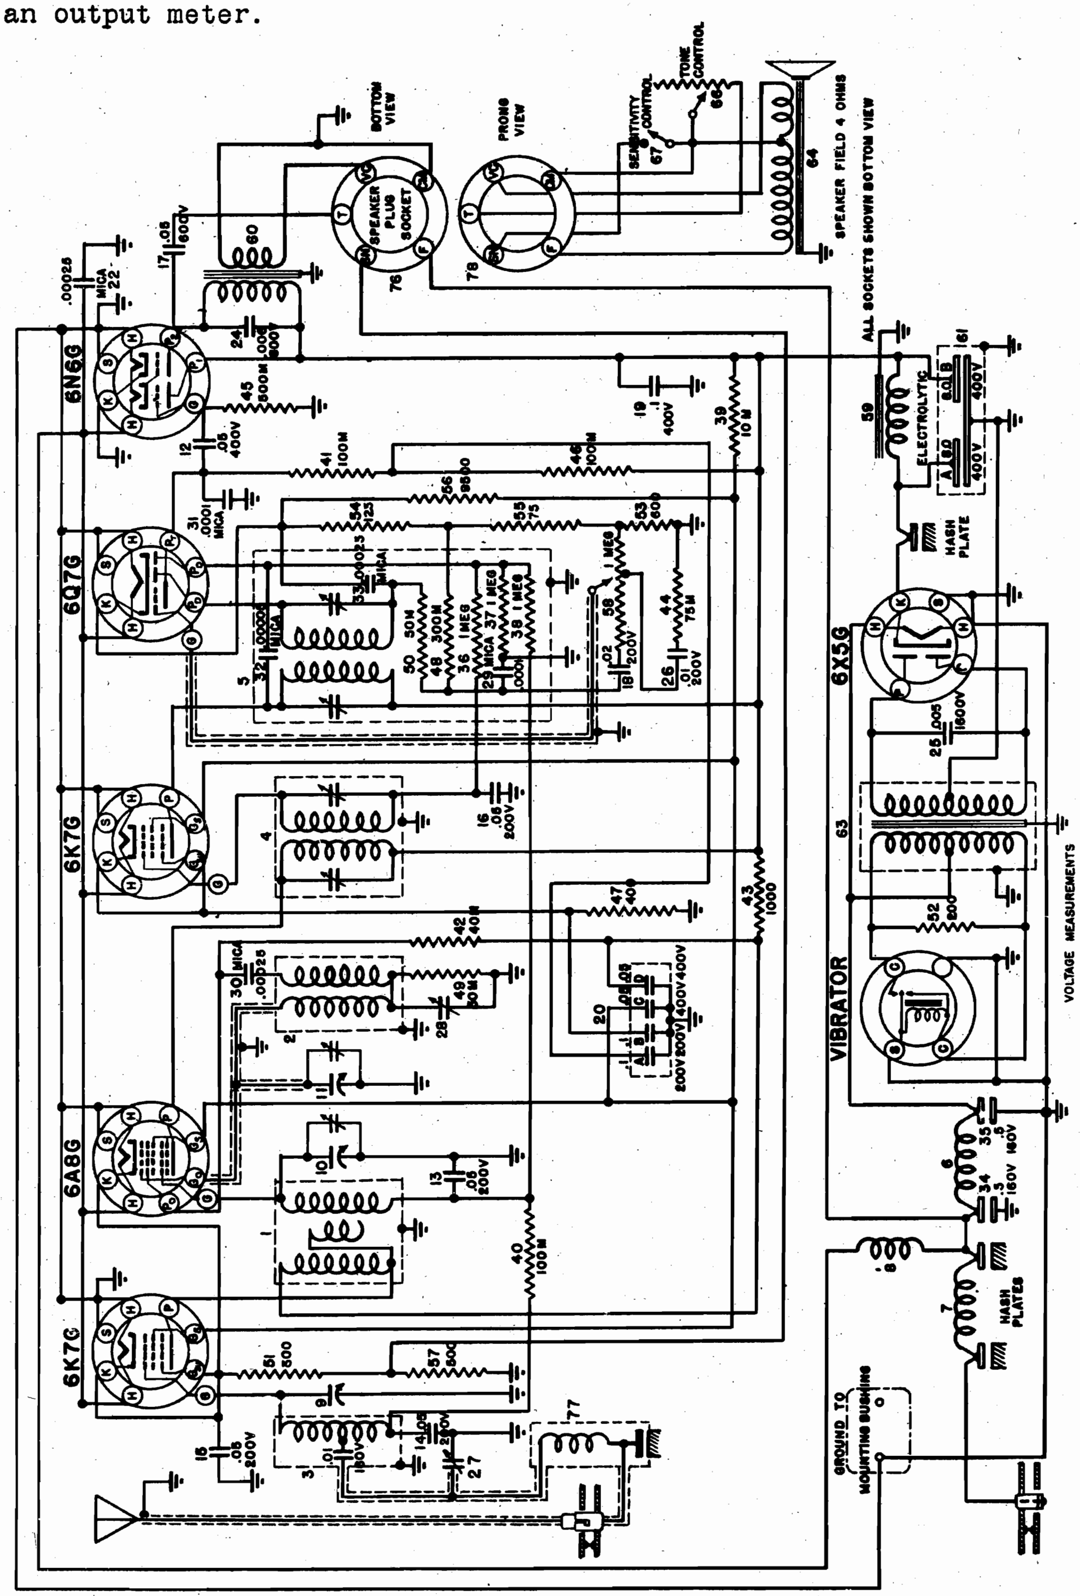
(b) Turn the condenser rotor plates until the signal from the signal generator is tuned in with maximum output.

(c) Maintain a low output signal from the signal generator and readjust the oscillator tracking condenser (Illus. 29, Fig. 3) while rocking the variable condenser gang tuning shaft back and forth through the signal. This operation should be continued until no further increase in output can be obtained.

UNITED MOTORS SERVICE

MODEL 983534 Pontiac
Schematic

If realignment is found necessary, the circuits can be properly adjusted only with the use of a calibrated test oscillator, or signal generator, and an output meter.



Pontiac 983534

Date: 3-7-38

GENERAL: The Pontiac Model 983534 is a six tube single unit auto radio, with tone and sensitivity controls and bass compensation. A non-synchronous vibrator and a tube type rectifier is used in the power supply in a full wave circuit.

CIRCUIT ALIGNMENT

1. Aligning I-F Stages at 262 Kilocycles

   (a) Connect the signal lead of the signal generator to the grid cap of the 6A8G translator tube, through a .1 mfd. condenser, leaving the tube's grid clip in place. Connect the ground lead of the signal generator to the chassis frame.

   (b) Connect the output meter from the plate of the 6N6G to ground. (Care should be taken when connecting the output meter to insert a series condenser to protect the meter from D.C. voltages.)

   (c) Set the signal generator to exactly 262 K.C.

   (d) Turn receiver volume control on full and tuning condenser plates out of mesh. Adjust the trimmers on the I-F coils (Illus. 4 and 5, Fig. 2) for maximum output. These adjustments should be repeated several times and during alignment the signal generator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.

2. Aligning at 1560 Kilocycles

   (a) Leave the signal generator leads connected the same as for aligning the I-F circuits.

   (b) Turn the rotor plates of the gang condenser all the way out and against the high frequency stop.

   (c) Set the signal generator to 1560 kilocycles.

   (d) Adjust the parallel trimmer for the oscillator section (middle) of the condenser gang (Illus. 11, Fig. 2) for maximum output. (It is very important that this frequency be set accurately as a slight mis-setting will cause the receiver to be out of track over the entire high frequency end of the dial.)

3. Aligning at 1400 Kilocycles

   (a) Remove the signal lead of the signal generator from the grid of the translator (6A8G) tube and connect to the antenna terminal of the receiver THROUGH A .0002 mfd. MICA CONDENSER connected in place of the .1 mfd. condenser previously used. (It is very important that this mica condenser be used in aligning the antenna stage of these receivers in order that this circuit can be made to track properly.)

   (b) Set the signal generator to 1400 K.C.

   (c) Turn the condenser rotor plates until the frequency is tuned in with maximum output.

   (d) Adjust the R-F parallel trimmer on the condenser gang (top section) and the antenna compensating condenser, (Illus. 27, Fig. 3) for maximum output.

4. Aligning at 600 Kilocycles

   (a) Set the signal generator on 600 K.C.

   (b) Turn the condenser rotor plates until the signal from the signal generator is tuned in with maximum output.

   (c) Maintain a low output signal from the signal generator and readjust the oscillator tracking condenser (Illus. 28, Fig. 3) while rocking the variable condenser gang tuning shaft back and forth through the signal.

   (d) This operation should be continued until no further increase in output can be obtained.

5. Realigning at 1400 Kilocycles

   (a) Recheck alignment of R-F section of condenser gang and antenna compensating condenser (Illus. 27, Fig. 3) as given in paragraph 3.

   (b) It will be necessary to readjust the antenna compensating condenser upon installation in a car.

CIRCUIT ALIGNMENT

If realignment is found to be necessary, the circuits can be adjusted only with the use of a calibrated test oscillator or signal generator, and an output meter.

Peaking I-F Stages at 262 Kilocycles (1)

(a) Connect the signal lead of the test oscillator to the grid cap of the 6A8G Oscillator Tube through a .1 mfd. condenser, leaving the tube's grid clip in place. Connect the ground lead of the test oscillator to the chassis frame.

(b) Connect the output meter from the plate prong of the 6F6G to ground. Care should be taken when connecting the output meter to insert a series condenser to protect the meter from D.C. voltages.

(c) Set the test oscillator to exactly 262 K.C.

(d) Adjust the trimmers on the I-F coils (Illus. 4 & 5) for maximum output. These adjustments should be repeated several times and during alignment the test oscillator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.

Aligning at 1560 Kilocycles (2)

(a) Leave the test oscillator leads connected the same as for aligning the I-F stages.

(b) Turn the rotor plates of the condenser gang all the way out and against the high frequency stop.

(c) Set the test oscillator to exactly 1560 K.C.

(d) Adjust the parallel trimmer for the oscillator section (middle) of the condenser gang (Illus. #8) for maximum output.

NOTE: It is very important that this frequency be set accurately as a slight mis-setting will cause the set to be out of track over the entire high frequency end of the dial.

Aligning at 1400 Kilocycles (3)

(a) Remove the signal lead of the test oscillator from the grid of the 6A8G Oscillator Tube and connect to the Antenna terminal of the receiver through a .0002 mfd. mica condenser.

(b) Set the test oscillator to 1400 K.C.

(c) Turn the condenser rotor plates until this frequency (1400 K.C.) is tuned in with maximum output.

(d) Adjust the R-F and Antenna parallel trimmer on the condenser gang (Illus. 6 & 7) for maximum output.

1. Peaking I-F Stages at 262 K.C.

   (a) Connect the signal lead of the test oscillator to the grid cap of the 6A8G Modulator-Oscillator tube, through a .1 mfd. condenser. Connect the ground lead of the test oscillator to the chassis frame.

   (b) Set the Test Oscillator at 262 K.C.

   (c) Turn volume control on full and tuning condenser plates completely out of mesh.

   (d) Adjust trimmers on the I-F coils (Illus. 4 and 5) for maximum output. These adjustments should be repeated several times and during alignment the test oscillator output should be kept to as low a value as is consistent with obtaining a readable indication on the output meter.

2. Aligning at 1560 Kilocycles

   Leave the test oscillator leads connected the same as for aligning the I-F Stages. Make sure the rotor plates of the condenser are turned all the way out and against the high frequency stop. Set the test oscillator to exactly 1560 K.C. Adjust the parallel trimmer for the oscillator section (middle) of the condenser gang (Illus. #11) for maximum output.

3. Aligning at 1400 Kilocycles

   Remove the signal lead of the test oscillator from the grid of the 6A8G Tube and connect to the antenna terminal of the receiver THROUGH A .0002 MFD. MICA CONDENSER. Set the test oscillator to 1400 K.C. Turn the condenser plates until this frequency is tuned in with maximum output. Adjust the R-F parallel trimmers on the condenser gang (Top section) for maximum output. Adjust the antenna compensating condenser (Illus. #27) for maximum output.

4. Aligning at 600 Kilocycles

   Set the test oscillator on 600 K.C. and turn the condenser plates until this signal is tuned in with maximum output (at approximately 600 K.C. position of plates). Maintain a low test oscillator signal and adjust the oscillator tracking condenser (Illus. #28) while rocking the condenser gang plates back and forth through the signal. This operation should be continued until no further increase in output can be obtained.

5. Realigning at 1400 Kilocycles

   Recheck alignment of the R-F section of the condenser gang and antenna compensating (Illus. #27) at 1400 K.C. as given in paragraph #3.

CIRCUIT ALIGNMENT

Chevrolet 985255

Aligning I-F Stages at 262.5 Kilocycles

(a) Connect the signal lead of the test oscillator to the grid cap of the 6K7G I-F Amplifier tube, through a .1 mfd. condenser, leaving the tube's grid clip in place. Connect the ground lead of the test oscillator to the chassis frame.

(b) Connect the output meter from the plate (P2) of one of the 6N6G Output tubes to the plate (P2) of the other 6N6G Output tube.

(c) Set the test oscillator carefully to 262.5 K.C.

(d) Turn the "Volume Expander" switch on the receiver to the "Off" position. Turn the volume control on full and turn the condenser gang plates so that they are completely in mesh. Leave the "Fidelity Control" Cable disconnected from the chassis.

Aligning I-F Stages at 262.5 Kilocycles--Cont'd.

(e) Adjust both trimmers located on the 2nd I-F coil (Illus. #9) for maximum output.

(f) Connect the signal lead of the test oscillator to the grid cap of the 6A8G Oscillator-Modulator tube, leaving the tube's grid clip in place.

(g) Adjust both trimmers located on the 1st I-F coil (Illus. #8) for maximum output.

NOTE: DO NOT READJUST THE TRIMMERS ON THE 2ND I-F COIL, ILLUS. #9.

Aligning at 1550 Kilocycles

Leave the test oscillator signal lead connected to the grid cap of the 6A8G tube. Turn the condenser rotor plates all the way out and against the high frequency stop. Set the test oscillator to exactly 1550 K.C. Adjust the parallel trimmer for the oscillator section (middle) of the condenser gang (Illus. #10C) carefully for maximum output.

Aligning at 1400 Kilocycles

Remove the signal lead of the test oscillator from the grid of the 6A8G tube and connect to the antenna terminal of the receiver THROUGH a .0002 MFD. MICA CONDENSER. Set the test oscillator to 1400 K.C. Turn the condenser plates until this frequency is tuned in with maximum output. Adjust the "R-F" and "ANT." sections of the condenser gang (Illus. #10) carefully for maximum output.

Adjusting Antenna Compensating Condenser

Leave the test oscillator leads connected the same as before. Set the test oscillator to 600 kilocycles. Tune in the 600 K.C. signal with the station selector for maximum output. Adjust the antenna compensating condenser (Illus. #12) while rocking the tuning condenser setting back and forth through the signal, until no further improvement in output can be obtained. Recheck the alignment of the "ANT" section of the condenser gang as given in paragraph #3.

GENERAL: The Chevrolet Model 985255 is a seven tube, dash speaker auto radio with an instrument panel tuning control, volume expander, "Music-Speech" and Audio Fidelity controls.

Date: 12-24-36

Automatic Volume Expansion: A new feature in automotive radio design is automatic volume expansion, made possible by the use of an "expander tube" connected across the voice coil of the speaker. The resistance of this tube varies with current, so as to increase the volume of loud tones, thus giving a wider volume range to reproduced music.

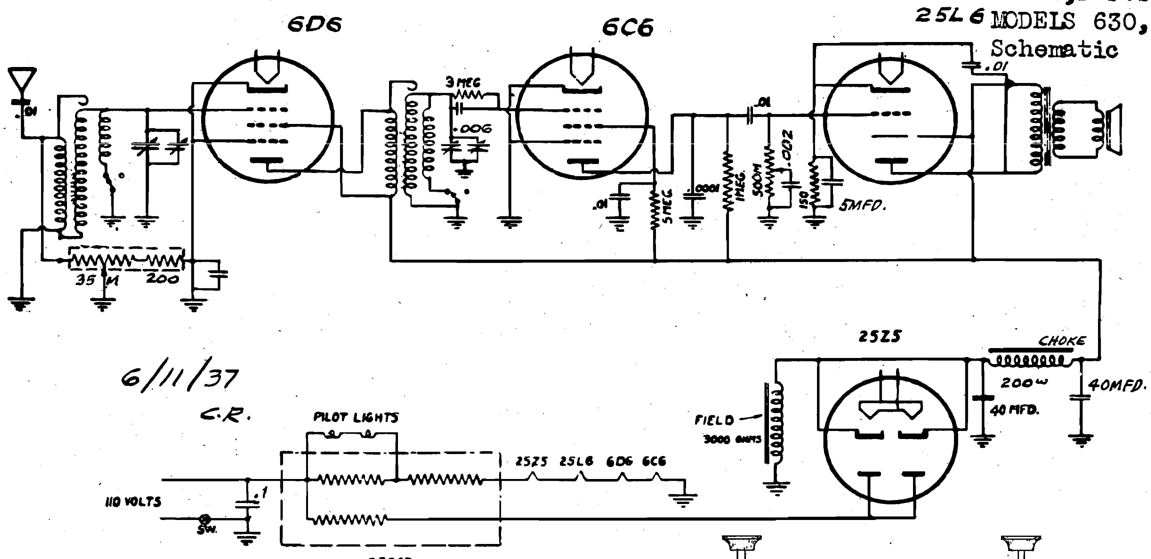
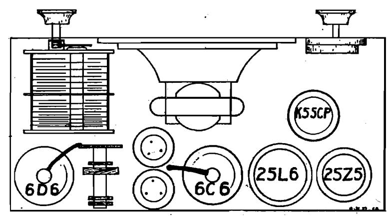
THE WALGREEN CO.



MODEL 255



VIEW SHOWING POSITION OF TUBES

Ground

Caution: Under no circumstance should a ground connection be used, or the far end of the aerial connected to radiators, water pipes, etc.

Current Supply

Any outlet used for household purposes and having a voltage of at least 105 volts and no more than 125 volts can be used. This current can be either direct or alternating current. If in doubt about the line voltage, consult your local power company. They will be pleased to furnish the necessary information. Do not attempt to operate receiver on a current of more than 125 volts. Should the line voltage be more than 125 volts, a special line voltage reducer is available at your neighborhood Walgreen Drug Store.

Aerial

The aerial can be either indoors or outside and in most instances should be no less than 20 feet in length or more than 40 feet. The aerial is to be connected to the short green wire protruding from the rear of the cabinet. When an indoor aerial is used it may be concealed under the base board or tacked to the top of the picture moulding around the room.
Should the receiver be operated in localities where there are no local broadcast stations, a longer outside aerial will be necessary for satisfactory reception. In highly congested metropolitan districts, where most of the apartments are in tall steel reinforced concrete buildings, it will be necessary to have an outside aerial to obtain satisfactory performance. The use of so called aerial eliminator's is not advised.

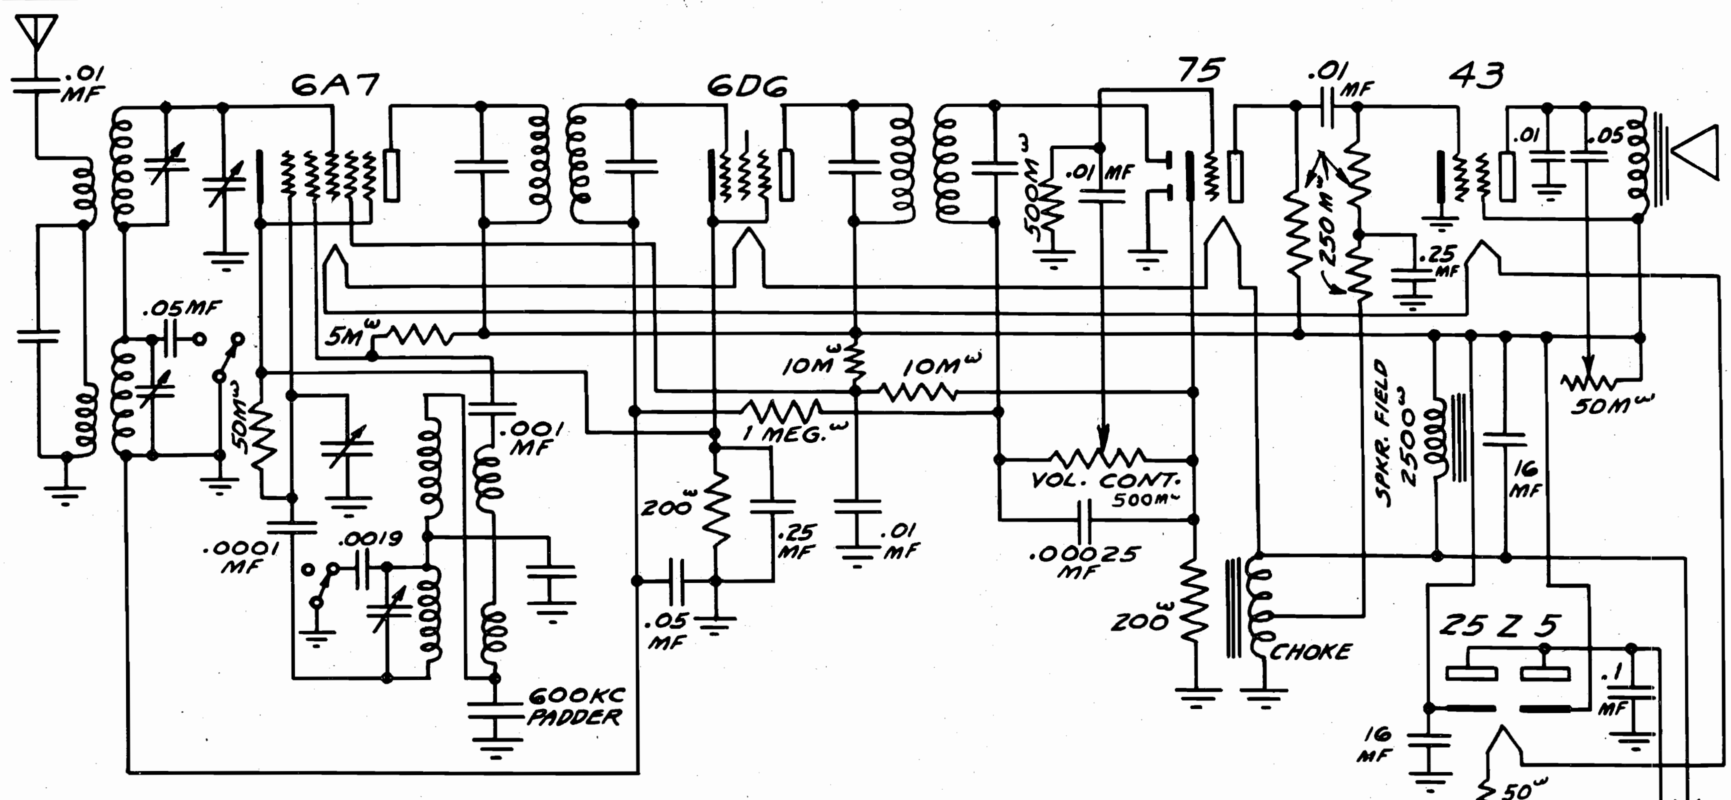
THE WALGREEN CO.



ALIGNMENT PROCEDURE

First, adj. IF transf. to 456 KC by feeding the signal thru the control grid of the 6A7 tube. Adj. the short wave band next;- set pointer at 6 MC & adj. osc. trimmer, located under chassis near filter conds. carefully to the fundamental rather than image(fund. is second peak as you adj. from max. cap.); then adj. the short wave ant. trimmer, located on top of chassis near var. cond., for max. signal; next dial across short wave band checking it at 2.5 and 4 MC to see that it does not stop oscillating. If this should occur, try changing 6A7 tubes to find one that will oscillate at 2.2 MC. If you experience any difficulty in finding a satisfactory tube, it may be necessary to use separate bias on 6A7(200 ohm res. and .1/4 mfd cond.) in order to use the tubes available.

Now, set band switch to broadcast position and adj. padder at about 600 Kc for max. gain, rocking the var. cond. with each adj. of the padder - then with gang all the way open, adj. B.C. osc. trimmer located under chassis near outer edge, to 1717 KC and set B.C. ant. trimmer located on top of chassis near outer edge, for maximum gain.

This set is designed to operate on 105-125 volts AC-DC

DO NOT CONNECT A GROUND TO THIS SET.

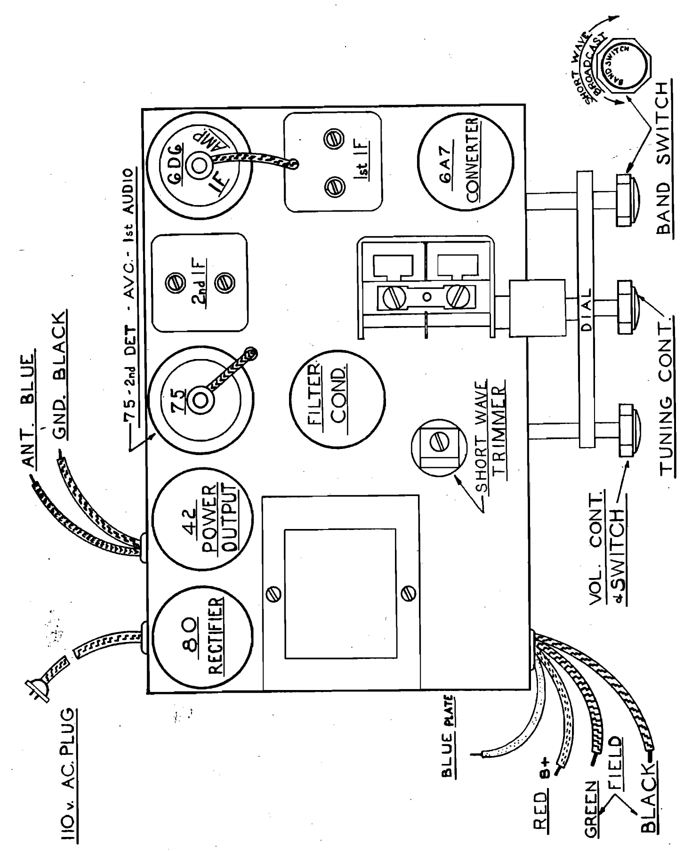
C16	8	"	450V				
C17	8	"	450V				
C18	.1	"	400V				

THE DIFFERENCE BETWEEN THESE TWO MODELS IS THE ADDITION OF THE TUNING EYE IN THE 6 TUBE MODEL.

6 Tube A. C. Superheterodyne with Cathode Ray Magic Eye

A good ground connection to a water pipe or other metallic conductor entering into the ground for some distance is ESSENTIAL.



The frequency range covered by this receiver is as follows: Broadcast band 540 KC to 1700 KC. Short-wave band 2.1 megacycles to 6.4 megacycles. These ranges are selected by turning the range switch knob. Turning this knob to the left switches to the broadcast band; to the right switches to the short wave band.

I. F. Alignment:

Connect a test oscillator or signal generator through a .1 mfd. condenser to the grid of the 6A7 tube and set the oscillator to 456 KC. Use an output meter connected to the speaker if possible, to obtain the most accurate adjustments. Peak each I.F. stage to maximum response, reducing the output of the oscillator as far as possible for final adjustments.

R. F. Alignment:

With the test oscillator set to 1720 KC and connected to the antenna wire of the receiver through a .00025 mfd condenser, switch the receiver to the broadcast band and set the pointer at the end of travel on the right (at the 1700 KC end). Adjust the rear trimmer on the top of the variable condenser, for maximum gain. Then set the test oscillator at 1400 KC and tune in this signal on the receiver as though tuning a station. If an adjustment at this point is necessary on your set, you will have a trimmer condenser to adjust on top of the variable condenser at the front; this is adjusted for maximum gain.

Now adjust the test oscillator to 600 KC and tune in this signal. Adjust the padder condenser (which is adjusted through the right hand end of the chassis) in the following manner: turn the dial slowly and repeatedly back and forth across the signal while adjusting the padder. Adjust for maximum gain.

Now switch the receiver to short wave. With the test oscillator set at 6 megacycles, tune in this signal on the receiver. Then adjust the short wave trimmer (which is located on top of the coil above the chassis) for maximum gain.

ALIGNMENT PROCEDURE

The equipment required for re-aligning this receiver is an output meter and a modulated source of radio frequency (a signal generator or microvolter). This source of radio frequency must be accurately calibrated in frequency and must have a method of varying the output.

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

1. Connect the signal generator to the grid cap of the 6A7 tube through a 1 M.F. condenser. Connect the ground of the generator to the ground post of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

2. Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1680 K.C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer and the 1500 K.C. broadcast preselector trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output **while tuning the receiver back and forth across the signal** from the generator. This completes the alignment of the broadcast band.

3. The police band is aligned by feeding 4.0 M.C. signal to the receiver antenna lead through the .00025 condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output.

4. The short wave band is aligned in the same way using a 15 M.C. signal and adjusting the 15 M.C. short wave antenna trimmer after having turned the wave switch to the right hand position.

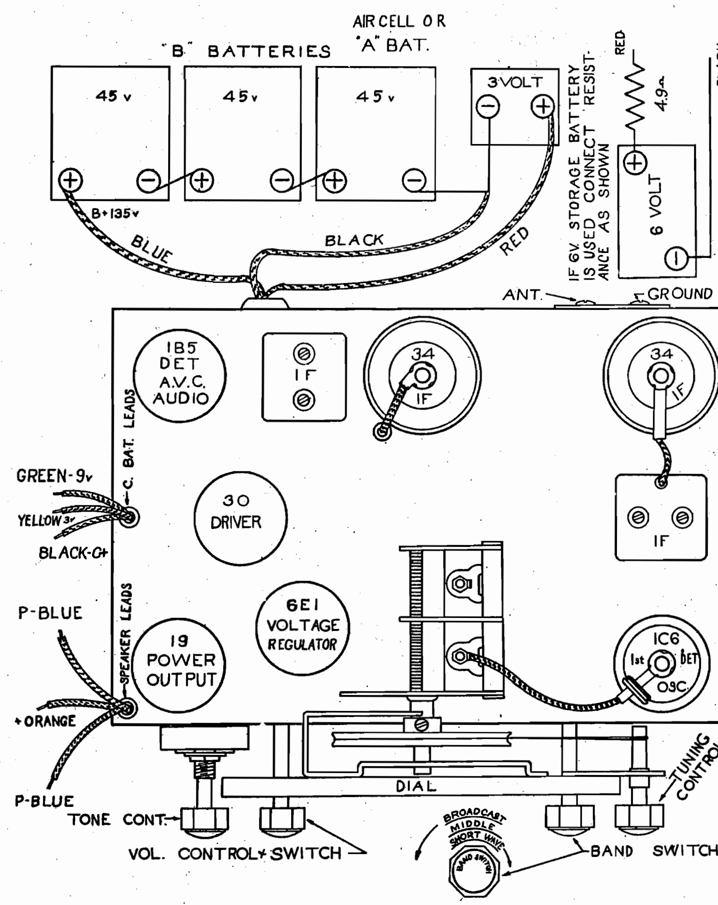
7-Tube, 2-Volt Battery Operated Superheterodyne



I. F. Alignment:

Connect the oscillator through a .1 condenser to the grid of the 1C6 tube and set the oscillator to 456 kilocycles. Peak each I. F. stage to resonance as indicated by maximum output on the output meter.

R. F. Alignment:

With the wave change switch in the broadcast position, set the oscillator to 1700 kilocycles and connect in series with a .00025 condenser to the antenna of the receiver. Rotate the variable condenser to the 1700 setting of the dial and adjust the trimmer condenser of the broadcast oscillator to resonance. This trimmer is located on the right side of the chassis, second position from the front. Reset the test oscillator to 1400 kilocycles and adjust antenna trimmer located under the chassis. Now set oscillator to 600 kilocycles and adjust padder located on top of the chassis. Check alignment at 1000 kilocycles.

For aligning the police band, set test oscillator to 5 megacycles and switch to the police band position on the set. With the condenser rotated to this frequency setting as indicated on the dial, adjust oscillator trimmer located on the right side of the chassis, first position from the front. Now adjust antenna trimmer located on the front of the chassis, left position, to resonance.

The short wave band is aligned by setting the condenser to 18 megacycles and adjust the oscillator trimmer located on the right side of the chassis, third position from the front to resonance with an 18 megacycle signal from the test oscillator. Turn dial to 16 M. C. and adjust antenna trimmer through right hand hole in front of chassis, rocking variable condenser slightly back and forth to get maximum peak.

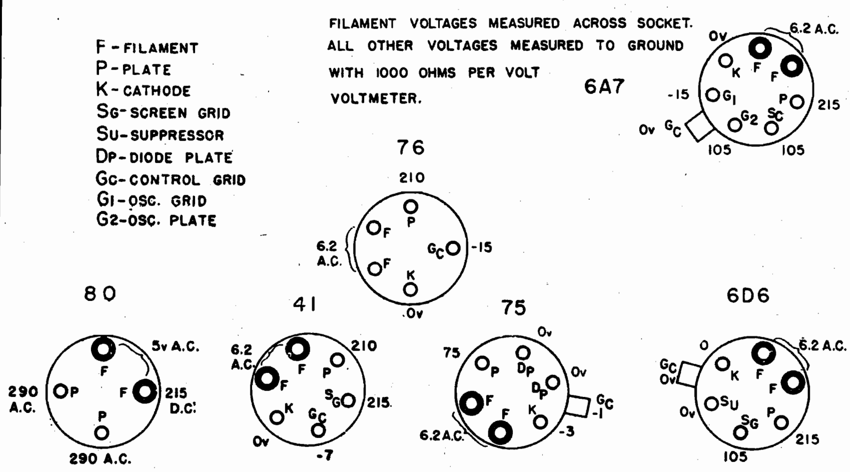
A good ground materially aids in the reception of distant stations.



ALIGNMENT PROCEDURE

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total meter resistance approximately 7000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

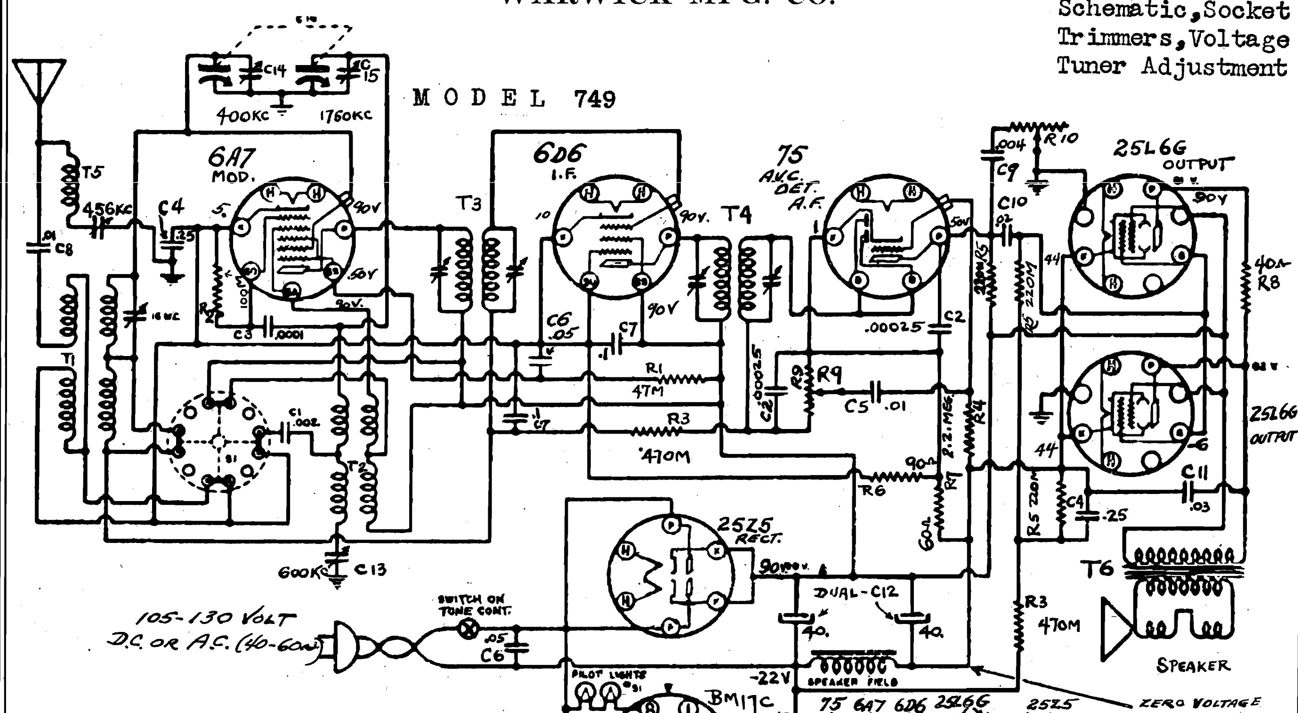
Connect the signal generator to the grid cap of the 6A7 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground lead of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1730 K.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Adjust the 1730 K.C. broadcast oscillator trimmer until maximum output is shown. Set the generator to 1400 K.C. and tune in this signal on the receiver. Then adjust the 1400 K.C. broadcast antenna trimmer to maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output **while tuning the receiver back and forth across the signal** from the generator. This completes the alignment of the broadcast band.

The short wave band is aligned while feeding a 6.0 M.C. signal to the receiver antenna lead through a .00025 M.F. mica condenser. Turn the wave switch to short wave position and tune in the 6.0 M.C. signal. Adjust the 6.0 M.C. short wave trimmer to maximum output.

WARWICK MFG. CO.

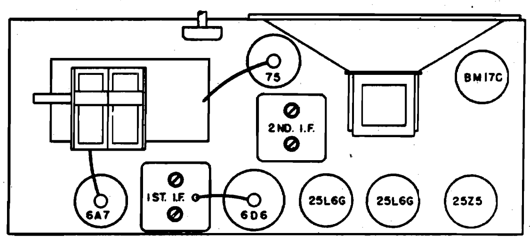
MODEL 749
Schematic, Socket
Trimmers, Voltage
Tuner Adjustment



Tube sockets are viewed from under side of chassis. Voltage readings at indicated socket prongs are to zero voltage point on circuit which is Ⓚ on 25L6G tube. Voltages must be measured with no signal. Alignment is to be made at the frequencies shown on the trimmer condensers.

Figures at cathodes are cathode currents in milliamperes. Capacity values are in microfarads.

Wave trap adjustment at 456 KC. Input is made to provide maximum reduction of signal. Where no voltage reading is shown at socket prongs, it indicates zero voltage or very low reading.



LOCATION OF PARTS ON TOP OF CHASSIS

IF PEAK 456 KC

SETTING PUSH-BUTTONS

1. By means of the Station Selector Knob, tune in **WITH THE RIGHT HAND AS ACCURATELY AS POSSIBLE** the station having the lowest frequency—that is, your selected station which is tuned in nearest the right-hand side of the dial.

2. After the station has been tuned in accurately with the right hand, continue to hold it in its exact position firmly, and with the left hand loosen the Push-Button to be set up for that station by unscrewing the Push-Button about one turn to the left (counter-clockwise).

3. Continuing to hold the Station Selector Knob in its exact position, **PUSH THE PUSH-BUTTON IN ALL THE WAY** with the left hand.

4. After the Push-Button has been depressed all the way, tighten it gently toward the right (clockwise). Release Push-Button slowly and when in normal position grip button and tighten firmly.

The Push-Button tuning system is now correctly set up for your first selected station of lowest frequency and the Call Letter Tab for this station should be at the extreme right of the Call Letter Holder.

Follow through with this same procedure, setting up the other 5 stations in the order of their frequency—that is, the second station set up will be second lowest in frequency and the third station set up will be third lowest in frequency.

Carefully check each Push-Button for the accuracy of its setting. If, when tuning in any station with its Automatic Push-Button it does not have equal volume or clarity to that obtained with manual tuning, this may indicate the automatic adjustment for that station was not made accurately. Should there be any inaccuracy in any one of the Push-Button adjustments, correction can be made by repeating the above procedure for that button only. Do not reset those Push-Buttons that are accurately adjusted.

No further adjustments are necessary to operate your radio automatically or manually. To receive any one of your six selected stations for automatic operation, merely push in **ALL THE WAY** the Button set up for that station.

To receive all other stations in the regular manner, push in the Station Selector Knob and turn it to the frequency of the station desired.

MODEL 751
Schematic, Socket

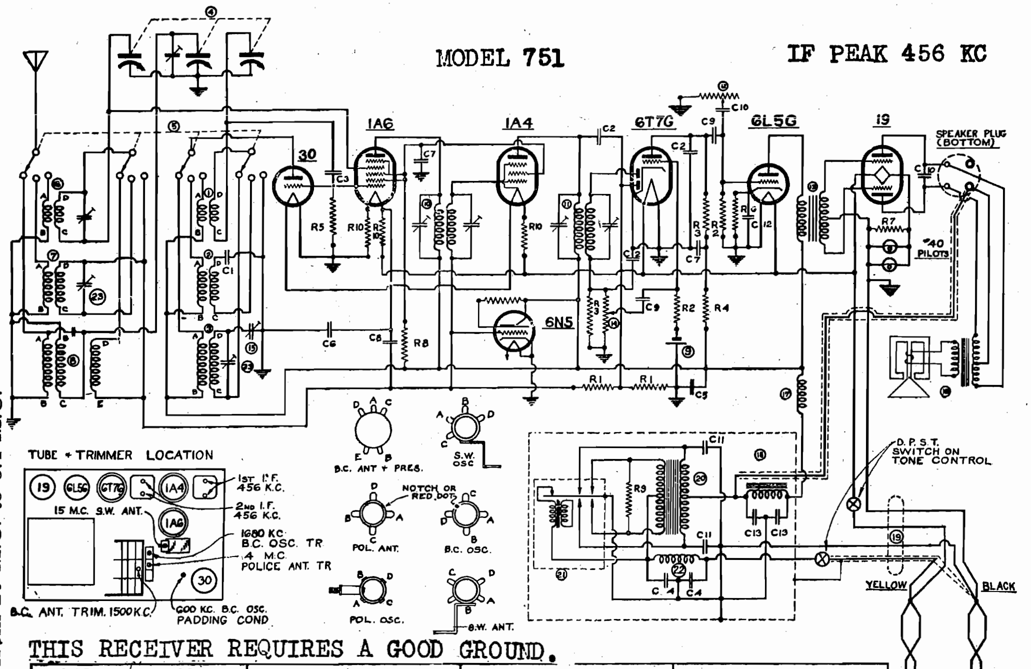
WARWICK MFG. CO.

Trimmers, Voltage
Alignment, Parts

This receiver is a 7 tube, 6 volt storage battery operated superheterodyne.

The tubes used are a 30 as oscillator, a 1A6 as modulator, a 1A4 as I.F. amplifier, a 6T7G as A. V. C. and audio rectifier and audio voltage amplifier, a 6L5G as audio driver, a 19 as power audio amplifier, and a 6N5 as tuning indicator.

This receiver is made to cover 3 tuning bands, the standard broadcast band which ranges from 1680 K.C. to 535 K.C., the middle or police band which has a frequency range of from 5.6 M.C. to 1.7 M.C. and high frequency or foreign band which is from 20 M.C. to 5.4 M.C.



THIS RECEIVER REQUIRES A GOOD GROUND.

ALIGNMENT PROCEDURE

All alignments must be made with the volume control turned full on and with the signal input from the generator reduced to as low a value as possible while still giving a sufficient output to be easily read on the output meter.

Connect the output meter, through a .5 M.F. condenser and a resistance of such a value as to make the total resistance approximately 10,000 ohms, to the two small pins of the speaker plug. The output meter remains connected during the entire alignment procedure.

Connect the signal generator to the grid cap of the IA6 tube through a .1 M.F. condenser. Connect the ground of the generator to the ground post of the receiver. With the wave switch on broadcast position and the dial set to about 1000 K.C., feed in a 456 K.C. signal. Adjust the trimmers on top of the first and second I.F. transformers until the maximum output is obtained. This aligns the I.F.

Leaving the wave switch on broadcast position turn the dial to the extreme high frequency end. Feed a 1680 K.C. signal to the receiver antenna post through a .00025 M.F. mica condenser. Adjust the 1680 K.C. broadcast oscillator trimmer for maximum output. Set the generator to 1500 K.C. and tune in this signal on the receiver. Then adjust the 1500 K.C. broadcast antenna trimmer for maximum output. Set the generator to 600 K.C. and adjust the 600 K.C. broadcast oscillator pad to maximum output **while tuning the receiver back and forth across the signal** from the generator. This completes the alignment of the broadcast band.

The police band is aligned by feeding 4.0 M.C. signal to the receiver antenna post through the .00025 condenser. Turn the wave switch to the center position and tune the receiver to this signal. Adjust the 4.0 M.C. police antenna trimmer for best output.

The short wave band is aligned in the same way using a 15 M.C. signal and adjusting the 15 M.C. short wave antenna trimmer after having turned the wave switch to the right hand position.

MODEL Phantom Light Dial Adjustments

WELLS-GARDNER & CO.

MODEL 17-Button Telephone Dial

This Supplements Series A1, A2, A3, A4, A5, and A7 Service Manuals and covers Dials and Drives used with these Chassis.

NOS. 9, 10, & 11 — 17 BUTTON TELEPHONE DIAL

NOS. 3 & 7 — PHANTOM LIGHT DIAL

APRIL, 1937

Identification of Dial and Chassis

The following description will identify the different dials:

No. 9 Dial—17 Button Telephone Dial—Station call letters in black push buttons.

No. 11 Dial—Same as No. 9 Dial except push buttons are brown.

No. 10 Dial—17 Button Telephone Dial—Station call letters are rectangular in shape and are mounted in rectangular openings in escutcheon ring. Equipped with visible tone and volume indicators.

No. 3 Dial—Glass dial—Moving beam of light indicators—Tone and volume indicated by series of circles.

No. 7 Dial—Glass dial—Moving beam of light indicators—Tone and volume indicated by slanting lines.

The following description will identify the chassis used with the above dials:

7 tube—Series A4	9 Tube—Series A7 (Export)
8 tube—Series A1	11 Tube—Series A2
9 tube—Series A5	13 Tube—Series A3

Telephone Dial Assembly

The telephone dial assembly provides a means of pre-setting a number of broadcasting stations and tuning in these stations at any time by depressing a button and rotating the dial to a stop position.

The apparatus is mounted on an assembly attached at the front of the chassis. An examination of this assembly will clearly show the method of operation.

Silencer Circuit—A silencer circuit is provided which results in silent tuning between stations when using the telephone dial buttons.

When a telephone dial button is depressed, a circuit is established between the ungrounded end of the volume control and the chassis ground. Referring to Fig. 1 it will be noted that contact is made between the line from the volume control, contact ring, contact washer arm (when button is depressed), spring and pulley ring stud. Since the pulley ring is at ground potential, this grounds the audio voltage and no signal will be heard until the button is released to break the contact.

It should be noted that the contact ring is part of the pulley ring assembly, but is insulated from it.

In the case of powerful local stations a slight amount of signal may be heard when the button is depressed.

Telephone Dial Adjustments

Noise When Tuning in a Signal with a Telephone Dial Button

As explained in the article on "Silencer Circuit" in this manual, no noise or signal should be heard when tuning in a signal with a telephone dial button until the button is released. If noise is heard while tuning in a signal with one of these buttons, it can be corrected as follows:

If Noise Occurs on All Buttons—This is probably due to a poor contact between the flat contact spring and the contact ring—See Fig. 1. Clean the flat contact spring and contact ring to insure a good electrical connection. Ordinary cleaning fluid may be used and will be effective in most cases in cleaning the surface without affecting the plating. If the contact is still not satisfactory, a piece of fine emery cloth may be used.

If Noise Occurs on One Button Only—This is due to a poor contact between the pulley ring stud, spring, contact washer, and contact ring—See Fig. 1. Clean all of these items of the particular button, in the same manner as mentioned previously, so as to provide a good electrical connection.

Telephone Dial Drive Cord Slipping

If the telephone dial drive cord slips on the tuning shaft pulley, this may be remedied by adjusting the drive cord tension pulley. Loosen the tension pulley bracket screw and adjust pulley assembly until the desired tension is obtained.

Position of Stop Pin

When the telephone dial assembly is on the chassis, the gang condenser rotor should not com-

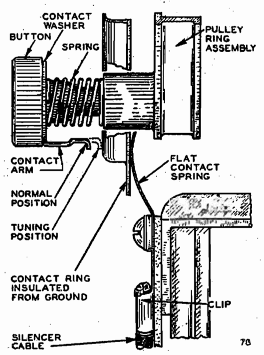

Fig. 1—Silencer Assembly

pletely open or close. The travel of the rotor in this respect is controlled by the gang stop pin on the pulley ring—See Fig. 4. This is necessary to protect the gang condenser in case the telephone dial is swung rapidly to either of the extreme positions. When the gang stop pin is properly set, it will serve as the stop at both extreme positions. If the rotor is seen to open completely or close completely, the stop pin should be pulled back and re-set to overcome this condition.

Greasing and Oiling

After a period of time, put some light grease on the pulley ring shaft and on the teeth of the pulley ring. Use light oil on the drive shaft assembly bearing, care being taken not to get any on the drive cord.

Telephone Dial Replacements

Replacing Complete Dial and Condenser Assembly

Remove the grid lead clip from tube grid cap.

Remove silencer cable from the contact spring assembly. Unsolder dial lamp lead from terminal of tube socket.

Unsolder the three stator section connections of the gang condenser. Unsolder the three braided shield leads which ground the gang condenser frame to the chassis, taking care not to loosen the connections of any other units which are grounded at these common points.

At the back of the gang condenser is a stud which secures the assembly to an "L" bracket which is secured to the chassis.

Through this stud is a cotter pin. Remove only the cotter pin, metal washer, and rubber washer.

Viewing the assembly from the back, on the left is a brass bolt which holds the dial support bracket to the chassis—remove this bolt from underneath the chassis.

Grasp the dial support brace and move entire assembly toward the front of the chassis. When the support casting rubber cushions slip clear of the slot in front of chassis, lift entire assembly clear of chassis.

To replace this assembly, reverse the procedure as given above.

Replacing Pulley and Button Ring Assembly Only

Remove drive cord.

From underneath the chassis, unsolder the dial lamp lead from prong of the tube socket. Pull this lead through and out to the front of the assembly.

Remove the four escutcheon screws which hold the escutcheon ring and glass crystal in place. The dial scale pointer is removed by unhooking it from the center stud. Unscrew and remove center stud, washers, and dial scale. Slide pulley ring assembly off the center shaft.

On the No. 10 dial, two strips of celluloid between the escutcheon ring and the glass crystal will have to be removed.

To replace the pulley ring assembly, proceed as follows: Lay the assembly face down and adjust the stop pin. The stop pin (Fig. 2) is directly in back of the wide spacer on the dial button ring. Pull this pin back and adjust it to the center position —See Fig. 2.

Rotate tuning condenser rotor counter-clockwise (from front) as far as possible—See. Fig. 2.

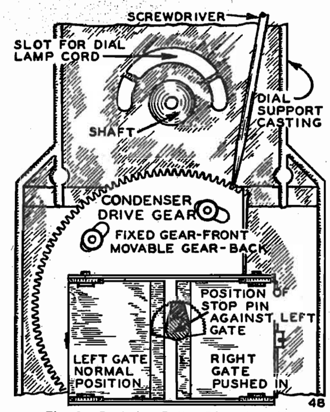

Fig. 2—Replacing Pulley Ring Assembly

Place the pulley ring assembly on the shaft with the knot of the dial lamp lead at the top—do not engage the gears.

Pull the dial lamp lead through the slot in the pulley ring gear and through the long slot in the dial support casting. Then place this lead through the clip under the dial support brace and out through the opening in the back of this brace.

With the gears still disengaged, rotate the pulley ring clockwise (from front) ½ revolution until the stop pin passes over the right gate and comes to rest against the left gate—See Fig. 2.

With the condenser rotor fully closed, push the pulley ring on the shaft until the pulley ring gear engages the *fixed gear only* (front) of the condenser drive gear assembly. Hold the pulley ring assembly and with a fine blade screw driver, move the movable (back) gear clockwise one tooth relative to the fixed gear—See Fig. 2. Then push the pulley ring all of the way on, engaging the movable gear.

Now lay the chassis on its back. Replace in the order given the large washer with rectangular hole, dial scale, washers, center stud, dial pointer, glass crystal, and escutcheon. Resolder the lamp lead.

For the No. 10 dial, before putting the escutcheon on, lay the two celluloid strips on the glass crystal with the inside flange facing away from the glass. Then lay the escutcheon on top of the celluloid strips. The section not cut out for station call letters should be at the wide spacer in the button spacer ring. Center the small holes in the celluloid discs in the station call letter openings and then tighten the escutcheon screws.

The stop pin must now be adjusted, as explained in article "Position of Stop Pin," until the condenser does not open or close fully. Injury to the condenser will result if allowed to open or close fully.

Replace the drive cord as explained in the article "Replacing Drive Cord."

Replacing Gates

After a great amount of use, one or both of the stop gates may wear, making it necessary to replace the stop gate assembly. This is done by first removing the pulley ring assembly as explained in the article "Replacing Pulley and Button Ring Assembly."

The stop gate assembly is then removed by taking out the two screws at the bottom of the assembly.

MODEL 17-Button
Telephone Dial

WELLS-GARDNER & CO.

MODEL Phantom
Light Dial
Replacement Data

Replacing Drive Cord

Remove the old drive cord and tension spring. Rotate telephone dial clockwise (from back of chassis) as far as it will go.

Viewing the pulley ring drum from above and to the back, place the knotted end of the drive cord in the slot provided for it, catching the knot in back of the rib as shown in Fig. 3.

Bring the cord down and around the right side

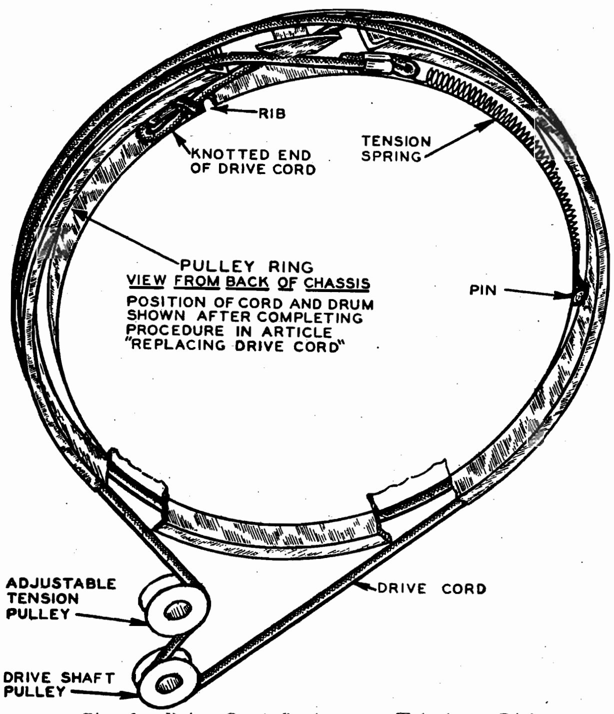

Fig. 3—Drive Cord Replacement–Telephone Dial

(from back) of the drum at front part of groove in pulley ring drum and under the drive shaft pulley making one-half turn on this pulley. Then bring the cord around the right side (from back) of the adjustable tension pulley and up to the upper left side of the pulley ring drum in front of the cord already on.

Hold the cord in the left hand and rotate the dial counter-clockwise with the right hand. Feed the cord on the drum in such a way that after passing the two openings at the top of the pulley ring drum, it passes to the back of the groove in the drum. After the pulley ring drum makes one complete revolution, place the cord through the left drum opening into the slot and secure the tension spring hook over the pin provided for it—See Fig. 3.

Replacing a Telephone Dial Button or Button Shaft

A telephone dial button or button shaft may be replaced without removing the chassis from the cabinet.

Rotate the dial until the button shaft to be replaced is in the position shown in Fig. 4. Using a wooden wedge block or any other wedge, hold this button shaft in place as shown. Remove the clear celluloid disc and the call letter disc with the point of a pin from the button of the shaft to be replaced (No. 10 dial—brown opaque celluloid disc only).

Remove the hairpin spring from the front of this shaft, spreading it with an ice pick or screwdriver. Take off the button, metal washer, molded bushing, and spring. Take out the wedge block, remove the button shaft to be replaced from the back of the dial assembly and put in the new one. Then put the wedge block back in place again as illustrated.

Lay the cabinet back down against a chair so that it will be about 30 degrees from the vertical position.

Assemble the spring, molded bushing, metal washer, and button in the order shown in Fig. 5. (Last three items may be in one unit). Push the button and spring assembly over the button shaft with the tab of the metal washer in the normal

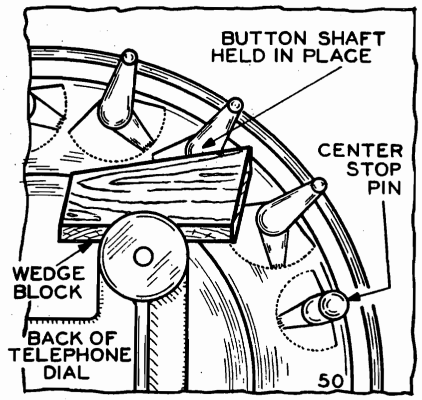

Fig. 4—Holding a Push Button Shaft in Place

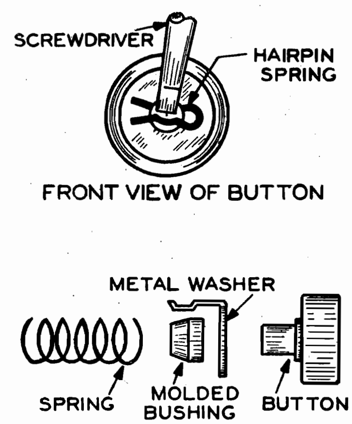

Fig. 5—Putting a Hair Spring on a Push Button Shaft

position—See illustration in instruction book. Hold the tab and rotate the button until the flat in the shank coincides with the flat on the shaft. Push the button all of the way on.

Put the hairpin spring in place, as shown in Fig. 5, with the upper part of the slot near the end of the button shaft and the lower part over the end of the shaft. Place the blade of a screwdriver at the center of the lower part of the spring and push down until the spring snaps into place in the slot on the shaft. Remove the wedge block.

Prices Subject to Change Without Notice.

Phantom Light Dial - Replacing Drive Cord

Remove the dial assembly as follows: Take out the screw which secures the dial frame brace to the back of the gang condenser. Take out the two screws which secure the brackets on the bottom of the dial frame to the chassis. Lay the dial assembly face down in front of the chassis—it is not necessary to remove the volume control and tone control indicator cords.

Remove the phantom light assembly from the drive drum by taking out the screw.

Take off the old cord and tension spring. Tie a knot with a small loop in it in one end of the new cord. Then tie the other end of this cord to the hook on the tension spring. The distance from the loop on one end to the tension spring is 17¾ inches.

From the front of the chassis, place the looped end of the cord through the drum hole located near the cord track opening, and hook it over the hook provided for it at the back of the drum.

Bring the cord up and around the right side of the drum, keeping the cord in the grooved track of the drum.

Bring the cord down to the right side of the drive shaft and wind it three and one-third times around this shaft progressing toward the back.

Then bring the cord up and around the left side of the drive drum. Hook the tension spring on the hook of the drive drum.

Replace the phantom light and the dial assembly.

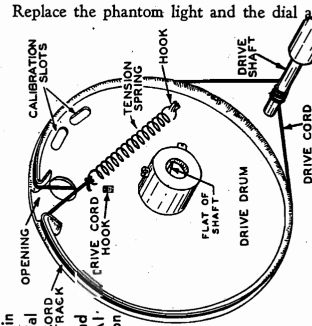

Fig. 6—Drive Cord Replacement, Phantom Light Dial

Phantom Light Dial Replacement Parts

See article "Identification of Dial and Chassis" in this manual in order to determine the correct dial and chassis assembly number.

The No. 3 Dial is used on the Series A1, A4, and A5 chassis. The No. 7 Dial is used on the Series A1 and A4 chassis only. The following parts are common to both groups unless otherwise specified.

DESCRIPTION	No. 3 DIAL PARTS		No. 7 DIAL PARTS	
DRIVE ASSEMBLY	PART NO.	LIST PRICE	PART NO.	LIST PRICE
Tuning Shaft Only	26X248	.15	26X248	.15
Tuning Drive Cord—20"	doz.	.45	doz.	.45
Tension Spring for Above Cord	28X27 ea.	.10	28X27 ea.	.10
Drive Drum & Hub	24X279	.40	24X279	.40
Rubber Cushion (Front) for Assembly Mounting	8X43 ea.	.10	8X43 ea.	.10

WELLS-GARDNER & CO.

This Supplements Series A1, A2, and A3 Service Manuals and covers the Electric Drive used with these Chassis.

ELECTRIC DRIVE PANEL ASSEMBLY

NOS. 14, 15, AND 16 DIALS

SEPT., 1937

Possible Troubles and Means of Correcting

The following list of possible troubles has been made up for your convenience in any servicing that may be required on the electric drive panel. Almost every condition that may be met with in the field is listed. A statement of the manner in which the difficulty may manifest itself and a brief statement of its cause and correction is made. In most cases, a reference is made to an illustration and a paragraph number in which the matter is discussed more fully. It may be necessary, occasionally, to read the entire article or a portion of it to fully understand the paragraph referred to. Undoubtedly very few of these manifestations will present themselves to the service man but it is our belief that any difficulty that may arise can be handled by the service man by referring to this manual.

A—If dial pointer reaches the end of the scale and stops.

1. The reversing switch does not operate properly—Adjust reversing switch and put on centering spring (early models).—Par. 185—Figs. 6 and 23.
2. Reversing switch or wiring defective—Replace switch or check wiring.—Par. 186, 193—Figs. 6 and 24.
3. (a) The stop lever does not go up into notch on setting disc far enough—Loosen set screws of setting disc corresponding to button which is depressed and adjust position of this disc relative to stop lever.—Par. 110—Figs. 10 and 15.
   (b) Stop lever spring may be too weak—Tighten spring.—Par. 110—Fig. 8.
4. Friction disc may slip in friction drive models or hub on gear No. 1 may slip on early gear drive models—Change friction drive panel to gear drive panel or replace faulty gear No. 1.—Par. 42, 62—Fig. 7.

B—After a tuning button has been depressed, the dial pointer goes back and forth without stopping.

1. Pawl on setting disc does not extend out far enough—Pinch into position.—Par. 102—Fig. 12.
2. Button may be set too close to the end of the dial pointer travel—Move drum in setting disc.—Par. 105, 106—Fig. 13.
3. Pawl stuck—See that pawl slides back freely.—Par. 104—Fig. 12.
4. Motor On-Off Switch may be stuck in On position—Adjust switch or release plunger.—Par. 135, 136—Figs. 8, 9, and 16.

C—If the dial pointer does not stop at the same point each time the tuning button is depressed.
If this occurs on one button only.

1. Drum slipping in setting disc—Replace setting disc corresponding to that button.—Par. 93, 94—Figs. 10 and 11.
2. High spot on setting disc may move the stop lever sufficiently to break the switch contact—Adjust the motor on-off switch a slight amount or file down high spot on setting disc.—Par. 96—Fig. 9.
3. Set screws of setting disc loose—Tighten set screws.—Fig. 6.
4. Brake drum not perfectly round—Replace setting disc.—Par. 95—Figs. 10 and 11.
5. Motor On-Off switch does not open fast enough after station is reached due to stop lever being too low or high—Adjust height of stop lever or switch lever until proper On position is reached.—Par. 138—Figs. 6 and 9.
6. Tuning eye cable may be caught in setting disc—Remove cable from setting disc assembly.

If this occurs on all buttons.

1. Main drive cable loose—Tighten by means of turn-buckle.—Par. 147—Fig. 21.
2. Set screws in top pulley of main drive cable loose—Tighten these.—Par. 147—Fig. 6.
3. Spring clip on drive drum of tuning condenser may fit loosely on drive arm—Bend this clip to provide a tight grip.—Par. 61A—Fig. 7.
4. Silencer switch spring assembly may not have sufficient tension to push back the motor armature after the circuit is broken—Increase tension by bending the spring.—Par. 39—Figs. 4 and 5.
5. Faulty action of motor On-Off switch—Adjust switch and switch lever.—Par. 135, 136, 137, 138—Figs. 8, 9 and 16.

D—If, when a setting button is depressed, dial pointer does not move at all or does not move properly when tuning knob is turned.

1. The back of the setting button plunger does not engage the rocker arm—Line up the rocker arm with the back of the plunger by bending.—Par. 97, 98—Fig. 11.
2. The top of the rocker arm does not engage the operating lever which releases the drum of setting disc—Loosen the setting disc set screws and line up the disc with the rocker arm.—Par. 98—Fig. 11.
3. Clutch plate does not engage drive pulley—Bend clutch plate forward.—Par. 171—Fig. 6.
4. Setting button may not be pushed in sufficiently—Push button in further.—Fig. 11.

E—After a tuning button has been depressed, the manual tuning knob rotates while the motor is in operation.

1. Chassis may be too far forward in cabinet and prevent clutch release lever from returning to electric position—Move chassis back.—Par. 51, 172.
2. Electric-manual die cast lever arm does not turn freely on the clutch assembly bearing and does not return to electric position—Bend or file down bearing so that this lever turns freely.—Par. 172—Fig. 3.
3. Tuning knob put on shaft while lever is in manual position—Loosen this knob and put it on when lever is in electric position.—Par. 172, 176.
4. Clutch releasing spring broken or of insufficient tension—Put on new spring or increase tension of old spring.—Par. 172—Fig. 6.

F—Manual tuning knob turns with difficulty when tuning the radio manually.

1. Motor pinion jammed against gear No. 1—Pull motor away from gear.—Par. 44—Fig. 6.
2. Fibre gear No. 1 riding on washer of motor pinion—Change to new type pinion.—Par. 46—Fig. 6.
3. Motor pinion sticks on bearing—Change to new type pinion.—Par. 46—Fig. 6.
4. Clutch releasing spring does not turn freely—Bend this spring so that it rotates freely.—Par. 173—Fig. 6.

G—Jumpy action when tuning the radio manually.

1. Faulty friction drive in original issue panels—Change to gear drive panel.—Par. 42.
2. Silencer spring has not enough tension to disengage rotor from pinion—Readjust tension of silencer spring.—Par. 39—Figs. 4 and 5.

H—Excessive backlash when tuning the radio manually.

1. Loose set screws on drive drum on tuning condenser—Tighten these screws.—Par. 61A.
2. Compression springs in gears of train of gears missing or not set properly—Replace or reset springs in gears.—Par. 60—Fig. 7.
3. Take-up spring on gear No. 5 missing or anchorage point of this spring broken.—Par. 60—Fig. 7.
4. Spring clip on drive drum on tuning condenser fits loosely on drive arm—Tighten this clip.—Par. 22, 61A—Fig. 7.
5. Loose bearings on setting disc shaft—Tighten right hand bearing (from back of panel).—Par. 112—Fig. 6.

I—Drive belt slips when tuning the radio manually.

1. Excessive amount of oil on drive belt—Clean off oil.—Fig. 6.
2. Increase tension on drive belt by readjusting position of idler (early models only).—Fig. 6.
3. Main drive cable too tight—Loosen tension on main drive cable by means of turn-buckle.—Fig. 21.
4. (Early models only) Friction disc in motor binds—Change to gear drive panel.—Par. 42.
5. Motor pinion jammed against gear No. 1—Pull motor back from gear.—Par. 44—Fig. 3.
6. Motor pinion sticks on bearing—Put in new type pinion.—Par. 46—Fig. 6.
7. Gear train jammed—Free gears which are not working smoothly.—Par. 61—Fig. 7.

J—Electric-manual lever cannot be pushed to manual position.

Early Models Only

Bend yoke track away from clutch release lever until it engages yoke of clutch shaft properly.—Par. 174—Fig. 22.

Early and Late Models

1. One or more of the tuning button plungers has not returned to the normal position—Stretch tuning plunger spring.—Par. 111—Fig. 8.
2. Chassis too far forward in cabinet—Move chassis back.—Par. 51.
3. Locking plate screws loose—Turn down screws.—Par. 181—Fig. 3.

K—Electric-manual lever will not stay in the manual position.

The tip on the clutch release lever slot may be broken off or down too low—Return electric drive panel to factory for new clutch release lever.—Par. 175—Fig. 3.

L—Electric-manual lever cannot be pushed back into electric position from manual.

1. The tip on the clutch release lever slot may be too high—Cut or file off the end of this tip.—Par. 175—Fig. 3.
2. 4 washers which hold locking plate are tight—Loosen these washers.—Par. 180—Fig. 3.
3. Interlocking lever binds—Free lever.—Par. 175, 180—Fig. 3.
4. Clutch release lever binds—Free lever.—Par. 175—Fig. 3.

M—Electric-manual lever apparently has no effect on mechanism.

1. Pin of electric-manual lever casting is not in hole of clutch release lever—Remove manual tuning knob and place pin of electric-manual lever in hole of clutch release lever—Replace manual tuning knob—see instructions in Par. 176—Fig. 3.
2. Washer in front of clutch release lever loose from bearing—Return electric drive panel assembly to factory for replacement of this item.—Fig. 3.

N—Motor rotates but dial pointer does not move (early models only).

1. Friction disc in motor may slip—Change to gear drive panel.—Par. 42.
2. Fibre gear No. 1 may be slipping on its hub—Replace this gear.—Par. 62—Fig. 7.

O—Motor rotates when no button is depressed.

Plunger of motor On-Off switch sticks in On position—Release switch plunger.—Par. 135, 136—Figs. 8, 9, and 16.

P—After a tuning button has been depressed, the motor does not operate.

1. Motor On-Off switch out of adjustment—Readjust or replace switch.—Par. 135, 136, 137—Figs. 8, 9, and 16.
2. Motor pinion jammed against gear No. 1—Move motor away from gear.—Par. 44—Figs. 3 and 6.
3. Fibre gear No. 1 riding on washer of motor pinion Change to new type pinion.—Par. 46—Fig. 7.

WELLS-GARDNER & CO.

MODELS 14,15,16
Electric Drive Dials
Notes, Changes
Replacement Data

4. (Early type drive cable) Cable slips—Turnbuckle take-up hitting top pulley or bottom idler—Return panel to factory for later type panel.—Par. 6.

Q—Excessive motor noise.

1. Chassis too far forward in cabinet and touching panel at some point—Move chassis back a slight amount by loosening wood support screws.—Par. 51.
2. Motor pinion chattering.
   (a) Silencer spring tension too great—Bend spring back to loosen tension.—Par. 40—Figs. 4 and 5.
   (b) Faulty pinion in motor—Replace pinion.
   (c) Pins on armature short or uneven so that they do not engage pinion properly—Replace motor.—Par. 49.
   (d) Motor bearing mounting clamps loose—Tighten these bearings or replace motor.—Par. 45.

R—After one tuning button has been depressed, pressing in another does not release the first nor permit the second to stay in.

Locking plate slightly distorted—Depress the first button again and then the second quickly.

This condition can be corrected by screwing in the locking plate screws in case they are out too far and by hitting the locking plate.—Par. 183—Fig. 3.

S—Tuning button does not push in easily or does not remain depressed.

1. Chassis may be too far forward in cabinet and prevent clutch release lever from returning to electric position—Move chassis back.—Par. 172.
2. Electric-manual die cast lever arm does not turn freely on the clutch assembly bearing and does not return to electric position—Bend or file down bearing so that clutch release lever turns freely.—Par. 172—Fig. 3.
3. (Applies only to buttons not pushing in easily) No grease on button shaft—Put some grease on shaft at point where it passes through locking plate.—Fig. 3.

T—Tuning button cannot be pushed all the way in.

1. Chassis too far back in cabinet—Move chassis forward but do not touch front panel.
2. Chassis too far forward in cabinet causing locking plate to contact cabinet—Move chassis back.—Par. 51.

U—If dial pointer does not move when tuning button is depressed.

(Early type friction drive only) Motor far enough away from gear No. 1 so that it does not engage friction disc—Move motor closer to friction disc.—Par. 6, 42.

V—Set dead.

1. Silencer switch shorted—Bend into proper position.—Par. 41—Figs. 4 and 5.
2. Armature tight in bearings and will not push back after switch is off—Free shaft in bearing or replace motor.—Par. 45—Fig. 5.

W—Signals can be heard with full volume between stations while tuning the radio electrically.

Silencer switch or silencer circuit open—Bend switch into position and check silencer circuit.—Par. 41—Figs. 4 and 5.

X—If creaking noise is heard on all buttons when tuning radio electrically.
Drive cable riding over itself on pulley B—Lay cable properly on this pulley.—Par. 158—Fig. 21.

Y—If setting disc stops in both directions of rotation. Pawl spring may be missing or pawl stuck so that stop lever drops in notch in either direction of rotation.—Par. 104—Fig. 12.

Changes Since Early Models

(1) A number of changes in the electric drive assembly have been made in the course of production. The following listing summarizes these changes and identifies the chassis which have these changes.

Issue No. — Blank

(2) The issue number of the electric drive panel is stamped on the bracket over the motor switch—See Fig. 6. In the early models, no issue numbers were used.

(3) Early 7-tube sets may be identified by the fact that when the electric-manual lever is in the electric position, all four red mounting screws are located, as shown in Fig. 1.

(4) In case major trouble is experienced on the electric drive panel of these sets, it will be necessary to return the entire chassis or complete radio to the factory for reconditioning. Replacement panels cannot be satisfactorily mounted on these models.

(5) Early 9, 11, 13, and intermediate 7-tube sets may be identified by the fact that the two top red screws are in the position shown in Fig. 2. (This is also true of all subsequent models.)

(6) In case of major difficulty on the electric drive panel of these sets, which cannot be repaired locally, the panel can be removed from the chassis and returned to the factory for replacement.

(7) A number of changes were made during production of the early models which can be summarized as follows: A new type drive cable (Fig. 6) was used. A reversing switch centering spring (Fig. 23) was added. An improved type clutch release lever was used (Fig. 3). Nos. 2, 3, and 4 compound gears (Fig. 6) were changed to die castings. The reversing switch lever was modified and an improved rocker arm (Fig. 8) used which permitted greater movement of the setting button plunger. The mounting screw hole on the On-Off switch mounting was enlarged to facilitate adjustment. The clutch releasing spring (Par. 172) was added.

Issue No. 2

(8) All shipments made after August 23, 1937, incorporate the above changes and two additional major changes as follows: Originally a friction drive was used between the motor and the first gear of the train of gears. This friction drive was replaced with a gear drive (Fig. 6) starting with the No. 2 issue panels. A new method of stringing the main drive cable (Fig. 21) was also used in No. 2 panels. This new method is not applicable to the old drive cable.

(9) **Almost any difficulty which may be encountered in these and subsequent issue number panels can be corrected in the field. The information contained in this manual will serve as a guide in making practically any repairs which may be required.**

(10) In later No. 2 issue panels, a new reversing switch (Fig. 24) was used. A change was also made in the silencer spring, a heavier spring with silver contact being added.

Issue No. 3

(11) The guard was placed over the silencer spring assembly (Fig. 4) in panels with this issue number. A specially hardened motor pinion replaced the previous type. Rubber cushions were placed on the back of the cabinet panel to prevent the chassis from touching.

Issue No. 4

(12) A covering was placed over the reversing switch and an adjustment stud added to the base of the motor On-Off switch.

Replacing Electric Drive Panel on Chassis

(13) The electric drive panel assembly is the same for all chassis and may be removed from the chassis and replaced as explained below (the early 7-tube chassis as explained at the last part of this article, is an exception).

(14) Remove the chassis from the cabinet using extreme care not to damage the setting button shafts. Remove the electric tuning buttons by pushing down the lower end of the small hairpin spring at the back of the button and at the same time, pulling the button off the shaft. It is not necessary to remove the setting buttons.

(15) The screws in the wooden support behind the electric drive panel must be unscrewed and the support removed from the cabinet.

(16) Remove the speaker plug from the socket at the back of the chassis and also the tuning eye tube from its clamp bracket. Loosen the screw holding the bottom shield connection to the back of the chassis. Unscrew and remove the two "L" bolts (located under the chassis shelf) which are secured to the two rear chassis mounting feet.

(17) To remove the panel from the chassis, turn the electric-manual lever to the electric position. Unsolder the wire on the silencer switch on the front panel and also the motor connections under the chassis.

(18) Remove the dial pointer by pulling it off.

(19) Remove the dial scale bracket from the panel by taking out the two top screws and one bottom screw. Pull off dial lamp sockets and unhook clutch release lever tension spring.

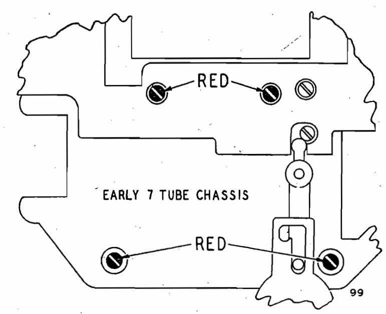

Fig. 1—Location of 4 Red Mounting Screws in Early Models

(20) Remove the four RED SCREWS shown in Figs. 1 and 2. DO NOT remove the screw on each side of the shaft extending through the center of the panel in the case of later models as shown in Fig. 2. *See special procedure at the last of this article for early 7-tube models.*

(21) The panel can then be pulled straight out from the chassis.

(22) To replace the assembly, reverse the above procedure. When mounting the panel, care must be taken that the drive arm (Fig. 6) on the drive gear and spring clip on gang condenser drive drum line up properly. To do this allow the front part of the chassis to project 2 or 3 inches over the edge of the table. Turn the gang condenser until the spring clip on the drive drum is at its lowest position. Spread this spring clip with a *small* screwdriver, bringing this screwdriver up from beneath the chassis. Care should be taken not to spread the spring clip too far. Turn the gears on the electric drive panel until the drive arm is at its lowest position. Gently push the drive arm into position in the spring clip on the drive drum. The screwdriver will drop to the floor.

(23) When installing a new replacement panel on a late model, the following points must be observed carefully:

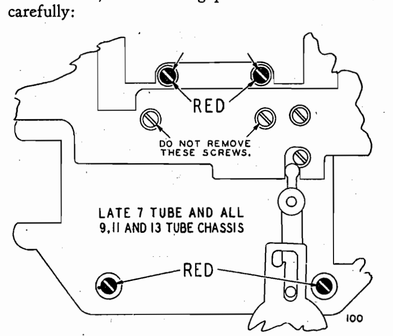

Fig. 2—Location of 4 Red Mounting Screws in Late Models

(24) MOUNTING SCREWS—Two screws with heads painted red are furnished with the new panel. These screws are longer than those used in the old panel and must be used in the TOP mounting holes only. The screws used on the old panel may be used in the two lower mounting holes of the new panel.

MODELS 14,15,16
Electric Drive Dials
Motor Connections
Motor-Silencer Spring
Data

WELLS-GARDNER & CO.

(25) **MOTOR CONNECTIONS**—The motor cable assembly in the new panel has only two lead wires extending from it, while the old motor cable assembly has three. The third lead on the old cable assembly was connected to a condenser which is not necessary when the new drive assembly is used.

(26) The two leads from this condenser (metal shell, tubular type) to the terminal strips should be disconnected. The condenser can be left in the chassis, or it may be removed.

(27) One cable lead is soldered to the terminal strip lug to which is connected one wire of the power cord and one power transformer primary lead. The other cable lead is soldered to the terminal strip lug to which is also connected the lead from the On-Off switch and the other power transformer primary lead.

(28) **CAUTION**—When the electric drive panel is removed from the chassis, lay it face down and not back down. The reason for this is that there is a possibility that the motor On-Off switch on the back of the unit will be damaged or thrown out of adjustment.

(29) In handling the electric drive panel, do not carry it by the switch lever (See Fig. 6) which actuates the motor On-Off switch. This bar may be bent and damaged by such handling.

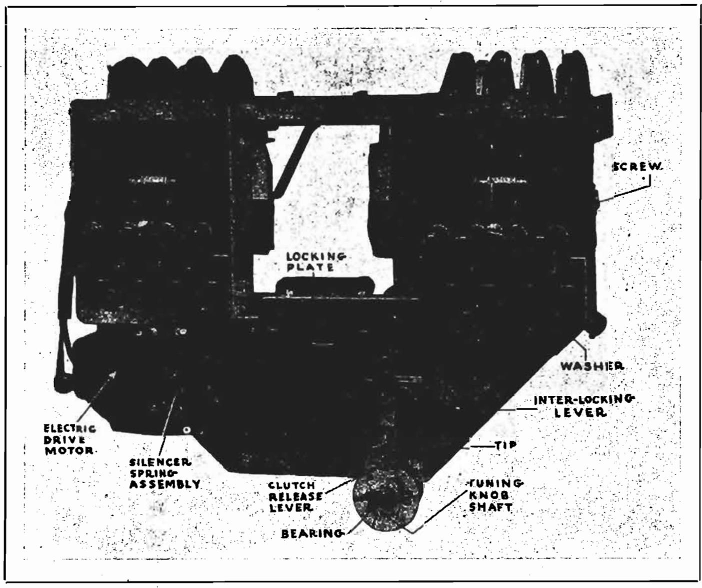

Fig. 3—Electric Drive Panel—Front View

A New Electric Drive Panel Cannot Be Mounted on the Early 7-Tube Models

(30) These models may be identified by the fact that when the chassis is removed from the cabinet and the electric-manual lever is in the electric position all four red mounting screws are located as shown in Fig. 1. On late models, the two top red screws are in the position shown in Fig. 2.

(31) If trouble serious enough to require replacement of the electric drive panel develops in the early model radio, it will be necessary to send the entire chassis or the complete radio to the factory to have this done. A replacement panel should not be ordered as it cannot be mounted on the early type 7-tube chassis.

(32) The following procedure for removing the panel from early models is given only in case minor repairs are necessary.

(33) Unsolder wires and remove mounting screws. Pull the panel away from the chassis about ½ inch, being careful not to damage the steel cable. Then tilt the upper part of the panel toward the chassis. Lower the panel about ½ inch and slide it to the left so the steel cable will pass under the bracket. After the cable clears this bracket, the panel may be removed.

Motor and Silencer Spring Assembly

(34) The electric motor supplies the mechanical power for tuning in a station when an electric tuning button is depressed. A reversible AC motor is used. It is mounted to the electric drive panel by means of two screws. Power is transmitted to the rotating mechanism by means of a pinion gear on the armature shaft which meshes with the first gear of a train of gears.

(35) At the front of the motor is an assembly shown in Fig. 3 and known as the silencer spring assembly. This assembly has a two-fold purpose. First, it establishes a contact *while the motor is operating* which completes a circuit to the chassis ground that silences the radio. This circuit is shown in the schematic circuit diagram of the chassis manuals. Its second function is to exert a slight amount of spring tension on the end of the armature shaft which extends from the motor.

(36) The small pinion gear inside of the motor rotates freely on the front motor bearing. This pinion is always in mesh with gear No. 1. There are two pins on the armature and two extensions on this pinion. The entire armature shaft assembly slides back and forth in its bearings.

(37) When the circuit through the motor is complete, magnetic action causes the armature shaft to slide toward the front of the panel. The force is strong enough to overcome the tendency of the silencer switch spring to prevent this movement.—Fig. 5.

(38) The pinion gear comes into close proximity with the armature and the two pins and two extensions mentioned above engage, causing this gear to rotate with the armature. The electric tuning mechanism turns as a result. When the circuit through the motor is broken, the magnetic pull on the armature is released and the silencer spring forces the armature toward the back of the panel, causing the pinion gear to disengage from the armature proper —Fig. 4.

(39) The tension of the silencer spring is of great importance. If the tension is insufficient it will not push back the armature shaft after the circuit is broken and the inertia of the motor will continue to exert a driving force on the train of gears. This will cause the tuning mechanism to go somewhat past the station after the setting disc has arrived at the stop position. The remedy is to tighten the spring by bending it.

(40) If the tension of the silencer spring is too great it will prevent the armature from moving forward when the circuit is completed and engaging the pinion gear. When this occurs the pinion will not turn at all or a chattering caused by the armature pins and pinion extensions will be heard. The remedy, of course, is to reduce the tension of the spring by bending.

(41) The contact and the spring of this assembly must close while the armature is in its operating position—otherwise the radio will not be silent between stations. Be sure that the assembly is not so bent that the contact and spring are permanently in contact. This condition would, of course, short out all signals.

(42) The early electric drive panels, those with no issue number on the switch bracket, used a friction drive between the motor and the first gear. A friction disc was used instead of the large toothed gear of gear assembly No. 1 shown in Fig. 7. This friction disc engaged a friction drive pinion on the motor. No. 2 and later issue panels all use the gear drive.

(43) There are several conditions under which the motor will not operate. External electrical faults, mainly open circuits, are discussed in other articles. Open windings within the motor will, of course, prevent its operation.

(44) If the motor is jammed against compound gear assembly No. 1 (see Fig. 6) it will not operate. The remedy is to loosen the two motor mounting screws (Fig. 6) slightly. Then insert a screwdriver between the upper right side of the bakelite motor case and the die cast frame at point "B" (Fig. 3). Turn the screwdriver to move the motor away from the frame and tighten the mounting screws. Care should be taken not to crack the bakelite case. In some cases it will be necessary to replace the top 8-32 screw with a 6-32 screw and nut in order to get proper spacing between the motor and the first gear.

(45) Tight bearings or a bent shaft will prevent motor operation. The remedy for tight bearings is to disassemble the motor, free and oil the bearings. In the case of a bent shaft a new motor will usually be required. On occasion, the bearing clamps may become loose—tighten the bearings or replace the motor.

(46) Still another item which prevents motor operation is the pinion gear jammed against the bearing. The bearing has a fillet or slightly rounded corner. Gear No. 1 pressing against the washer of the pinion gear may jam this gear against the bearing. Or, the pinion itself may jam against the bearing. In either case it will not turn. The remedy is to replace the pinion with a new type pinion that is rounded out to take care of the bearing fillet. One of these may be obtained at the factory.

(47) Jamming and tightness at various points of the rotating mechanism such as gears, belts, shafts and pulleys will cause an excessive load and prevent motor operation.

Fig. 4—Silencer Assembly—Off Position

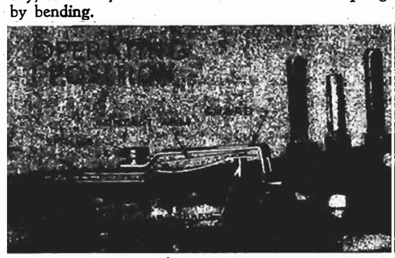

Fig. 5—Silencer Assembly—Operating Position

WELLS-GARDNER & CO.

MODELS 14,15,16
Electric Drive Dials
Motor Notes,Part 2
Gear Train Data

(48) If the motor operates but does not drive the rotating mechanism, the following conditions may prevail: The early type friction drive disc may be slipping. The remedy is to replace the early friction electric drive panel with the gear type panel. In a few of the first sets incorporating the gear drive from the motor, the fibre gear of compound gear No. 1 (see Fig. 7) may slip on its hub. There is a spring washer which holds this gear to its hub and this washer may become too loose. The method of detecting this trouble and the correction of it are explained fully in the article "Train of Gears."

(49) Worn pins on the armature and worn projections on the pinion gear will prevent engaging of these two pieces. The silencer spring assembly may be too tight as explained above.

(50) If the motor runs only in one direction, check for a defective reversing switch or open wiring.

(51) If the electric drive panel or chassis comes in contact with the cabinet at any point, motor vibration will be transmitted to the cabinet and excessive noise will be heard while the motor is in operation. If the chassis is too far forward, it may touch at some point. There are 4 wood screws. 2 at each side of the wood support at the back of the electric drive panel. Unscrew these screws 2 or 3 turns or enough to pull the chassis back about 1/8 inch. This will prevent the electric panel from touching the cabinet. Do not pull the chassis too far back as this would prevent the buttons from being properly depressed.

Replacing Silencer Spring Assembly

(52) Unsolder the wire connected to the switch. Unscrew and remove the large brass screw at the center of the switch. All parts may now be removed from the front of the panel. Replace the assembly in the following order: Armature shaft spring, fibre strip, contact arm, fibre washer, guard, and brass screw. The guard is used on issue No. 3 or higher models only. Resolder the wire to the switch.

Replacing Motor

(53) Remove the drive panel from the chassis. It is not necessary to unsolder the silencer switch wire.

(54) Loosen the screws holding the cable clamps enough so that the cables to the reversing switch and the motor on-off switch can be removed. Unsolder the cable wires connected to the reversing switch, motor on-off switch and to the terminal strip under the chassis base. Save the varnished tubing and the wire connected between the motor on-off switch and the terminal strip under the chassis base. If the chassis is of the early type using the tubular condenser connected to the reversing switch, save this connecting wire also.

(55) Remove the two screws holding the motor to the support casting from the back of the panel. The motor and cable assembly can now be removed.

(56) To replace the motor, reverse the above procedure. The five leads from the motor are connected as shown in Fig. 24. Be sure to enclose these leads and the other lead from the motor on-off switch in the proper varnished tubing. If the chassis is of the early type using the tubular condenser connected to the reversing switch, run this lead wire through the proper varnished tubing.

(57) If, after the motor is replaced and all parts reassembled, the motor appears to be jammed as indicated by the manual tuning knob turning very hard with the electric-manual lever in the manual position, the following remedy should be tried.

(58) Loosen the two motor mounting screws slightly and move the motor away from gear No. 1 as explained in paragraph 44.

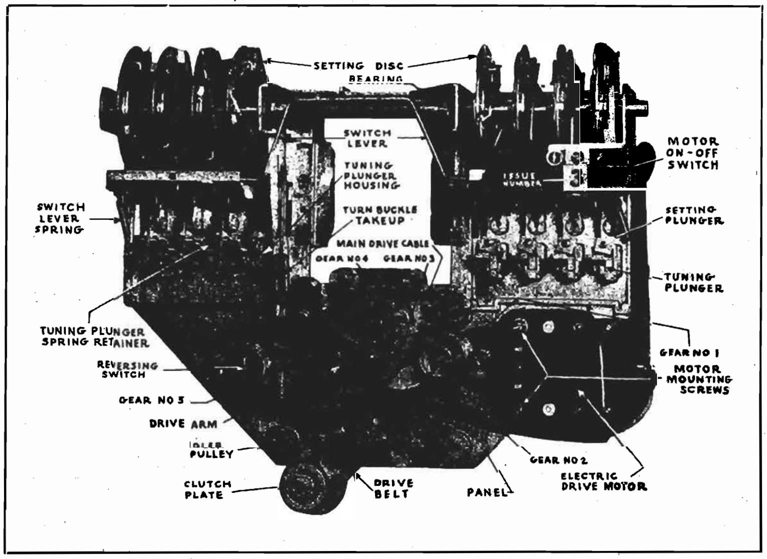

Fig. 6—Electric Drive Panel—Back View

Train of Gears

(59) The train of gears from the motor shown in Fig. 6 reduces the speed and increases the torque. It transmits power to gear No. 5, which drives the tuning condenser, and to gear No. 4, on the shaft of which is the setting disc cable pulley. Gear No. 2 is belt connected to the clutch assembly pulley—Fig. 6. The latter permits manual tuning of the radio and the manual setting of the buttons for electric operation.

(60) Gear assemblies Nos. 3 and 4 have compression springs between the fixed and movable gears of the assembly. Gear No. 5 has a takeup spring in front of it (from back of panel). All of these springs must be properly inserted to prevent backlash. The proper method of inserting the compression spring in gear assembly No. 3 is explained below.

(61) It is essential that the train of gears mesh properly and rotate freely. In case the gears are jammed, look for a foreign object caught between the gears or a compression spring partly out of the slot.

(61A) The drive arm on gear No. 5 should fit tightly in the spring clip on the tuning condenser drive drum. The drive drum is the drum secured by means of set screws at the front of the condenser shaft. Remove the panel and tighten the spring clip by bending, if it is loose. (See par. 22 for insertion of arm in clip.) If the set screws on the drive drum are loose, there will be backlash in tuning. These set screws can be reached and tightened from the bottom of the chassis with a thin blade screwdriver. Rotate the tuning condenser until first one and then the other of the screws is at the bottom.

Replacement of Gear No. 1

(62) In a few of the first sets incorporating the gear drive from the motor, the fibre gear of compound gear No. 1 (See Fig. 7) may slip on its hub. There is a spring washer which holds this gear to its hub and this washer may become too loose. When this occurs, the large fibre gear will be seen to rotate while the hub and small metal pinion gear which engages with gear No. 2, remains stationary.

(63) In a case of this kind, compound gear No. 1 must be replaced. In the later type, the metal hub is rigidly secured to the fibre gear. Following is the replacement procedure:

(64) Remove electric panel assembly from chassis and lay it face down on the bench.

(65) Remove belt and idler pulley—See Fig. 7.

(66) Refer to turn-buckle take-up on steel drive cable—See Fig. 7. Observe position of hex nut on the stud of this turn-buckle, that is, see how many threads this nut is from the end of the stud.

(67) Loosen the main drive cable by loosening the hex nut on turn-buckle and backing off the round knurled nut about 5 half turns.

(68) Remove horseshoe washer from gear Nos. 1 and 2, spreading the horseshoe washers by means of long nose pliers and screwdriver.

(69) Take out the 2 motor mounting screws and lift the motor out of place—See Fig. 7.

(70) Lift up the main drive cable to clear the teeth at the top of gear No. 2—take care not to nick the cable.

(71) Remove gear Nos. 2 and 1.

(72) Put the new fibre tooth gear No. 1 on the shaft and replace horseshoe washer.

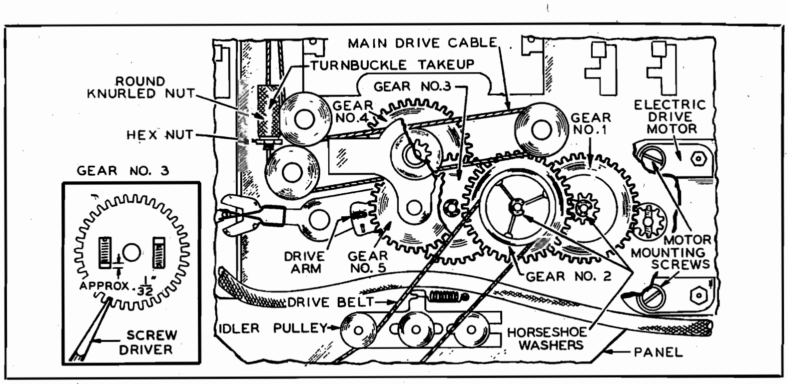

Fig. 7—Replacement of Gear No. 1

MODELS 14,15,16
Electric Drive Dials
Discs and Buttons
Adjustments, Part 1

WELLS-GARDNER & CO.

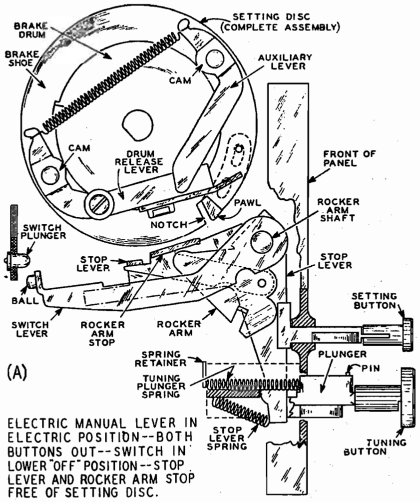

Fig. 8—Setting Disc—Off Position

(73) Now refer to gear assembly No. 3—See Fig. 7. The top gear of this assembly is movable and the bottom gear is fixed. Rotate the top gear one tooth clockwise relative to the bottom gear and hold the two in this position with a screwdriver as illustrated.

(74) Slide gear No. 2 on its shaft, pulling the main drive cable over the top of the teeth—again care must be taken not to nick the cable.

(75) Push gear No. 2 all the way on its shaft, engaging gear Nos. 1 and 3. Replace the horseshoe washers.

(76) Check for take-up on gear No. 3. Approximately 1/32 inch of the fixed gear (bottom) will show through slot in top gear—See Fig. 7.

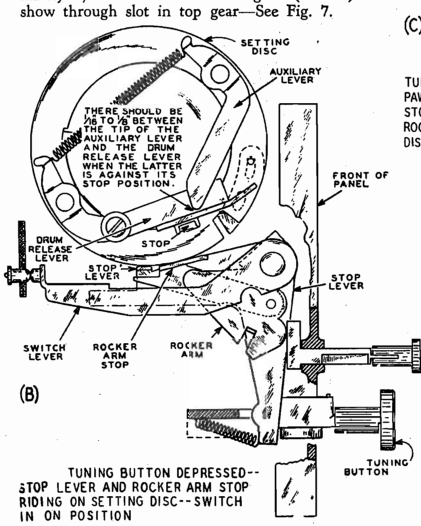

Fig. 9—Setting Disc—On Position, Stop Lever on Edge of Disc

(77) Reassemble motor to frame, pushing tension spring under motor shaft. Be sure to use the same screws to mount the motor to the frame that were taken off. Care must be taken that the pinion gear in the motor meshes properly with the teeth of fibre gear No. 1. If these two gears appear to be so close together that they bind, pull the motor away from gear No. 1 before tightening the mounting screws.

(78) Replace belt and idler pulley.

(79) Retighten turn-buckle on main drive cable bringing hex nut to its former position and round knurled nut down tight against hex nut washer.

(80) Reassemble electric drive panel to chassis.

Setting Discs, Tuning and Setting Buttons, and Associated Levers

(81) The setting discs, tuning and setting buttons, and the levers immediately below the discs, provide a stop position by means of which the electric circuit through the motor can be broken and a mechanical stop provided when a predetermined station has been tuned in.

(82) The essential movements are illustrated in Figs. 8, 9, 10, and 11. The actions of the reversing switch, motor switch, locking plate and clutch, tie in closely with this procedure but are more fully explained in separate articles under those names.

(83) Referring to Fig. 8, the electric-manual lever has been thrown to the electric position. Both the tuning and setting buttons are out. The stop lever and rocker arm stop are in line and free of the setting disc.

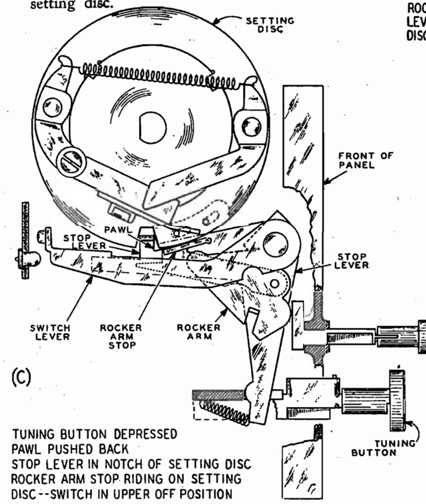

Fig. 10—Setting Disc—Stop Lever in Notch

(84) In Fig. 9, the tuning button has been depressed. The bottom part of the stop lever (portion adjacent to plungers) has been pulled over so that the top part of the stop lever and the rocker arm stop are riding on the edge of the setting disc. The extreme back portion of the stop lever has lifted the switch lever, bringing the motor switch to the On position.

(85) With the motor switch in the On position, the motor drives the train of gears and the setting discs rotate. Now refer to the pawl on the setting disc (Fig. 8), which partially covers the notch in the setting disc.

(86) The purpose of the pawl on the setting disc is to permit the stop lever to fall into the notch in the setting disc in only one direction of rotation. All stations are tuned in, therefore, with the rotating mechanism moving in one direction of rotation. All cable slack and play in gears is taken up in the same direction. If, when stations are set, the tuning knob is turned in this same direction as covered in the instructions, the stations will be tuned in very accurately by the electric tuning mechanism.

(87) Now refer again to the rotating setting disc. Let us say that the direction of rotation is such that the stop lever rides over the pawl and does not drop into the notch. Just before the tuning condenser has reached the end of its travel, the pin on the No. 4 gear assembly casting (Fig. 6) throws the reversing switch lever and the motor changes its direction of rotation. When the pawl reaches the stop lever, the latter will engage the tip of the pawl which extends just beyond the edge of the setting disc, causing the pawl to slide over, opening the notch in the setting disc. The stop lever falls into this notch.

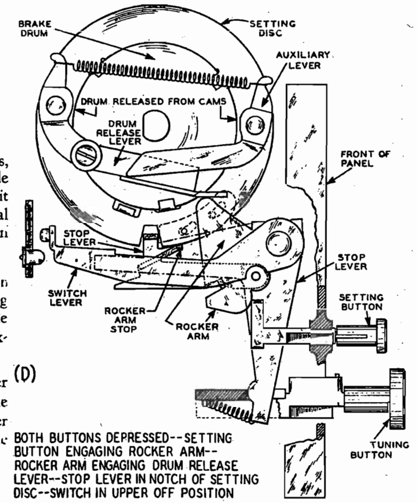

Fig. 11—Setting Disc—Setting Button Depressed

(88) Referring to Fig. 10, the entry of the stop lever into the notch on the setting disc has raised the switch lever until the motor switch is in the Upper Off position. The motor stops and the setting disc is held by the stop lever in the notch. The rocker arm stop still rides on the edge of the setting disc and is no longer lined up with the stop lever.

(89) In Fig. 11, the setting button is depressed. The rocker arm stop, moves toward the back and permits the rocker arm to lift the end of the drum release lever of the setting disc. As will be seen in the illustration, the drum release lever lifts the auxiliary lever and the cams of these two levers move off of the brake drum. This allows the drum to rotate inside of the brake shoes (Fig. 8) or outer portion of the setting disc.

(90) The rocker arm can engage the drum release lever only when the rocker arm stop can move toward the back, and this can be done only when the stop lever is in the notch of the setting disc. It is only when the stop lever is in the notch that the rocker arm can engage the drum release lever properly. That is why in all other positions of the stop lever the latter is lined up with the rocker arm stop and prevents the rocker arm from moving upward.

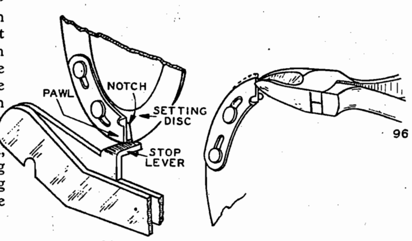

Fig. 12—Pinching Pawl of Setting Disc

(91) When the setting button was depressed, the plunger of this button working against the locking plate (Fig. 3) moved this plate over sufficiently to engage the clutch. Now when the manual tuning knob is turned, the setting discs, except the one which has its setting button depressed, will rotate. The brake drum of the setting disc which we are discussing and which has its setting button depressed, will also rotate, but the brake shoe, or outer portion, remains stationary (Fig. 11). When the station is tuned in, the setting button is released and this causes the cams of the drum release lever and auxiliary levers to bear down on the brake drum, holding this drum firmly in position.

(92) Throwing the electric-manual lever to the manual position will lower the switch lever to the Lower Off position—See Fig. 8. Pushing in another tuning button will release the tuning button we have discussed and bring the tuning button mechanism of the button which is depressed to the position shown in Fig. 9.

Adjustments, Part 2
Replacements

MODELS 14, 15, 16
Electric Drive Dials
Discs and Buttons

Adjustments

(93) The cams must be tight against the brake drum of the setting disc (Fig. 8) otherwise this drum will slip and the dial pointer will not stop at the proper point. In Fig. 9 is shown the proper distance between the end of the auxiliary lever and the drum release lever bar when the latter is against its stop. If this spacing is not correct, the cams will not grip and release properly. A new setting disc will be required in this case.

(94) If the rivets which hold the drum release lever and the auxiliary lever are loose, the cams will not close down tightly on the brake drum. Tighten these rivets or replace the entire setting disc.

(95) A brake drum which is not perfectly round will not be gripped properly by the cams of the auxiliary and drum release lever. A new setting disc will also be required in this case.

(96) A high spot on the outer edge of the setting disc may cause the stop lever to move sufficiently to break the motor switch contact. File down the setting disc or adjust the motor switch if this occurs.

(97) If the rocker arm is bent, it may not engage the back of the setting button plunger as shown in Fig. 11.

(98) Bend the rocker arm to the proper position. The rocker arm may, instead of engaging the drum release lever, come between this lever and the brake drum of the setting disc. Correct this condition by bending the rocker arm and by shifting the position of the setting disc on the shaft.—See Par. 128.

(99) As explained above, when the setting disc rotates, the stop lever will pass over the pawl in one direction of rotation. In the other direction of rotation the stop lever will engage the tip end of the pawl, cause the pawl to slide over and permit the stop lever to fall into the notch of the setting disc.

(100) If the tip end of the pawl does not extend a sufficient amount beyond the outer edge of the setting disc, this action will not take place and the setting disc will rotate beyond the stop lever in either direction of rotation.

(101) Should this faulty condition exist on one of the setting discs, whenever the electric tuning button corresponding to this disc is depressed, the dial pointer will continue to move back and forth without stopping.

(102) This condition is easily corrected as follows: Using a pair of side cutters, grip the tip of the pawl as shown in Fig. 12 about 1/32 inch from the edge. Pinch firmly and push outward (away from the center of setting disc). Do this until the tip of the pawl is a little more than 1/64 inch beyond the outer edge of the setting disc.

(103) After this procedure has been followed, depress the setting button corresponding to this setting disc and see whether the stop lever edge engages the pawl properly.

(104) If the pawl spring is missing, the stop lever can drop into the notch of the setting disc in both directions of rotation. This same condition can take place if the pawl should stick in the open position. If the pawl should stick in the closed position, the setting disc will continue to rotate, first in one direction and then the other without stopping. The remedy is to free the pawl so that it slides back easily. Do this by loosening the rivet with a screwdriver.

(105) It is not advisable to set a station close to the end of the dial pointer travel, at the point where the reversing switch operates. If, when a setting button is depressed you should turn the tuning knob too far, a click will be heard near the end of the dial pointer travel. Then, whenever THIS electric tuning button is depressed, the dial pointer will continue to move back and forth without stopping.

(106) This condition is easily corrected as follows: Turn the electric-manual lever to the manual position. Then turn the tuning knob and observe the setting disc corresponding to the button on which the above condition takes place. Stop turning the knob when disc is in position shown in Fig. 13.

(107) Then with the flat end of a long pencil or thin piece of wood, carefully depress the drum release lever (Fig. 13) and rotate the setting disc about one inch in the direction shown by the arrow.

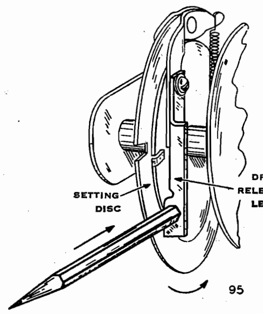

Fig. 13—Adjusting Position of Brake Drum

Do not use a metal rod or the pointed end of the pencil. The setting disc will turn readily after the drum release lever has been depressed.

(108) This will correct the condition, the stations may be set, and the radio operated in the usual manner.

(109) Of course, when tuning in a station manually, as explained in the instruction book, you can tune to the extreme end of the dial pointer travel without the above condition taking place.

(110) The stop lever may not enter far enough into the notch in the setting disc due to the setting disc being at the incorrect position on the shaft (See Par. 129) or the stop lever spring (Fig. 8) may be of insufficient tension to force this lever into the notch. In a case of this kind, the brake shoe (Fig. 8) stops while the brake drum continues to rotate with the motor. The motor has sufficient power through the gears to rotate the brake drum even though the cams (Fig. 8) have not been released. When the end of the dial scale is reached, the thump of the reversing switch is usually sufficient to force the stop lever into the notch sufficiently to throw the motor switch to the Off position. The remedy is to loosen the setting disc set screws and move the disc to the correct position—See Fig. 15—Par. 129. If the main drive cable has been stretched, take up the slack by means of the turn-buckle take-up (Fig. 21). If the stop lever spring (Fig. 8) was responsible for the above condition, tighten this spring.

(111) If the tuning plunger spring (Fig. 8) is weak, it will not return the tuning button to its normal position and it will not be possible to push the electric-manual lever to the manual position as the movement of the locking plate will be prevented. The remedy is to stretch the tuning plunger spring. This can be removed and replaced as explained in the article on replacement of the tuning button plunger.

(112) Backlash may be caused by loose bearings in the setting disc shaft. This may be corrected as follows: Loosen the set screw in the right bearing (from back of panel). Location of this bearing is shown in Fig. 6. Grasp the setting disc shaft at the center and pull toward the left. Push the bearing toward the right and tighten the set screw.

Replacing an Electric Tuning Button Plunger

(113) Remove electric drive panel from the chassis and mount it in a vertical position by means of clamps or a vise. Turn the clutch release lever to the electric position.

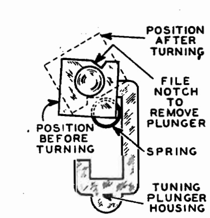

Fig. 14—Tuning Plunger Spring Retainer

(114) Remove the pin from the front of the button plunger—See Fig. 8—by pulling it out. If this cannot be done file the pin flush with the plunger. Unhook the stop lever spring from the back end of the button.

(115) File a V shaped notch in the rectangular spring retainer at the back of the tuning plunger housing—See Fig. 14. The location of the notch is illustrated. Then turn the spring retainer to the position shown in this illustration with the notch at the upper left corner of the housing. When this is done the spring in the housing will spring out. Then push the plunger out from the front of the panel.

(116) To replace the plunger push it into the housing from the back at the same time moving the clutch release lever slowly toward the manual position until the plunger slides all the way into place.

(117) Replace the spring in the plunger housing depressing it and at the same time moving the spring retainer into position to hold the spring in place. Hook the stop lever spring to the back of the plunger.

(118) Insert the smooth end of the new stop pin in the hole in the front of the shaft, forcing it in by squeezing with pliers. Caution—Leave about 1/16 inch of the pin extending above the surface of the plunger.

(119) Replace the electric drive panel on the chassis.

Replacing a Setting Button Plunger

(120) It is advisable to remove the electric drive panel from the chassis and mount it in a vertical position by means of clamps or a vise. Turn the clutch release lever to the manual position.

(121) Remove the switch lever as explained in the article "Replacing Switch Lever."

(122) Move the rocker arm shaft to the left or right, as necessary, to allow the stop lever and rocker arm above the setting button plunger to be taken off from the rocker arm shaft. After these are removed the setting button plunger may be pushed out from the front of the panel.

(123) Replace the new plunger from the back of the panel and reassemble rocker arm and stop lever to the rocker arm shaft.

(124) Reassemble the switch lever and replace the electric drive panel on the chassis.

Replacing a Setting Disc

(125) Turn the clutch release lever to the manual position.

(126) Remove the support bracket at either end of the setting disc shaft by taking out the two screws holding it in place. The bracket to be removed depends upon which side of the center of the panel the setting disc to be replaced is located.

(127) Unscrew the two set screws in the hub of the disc. If the disc to be replaced is any other than the end one, all discs from the end of the shaft to the one being replaced must also be removed.

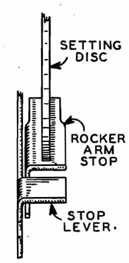

Fig. 15—Positioning Setting Disc

(128) When replacing the disc, it must be placed on the shaft with the hub toward the left (from back). The edge of the setting disc should be directly over the middle of the rocker arm stop—See Fig. 15.

(129) If the disc is set too far to the right (from the back) a condition may exist in which a station cannot be set because the rocker arm will not engage the drum release lever. If the disc is set too far to the left, the pawl will prevent the stop lever from falling far enough into the notch in the setting disc to operate the switch lever although the setting disc is stopped.

MODELS 14,15,16
Electric Drive Dials
Motor Switch,Drive Cable
Data

WELLS-GARDNER & CO.

Motor On-Off Switch and Switch Lever

(130) The function of the motor On-Off switch is to complete the electric circuit through the motor when an electric tuning button is depressed and to break the circuit at the proper instant when the station has been tuned in by the rotating mechanism.

(131) The essential parts of the switch, see Figs. 8 and 16, are an insulated base, two contacts, one fixed and the other on a movable reed, and a plunger. The latter, when pushed in, causes the movable reed to bend until the contact which is on it, touches the fixed contact. When the plunger is out the reed bends back and the two contacts separate.

(132) There are three positions of the switch known as the Upper Off, the On and the Lower Off position.

(133) These positions are illustrated in Figs. 8, 9, and 10. As will be seen in Fig. 9, the switch is in the On position when the ball on the switch lever moves against the rounded outside face of the plunger and forces it inward.

(134) The proper operation of the switch depends on the correct relative position of the switch plunger and the ball on the switch lever.

(135) The bakelite switch base should be parallel with the switch lever as shown in Fig. 16. If the switch base is further out the plunger may not be pushed in sufficiently to throw the switch to the On position and if the base is too close the ball may jam against the plunger instead of the two rounded surfaces of these items engaging properly. Bend the switch base in or out until proper interaction is obtained. (In issue No. 4 and later panels there is an adjustment screw for this purpose.)

(136) The plunger on the switch base and the ball on the switch arm must also be at the correct height relative to each other. The ball should line up with the plunger when one of the tuning buttons is depressed and the stop lever is riding on the edge of the setting disc—See Fig. 9. From this On position there should be an approximately equal throw of the switch lever to either the Upper or Lower Off positions—See Figs. 8 and 10.

(137) To adjust the height, loosen the two screws which hold the switch base in place. Grasp the bakelite switch base at the left side (from back of panel) and raise or lower it.

(138) In some cases bending of the switch lever at either side may also be required. The switch lever should rest on or be very close to all eight of the stop lever extensions when no tuning button is depressed. Push in each of the tuning buttons, one at a time and see if the ball on the switch lever lines up with the switch plunger in the On position (Fig. 9).

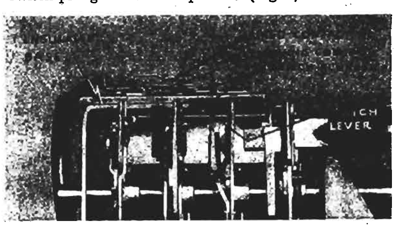

Fig. 16—Motor On-Off Switch—Top View

Replacing Motor On-Off Switch

(139) If the switch mechanism is broken or cannot be put in proper working order, a new one may be ordered. The old switch is removed by taking out the 2 screws which hold it in place and unsoldering the 2 switch leads.

Replacing Switch Lever

(140) The switch lever (Fig. 6) consists of three distinct sections—a center section, left section, and right section (from back of panel). Each section may be replaced separately.

(141) Turn the clutch release lever to the manual position. All the following operations are performed from the back of the panel.

(142) CENTER SECTION—To remove this section, take out the screws at each end and lift the section off. When replacing this section, the end with the cutout portion must be on the right side.

(143) LEFT SECTION—Unhook the switch lever spring from the left side of the lever. Remove the horseshoe washer from the left end of the rocker arm shaft. Push shaft toward right side far enough so that the horseshoe washer on the right end of the shaft is accessible. Remove this washer. Then lift the left end of the switch lever high enough so that the rocker arm shaft will slide under the lever when the shaft is pushed toward the left. Push the shaft toward the left far enough to allow the right end of the lever to slip off the shaft. To replace this section, reverse the above procedure.

(144) RIGHT SECTION—Unhook the switch lever spring from the right side of the lever. Remove the horseshoe washers from the ends of the rocker arm shaft. Push the shaft to the right enough to allow the left end of the lever to be lifted. Then push the shaft to the left enough to allow the right end of the lever to slip off the shaft. To replace this section, reverse the above procedure.

Replacement

(148) EARLY MODEL CABLE — Early electric drive panels, those without an issue number on the switch bracket, used a different drive cable than the one shown in Fig. 21. If the cable breaks on these models, do not attempt to restring the cable. Instead, the electric drive panel will have to be returned to the factory to have this done.

(149) LATER MODEL CABLE — These may be identified by the issue No. 2 or higher number stamped on the switch bracket. Should cable restringing be required in the case of the later type, this can readily be accomplished by ordering a new drive cable, if one is necessary, and putting it on in accordance with the following instructions:

(150) Remove electric drive panel from chassis.

(151) Remove the old drive cable. It will have to be unsoldered at pulleys B and E—See Fig. 21. Turn clutch release lever to manual position.

(152) From the front of the panel, turn manual tuning knob to the right (clockwise) as far as it will go. This will bring the drive arm on gear No. 5 to the left (from back of panel)—See Fig. 7.

(153) Now support the panel in such a manner that it is held firmly in an upright position, the back of the panel toward the operator. The bottom of the casting can be gripped at a number of points in a vise or clamp —care should be taken not to distort the casting.

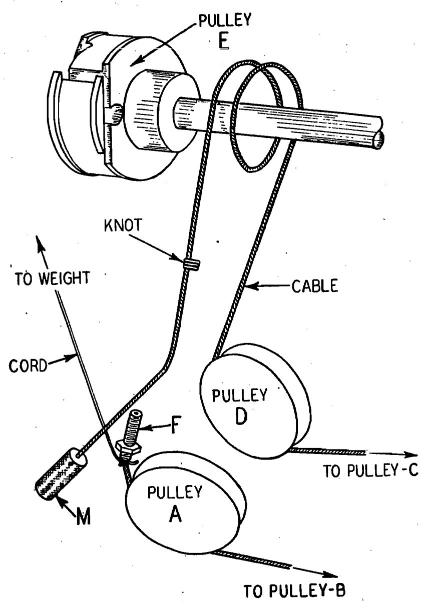

Fig. 18—Drive Cord Replacement—Step No. 2

(154) Referring to the new drive cable, it will be noted that one end has a screw fitting and the other end has a round knurled nut fitting. These two fittings together with the hex nut and lock washer comprise the turn-buckle take-up.

(155) With screw end F (Fig. 17) hanging down, place the cable into the vertical slot at the back of pulley B with the knot inside of the opening at point G.

(156) Then wind the screw end of the cable on pulley B in a clockwise direction one turn, passing over the portion of this cable which is in slot H.

Main Drive Cable

(145) The function of the main drive cable is to rotate the setting discs in conjunction with the train of gears and keep the rotation at a definite fixed position in relation to the rotational position of the drive gears. The cable is rigidly secured to a pulley on the shaft of gear No. 4 and passes over a series of other pulleys to a pulley on the setting disc shaft where it is also rigidly secured.

(146) It is important that this cable ride freely over all pulleys and with all slack taken out. The turn-buckle take-up, as shown in Fig. 21, is provided to take up slack.

(147) If the drive cable is loose the dial pointer will not stop at the same point each time a tuning button is depressed, because of the lack of fixed relation between the setting discs and the drive gears. Take up the slack by means of the turn-buckle. Loose set screws on the top pulley of this cable will also bring about this same condition. Tighten these screws.

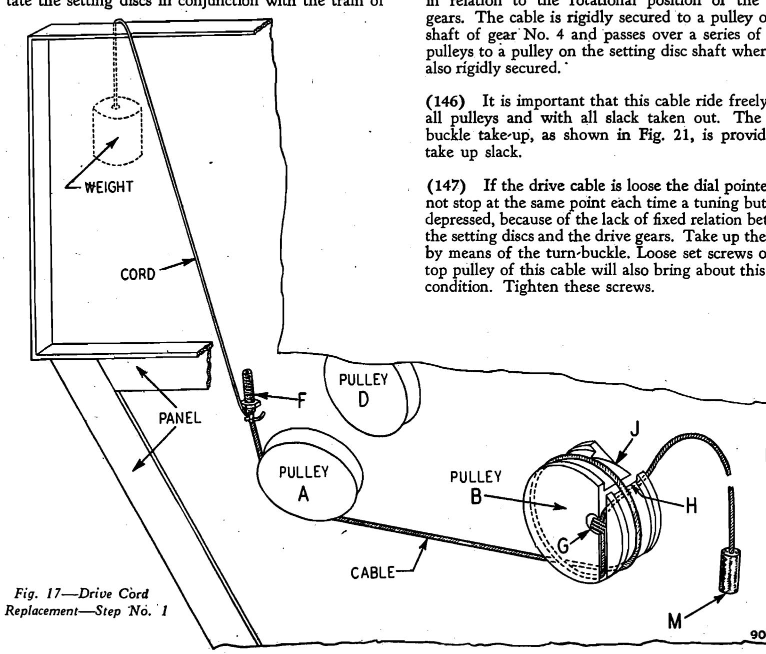

Fig. 17—Drive Cord Replacement—Step No. 1

WELLS-GARDNER & CO.

MODELS 14,15,16
Electric Drive Dials
Cable Data,Part 2

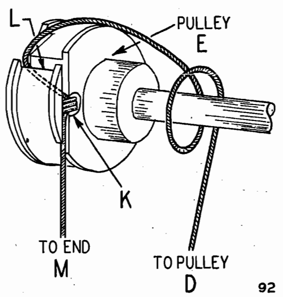

Fig. 19—Drive Cord Replacement—Step No. 3

(157) Bring the screw end of the cable over to pulley A and hold it in this position. This can be done by fastening a 10 inch stout cord to the end of cable F. Attach a weight to the other end of this cord and let the weight hang over the top of the panel as shown in Fig. 17. Instead of a stout cord, the round knurled nut and old cable can be secured to the screw end of the new cable.

(158) Now refer to the portion of the cable that is in the slot at point H pulley B. Using a small wooden prod, bend this cable and bring it back onto pulley B at groove J. CAUTION: Do not use a metal prod as this may damage the cable. It is important that the cable at groove J be kept close to the front flange of pulley B (flange nearest panel) while the portion of the cable which extends downward from point G be kept close to the back flange of this pulley so that the cable from pulley A will ride freely in the center of pulley B—as shown in Fig. 21.

(159) Then from groove J bring the cable in a counterclockwise direction ½ turn around pulley B, over to pulley C, ½ turn around pulley C, over to the bottom of pulley D, and then up to the shaft at the right of pulley E—Be sure the cable is well down in slot H, pulley B.

(160) Wind the cable LOOSELY one and one-half turns around this shaft, progressing toward the left as shown in **Fig. 18.**

(161) Rotate the setting discs until pulley E is approximately in the position shown in Fig. 19 Using a thin wooden prod, place cable in slot L with knot in hole at point K of pulley E. Rotate the setting discs a slight amount back and forth. This will provide clearance while getting the cable in the slot. Push the cable well down into slot L—See **Fig. 19.**

(162) Rotate the setting discs ¾ of a complete revolution in such a direction that the top of the discs move toward the front of the panel. Bring the round knurled nut under the loop of the cable as shown in Fig. 20.

(163) Place cable from pulley D on pulley E at left flange (from back of panel). Now holding cable from pulley D, rotate setting discs in such a direction that the top of the discs move away from the front of the panel. Rotate the discs approximately ¾ of a turn or until the slack in the cable from pulley D is all taken up. Pulley E and the cable will then be in the position shown in Fig. 21 and the knurled nut end M of the cable will be hanging down from pulley E and must be held in tension.

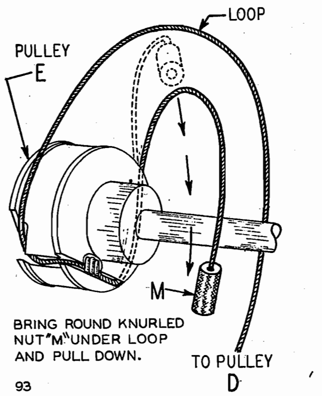

Fig. 20—Drive Cord Replacement—Step No. 4

(164) The next step is to connect the two portions of the turn-buckle together. Before doing this, see that the cable is on all of the pulleys as shown in Fig. 21. Tension should still be applied to both ends of the cable.

(165) Remove weight and cord (or round nut) from screw end F of the cable. Put the lock washer against the hex nut on this cable. Screw round knurled nut onto screw end of cable. While this is being done, the setting discs should be grasped by another person and rotated as far as they will go in such a direction that the top of the discs moves away from the front of the panel. The purpose of this is to take up all slack in the cable and to enable the two ends of the turn-buckle to be secured together.

(166) The cable must be firm and with all slack out. It should not be so tight, however, that the setting discs and pulleys do not turn freely. Tension of the cable is regulated by the position of the hex nut. The round knurled nut must be screwed tightly against the lock washer next to the hex nut.

(167) Solder knots at points G and K on pulleys B and E respectively. Reassemble the electric drive panel to chassis.

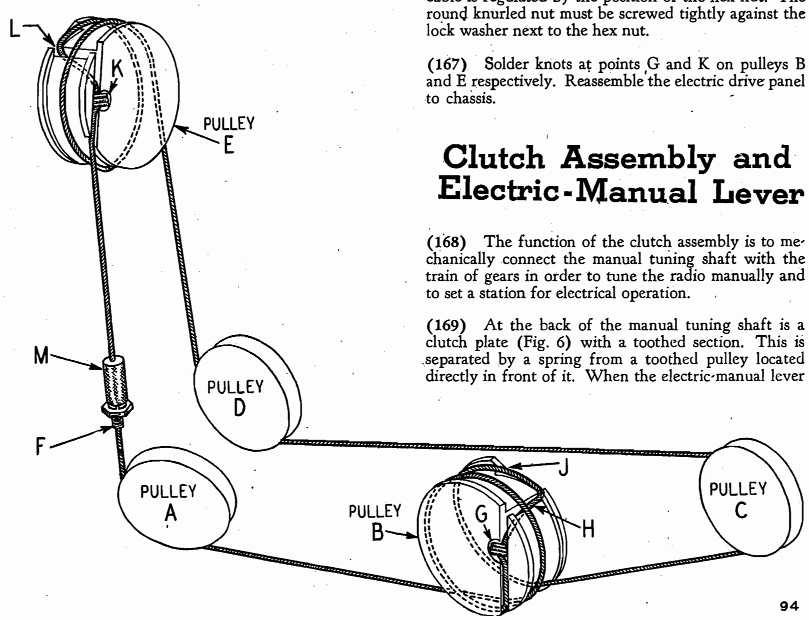

Fig. 21—Drive Cord Replacement—Complete Assembly

Clutch Assembly and Electric-Manual Lever

(168) The function of the clutch assembly is to mechanically connect the manual tuning shaft with the train of gears in order to tune the radio manually and to set a station for electrical operation.

(169) At the back of the manual tuning shaft is a clutch plate (Fig. 6) with a toothed section. This is separated by a spring from a toothed pulley located directly in front of it. When the electric-manual lever is in the electric position, the clutch plate is free of the pulley. When the lever is turned to the manual position, a yoke, or crosspiece, on the front of the manual tuning shaft is pulled forward on the yoke track of the clutch release lever (Fig. 3) pulling the tuning shaft forward. This causes the clutch plate to engage the toothed pulley. This pulley is belt-connected to gear No. 2 on the train of gears. As a result, the gears rotate when the manual tuning knob is turned. When the setting button is depressed, the plunger moves the locking plate over. This, in turn, moves the interlocking lever which throws the clutch release lever *toward* the manual position. The movement of the clutch release lever is sufficient to cause the clutch plate (Fig. 6) to engage the toothed pulley.

(170) To avoid misunderstanding in the following paragraphs, the electric-manual lever is the separate die-cast lever bearing the words "Electric-Manual" visible from the front of the cabinet panel, and the clutch release lever is the stamped lever shown in Fig. 3.

(171) If the clutch plate is bent too far back, it may not engage the pulley teeth properly when the lever is thrown to the manual position or when the setting button is depressed. Bend this plate forward at the toothed section until it meshes properly under the above conditions. Also, be sure the clutch plate releases properly when the electric manual lever is in the electric position.

(172) When the electric-manual lever is in the electric position, the tuning knob should not turn when a tuning button is depressed and the motor is operating, since the clutch plate should be disengaged from the pulley. If this knob rotates while the motor is operating, the chassis may be too far forward in the cabinet preventing the clutch release lever from returning to the electric position. Move the chassis back (Par. 51). The electric-manual die cast lever may not turn freely on the clutch bearing (Fig. 3) and may not return to the electric position. Bend the upper and lower portion of the bearing together with heavy pliers, or file the surface down until this lever turns easily. The tuning knob may have been put on the shaft while the electric-manual lever was in the manual position. Loosen this knob and put it on when the lever is in the electric position. The clutch releasing spring between the clutch plate (Fig. 6) and the toothed pulley may be broken or of insufficient tension to properly separate these two items. Put on a new spring or increase the tension of this spring.

(173) If the manual tuning knob turns very hard when tuning the radio manually, the clutch releasing spring which is just in front of the clutch plate, may have become caught in some manner and not rotate freely on the shaft. Bend this spring so that it rotates freely on the shaft, or put on a new one.

Fig. 22—Clutch Release Lever—Early Models

(174) In Fig. 22 is shown a side view of the early type of clutch release lever. On occasion the yoke track was too close to the lever proper and when the electric-manual lever was pushed to the manual position, the yoke jammed against the end of the track instead of sliding up on it. The remedy for this is to bend the yoke track away from the lever $\frac{1}{32}$ or $\frac{1}{16}$ of an inch until proper action is obtained.

(175) The tip on the clutch release lever slot (Fig. 3) may be too high or too low. If too high, it will prevent the electric-manual lever from being pushed into the electric position. The remedy is to cut or file a slight amount off the top of this tip. If the tip is too low, the clutch release lever will not stay in the manual position. As a general rule, the electric drive panel will have to be returned to the factory to have this corrected. Binding of the clutch release lever and interlocking lever (Fig. 3) might also prevent the electric-manual lever from being thrown to the electric position. Free these levers so that they operate easily if this condition occurs.

Locking Plate and
Reversing Switch,Notes

Replacing Electric-Manual Lever and Manual Tuning Knob

(176) Before removing the electric-manual lever turn it to the electric position. When replacing the lever, place it on the tuning shaft, line up the pin on the back of the lever with the hole in the clutch release lever and push the lever on the shaft. When replacing the tuning knob on the shaft, push it all the way on and tighten the set screw.

Replacing Clutch Releasing Spring or Clutch Plate

(177) Remove the electric drive panel from the chassis and lay it face down in front of the chassis. It is not necessary to unsolder the wire on the silencer assembly or the wires on the motor cable asembly to the chassis.

(178) Hold the front end of the tuning knob shaft with pliers and, at the same time, loosen the hex nut at the back end of the shaft. Remove the nut, lock washer, and clutch plate. Replace the clutch spring and, if necessary, the clutch plate, and reassemble, reversing the above procedure. Correct adjustment of the clutch plate is important and the instructions given in Par. 171 should be carefully followed.

(181) If the locking plate screws at the top of the locking plate are too loose, it may not be possible to push the electric-manual lever to the manual position. The reason for this is that the tip of the locking plate is so far out that it does not move into the slot on the tuning button plunger. The remedy, of course, is to tighten these screws.

(182) If a tuning button is depressed and pressing in another button does not release the first nor permit the second button to stay in, it is due to a slight distortion in the locking plate or to the fact that the locking plate screws are out too far.

(183) This condition can be overcome without removing the chassis from the cabinet by depressing the first button again and then depressing the second quickly. However, it may be permanently corrected as follows: The two locking plate screws (Fig. 3) may be out too far. Turn these screws down and see if this corrects the condition. If it does not, the plate is distorted. If the left hand group (from front) of buttons will not remain depressed and will not release the right hand group, tap the locking plate lightly with a hammer at point A, Fig. 3. If the right hand group of buttons will not remain depressed and will not release the left hand group, tap the locking plate at the bottom of the plate directly under point A. This will overcome the distortion on the plate and should correct this condition.

(186) If trouble develops in the reversing switch circuit, carefully check the wiring for loose or broken connections. Carefully check the switch to see that it is making proper contact in both positions. If it is not, it will have to be replaced. Early models used a switch which required a tubular condenser across the contact points. Do not operate this type switch without the condenser being connected to it as the contact points will be damaged. The switch used on later models and for replacement purposes does not use this condenser. If an old switch is replaced by one of the new type, disconnect the condenser from the circuit.

Replacing Reversing Switch

(187) Remove the electric drive panel from the chassis (See article on this procedure). It is not necessary to unsolder the silencer or motor connections.

(188) The location of the reversing switch is shown in Fig. 6. Unscrew and remove the two small bolts which hold the switch to the bracket. Unsolder the leads to the switch.

(189) To replace the switch, reverse the above procedure. The connections to the switch are shown in Fig. 24. If an early type switch requiring a condenser is replaced by a new type switch, the two leads from the metal shell tubular condenser should be disconnected and also the extra lead from the condenser to the switch.

Locking Plate

(179) The locking plate (Fig. 3) has three main functions. First, it holds the tuning button in, after the button has been depressed and releases any other tuning buttons which have previously been depressed. Second, it shifts the electric-manual lever, when the setting button is depressed, to engage the clutch. It does this by moving the interlocking lever which, in turn, shifts the clutch release lever. Third, when the electric-manual lever is turned to the manual position, the locking plate releases any buttons that are depressed and locks these buttons to keep them from being depressed.

(180) The locking plate must slide freely on the 4 studs and in back of the 4 washers (Fig. 3) which hold it in place. If the plate appears to bend at these washers, loosen them with a screwdriver and place a small amount of grease in back of the washer. The interlocking lever (Fig. 3) must also work freely and should be loosened until it turns easily.

Reversing Switch

(184) The function of the reversing switch is to provide a means of reversing the direction of the motor rotation just before the gang condenser rotor reaches maximum open or closed position as the radio is being tuned electrically. This is accomplished by means of the pin on the No. 4 drive gear casting operating the reversing switch lever. This lever trips the reversing switch which changes one of the motor windings from one side of the line to the other causing a reversal of the direction of rotation of the motor. The electrical connections for this circuit are shown in Fig. 24.

(185) If the dial pointer reaches the end of the scale and stops, but the motor continues to operate, loosen the reversing switch mounting screws and adjust the position of the bracket up or down until the switch operates properly. If this procedure does not remedy the condition, put one of the centering springs on the reversing switch—one of these can be obtained from the factory. Later models are already equipped with this spring—See Fig. 23.

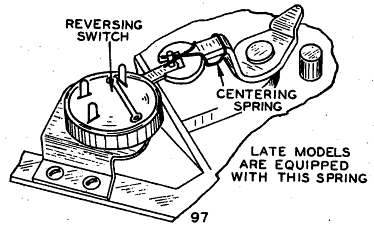

Fig. 23—Centering Switch on Reversing Switch Lever

(190) In Fig. 24 is shown the electrical wiring of the electric drive panel. Three distinct units, the motor, the on-off switch, and the reversing switch enter into the electrical operation. Since the operation of each of these units is discussed fully in the articles covering them, it will not be repeated here.

(191) One other electric circuit which is associated with the electric drive panel is the silencer circuit. This circuit silences the radio while the motor is operating. The mechanical operation of the silencer circuit is discussed fully in the article "Motor and Silencer Spring Assembly."

(192) The silencer circuit is shown in the schematic circuit diagram of the service manuals of the various chassis using the electric drive.

(193) If there is reason to believe that one or more of the electrical connections are open, check for continuity using Fig. 24 as a guide. Following are the D.C. resistances of the motor windings:

Field—tap to black wire—13.6 ohms
Field—tap to red wire—16.3 ohms
Shading Winding —99.7 ohms

Electric Circuit of the Motor Drive

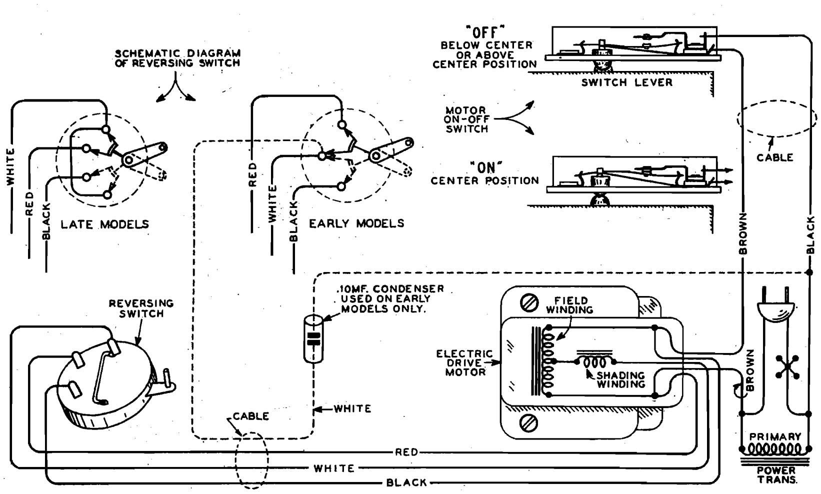

Fig. 24—Electric Drive Panel Wiring

MODELS 14,15,16
Electric Drive Dials
Parts List

CONTAINING 25 AND 40 CYCLE DATA AND PARTS LIST

SEPT., 1937

25 Cycle Electric Drive Panel

The 25 cycle electric drive panel assembly is identical to the 60 cycle assembly except that a 25 cycle motor and a different gear No. 1 (see Fig. 6 in electric drive notes) are used.

The pinion gears in the 25 and 60 cycle motors are not the same. If, therefore, one of these pinions is ordered, the type of motor must be specified. (Both 25 and 60 cycle motors are furnished with pinion included.)

40 Cycle Power Supply

An electric drive chassis equipped with a 117-234 volt 40 to 60 cycle power transformer can be used on a 60 cycle power supply only, unless changed as mentioned below. The electric drive panels of these sets are equipped with 60 cycle motors and these will function satisfactorily only at that frequency.

If one of these radios is to be used on a 40 cycle power supply, it will be necessary to change the motor. The motor regularly supplied with the 25 cycle model is used for this purpose.

Electric Drive Panel Replacement Parts

There is a number on the On-Off switch bracket which identifies the panel as to major part changes. Be sure to mention this issue number when ordering parts for the Electric Drive Panel.

For names of parts shown in the Electric Drive Panel list, refer to the illustrations in the Electric Drive NOTES, especially Figs. 3, 6, 7, 8, 9, 10 and 11.

Part No.	Description	List Price
25A217	60 Cycle Electric Drive Panel Complete—Includes Main Casting, Gears, Pulleys, Switches, Motor, Setting Discs, Tuning and Setting Button Plungers—less Gang Condenser, Condenser Support Bracket, Upper Triangular Support Bracket, Dial Scale and Bracket, Dial Pointer and Cap	$27.80
25A249	25 Cycle Electric Drive Panel Complete—Same as above except with 25 Cycle Motor and No. 1 Gear Assembly	29.20
57X8	Locking Plate	.60
28X139	Spring for Locking Plate ..... Doz.	.30
37X93	Interlocking Lever	.10
37X95	Clutch Release Lever	.10
28X137	Spring used on above Lever ..... Doz.	.35
26X259	Tuning Knob Shaft	.10
37X94	Yoke for Clutch Lever (Fits in Groove on above Shaft)	.10
19X88	Keyway Washer (Used on Clutch Bearing) ..... Doz.	.15
24X294	Pulley for Manual Drive Belt (On Back of Tuning Shaft)	.30
20X212	Roller Bearing for Above Pulley ..... Doz.	.15
57X10	Clutch Plate	.10
28X152	Clutch Release Spring (In front of Clutch Plate from Back of Panel) ..... Doz.	.05
8X57	Manual Drive Belt	.35
26A74	Belt Tension Pulley and Bracket Assembly	.20
28X150	Spring for above Assembly ..... Doz.	.20
24X316	Belt Idler Pulley only	.10
25A178	Setting Disc Assembly	.75
28X134	Tension Spring (Fastened to Auxiliary and Drum Release Levers) ..... Doz.	.25
28X151	Tension Spring for Pawl of Setting Disc ..... Doz.	.25
26X255	Setting Disc Shaft	.40
20X192	Ball Bearings in Retainer (For Setting Disc Shaft)	.10
20X207	Bearing Cone (Without Set Screw)—On Setting Disc Shaft	.15
20X195	Bearing Cone (With Set Screw)—On Setting Disc Shaft	.20
24X288	Pulley for Drive Cable (On Setting Disc Shaft)	.15
25X403	Support Bracket for Setting Disc Shaft (Left side from back)	.10
25X412	Support Bracket for Setting Disc Shaft and Motor On-Off Switch	.15
26A75	Adjusting and Support Rod for Motor On-Off Switch (Panel Issue No. 4 and Later)	.10
2A105	Motor On-Off Switch Assembly Complete	.95
37X85	Switch Lever (Right section from back)	.20
37X96	Switch Lever (Left section from back)	.20
25X413	Switch Lever (Center section)	.15
28X137	Switch Lever Spring ..... Doz.	.35
37X82	Stop Lever	.10
28X148	Stop Lever Spring ..... Doz.	.15

Part No.	Description	List Price
25A181	Rocker Arm and Rocker Arm Stop Assembly Complete with Spring	$0.20
28X131	Spring for Rocker Arm Stop ..... Doz.	.10
26X256	Rocker Arm Shaft	.10
26X261	Setting Button Plunger	.10
10A121	Setting Button only	.10
26X254	Tuning Button Plunger with Stop Pin	.15
28X138	Tuning Plunger Spring ..... Doz.	.10
10A120	Tuning Button only	.10
28X129	Hairpin Springs for Tuning Buttons ..... Doz.	.10
10X26	Main Drive Cable Complete with Turnbuckle	.75
12X75	60 Cycle Motor Complete	4.55
24X296	Pinion Gear only (On Motor Armature Shaft)—60 Cycle	.10
12X82	25 Cycle Motor Complete	6.15
25A233	No. 1 Pinion and Gear Assembly (For 60 Cycle Operation)	.45
25A248	No. 1 Pinion and Gear Assembly (For 25 Cycle Operation)	.60
24X307	No. 2 Gear and Pulley	.20
25A184	No. 3 Gear Assembly	.35
25A221	No. 4 Gear Assembly	.55
28X141	Spreader Springs for Gears No. 3 and 4 ..... Doz.	.05
26A73	Pulley Bracket Assembly complete with Gear No. 5, Pulleys and Roller Bearing Assembly	1.70
25A186	No. 5 Gear and Drive Arm Assembly only	.30
2A97	Reversing Switch	.35
37X98	Lever for Operating Reversing Switch	.10
28X158	Centering Spring (Used on Reversing Switch Lever)	.10
25X430	Bracket for Reversing Switch	.10
25A239	Silencer Spring Assembly complete with Shield	.20
26A79	Drive Drum for Gang Condenser	.50
25X401	Front Support Bracket for Gang Condenser	.65
8X43	Rubber Cushion (Used for Mounting above Bracket)	.10
20X152	Stud (Used with Rubber Grommet—6X8—for Mounting above Bracket to Chassis)	.10
6X8	Rubber Grommet (Used with above Stud) ..... Doz.	.15
25X424	Triangular Support Bracket (Holds Electric Drive Panel to Gang Condenser Support Bracket)	.10
Specify Name & Model Number of Radio	Dial Scale Mounting Bracket Complete with Dial Scale (Less Pointer and Pointer Cap)	1.80
	Dial Scale only	1.35
25X417	Mounting Bracket only for Dial Scale	.35
15X111	Dial Pointer only	.20
15X104	Cap for Dial Pointer	.10
26X265	Stud for Mounting Pointer	.10
10A125	Electric-Manual Lever	.20
7A67	Dial Lamp Socket Assembly (2 Sockets) less Lamps	.30
	Dial Lamp only (No. 51 Bayonet Type)	.20
17X23	Glass Crystal	.10
28X25	Retaining Spring for Glass Crystal	.10
25X362	"L" Bracket (For Mounting Rear of Gang Condenser to Chassis)—Series A1 and A2	.10
25X382	"L" Bracket (For Mounting Rear of Gang Condenser to Chassis)—Series A3	.10
20X150	Stud (For Mounting above Bracket to Gang Condenser)	.10
6X18	Rubber Grommet (Used on above Stud) ..... Doz.	.30
2X236	Rubber Washer—Flat (Used with above Grommet) Doz.	.15
26A56	Station Call Letter Discs and 25 Celluloid Discs	.35
25X405	Shipping Support Bracket (Top of Electric Drive Panel to Wood Brace)	.20
8X23	Rubber Cushion (Used with Shipping Support Bracket)	.10

FORM 1589

MODEL A-1 Series
Coils, Phono. Socket
Notes, Parts List

WELLS-GARDNER & CO.

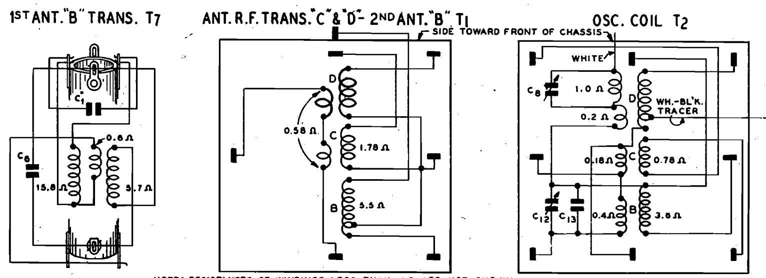

Fig. 7—Coil Terminal Arrangement and D.C. Resistance of Windings

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the side panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 2.

Early Models—A few of the early models did not have the circular knockout for the phonograph socket as mentioned above. If a phonograph installation is to be made in connection with one of these early models, write the factory for detailed instructions.

117-234 Volt Power Transformers

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Notes issued for this chassis. (see index)

NOTE: METAL TUBES ARE IN THE SAME POSITIONS AS THE GLASS EQUIVALENTS SHOWN IN THE LAYOUT

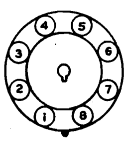

Fig. 5—Octal Tube Terminal Numbering (bottom of socket)

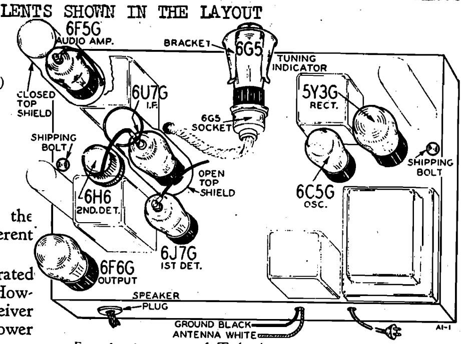

Fig. 4—Location of Tubes

Twenty-five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

Series A1 - Replacement Parts

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter. With the exception of the parts otherwise indicated, the following parts are common to Series A1 chassis using either the Telephone Dial or the Phantom Light Dial.

MISCELLANEOUS

SOCKETS

Part No.	Description	List Price
3A256	Tube Socket—Octal (7 Prong)	$0.15

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT

7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C8)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

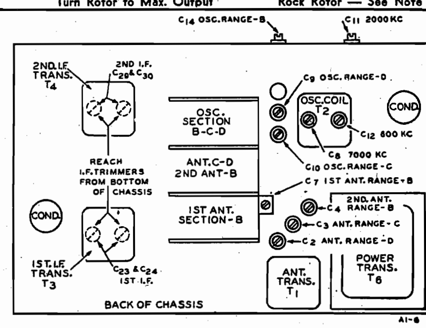

Fig. 3—Location of Trimmers

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T7 are the antenna coil assemblies and T2 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. When it is in the Range B position, a double tuned antenna R.F. stage is used while for the C and D Ranges, a single tuned secondary is used.

A type 6J7 tube functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

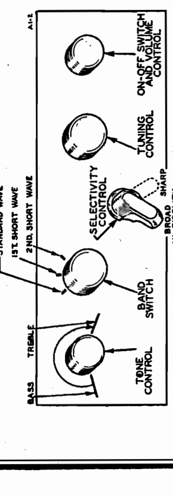

Fig. 1—Arrangement of Controls

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T3. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the 1st detector and I.F. tubes.

A 6F5 triode tube functions as the first audio amplifier while the output stage uses a 6F6 output pentode tube. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6G5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C17)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

On the electric drive models, the pointer is held to the shaft by a friction clip arrangement. With the electric-manual lever in the manual position, hold the tuning knob and move the pointer to the 1500 KC mark on the dial.

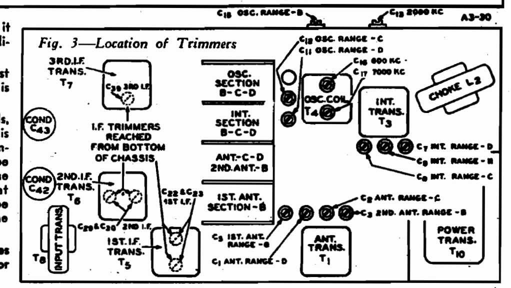
In sets using any other type of dial mechanism, it will be necessary to adjust the position of the indicator until it is at the 1500 KC mark.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Fig. 3—Location of Trimmers



117-234 Volt Power Transformer

Some models are equipped with a 117-234 volt universal power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

Models without the electric drive, which are equipped with this transformer, may be used on a power supply of 40 to 60 cycles. If an electric drive motor is used, however, it is important that the set be operated on a 60 cycle power supply only. The reason for this is that the 60 cycle motor in the electric drive panel of this model will not operate satisfactorily at any frequency other than 60 cycle. Consequently, if one of these radios is to be used on a 40 cycle power supply, it will be necessary to change the motor. The motor regularly supplied with the 25 cycle model, is used for this purpose.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Twenty-Five Cycle Models

Twenty-five cycle receivers not equipped with an electric motor drive, differ from sixty cycle receivers only in the fact that a different power transformer is used. The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true—a sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

ELECTRIC DRIVE MODELS—In twenty-five cycle electric drive sets, in addition to the power transformer change mentioned above there is also a twenty-five cycle motor. Since these motors will not operate satisfactorily on a sixty cycle power supply, it follows that the twenty-five cycle electric drive sets cannot be used on sixty cycle power.

(6) A.C. voltage as read across terminals 4 and 6.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the front panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 2.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6G5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

MODELS A3,A6 Series
Circuit Data,Socket
Parts List

WELLS-GARDNER & CO.

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna R.F. transformer assemblies, T3 is the interstage R.F. transformer assembly, and T4 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C, and D respectively.

The band switch completes connections to the coils in use. The band switch sections are designated in the schematic as section 1 and section 2. When the switch is in the Range B position, a double tuned antenna R.F. stage is used while for the C and D Ranges a single tuned R.F. stage is used.

A 6K7 tube functions as an R.F. amplifier. The output of this tube is fed into a tuned R.F. stage. The output of the latter actuates the control grid of a 6J7 tube which functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillator circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

Two stages of I.F. amplification are employed using 6K7 tubes. The primaries and secondaries of the 1st and 2nd I.F. transformers and the primary of the 3rd I.F. transformer are tuned by small trimmer condensers.

Referring to the 1st and 2nd I.F. transformers T5 and T6 in Fig. 2, it will be noted that there are coupling windings shown below the primaries.

When the selectivity control is in the sharp position, the coupling windings are open-circuited and the loose coupling which exists between the primary and the secondary of these transformers results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A type 6H6 twin diode functions as the 2nd detector and AVC tube. Referring to Fig. 2, the 3rd I.F. transformer has two secondary windings, each of which works into one of the 6H6 diodes.

Referring to the circuit associated with the audio winding (lower diode winding—Fig. 2) the audio component is developed across volume control resistor R27 and transmitted through the movable arm to the control grid of the 6C5 1st A.F. amplifier. The DC component of the voltage developed in this circuit is applied through resistor R22 to the control grid of the 6C5 AVC tube.

The AVC voltage developed in the circuit of the upper diode winding is applied through isolating resistors to the control grid circuits of the R.F. and 1st I.F. tubes. The cathode of the AVC diode is connected to the plate of the AVC tube. This tube under no-signal conditions operates at a very low voltage on the plate by virtue of the drop across plate resistor R24. **When there is a signal voltage** in the audio circuit, the DC component of this voltage, as mentioned above, is applied to the control grid of the AVC tube. This voltage makes the grid more negative and reduces the plate current. The reduction in plate current lessens the drop across the plate resistor and brings the plate to a higher positive potential. This positive potential is applied through resistor R19 to the AVC line, subtracting from the AVC voltage developed across R19. As a consequence of this cancellation, there is practically no AVC voltage applied to the controlled tubes until the AVC tube reaches cut-off after which the plate potential of this tube ceases to become more positive with increasing signal voltage and the AVC functions in the normal manner. The audio output increases rapidly with the input signal for low values of signal input, reaching maximum power output for an input signal of but a few microvolts. At this point the AVC commences to act and further signal input increase causes very little change in output signal level.

Across the volume control resistor R27 is a filter composed of condensers C49 and C50 and resistor R28. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

The output stage employs two type 6L6G power amplifier tubes in a stage of push-pull amplification. Two type 5Y3G rectifiers are used in the power unit.

The 6G5 tuning indicator tube is employed.

Two single speaker and one dual speaker arrangements are used with this chassis. Connections for each of the three types are shown in the schematic circuit diagram Fig. 2.

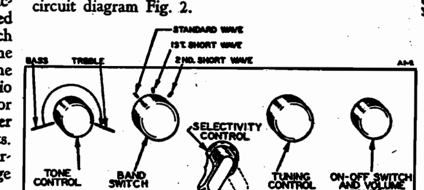

Fig. 1—Arrangement of Controls

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Replacement Parts

Series A3 also Series A6

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

TRANSFORMERS AND COILS

Part No.	Code	Description	List Price
9A794	T1	Antenna Transformer and Can Assembly—B Range Secondary; C & D Range	$2.00
9A795	T2	Antenna Coil Assembly "B" Range	1.25
9A796	T3	R.F. Interstage Transformer and Can Assembly	2.20
9A797	T4	Oscillator Coil and Can Assembly	$3.60
9A798	T5	1st I.F. Transformer and Can Assembly	2.65
9A799	T6	2nd I.F. Transformer and Can Assembly	2.40
9A800	T7	3rd I.F. Transformer and Can Assembly	2.40
50X34	T8	Input Transformer	1.50
	T9	Output Transformer (See Speakers)	
53X152	T10	117-234 Volt, 40-60 Cycle, Universal Power Transformer	8.70
53X165	T10	117 Volt, 60 Cycle, Power Transformer	6.25
53X166	T10	117 Volt, 25 Cycle, Power Transformer (When replacing a 60 Cycle Transformer with a 25 Cycle Transformer, a 25 Cycle Motor must also be ordered for the Electric Drive Models.)	9.90
52X49	L2	Filter Choke	2.40

3A12	Phono Jack only, of phono cable	.10
10A90	Knob only, of phono cable	.20

DIAL AND DRIVE ASSEMBLY

DIAL AND DRIVE PARTS WILL BE FOUND IN SPECIAL DIAL AND DRIVE NOTES (see index)

METAL TUBES ARE IN SAME POSITIONS AS GLASS EQUIVALENTS SHOWN IN LAYOUT.

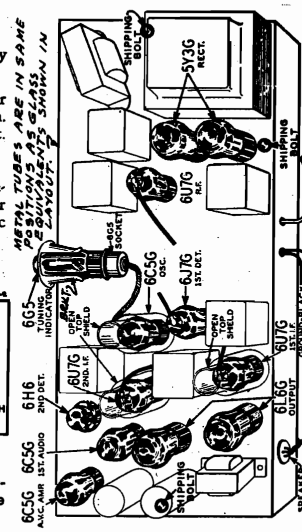

Fig. 5—Location of Tubes

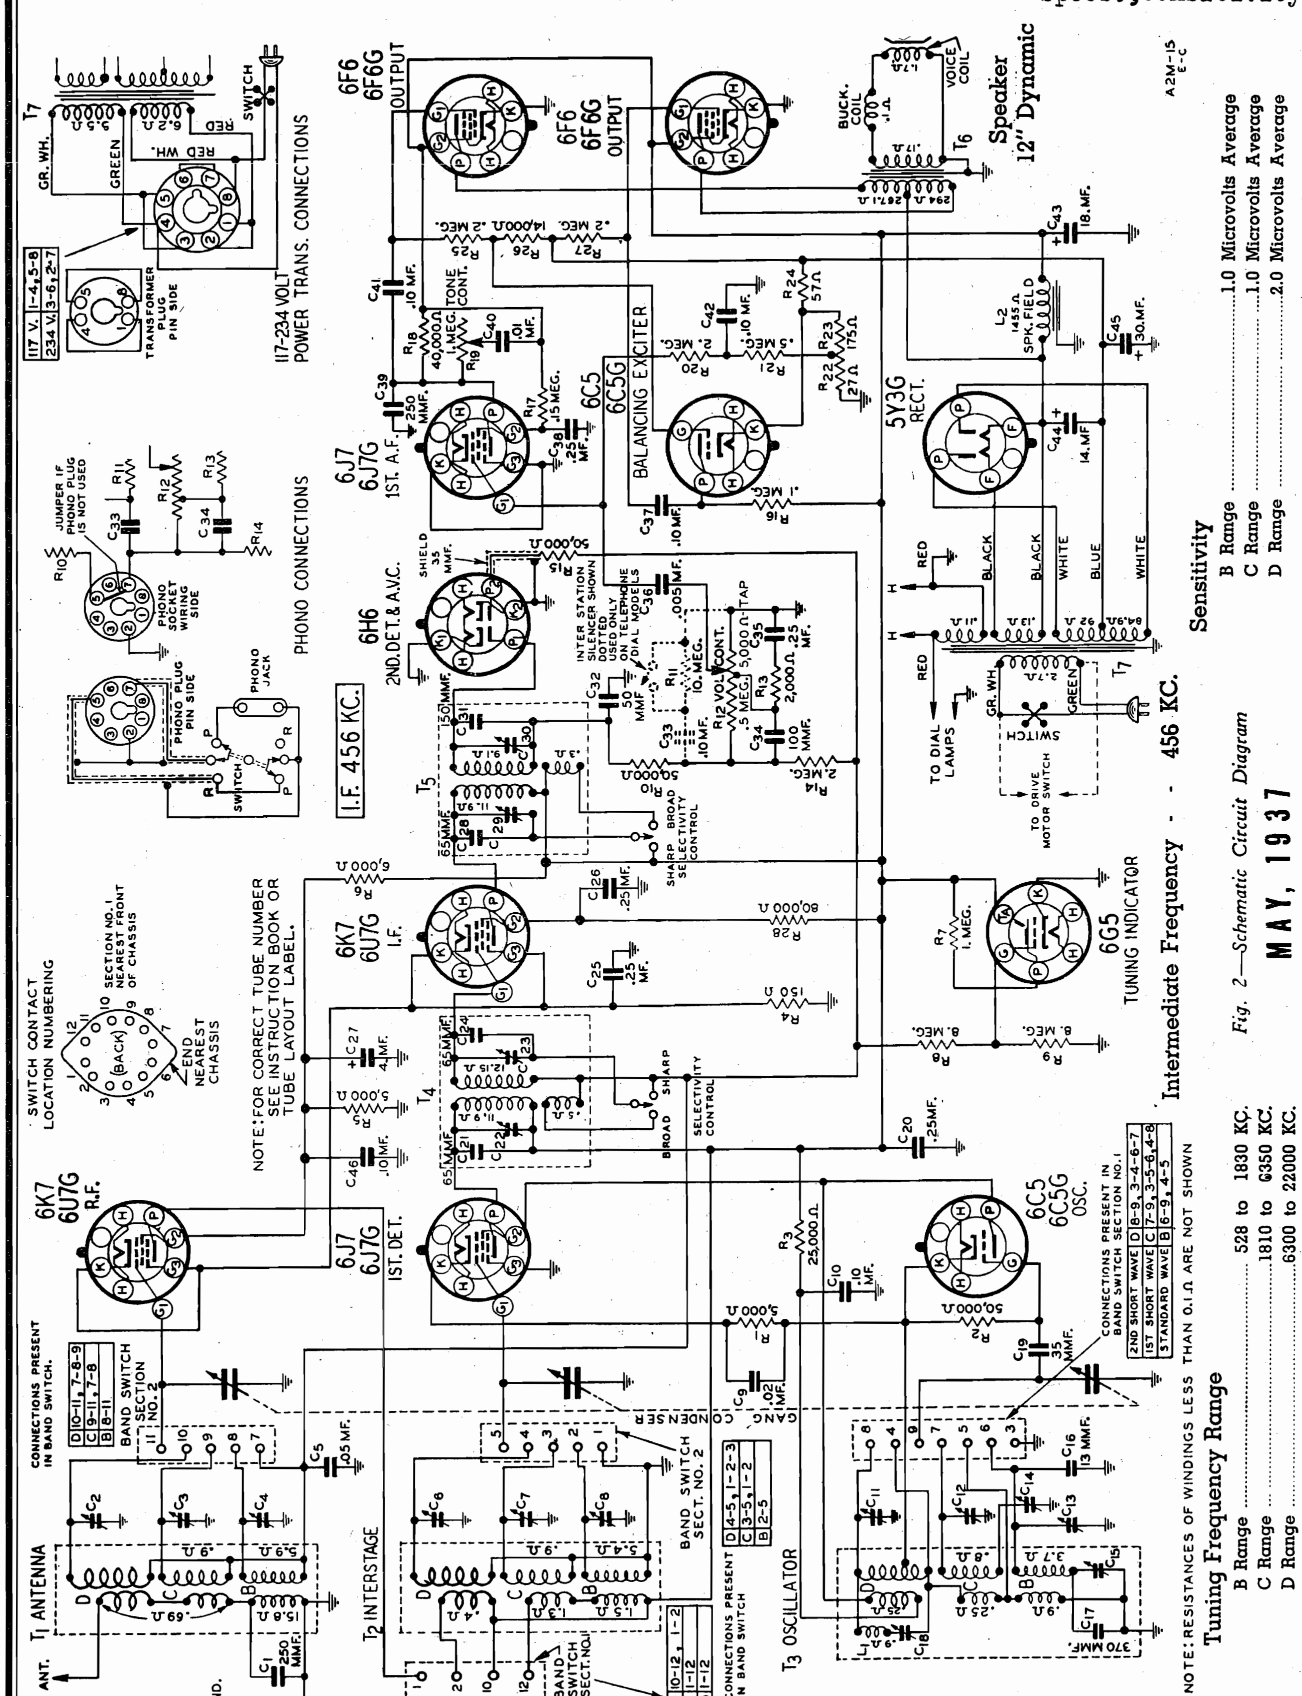
Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service NOTES, issued for this chassis. (see index)

MODEL A2 Series
Schematic, Phono.
Specs., Sensitivity

WELLS-GARDNER & CO.



Sensitivity

B Range .... 1.0 Microvolts Average
C Range .... 1.0 Microvolts Average
D Range .... 2.0 Microvolts Average

Intermediate Frequency - - 456 KC.

Fig. 2—Schematic Circuit Diagram

MAY, 1937

NOTE: RESISTANCES OF WINDINGS LESS THAN 0.1 Ω ARE NOT SHOWN

Tuning Frequency Range

B Range .... 528 to 1830 KC.
C Range .... 1810 to 6350 KC.
D Range .... 6300 to 22000 KC.

Power Consumption - 100 Watts (At 117 volts 60 cycles)

Selectivity (Sharp) - - 27 KC Broad at 1000 times Signal

Power Output - - - - - - - 9.8 Watts Undistorted, 12 Watts Maximum

MODEL A2 Series
Trimmers, Alignment
Circuit Data, Coils

WELLS-GARDNER & CO.

SERIES A2

11 TUBE • 3 BAND • ALL WAVE

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter — Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED *See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT
I. F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C29) & (C30)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C22) & (C23)	Turn Rotor to Full Open	Adjust to Maximum Output
RANGE B							
1830 KC	Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C13)	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	Ant. Range B (C4) Int. Range B (C8)	Turn Rotor to Max. Output Set Indicator to 1500 KC— See Note A	Adjust to Maximum Output
600 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C15)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE C							
6350 KC	Range C	400 Ohm	6350 KC	Antenna Lead	Oscillator Range C (C12)	Turn Rotor to Full Open	Adjust to Maximum Output
6000 KC	Range C	400 Ohm	6000 KC	Antenna Lead	Antenna Range C (C3) Int. Range C (C7)	Turn Rotor to Max. Output	Adjust to Maximum Output
2000 KC	Range C	400 Ohm	2000 KC	Antenna Lead	2000 KC (C14)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE D							
22,000 KC	Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C11)	Turn Rotor to Full Open	Adjust to Maximum Output
20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Ant. Range D (C2) Int. Range D (C6)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C18)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

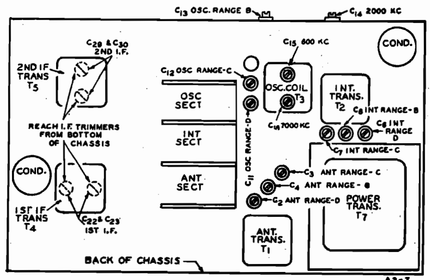


Fig. 3—Location of Trimmers

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R.F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. The band switch sections are designated in the schematic as section 1 and section 2.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed through the interstage R.F. transformer with tuned secondary into a 6J7 tube which functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

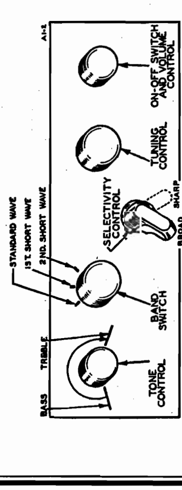

Fig. 1—Arrangement of Controls

Referring to the 1st and 2nd I.F. transformers T4 and T5 in Fig. 2, it will be noted that there is a coupling winding shown below the primary of T4 and below the secondary of T5.

When the selectivity control is in the sharp position, the coupling windings are open circuited and the loose coupling which exists between the primary and secondary of these transformers results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary in the case of T4 is connected in series with the secondary. In the case of T5, the coupling winding which is wound under the secondary is in series with the primary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R.F. and I.F. tubes.

Across the volume control resistor R12 is a filter composed of condensers C34 and C35 and resistor R13. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

The output of the 2nd detector is applied to the 6J7 1st A. F. tube. The output of this tube is fed thru resistance coupling into the 6F6 output tube shown nearest to it in the schematic.

A portion of the voltage developed across the output tube grid resistor is applied to the control grid of the 6C5 balancing exciter tube. This tube functions as a phase inverter and applies the audio voltage of proper phase and amplitude to the other 6F6 output tube. The two output tubes operate as a stage of Class A push-pull amplification. The balancing exciter tube thus replaces a push-pull input transformer. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

Glass and Metal Tubes

All sets of this series use a 6H6 metal tube and 5Y3G and 6G5 glass tubes.

It will be noted in the schematic that there are two tube type numbers shown at the other sockets. The "metal" tube sets use the upper tube type numbers which are for metal tubes while the "glass" tube sets use the lower tube type numbers which are for glass tubes.

Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

WELLS-GARDNER & CO.

MODEL A2 Series
Socket, Voltage
Changes, Data
Parts List

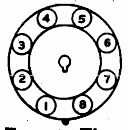

Fig. 7—Octal Tube Terminal Numbering (bottom of socket).

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true—the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the front panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

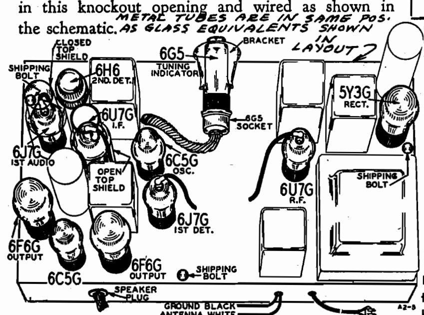

Fig. 4—Location of Tubes

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—see Fig. 2.

117-234 Volt Power Transformers

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Notes issued for this chassis. (see index)

Changes in Later Models

Later models of this series have the following changes incorporated in them.

On the first models, the 2nd I.F. Coil was not expanded. In other words, the extra selectivity coupling winding was not incorporated in the early type coil. Models with the letter "C" or any later issue stamped on the chassis use the new type coil with the selectivity coupling winding. Because of the change in coil connections, the selectivity switch used on the late model is not interchangeable with that on the early model.

When ordering parts, therefore, it is important that the issue letter on the chassis be noted and the correct part number as shown in the parts list be specified.

VOLTAGES AT SOCKETS

Line Voltage: 117—Volume Control: Maximum
Readings taken with 1000 Ohm-per-volt meter.
Antenna Shorted to Ground
Position of Band Switch: Standard Wave

TUBE	FUNCTION	VOLTAGE BETWEEN SOCKET PRONG AND GROUND (Unless otherwise indicated)							
		Prong No. 1	Prong No. 2	Prong No. 3	Prong No. 4	Prong No. 5	Prong No. 6	Prong No. 7	Prong No. 8
6K7 6U7G	R.F.	0	6.1(1)	250	105	2.5		6.1(1)	2.5
6J7 6J7G	1st Det.	0	6.1(1)	250	125	0		6.1(1)	5.8
6C5 6C5G	Osc.	0	6.1(1)	125(2)				6.1(1)	0
6K7 6U7G	I.F.	0	6.1(1)	250	100	2.5		6.1(1)	2.5
6H6	2nd Det.—A.V.C.	0	6.1(1)					6.1(1)	0
6J7 6J7G	1st A.F.	0	6.1(1)	110	120	0(3)		6.1(1)	0(3)
6C5 6C5G	Balancing Exciter	0	6.1(1)	100				6.1(1)	18.5
6F6 6F6G	Output	0	6.1(1)	330	250			6.1(1)	0(4)
5Y3G	Rectifier	0	4.8(5)		730(6)		730(6)		4.8(5)
6G5	Tuning Indicator	Plate to Ground 20		Target to Ground 250		Cathode to Ground 0		Across Heater 6.1 A.C.	

(1) A.C. voltage as read across heater terminals 2 and 7.
(2) Subject to variation.
(3) Bias (2.5 volts) as read across resistor R22.
(4) Bias (24 volts) as read across resistors R22, R23, & R24.
(5) A.C. voltage as read across filament terminals 2 and 8.
(6) A.C. voltage as read across terminals 4 and 6.

The R.F. circuit of early models was slightly different from that used in later models. The screen grids of the R.F. and I.F. tubes now supplied by separate voltage sources were formerly connected together and supplied from a single source. On the latter models, resistor R 28 and condenser C 46 were not used.

Series A2 Replacement Parts

NOTICE—There is a large letter on the chassis which identifies the set as to major part changes. When ordering parts, please be sure to mention the series number and this large letter.

SERIES A4

HOME RADIO
A. C. POWER SUPPLY
7 TUBE • 2 BAND
JULY, 1937

Phonograph Connections

Phonograph connections are made as shown in Fig. 7. On the side panel of the chassis base is a round knockout 1⅛ inch in diameter. An octal base socket is mounted in this knockout opening and wired as illustrated.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

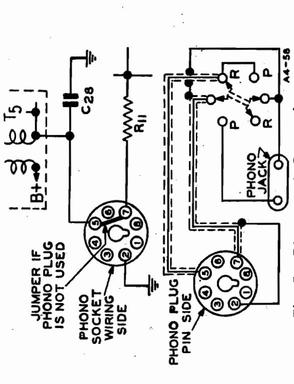

Fig. 7—Phonograph Connections

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Notes for this chassis. (see index)

117-234 Volt Power Transformer

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

SERIES A4

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator With a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter; Non-Metallic Screwdriver.
Dummy Antennas — .1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT
I.F.							
2nd I.F.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C25) & (C26)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C19) & (C20)	Turn Rotor to Full Open	Adjust to Maximum Output
Range B							
1830 KC	Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C12)	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	1st Ant. Range B (C2) 2nd Ant. Range B (C4)	Turn Rotor to Max. Output Set Indicator to 1500 KC—See Note A	Adjust to Maximum Output
600 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C9)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B
Range D

6000 KC	Range D	400 ohm	6000 KC	Antenna Lead	6000 KC (C8)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor—See Note B

7 TUBE • 2 BAND

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

In sets using a pointer or any other type of dial mechanism, it will be necessary to adjust the position of the indicator until it is at the 1500 KC mark.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave band, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 15,000 KC. The signal will then be heard at 15,000 on the dial of the radio. The image signal, which is much weaker, will be heard at 15,000 less 912 KC, or 14,088 KC on the dial. It may be necessary to increase the input signal to hear the image.

Notice—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

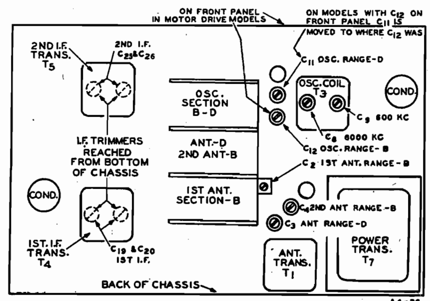

Fig. 3—Location of Trimmers

Circuit

This model is a two band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna coil assemblies and T3 is the oscillator coil assembly. The standard wave and short wave coils in each assembly are indicated by the letters B and D respectively.

The band switch completes connections to the coils in use. When it is in the Range B position, a double tuned antenna R.F. stage is used while for the D Range, a single tuned secondary is used.

A type 6J7 tube functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T4. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

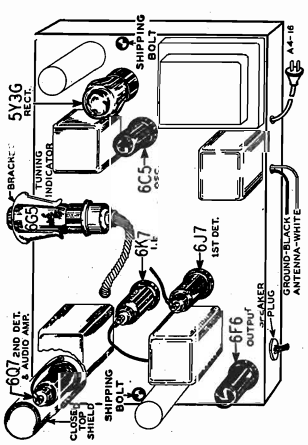

Fig. 5—Location of Tubes

A type 6Q7 duo-diode triode functions as the second detector and a one stage audio amplifier. AVC voltage is applied to the 1st detector and I.F. tubes.

Resistance coupling is used between the 1st audio stage and the output stage which employs a type 6F6 ouput pentode tube. A dynamic reproducer is used.

The power unit uses a 5Y3G full wave rectifier.

A 6G5 tuning indicator tube is employed.

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true, the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

SERIES A5

9 TUBE • 3 BAND • ALL WAVE

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator With a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for Several Minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter; Non-Metallic Screwdriver.
Dummy Antennas—.1 mf., 200 mmf., and 400 ohms.

STEP (Follow Order as Given)	BAND SWITCH SETTING	DUMMY ANTENNA	SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	TRIMMERS ADJUSTED See Illustration	PROCEDURE INITIAL STEPS	PROCEDURE ADJUSTMENT
I.F.							
2nd I.F. Adj.	Range B	.1 mf.	456 KC	Grid of I.F. Tube	2nd I.F. (C28) & (C29)	Turn Rotor to Full Open	Adjust to Maximum Output
1st I.F. Adj.	Range B	.1 mf.	456 KC	Grid of 1st Det.	1st I.F. (C22) & (C23)	Turn Rotor to Full Open	Adjust to Maximum Output
RANGE B							
1830 KC	Range B	200 mmf.	1830 KC	Antenna Lead	Oscillator Range B (C14)	Turn Rotor to Full Open	Adjust to Maximum Output
1500 KC	Range B	200 mmf.	1500 KC	Antenna Lead	Ant. Range B (C4) Int. Range B (C8)	Turn Rotor to Max. Output Set Indicator to 1500 KC—See Note A	Adjust to Maximum Output
600 KC	Range B	200 mmf.	600 KC	Antenna Lead	600 KC (C10)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE C							
6350 KC	Range C	400 Ohm	6350 KC	Antenna Lead	Oscillator Range C (C13)	Turn Rotor to Full Open	Adjust to Maximum Output
6000 KC	Range C	400 Ohm	6000 KC	Antenna Lead	Antenna Range C (C3) Int. Range C (C7)	Turn Rotor to Max. Output	Adjust to Maximum Output
2000 KC	Range C	400 Ohm	2000 KC	Antenna Lead	2000 KC (C15)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
RANGE D							
22,000 KC	Range D	400 Ohm	22,000 KC	Antenna Lead	Oscillator Range D (C12)	Turn Rotor to Full Open	Adjust to Maximum Output
20,000 KC	Range D	400 Ohm	20,000 KC	Antenna Lead	Ant. Range D (C2) Int. Range D (C6)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B
7000 KC	Range D	400 Ohm	7000 KC	Antenna Lead	7000 KC (C9)	Turn Rotor to Max. Output	Adjust to Maximum Output Rock Rotor — See Note B

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—In sets using the telephone dial tuning, there will be seen inside the telephone dial button ring an escutcheon plate held in place by four screws. Loosen the 2 screws nearest the pointer. An extension of the pointer will be seen protruding over the edge of this escutcheon plate. Move the pointer to the 1500 KC mark on the dial and then tighten the 2 escutcheon screws. (Do not tighten these screws too much.)

In sets using the moving beam of light indicator, there is a moving light assembly held to the front of the drive drum by means of a screw. Loosen this screw and move the light assembly until the beam is at the 1500 KC mark on the dial. Retighten the screw.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

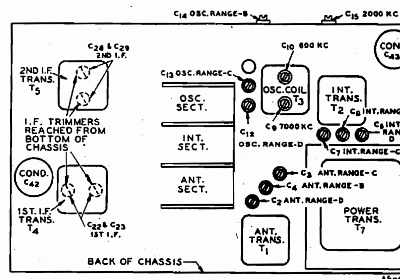

Fig. 3—Location of Trimmers

Circuit

This model is a three band AC operated radio with a tuning range as shown in the specifications above.

Referring to the schematic circuit diagram, Fig. 2, T1 and T2 are the antenna and interstage R.F. transformer assemblies and T3 is the oscillator coil assembly. The standard wave, 1st and 2nd short wave coils in each assembly are indicated by the letters B, C and D respectively.

The band switch completes connections to the coils in use. The band switch sections are designated in the schematic as section 1 and section 2.

The antenna transformer with tuned secondary feeds into a type 6K7 R.F. amplifier tube. The output of this tube is fed through the interstage R.F. transformer with tuned secondary into a 6J7 tube which functions as the 1st detector.

A separate type 6C5 tube is employed in the oscillator circuit. The oscillating circuit is always resonant at 456 KC above the frequency to which the R.F. amplifier is tuned.

One stage of I.F. amplification is employed using a 6K7 tube. The primaries and secondaries of the 1st and 2nd I.F. transformers are tuned by small trimmer condensers.

Referring to Fig. 2, it will be noted that there is a coupling winding connected in series with the secondary of I.F. transformer T4. When the selectivity control is in the sharp position, the coupling winding is open circuited and the loose coupling which exists between the primary and secondary of this transformer results in high selectivity.

When the selectivity control is in the broad position, the coupling winding which is wound under the primary is connected in series with the secondary. This provides overcoupling which results in a greatly widened resonance curve. Passage of a wide range of audio frequencies is thus obtained.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R.F. and I.F. tubes.

Across the volume control resistor R15 is a filter composed of condensers C32 and C33 and resistor R14. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

A 6F5 triode tube functions as the first audio amplifier while the output stage uses a 6F6 output pentode tube. A dynamic reproducer is employed.

The power unit uses a 5Y3G full wave rectifier. A 6G5 tuning indicator tube is employed.

MODEL A5 Series
Socket, Coils, Data
Parts List

General Service Data

117-234 Volt Power Transformer

Some models are equipped with a 117-234 volt 40 to 60 cycle power transformer. Connections as shown in Fig. 2 are completed to a special octal socket mounted on the back panel of the chassis. A plug which goes with this socket may then be inserted for either the 117 volt or 234 volt connection.

If one of these transformers is to be installed in a chassis equipped with a regular transformer, there is a 1⅛ inch round knockout on the back panel which may be removed to permit installation of the octal socket mentioned above.

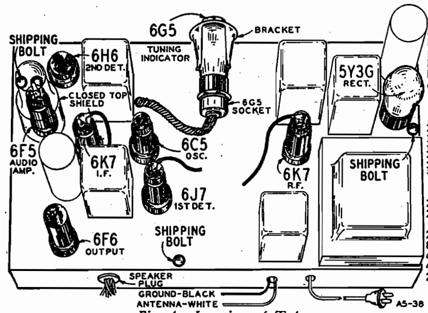

Fig. 4—Location of Tubes

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

The twenty-five cycle receiver can be operated satisfactorily from a sixty cycle power supply. However, the reverse is not true—the sixty cycle receiver cannot be operated from a twenty-five cycle power supply.

Dial and Drive Assembly

Complete information regarding the dial and drive assemblies will be found in the Dial and Drive Service Notes issued for this chassis. (see index)

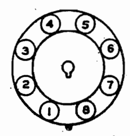

Fig. 5—Octal Tube Terminal Numbering (bottom of socket).

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 2. On the front panel of the chassis base is a round knockout 1⅛ inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 2.

Series A5 - Replacement Parts

MISCELLANEOUS

SOCKETS

Part No.	Description	List Price
3A263	Tube Socket—Octal (8 prong)	$0.15
3A256	Tube Socket—Octal (7 prong)	.15

Series C6 Replacement Parts

The following parts list covers two types of the Series C6 auto radio.

Type "A" has a rectangular dial scale with a sliding pointer.

Type "B" has a circular dial scale with a rotating pointer disc.

All parts shown are common to both types of radios except in the case of part numbers with the letter "A" or "B" in front of them.

Part numbers with a letter in front of them are used only on the type radio indicated by the letter.

NOTICE—There is a chassis number label on the inside of the bottom chassis cover. This chassis number identifies the radio as to chassis, dial, and issue number. When ordering parts or writing, be sure to mention the chassis number.

	3	¼" Split Lockwashers (Used with above Wing Nuts) ... Doz.	.05
	1	¼"—20 X 1" Flat Head Bolt (Used to hold Mounting Strap to Fire Wall or Cowl) ... Doz.	.10
	1	¼"—20 Hex Nut (Used on above Flat Head Bolt) Doz.	.05
19X42	1	Flat Washer (Used on above Flat Head Bolt) ... Doz.	.05

Issue Number

The last number of the number on the chassis number label identifies the radio as to the issue number. In this model, this label will be found on the inside of the bottom chassis cover.

Issue No. 1

Mechanical Assembly—The 2 front mounting studs are attached to the top of the chassis case.

The I.F. coil cans have a spring clip by means of which they are secured to the chassis.

The back of the chassis case is not removable.

Electrical Assembly—See electrical changes under "Issue No. 2."

Issue No. 2

Mechanical Changes—The chassis case is supplied with a front mounting bracket and this bracket is secured to the instrument panel of the car by means of 2 separate bolts.

The I.F. cans use a threaded spade lug which extends through the chassis base and is secured in place with nuts and lock washers.

The back of the chassis case can be removed.

Electrical Changes—The following changes are all illustrated in the schematic—Fig. 1.

The 6H6 tube plate No. 1, which was connected originally to ground is removed from ground and connected as shown in the schematic.

Condenser C20 is removed.

The position of condenser C21 is changed as shown.

Resistor R15 (200 ohms) is removed and replaced by choke L4.

Two Models of C6 Radio

There are 2 models of Series C6 auto radio.

One model has a rectangular dial scale with a sliding pointer.

The other model has a circular dial scale with a rotating pointer disc.

The 2 models also differ in the capacities of the antennas which may be used. The values are shown in article "Antenna Capacity."

MODEL C6 Series
Socket, Circuit Data
Drive Cord Data
Alignment

WELLS-GARDNER & CO.

Circuit

This model is a 5 tube automobile radio with a tuning range as shown in the specifications above. The signal is fed through an antenna transformer with tuned secondary into a 6A8G tube which functions as the 1st detector and oscillator. The end connection and tap connection on the primary of the antenna transformer permit the use of a high or low capacity car antenna.

The oscillating circuit is always resonant at 456 KC above the frequency to which the antenna circuit is tuned.

Resistance coupling is used between the 1st audio stage and the output stage, which employs a type 6K6G pentode output tube. A dynamic reproducer is used.

One stage of I.F. amplification is employed using a 6U7G tube.

A type 6H6 tube functions as the 2nd detector and AVC tube. AVC voltage is applied to the control grid circuits of the 1st detector and I.F. tubes.

A 6F5G tube is used in the first audio stage.

A synchronous type vibrator is used in the power unit. This vibrator interrupts the current through the primary of the power transformer and also rectifies the current in the secondary circuit.

Polarity in inserting the vibrator must be observed. It can be inserted in two ways, and the correct method depends on which terminal of the car storage battery is grounded.

SERIES C6

5 TUBE

AUTO RADIO

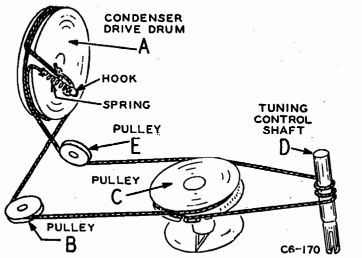

Fig. 2—Replacing Drive Cord—Rotating Pointer Models

Drive Cord Replacement—Rotating Pointer Models

Tie a knot with a small loop at one end of the new drive cord. The free end of the drive cord is tied to the tension spring. The distance between knots should be 23⅙ inches.

Turn the gang condenser to full open position.

Place the looped end of the drive cord over the hook on condenser drive drum A—See Fig. 2 (Shown with gang condenser half open). Bring the cord up through the slot in the drum rim and wind one-half turn to the rear (from front of chassis) around the drive drum. Pass cord around the pulley B as shown. Wind one turn clockwise (from front of chassis) around pointer disc pulley C. Loop cord through the notches on the outside rim of the pointer disc pulley as shown. Wind 2½ turns clockwise, progressing from a point midway between the bracket arms toward the chassis, on tuning control shaft D. Bring cord to the left under pointer disc pulley C and around pulley E as shown. Pass cord to top of drive drum A and wind one turn to the rear around the drum rim.

Pass the remaining drive cord and tension spring through the slot in the drum rim. Place free end of spring over the hook on the condenser drive drum.

Setting Pointer Disc—Tune in an 800 KC signal. Hold the tuning shaft and turn the pointer disc until the pointer is at the correct position when the chassis front cover is put back in place.

Drive Cord Replacement—Sliding Pointer Models

Remove the celluloid dial scale. Open the clamps on the back of the dial pointer in order to remove the old drive cord.

It is not necessary to remove the dial and drive bracket assembly in order to replace the drive cord.

Tie a knot with a small loop at one end of the new drive cord. Slide a ½ inch length of fabric tubing on the cord. Tie the free end of the drive cord to the tension spring. The distance between knots should be 28⅝ inches.

Turn the gang condenser to full open position.

Place the looped end of the drive cord over the hook on condenser drive drum A—See Fig. 3. Bring the cord up through the slot in the drum rim.

Turn the drive drum to the position shown in Fig. 3.

Wind one turn down and around drive drum A and around pulley B as shown. Wind 3½ turns on tuning control shaft C, progressing from a point midway between the two bracket arms toward the chassis. Bring cord under pulley D and around pulleys E and F as shown. See that the fabric tubing is now between pulleys E and F. Bring the drive cord to the rear around drive drum A and through the slot in the drum rim as shown.

Turn the gang condenser to full open position and place the free end of the tension spring over the hook on drive drum A.

Dial Pointer Adjustment—Mount the celluloid dial scale on the dial bracket. Tune in a signal of known frequency near one end of the dial scale. Move the pointer assembly to this frequency on the dial scale and tighten the clamps with long nose pliers.

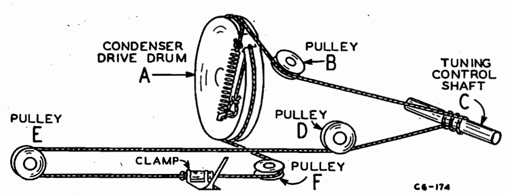

Fig. 3—Replacing Drive Cord—Sliding Pointer Models

Alignment Procedure

Remove the bottom and front chassis covers. Directions for removing the bottom cover are in the instruction book.

To remove the front cover, first pull the knobs and buttons off the shafts. Remove the 2 screws at the top and the 2 screws at the sides of the front cover. Press in the sides of the chassis case to release the lugs at the sides of the front cover. Pull outward on the bottom of the front cover and then push the cover up until the lugs at the top are released.

Do not remove the back of the chassis case. This back can be taken off of the No. 2 and later issue sets.

Set the signal generator for 456 KC and connect the output of the signal generator through a .05 mf. condenser to the control grid of the 1st Detector. Connect the ground lead of the signal generator to the chassis. Set the volume control at maximum. Attenuate the signal from the signal generator to prevent the leveling off action of the AVC.

Then adjust the 4 I.F. trimmers until maximum output is obtained. These trimmers can be reached through the 4 holes in the back wall of the chassis case. It will be necessary to pull out the fiber insulating sheet a slight amount.

Insert the antenna cable plug in the antenna socket on the chassis.

Rotating Pointer Models—If the antenna is connected at the HC terminal and the entire 60-inch shielded cable (70 mmf.) is being used, connect the antenna wire at the other end through a 120 mmf. condenser to the antenna post of the signal generator.

If the antenna is connected at the LC terminal, the antenna cable has been cut as explained in the instructions. If cut in half (30-inch length), the capacity of the antenna cable is approximately 35 mmf. Connect the antenna wire, in this case, through a 25 mmf. condenser to the antenna post of the signal generator.

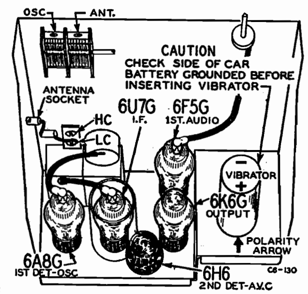

Fig. 4—Location of Tubes

Sliding Pointer Models—If the antenna is connected at the HC terminal and the 60-inch shielded cable (70 mmf.) is being used, connect the antenna wire at the other end through a 230 mmf. condenser to the antenna post of the signal generator.

If the antenna is connected at the LC terminal and the short shielded cable (19 mmf.) is being used, connect the antenna wire, in this case, through a 20 mmf. condenser to the antenna post of the signal generator. If the long cable has been cut to length and is being used, the total capacity of the cable and the series condenser should be 38 to 40 mmf.

Both Models—Set the signal generator for 1550 KC. Turn the rotor of the tuning condenser to the full open position. Adjust the trimmer of the oscillator section of the gang condenser until maximum output is obtained. See Fig. 4 for location of this trimmer.

Set the signal generator for 1400 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the trimmer of the antenna section of the gang condenser for maximum output.

Calibration—Rotating Pointer Models—To obtain dial scale calibration, tune in an 800 KC signal. Hold the tuning shaft and turn the pointer disc until the pointer is at the correct position when the chassis front cover is put back in place.

Calibration—Sliding Pointer Models—The pointer assembly is clamped to the drive cord and it is seldom necessary to reset it to obtain proper dial calibration. If re-calibration is required, loosen the clamps with a screw driver, bringing the pointer assembly first down to one end of the dial scale and then down to the other end. Tune in a signal of known frequency near one end of the dial scale. Move the pointer assembly to this frequency on the scale and tighten the clamps with long nose pliers.

Inserting Vibrator Unit

IMPORTANT—The vibrator unit can be inserted in two ways. The proper method of insertion will depend on which terminal of the car battery is grounded. If the POSITIVE (+) terminal of the car battery is grounded, line up the + mark on the top of the vibrator with the arrow on the chassis base. If the NEGATIVE (−) terminal of the car battery is grounded, line up the − mark on the top of the vibrator with the arrow on the chassis base.

Antenna Capacity

Rotating Pointer Models—The antenna coil is designed for car antennas with a capacity of 190 mmf. for the HC connection and 60 mmf. for the LC connection. This capacity is the total capacity of the antenna and the shielded lead.

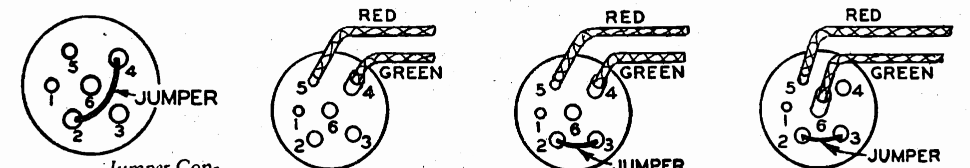
Complete information regarding car antenna installation will be found in the instruction book packed with the radio.

Sliding Pointer Models—The information for this type of radio is the same as above except that the HC capacity is 300 mmf. and the LC capacity is 38 mmf.

MODEL 6J Series
Schematic, Notes
Speaker Connections

WELLS-GARDNER & CO.

Roof Speaker and Dual Speaker Connections



-Jumper Connection for Chassis Speaker only

-Single 5¼ Inch Roof Speaker

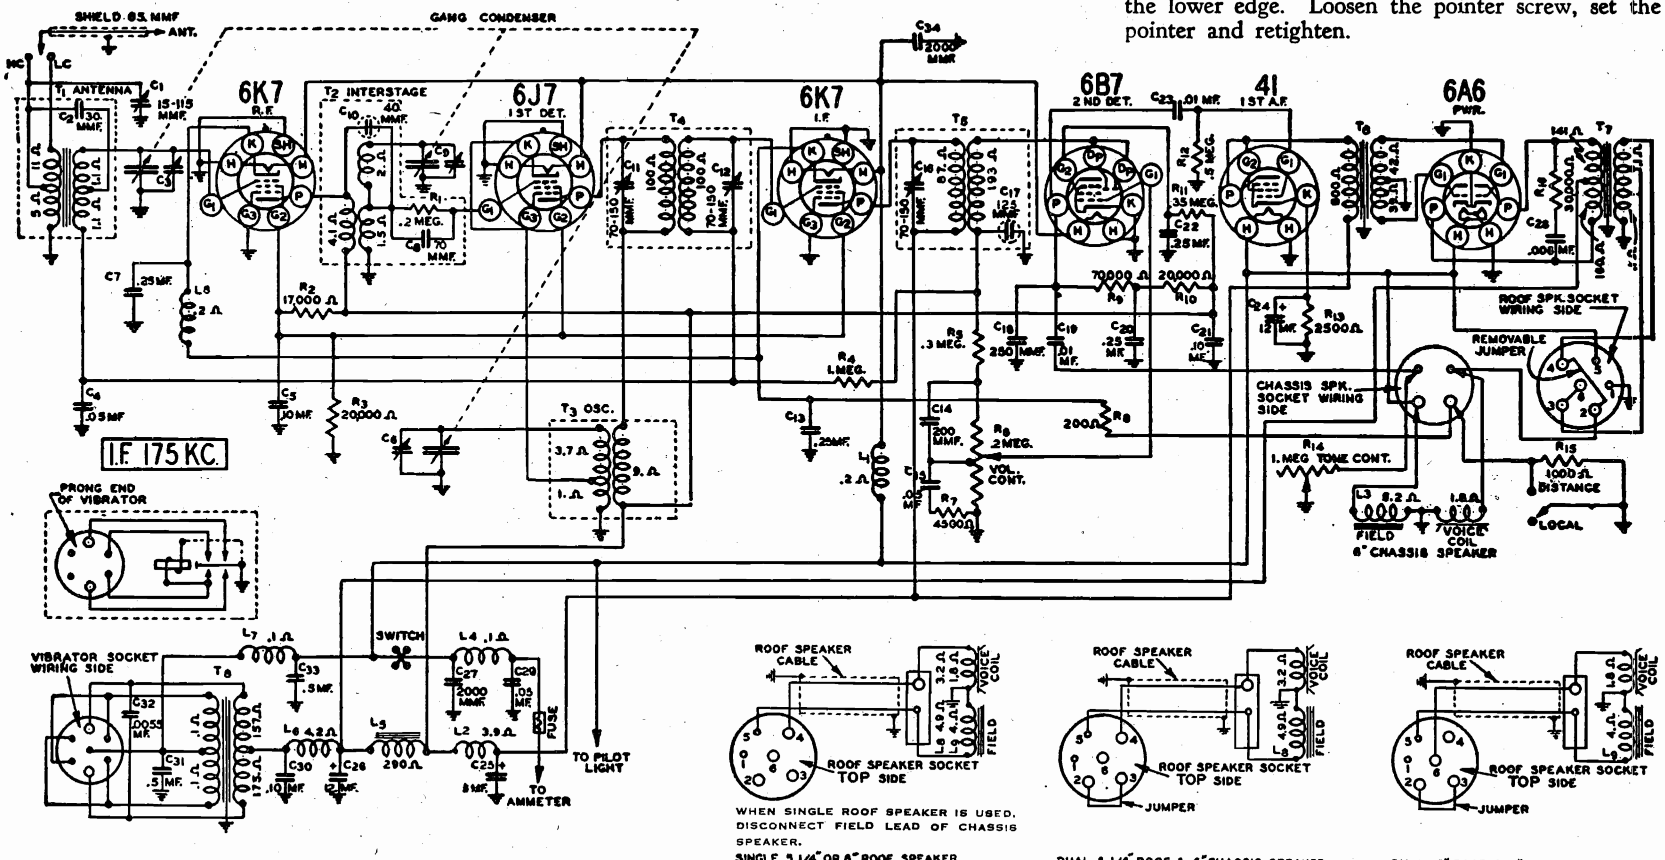
Dual 5¼ In. Roof & 6 In. Chassis Speakers

-Dual 8 Inch Roof and 6 Inch Chassis Speakers.

Calibrating the Radio

To calibrate the radio, tune in a station of known frequency. At the back of the control head is the calibration screw—see Fig. 10. Remove the pilot lamp assembly. Insert a fine blade screwdriver and turn this screw until the pointer on the dial scale is at the frequency of the station being received. The knob must be held during this adjustment.

If the control head is inaccessible it may be calibrated by setting the pointer from the front. Remove the crystal by inserting a knife blade under the lower edge. Loosen the pointer screw, set the pointer and retighten.



Inserting Vibrator Unit

Note that the vibrator unit can be inserted in two ways. The proper method of insertion will depend on which side of the car battery is grounded. Complete information is shown on the label on the vibrator.

Series 6J

MODEL 6J Series
Socket, Trimmers
Alignment, Changes

WELLS-GARDNER & CO.

CHANGES IN LATER MODELS

SERIES 6J — June, 1937

Later models of the Series 6J have changes incorporated in them which are explained **below.** The models which have these changes may be identified by the issue letter which is a large letter stamped on top of the chassis base. The tube arrangement label on the chassis case cover also shows this issue letter.

When ordering parts, it is important that the issue letter be noted and the correct part number, as shown in the parts list, be specified.

The "D" issue Series 6J is different from the "B" and "C. The gang condenser used in the "D" issue radios does not have the cut plate oscillator section. A padding condenser (600 KC) was added in series with the oscillator section of this gang condenser and the oscillator coil. The padding condenser is a part of the 2nd I. F. trimmer unit and is mounted in the 2nd I. F. coil can.

The capacity (C17) shown within a dotted circle in the 2nd I.F. coil assembly on the schematic has been changed to an actual part as shown in the supplementary parts list.

The antenna, R.F. Interstage, oscillator, and 2nd I.F. coil assemblies have been changed and have been given new part numbers as shown in the supplementary parts list.

SUPPLEMENTARY REPLACEMENT PARTS

The PARTS of the Series 6J are used on the Series 6J "D" issue Radio with the following EXCEPTIONS:

PRICES ARE SUBJECT TO CHANGE WITHOUT NOTICE

THE FOLLOWING NEW PARTS ARE USED:

No.	Code	Description	List Price
9A859	T1	Antenna Transformer and Can Assembly.......	$1.65
9A861	T2	R. F. Interstage Transformer and Can Assembly....................................	1.75
9A862	T3	Oscillator Coil and Can Assembly....	.95
9A858	T5	2nd I. F. Transformer and Can Assembly.....	2.35

17A79	(C16 (	30-100 mmf. 2nd I.F. Trimmer) 900-1300 mmf. Oscillator 600 KC Padder)...	.45
14A77		3 Section Gang Condenser Complete with Drive Gears......................................	5.05

THE FOLLOWING PARTS OF THE SERIES 6J ARE NOT USED ON THE SERIES 6J "D" ISSUE RADIO:

9A740) or 9A771)	T1	Antenna Transformer and Can Assembly.......	$1.65
9A741) or 9A765)	T2	R.F. Interstage Transformer and Can Assembly....................................	1.70
9A742) or 9A772)	T3	Oscillator Coil and Can Assembly...........	.85
9A744	T5	2nd I.F. Coil and Can Assembly.............	1.60
17A65	C16	30-100 mmf. 2nd I.F. Trimmer.............	.20
14A65		3 Section Gang Condenser Complete with Drive Gears..................................	5.85

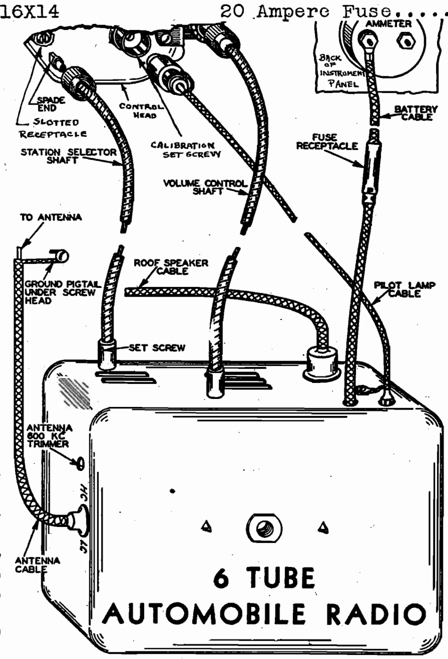
The Following Changes apply to all Issues of the Series 6J:

THE FOLLOWING NEW PARTS ARE USED:

46X213	C29	.5 mf. 180 volt Tubular Condenser........	$0.30
16X16		15 Ampere Fuse..............................	.10

THE FOLLOWING PARTS ARE NOT USED:

46X207	C29	.5 mf. 180 volt Tubular Condenser........	$0.30
16X14		20 Ampere Fuse..............................	.10



General Installation View

Alignment Procedure

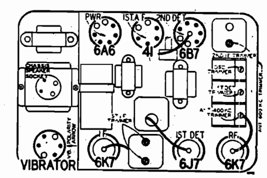
Set the signal generator for 175 KC and connect the output of the signal generator through a .05 mf. condenser to the stator of the 1st detector section of the tuning condenser. Set the volume control at the maximum position and attenuate the signal from the signal generator to prevent the levelling off action of the AVC. Then adjust the three IF trimmers until maximum output is obtained

Set the signal generator for 1581 KC. Turn the rotor of the tuning condenser to the full open position. Insert the antenna plug with the mark on the high capacity (HC) side. Connect the shielded antenna lead from the chassis through a 120 mmf. condenser to the antenna post of the signal generator. Adjust the trimmer of the oscillator section of the three gang condenser until maximum output is obtained.

Set the signal generator for 1400 KC. Turn the rotor of the tuning condenser carefully until maximum output is obtained. Adjust the 1st detector and antenna 1400 KC trimmers for maximum output. Do not change the setting of the oscillator trimmer.

Then set the signal generator for 600 KC and adjust the 600 KC antenna trimmer to maximum (see Fig. 10 for location of this trimmer).

After the alignment procedure is completed, the antenna plug may be withdrawn and reinserted on the LC side if a low capacity (70 mmf.) car antenna is used.



Location of Tubes and Vibrator

Adjusting Antenna 600 KC Trimmer

Tune in a weak signal at approximately 600 KC with the volume control about three-fourths on. Turn the adjusting screw of the antenna 600 KC trimmer up or down until maximum output is obtained. See Fig. 9 for location of this trimmer.

Antenna

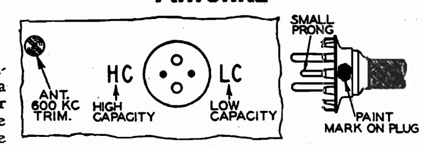


Fig. 9—Antenna Plug Insertion

IMPORTANT—The antenna plug can be inserted in two ways depending on whether the antenna is of high or low capacity.

If the total capacity of the antenna and shielded lead is approximately 200 mmf., which would be the case in a running board or ordinary roof antenna (not metal roof), insert the antenna plug with the mark on the HC side—See Fig. 9.

If the total capacity of the antenna and shielded lead is approximately 70 mmf., such as is the case if a "fish pole" antenna is used, insert the antenna plug with the mark on the LC side.

APRIL, 1938

Oscillation on D Band

If oscillation is encountered on the D band, change the oscillator grid resistor to 35,000 ohms.

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

Readings taken with 1000 ohm-per-volt meter.

The voltage between the control grids of the 6J5G balancing exciter and the 6F6G output tubes and ground is 22. This voltage cannot be read at the socket terminal because of the high resistance circuit, but can be read across resistors R18, 19, and 20.

This model is a 3 band AC operated radio with a 6 button automatic tuning unit. I.F. 456 KC.

RANGE B 528 TO 1830 KILOCYCLES
RANGE C 1.81 TO 6.35 MEGACYCLES
RANGE D 6.30 TO 22.0 MEGACYCLES

Voltages at Sockets

The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage is between the socket terminal and ground.

These voltages are read under the following conditions:
Line Voltage—117.
Volume Control—Maximum.
Antenna Shorted to Ground.

1100 KC	Antenna Lead	200 mmf.	No. 6	Setting Screw No. 6	Antenna Coil No. 6

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

NOTE C—Leave condenser rotor at the 600 KC setting and adjust the signal generator until maximum output is obtained at or near 456 KC.

NOTE D—At the bottom of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.

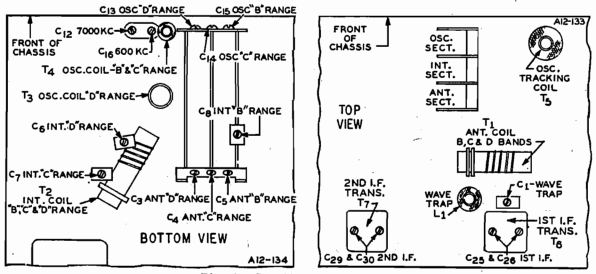

Fig. 1—Location of Trimmers

CAUTION—When aligning the short wave bands be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial. It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

Circuit

Ten buttons are provided on the front panel. Three buttons actuate linear band switches for a broadcast and 2 short wave manual tuning ranges. Six buttons actuate switches which connect fixed tuned circuits for automatic tuning. Depressing any of the 9 band and automatic tuning buttons also turns on the radio. Depressing the 10th button will turn the radio to the off position.

The band switch has 4 arms as shown in Fig. 5, one each for the B, C, and D bands (broadcast, 1st and 2nd short wave, respectively) and one called the "Master" arm. The master arm switches from manual to automatic tuning and vice versa. This arm is actually over the other 3 arms rather than in back of them, as shown in the illustration. Depressing any of the B, C, or D band buttons actuates the arm for that band and also the master arm. The latter is in only when one of the 3 band switch buttons is depressed.

In manual tuning, an R. F. antenna transformer with tuned secondary is used before the 6U7G R.F. tube. The output of this tube is fed through another R. F. transformer with tuned secondary into the 6J7G 1st detector tube. A 6J5G tube functions as a separate oscillator. The antenna, interstage, and oscillator circuits are tuned by sections of the gang condenser.

In automatic tuning, the gang condenser is not used. A single tuned circuit is used before the R. F. tube while a stage of resistance coupling is employed between this tube and the 1st detector. The other automatic tuned circuit is the oscillator grid circuit. Tuning of the R. F. and oscillator fixed tuned circuits to the desired frequency is accomplished by varying the inductance of tuning coils by changing the permeability of the magnetic circuit. This is done by moving an iron core in and out of the coil.

The iron cores within the automatic tuning antenna and oscillator coil forms are secured to a brass rod. This rod is moved back and forth by a screw at the front of the radio.

Alignment between the oscillator and antenna automatic tuning coils is obtained by changing the antenna (rear) coil position while the iron core is held in place on the shaft.

In the schematic, the band switch and the automatic tuning switch are broken into sections each of which is given a name that is, to some extent, descriptive of its location in the circuit. Ant. D, for example, completes the antenna coil D band connections when the D range button is depressed. The location of the Ant. D connections on the band switch is shown in Fig. 5. All of the switches have only 2 positions. In the schematic, they are in the normal or button out position.

Now, to describe the connections for one manual tuning range: Let us assume that the B band button is depressed. The antenna transformer B band secondary is connected to the R. F. tube grid circuit through the Ant. B and Ant. M sections of the B band and master switch arms. The antenna transformer C and D band secondaries are short circuited.

The interstage transformer B band secondary is connected to the 1st detector tube grid circuit through the Int. B and Int. M sections of the switch arms mentioned above. The interstage transformer C band secondary is short circuited and the D band secondary is open circuited.

The oscillator B band grid coil is connected to the grid circuit of the oscillator tube through the Osc. B and Osc. M sections of the same switch arms as mentioned above. The oscillator B band cathode coil is connected to ground through the Osc. B section. The oscillator C and D band grid coils are short circuited.

The permeability tuning coils are open circuited.

In like manner, to describe the connections for one automatic tuning circuit, assume that button number 1 is depressed.

The antenna circuit is connected to the R. F. tube grid circuit through the Ant. M section of the master switch arm. The antenna circuit is also connected to the antenna No. 1 permeability coil through Ant. 1 switch. The antenna No. 1 coil is shunted by fixed condenser C17. The connections from the antenna and interstage transformer secondaries are open circuited.

The plate of the R. F. tube is connected in series with resistor R2 to the B+ line. It is also connected through coupling condenser C21 to the grid of the 1st detector. The latter is connected through grid leak R4 to ground.

The oscillator cathode circuit is connected through the tap on tracking coil T5 to ground. This tracking coil is connected through the Osc. M switch section to the control grid circuit of the oscillator tube. It is also connected to oscillator No. 1 coil through the Osc. 1 switch section. The tracking or oscillator grid coil is tuned by fixed condenser C23 and the inductance of oscillator coil No. 1.

One stage of I. F. amplification is employed using a 6U7G tube. An expander is used in the 1st I. F. transformer for high fidelity reception.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R. F. and I. F. tubes.

Across the volume control resistor R16 is a filter composed of condensers C33 and C34 and resistor R17. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

The output of the 2nd detector is applied to the 6J7G 1st A. F. tube. The output of this tube is fed through resistance coupling into the 6F6G output tube immediately to the right of it in the schematic.

A portion of the voltage developed across the output tube grid resistor is applied to the control grid of the 6J5G balancing exciter tube. This tube functions as a phase inverter and applies the audio voltage of proper phase and amplitude to the other 6F6G output tube. The two output tubes operate as a stage of Class A push-pull amplification. The balancing exciter tube thus replaces a push-pull input transformer. A dynamic reproducer is employed.

Degeneration or negative feedback is used in the audio amplifier. A portion of the voltage developed across the secondary of the output transformer is fed back into the cathode circuit of the 1st audio tube. The voltage fed back is of the proper phase to reduce the amplitude of certain frequencies. This results in a reduction in distortion.

The power unit uses a 5Y3G full wave rectifier. A 6U5 tuning indicator tube is employed.

WELLS-GARDNER & CO.

MODEL A12 Series
Tuner, Drive Cord Data
Phono. Data.

Drive Cord Replacement

LATE MODELS—Tie a knot with a small loop at one end of the new drive cord. Slide a 1¾ inch length of fabric tubing on the cord. The free end of the drive cord should be tied to the tension spring in such a manner that there is a distance of 56⅜ inches between the knots.

Turn the gang condenser to full open position.

Place the looped end of the drive cord over the hook on condenser drive drum A—See Fig. 2. Bring the cord up through the slot in the drum rim and pass to the right (from back of chassis) and around pulley B. Then bring the cord to the left and over pulley C. See that the fabric tubing is now between pulleys B and C. Continue cord down to control shaft D and wind 3½ turns counter-clockwise (from back of chassis) on shaft D. Bring cord up to and over pulley E. Bring cord down to top of drive drum A and wind one turn clockwise around the drum rim.

Pass the remaining drive cord and tension spring through the slot in the drum. Place free end of spring over the hook on the condenser drive drum.

EARLY MODELS—The procedure is the same as for the late models with the following exceptions:

The distance between the knots on the drive cord should be 49¼ inches.

Leaving shaft D (Fig. 3), the drive cord is brought directly to the top of drive drum A and then continued as in late models.

Permeability Tuning and Band Switch Assemblies—Differences in Early Models

A few of the first models used a station button plunger 6¹³⁄₃₂ inches long. These models may be identified by a red paint mark on the front bracket of the tuning unit at the upper right corner. On later models, this length was changed to 6⁹⁄₁₆ inches. These models have an orange paint mark in place of the red mark. It is important, therefore, that the length be noted when ordering this part and the correct part number, as shown in the parts list, be specified.

The plungers are replaceable only on the permeability (6 button) tuning unit. In the case of the band switch unit, if any parts require replacing, the entire assembly must be ordered. Two of these assemblies are listed, one using the early short shaft and the other using the later long shaft. The short shaft (early unit) has no paint mark on it. The long shaft (late unit) has an orange paint mark on it.

A change was also made on the tuning rod assembly (Rod on which 2 iron cores are mounted). The rod used on early models was 3¾ inches long and the back end of the rod rested in a small cup in the end of the compression spring. The rod used on late models is 4¾ inches long, extends through the compression spring and projects beyond the rear bracket of the tuning assembly. Only the later type rod complete with the compression spring and a small washer is being furnished for replacement. This complete assembly is interchangeable with the early type.

ATTACHING DIAL POINTER—Tune in a 1500 KC signal. Move the pointer to the 1500 KC mark on the dial and clamp it tightly over the fabric tubing on the cord.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram. On the back panel of the chassis base is a round knockout 1⁹⁄₆₄ inches in diameter. An octal base socket is then mounted in this knockout opening. In the case of the early models a 1⁹⁄₆₄ inch hole must be drilled in the back panel. A phono cable assembly may then be purchased (see parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

DIAL AND DRIVE ASSEMBLY

Part No.	Description	List Price
26A96	Dial Mounting Plate only—Complete with 3 Idler Pulleys and Felt Dial Background less Tuning Knob Shaft, Volume and Tone Controls. (See Fig. 2 for method of replacing drive cord)	$1.25
25X520	Brace for above Mounting Plate (Top of Dial Mounting Plate to back of Chassis)	.10
[illegible]521	Brace for Gang Condenser (Gang Mounting Bracket to side of Dial Mounting Plate)	.05
25A267	Tuning Eye Tube Clamp Assembly	.10
26X286	Tuning Knob Shaft only	.10
19X67	Horeshoe Washers for above Shaft Doz.	.10
24X350	Drive Drum for Condenser	.10
20X250	Spring Clamp to Hold Drive Drum to Shaft Doz.	.20
	60" Drive Cord (See Figs. 2 and 3) Ea.	.20
28X174	Tension Spring for Drive Cord Doz.	.25
	Dial Glass (Specify Name and Chassis Number of Radio)	.40
7X20	Felt Dial Background	.10
15X120	Pointer for Dial	.10
4X252	Dial Escutcheon and Celluloid Crystal Assembly	1.40
7A69	Dial Lamp Socket Assembly (2 Sockets with Wire)	.20
	Dial Lamp—No. 51	.20

PHONO ATTACHMENT PARTS

Part No.	Description	List Price
13X298	30" Phono Cable Assembly Complete (Includes Plug, Double-tip Phono Jack, Switch, and Knob)	$2.70
3A266	Phono Socket—Octal (4 Prong)—Must be ordered for Chassis not equipped with this socket	.10
6A218	Plug (8 Prong) Only of Phono Cable	.15
3A12	Phono Jack Only of Phono Cable	.10
2A50	Phono Switch Only of Phono Cable	.70
10A90	Knob Only of Phono Cable	.20

PERMEABILITY TUNING AND BAND SWITCH ASSEMBLIES

Part No.	Description	List Price
2A109	Band Change Switch Assembly Complete with Trimmer Condensers less Push Buttons (Assembly with 4 push button shafts) Early, Short Shaft Type (No Paint Mark on Assembly)	$4.30
2A125	Same as above—Late, Long Shaft Type (Orange Paint Mark on Assembly)	4.30
25A265	Permeability Tuning Push Button Assembly Complete with 12 Coils less Push Buttons (Assembly with 6 push button shafts)	5.55
26A89	Front Bracket for Tuning Assembly—Includes 6 Setting Screws and Front Switch Contact Spring Strip	.75
20X249	Setting Screw Only—Part above Bracket Doz.	.20
26A90	Rear Bracket for Tuning Assembly—Includes Rear Switch Contact Spring Strip	.60
26A91	Station Button Plunger with 2 Switch Contacts mounted on Fiber Strips and 1 Rubber Bumper (Early Type—Length 6 13/32")	.10
26A92	Station Button Plunger with 2 Switch Contacts mounted on Fiber Strips and 1 Rubber Bumper (Late Type—Length 6 9/16")	.10
8X64	Rubber Bumper only for above Station Button Plunger and Band Switch Plunger Doz.	.10
28X182	Compression Spring for Station Button Plunger Doz.	.10
37X112	Locking Plate for Button Plungers (At Rear of Assembly—Length 7¼")	.10
28X183	Flat Pressure Spring for Locking Plate Doz.	.25
25X522	"L" Shaped Stop Bracket used behind above Spring (At back of Tuning Push Button Assembly) Doz.	.10
26A88	Fiber Blinder and Felt Pad (Used on Button Plungers and located behind Button Escutcheon) Doz.	.10
25X504	Adjustable Coil Support Bracket for Rear (Antenna) Coils	.10
28X184	Spring Clamps for holding front and rear coils in place Doz.	.10
26A93	Tuning Rod Assembly—Includes 2 Iron Cores, One 3/16" Washer, and 1 Compression Spring (for Buttons Nos. 1 and 2—520-980 KC)	.30
26A94	Tuning Rod Assembly—Includes 2 Iron Cores, One 3/16" Washer, and 1 Compression Spring (for Buttons Nos. 3 and 4—650-1250 KC)	.30
26A95	Tuning Rod Assembly—Includes 2 Iron Cores, One 3/16" Washer, and 1 Compression Spring (for Buttons Nos. 5 and 6—820-1600 KC)	.30
9A925	Antenna Coil Assembly (Color—Orange; Range 520-980 KC; Buttons 1 and 2)	.15
9A936	Antenna Coil Assembly (Color—White; Range 650-1250 KC; Buttons 3 and 4)	.15
9A926	Antenna Coil Assembly (Color—Blue; Range 820-1600 KC; Buttons 5 and 6)	.15
9A927	Oscillator Coil Assembly (Color—Green; Range 520-980 KC; Buttons 1 and 2)	.15
9A937	Oscillator Coil Assembly (Color—Red; Range 650-1250 KC; Buttons 3 and 4)	.15
9A928	Oscillator Coil Assembly (Color—Yellow; Range 820-1600 KC; Buttons 5 and 6)	.15
9X47	Fiber Strip to Cover Setting Screws Doz.	.15
26A87	2 Call Letter Sheets and Celluloid Tabs	.45

Circuit

This model is a 3 band A.C. operated radio with a 6 button inductive type automatic tuning system.

A 4 position rotary switch is used to switch the tuning circuits from automatic (push button) tuning to any of the 3 manual tuning ranges (one broadcast and 2 short wave ranges).

In MANUAL TUNING, an R. F. antenna transformer with tuned secondary is used before the 6U7G R. F. tube. The output of this tube is fed through another R. F. transformer with tuned secondary into the 6J7G 1st detector tube. A 6J5G tube functions as a separate oscillator. The antenna, interstage, and oscillator circuits are tuned by sections of the gang condenser.

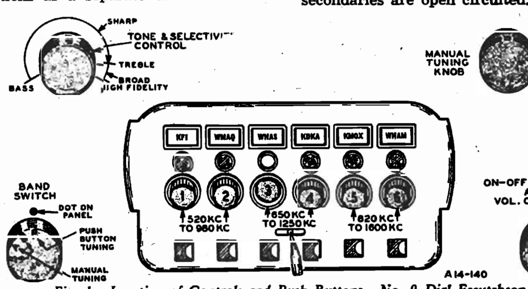

Fig. 1—Location of Controls and Push Buttons—No. 9 Dial Escutcheon

In AUTOMATIC TUNING, the gang condenser is not used. A single tuned circuit is used before the R. F. tube while a stage of resistance coupling is employed between this tube and the 1st detector. The other automatic tuned circuit is the oscillator grid circuit. Tuning of the R. F. and oscillator fixed tuned circuits to the desired frequency is accomplished by varying the inductance of tuning coils by changing the permeability of the magnetic circuit. This is done by moving an iron core in and out of the coil.

The iron cores within the automatic tuning antenna and oscillator coil forms are secured to a brass rod. This rod is moved back and forth by a screw at the front of the radio.

Alignment between the oscillator and antenna automatic tuning coils is obtained by changing the antenna (rear) coil position while the iron core remains stationary.

Now, to describe the connections for one MANUAL TUNING range: Let us assume that the rotary band switch is turned to the range B position. The antenna transformer B band secondary is connected to the R. F. tube grid circuit. The antenna transformer C and D band secondaries are open circuited.

In issue No. 1 sets, if any automatic tuning button is depressed, the automatic tuning antenna coil corresponding to that button is short circuited. In issue No. 2 sets, the connection between the antenna circuit and the automatic tuning antenna coils is open circuited by the band switch.

The interstage transformer B band secondary is connected to the 1st detector tube grid circuit. The interstage transformer C and D band secondaries are open circuited.

The oscillator B band grid coil is connected to the grid circuit of the oscillator tube. The oscillator B band cathode coil is connected to ground. The oscillator C and D band grid coils are open circuited. If any automatic tuning button is depressed, the automatic tuning oscillator coil corresponding to that button is short circuited.

In like manner, to describe the connections for one AUTOMATIC TUNING circuit, assume that the band switch is in the push button position and button number 1 is depressed.

In issue No. 1 sets, the antenna circuit is connected to the R. F. tube grid circuit through the band switch. The antenna circuit is also connected to the antenna No. 1 automatic tuning coil through Ant. 1 switch. The antenna No. 1 coil is tuned by fixed condenser C19.

In issue No. 2 sets, the antenna circuit is connected to the automatic tuning antenna coils through the band switch. The antenna No. 1 automatic tuning coil is connected to the R. F. tube grid circuit through the Ant. 1 switch. Antenna No. 1 coil is tuned by condensers C44 and C45.

In both issues, the connections from the antenna and interstage transformer secondaries are open circuited.

The plate of the R. F. tube is connected in series with resistor R1 to the B+ circuit. It is also connected through coupling condenser C22 to the grid of the 1st detector. The latter is connected through grid leak R4 to ground.

The oscillator cathode circuit is connected through the tap on tracking coil L2 to ground. This tracking coil is connected through the band switch to the control grid circuit of the oscillator tube. It is also connected to oscillator No. 1 coil through the Osc. 1 switch. The tracking or oscillator grid coil is tuned by fixed condenser C17 and the inductance of oscillator coil No. 1.

One stage of I. F. amplification is employed using a 6U7G tube. An expander is used in the 1st I. F. transformer for high fidelity reception.

A 6H6 tube functions as a diode 2nd detector. AVC voltage is applied to the control grid circuits of the R. F. and I. F. tubes.

Across the volume control resistor R16 is a filter composed of condensers C33 and C34 and resistor R15. At high volume settings, the filter is not effective. At low volume settings, the action of this filter results in an increase of high and low frequency amplitudes relative to the other frequency amplitudes.

The output of the 2nd detector is applied to the 6F5G A. F. tube. The output of this tube is fed through resistance coupling into the 6K6G output tube.

A dynamic reproducer is employed.

Degeneration or negative feedback is used in the audio amplifier. A portion of the voltage developed across the secondary of the output transformer is fed back into the cathode circuit of the 1st audio tube. The voltage fed back is of the proper phase to reduce the amplitude of certain frequencies. This results in a reduction in distortion.

The power unit uses a 5Y3G full wave rectifier. A 6U5 tuning indicator tube is employed.

General Service Data

Issue Number

The last digit of the number on the chassis number label identifies the radio as to the issue number.

Issue No. 1

Mechanical Assembly—The station button plunger has a length of 6 9/16 inches.

The locking plate for the station button plungers has 2 swivel tabs which fit into slots in the rear bracket of the tuner assembly—See Fig. 8.

Electrical Assembly—The schematic circuit diagram (Fig. 3) is that of issue No. 2 sets. The partial schematic illustration (Fig. 4) shows the sections of the issue No. 1 circuit which differ from the issue No. 2 circuit.

The A. V. C. voltage is applied directly to the R. F. tube grid circuit through a resistor.

Wave trap (L1 and C2) is in the antenna circuit.

Lugs 11 and 12 of band switch section No. 3 are used to connect a pilot lamp when the rotary band switch is in the automatic tuning (push button) position.

Issue No. 2

Mechanical Changes—The station button plunger has a length of 7 3/16 inches.

The locking plate for the station button plungers has been re-designed and now employs 2 side arms mounted in rubber cushioned hinge brackets which are attached to the rear bracket of the tuner assembly by 2 screws—See Fig. 7.

Electrical Changes—The schematic circuit diagram (Fig. 3) is that of issue No. 2 sets.

The A. V. C. is fed into the R. F. tube grid circuit through the manual and the automatic tuning antenna coils.

The wave trap is in the R. F. tube plate circuit.

Lugs 11 and 12 of band switch section No. 3 are used to open the connection between the antenna circuit and the automatic tuning antenna coils.

The following changes are made to bring about the change mentioned above in the A. V. C. circuit:

C43 is inserted between the secondary of the antenna transformer and ground to isolate the A. V. C. from ground. C21 is replaced by C43. R23 is added to isolate the automatic tuning coils from the manual tuning coils. C1 is replaced by C42 and C45 in the automatic tuning coil circuit. R3 and C20 are removed from the R. F. tube grid circuit. C19 is replaced by C44 in the automatic tuning coil circuit.

Drive Cord Replacement

SEE A12 SERIES.

ATTACHING DIAL POINTER—Tune in a 1500 KC signal. Move the pointer to the 1500 KC mark on the dial and clamp it tightly over the fabric tubing on the cord.

Phonograph Connections

Phonograph connections are made as shown in the schematic circuit diagram Fig. 3. On the top of the chassis base and between the 6H6 and 6F5G tube sockets is a round knockout opening 1 3/64 inches in diameter. An octal base socket is mounted in this knockout opening and wired as shown in the schematic.

A phono cable assembly may then be purchased (See parts list). On one end of this cable is an octal plug and on the other end is a phonograph-radio switch and double tip jack.

Some models are shipped from the factory equipped with the phono socket. A jumper is inserted in this socket which must be removed if the phonograph installation is made—See Fig. 3.

Voltages at Sockets

The voltages at sockets are shown on the schematic circuit diagram. Unless otherwise specified, the voltage indicated is between the socket terminal and ground.

These voltages are read under the following conditions:

Line Voltage—117.
Volume Control—Maximum.
Antenna Shorted to Ground.
Readings taken with 1000 ohm-per-volt meter.

Twenty-Five Cycle Models

The twenty-five cycle receiver differs from the sixty cycle receiver only in the fact that a different power transformer is used.

ALIGNMENT PROCEDURE

Volume Control—Maximum All Adjustments.
Selectivity Control—Sharp Position All Adjustments.
Connect Radio Chassis to Ground Post of Signal Generator with a Short Heavy Lead.
Allow Chassis and Signal Generator to "Heat Up" for several minutes.

The following equipment is required for aligning:
An All Wave Signal Generator which will provide an accurately calibrated signal at the test frequencies as listed.
Output Indicating Meter—Non-Metallic Screwdriver.
Dummy Antennas—.1 mf., 200 mmf., and 400 ohms.

SIGNAL GENERATOR FREQUENCY SETTING	SIGNAL GENERATOR CONNECTION AT RADIO	DUMMY ANTENNA	BAND SWITCH SETTING	CONDENSER SETTING	ADJUST TRIMMERS TO MAXIMUM (Unless otherwise specified)
I. F.					
456 KC	Grid of I.F. Tube	.1 mf.	B Range	Turn Rotor to Full Open	2nd I.F. (C29) & (C30)
456 KC	Grid of 1st Det.	.1 mf.	B Range	Turn Rotor to Full Open	1st I.F. (C25) & (C26)
WAVE TRAP					
456 KC	Antenna Lead	200 mmf.	Push Button Position Button No. 1 Depressed		Wave Trap (C2) Adjust for MINIMUM Output
RANGE B					
1830 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Full Open	Oscillator Range B (C15)
1500 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output Set Indicator to 1500 KC—See Note A	Ant. Range B (C5) Int. Range B (C9)
600 KC	Antenna Lead	200 mmf.	B Range	Turn Rotor to Max. Output	600 KC (C12) Rock Rotor—See Note B
RANGE C					
6350 KC	Antenna Lead	400 Ohm	C Range	Turn Rotor to Full Open	Oscillator Range C (C14)
6000 KC	Antenna Lead	400 Ohm	C Range	Turn Rotor to Max. Output	Antenna Range C (C4) Int. Range C (C8)
RANGE D					
22,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Full Open	Oscillator Range D (C13)
20,000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	Ant. Range D (C3) Int. Range D (C7) Rock Rotor—See Note B
7000 KC	Antenna Lead	400 Ohm	D Range	Turn Rotor to Max. Output	7000 KC (C11) Rock Rotor—See Note B
PERMEABILITY TUNING UNIT			BUTTON DEPRESSED (Band Switch In Push Button Position)	TURN SETTING SCREW TO MAXIMUM OUTPUT —See Instruction Book	ADJUST COIL POSITION TO MAXIMUM OUTPUT —See Note C
700 KC	Antenna Lead	200 mmf.	No. 1	Setting Screw No. 1	Antenna Coil No. 1
700 KC	Antenna Lead	200 mmf.	No. 2	Setting Screw No. 2	Antenna Coil No. 2
850 KC	Antenna Lead	200 mmf.	No. 3	Setting Screw No. 3	Antenna Coil No. 3
850 KC	Antenna Lead	200 mmf.	No. 4	Setting Screw No. 4	Antenna Coil No. 4
1100 KC	Antenna Lead	200 mmf.	No. 5	Setting Screw No. 5	Antenna Coil No. 5
1100 KC	Antenna Lead	200 mmf.	No. 6	Setting Screw No. 6	Antenna Coil No. 6

Attenuate the signal from the signal generator to prevent the leveling-off action of the AVC.

After each range is completed, repeat the procedure as a final check.

NOTE A—If the pointer is not at 1500 KC on the dial, loosen the 2 clamps which hold the pointer assembly on the cord, move the pointer to the 1500 KC mark, and tighten the clamps.

NOTE B—Turn the rotor back and forth and adjust the trimmer until the peak of greatest intensity is obtained.

NOTE C—At the bottom of the permeability tuning unit can be seen six "W" openings. Insert the end of a pair of long nose pliers or a screwdriver in the "W" opening of the proper button and adjust the position of the antenna (rear) coil by twisting the pliers or screwdriver until maximum output is obtained.

CAUTION—When aligning the short wave bands, be sure NOT to adjust at the image frequency. This can be checked as follows: Let us say the signal generator is set for 5000 KC. The signal will then be heard at 5000 KC on the dial of the radio. The image signal, which is much weaker, will be heard at 5000 less 912 KC, or 4088 KC on the dial.

It may be necessary to increase the input signal to hear the image.

NOTICE—Re-alignment is necessary if glass tubes are replaced by their equivalent in metal tubes, or vice versa, in the R.F. and I.F. stages.

WESTERN AUTO SUPPLY CO.

Factory Number 840

8 Tube Including Cathode-Ray Tuning Indicator
3-Band All-Wave A.C. Superheterodyne Receiver

INSTRUCTIONS FOR INSTALLING, OPERATING AND SERVICING

BAND	DIAL SCALE	FREQUENCY RANGE
Broadcast	Outer Scale	540 to 1720 K.C. (Kilocycles)
Middle Wave	Center Scale	1690 to 5500 K.C. (Kilocycles)
Short Wave	Inner Scale	5.35 to 18.1 M.C. (Megacycles)

I. F. Frequency 465 K.C.

DESCRIPTION:

The tube complement of this chassis consists of the following metal and octal base glass tubes which are interchangeable with metal tubes:

1—Type 6A8G—Pentagrid mixer, first detector and oscillator.
1—Type 6K7 Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6Q7G duplex diode triode second detector, A.V.C. and audio.
1—Type 6C5 Inverter stage.
2—Type 6F6G—pentode push-pull output amplifier.
1—Type 5Y3G high vacuum rectifier.
1—Type 6G5 Cathode ray tuning indicator.

Transformers are available and chassis are sometimes equipped with universal transformers for operation on 25, 40 and 60 cycles and with primary taps for 108, 127, 150, 225, and 260 volts, (see instructions) and also sometimes equipped with 25 cycle transformers with 105-115 volt or 220 volt primaries, not universals.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

IN ORDER TO PREVENT SIGNAL FROM ACTING UPON AVC AND AFFECTING ACCURACY OF VOLTAGE MEASUREMENTS, AERIAL AND GROUND LEADS SHOULD BE SHORT CIRCUITED WHILE MAKING MEASUREMENTS.

All voltages are to measured with 115 volts on the primary of the power transformer.

Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagrams.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Excessive hum, stuttering, low volume and a reduction in all D.C. voltages is usually caused by a shorted electrolytic condenser, open by-pass condensers frequently cause oscillation and distorted tone.

ALIGNING INSTRUCTIONS:

CAUTION: No aligning adjusments should be attempted without first thoroughly checking over all other possible causes of trouble, such as defective tubes, poor installations, open or grounded antenna systems, defective condensers and resistors.

In order to properly align this chassis, an oscillator (generator) is necessary.

All adjustments should be made with a non-metallic screw driver.

CATHODE-RAY TUNING INDICATOR:

A cathode-ray tube is used for visually indicating when the receiver is accurately tuned to the incoming signal. The signal from the receiver is applied to the tube in such a manner as to cause a triangular shadow on the luminescent screen. The size of the shadow is determined by the strength of the incoming signal so that a change of tuning is readily exhibited on the cathode-ray screen, and therefore tuning to exact resonance can be definitely obtained.

The cathode-ray screen shows the dark sector (shadow) in the middle portion of the illuminated area at its minimum width when ideal tuning position (resonance) is attained for any particular station (see dotted lines on illustration of cathode-ray tuning indicator. (Fig. 2, Page 2.)

TUNING:

Set Band changing switch to the band desired, turn volume control to the right approximately three-quarters of its rotation, turn tuning knob slowly until a signal is heard, then turn slowly back and forth, noting the width of the shadow indicated on the screen of the Cathode-Ray Tuning Indicator. Minimum width indicates the ideal tuning position (resonance).

NOTE: Tuning on the short wave band is very critical. The tuning knob has been provided with a vernier mechanism to assist in tuning. The knob should be turned very slowly as the pointer passes over the shaded sections of the short wave band scale. A signal of suitable strength could easily be passed if tuned through in a rapid or haphazard manner.

The operation of this receiver is like that of any conventional receiver, with the exception that greater care must be exercised when tuning on the short wave band. It is also desirable that the user have a practical knowledge of the operating schedules and time differences of the broadcasting stations. A short wave map is included with your radio for your convenience.

Reception on the short wave band is often affected by interference from telephones, electrical appliances, automobile motors, oil burners, etc.

A GOOD ANTENNA IS ESSENTIAL FOR SATISFACTORY RECEPTION ON SHORT WAVES.

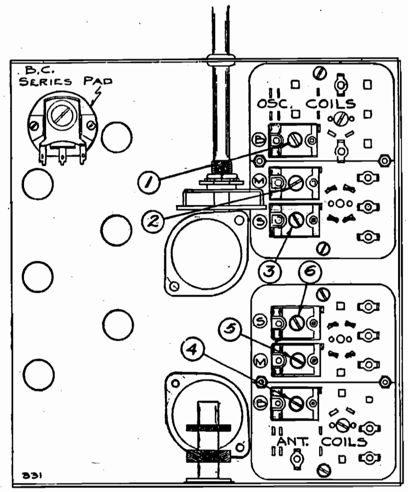

FIG. 3.—BOTTOM VIEW SHOWING TRIMMERS

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer or by means of an adapter between the plate and cathode terminals of the 5 prong speaker socket. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-106 Output I.F. Transformer
Part No. 108-105 Input I.F Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6K7 tube, and adjust the output I.F. transformer (No. 108-106) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6K7 to grid cap of 6A8G and adjust input I.F. transformer (No. 108-105) to resonance

BROADCAST BAND ALIGNMENT:
540 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to tan antenna lead and black ground lead, make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance (adjustment number 1; see bottom view of coil assembly. Fig. 3.)
   (b) Re-set external oscillator to 1550 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast antenna trimmer (Adjustment number 4) to resonance; also adjust preselector trimmer which is mounted on the top of the rear section of the three gang variable tuning condenser to resonance. (See top view of chassis, Fig. 1, for location of this adjustment.)
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3.)
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1000 kilocycles. **Under no circumstances bend plates of variable condenser sections to correct tracking.**

SHORT WAVE BAND ALIGNMENT:
5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 17 megacycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 17 megacycles and adjust short wave oscillator (Adjustment number 3) and short wave antenna (Adjustment number 6) to resonance.
   (b) Re-set external oscillator to 6 megacycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 18.1 megacycles and 5.3 megacycles for band coverage.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental. An example of this is an image of a fundamental 18.3 megacycle signal appears near 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:
1690 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5000 kilocycles and connected in series with "Dummy 3" to the tan antenna and black ground lead, make the following adjustments:
   (a) Move dial pointer to 5000 kilocycles and adjust middle wave oscillator (Adjustment number 2) and middle wave antenna (Adjustment number 5) to resonance.
   (b) Re-set external oscillator to 1800 kilocycles and pick up signal by rotating variable condenser and check sensitivity.
   (c) Re-set external oscillator and check set at 5400 kilocycles and 1700 kilocycles for band coverage.
   (d) Recheck broadcast band alignment.

WESTERN AUTO SUPPLY CO.

Factory Number 804

8 Tube Including Cathode-Ray Tuning Indicator
3-Band All-Wave 6-Volt Battery Superheterodyne Receiver

INSTRUCTIONS FOR INSTALLING, OPERATING AND SERVICING

BAND	DIAL SCALE	FREQUENCY RANGE
Broadcast	Outer Scale	540 to 1720 K.C. (Kilocycles)
Middle Wave	Center Scale	1690 to 5500 K.C. (Kilocycles)
Short Wave	Inner Scale	5.35 to 18.1 M.C. (Megacycles)

I. F. Frequency 465 K.C.

CATHODE-RAY TUNING INDICATOR

A cathode-ray tube is used for visually indicating when the receiver is accurately tuned to the incoming signal. The signal from the receiver is applied to the tube in such a manner as to cause a triangular shadow on the luminescent screen. The size of the shadow is determined by the strength of the incoming signal so that a change of tuning is readily exhibited on the cathode-ray screen, and therefore tuning to exact resonance can be definitely obtained.

The cathode-ray screen shows the dark sector (shadow) in the middle portion of the illuminated area at its minimum width when ideal tuning position (resonance) is attained for any particular station (see dotted lines on illustration of cathode-ray tuning indicator. (Fig. 2, Page 2.)

TUNING:

Set Band changing switch to the band desired, turn volume control to the right approximately three-quarters of its rotation, turn tuning knob slowly until a signal is heard, then turn slowly back and forth, noting the width of the shadow indicated on the screen of the Cathode-Ray Tuning Indicator. Minimum width indicates the ideal tuning position (resonance).

NOTE: Tuning on the short wave band is very critical. The tuning knob has been provided with a vernier mechanism to assist in tuning. The knob should be turned very slowly as the pointer passes over the shaded sections of the short wave band scale. A signal of suitable strength could easily be passed if tuned through in a rapid or haphazard manner.

The operation of this receiver is like that of any conventional receiver, with the exception that greater care must be exercised when tuning on the short wave band. It is also desirable that the user have a practical knowledge of the operating schedules and time differences of the broadcasting stations. A short wave map is included with your radio for your convenience.

Reception on the short wave band is often affected by interference from telephones, electrical appliances, automobile motors, oil burners, etc.

A GOOD ANTENNA IS ESSENTIAL FOR SATISFACTORY RECEPTION ON SHORT WAVES.

ANTENNA AND GROUND LEADS:

You will notice three wires coming out of the back of the chassis, — the **yellow** wire and the **black with yellow tracer** wire are used for doublet antenna connections. The **black** wire is the ground connection.

For conventional types of antennas connect the **yellow** wire to the antenna lead and the **yellow with black tracer** and the **black** wire together to the ground lead.

When a doublet antenna is used connect the **yellow** wire and the **yellow with black tracer** wire to the doublet antenna and the solid **black** wire to the groud lead. (See Fig. 1—Top View,

DESCRIPTION:

TUBES:

The tube complement of this chassis consists of the following octal base glass tubes which are interchangeable with metal tubes.

The type and function of each tube is as follows:

1—Type 6S7G Remote cut-off pentode R.F. amplifier.
1—Type 6D8G Pentagrid first detector.
1—Type 6L5G Oscillator.
1—Type 6S7G Remote cut-off pentode I.F. amplifier (465 K.C.)
1—Type 6T7G duplex diode triode second detector, A.V.C. and audio.
1—Type 6L5G Driver Amplifier.
1—Type 19 Class "B" Push-Pull Output Amplifier.
1—Type 6N5 Cathode Ray Tuning Indicator.

SERVICE NOTES:

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on the schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Failure to operate, noisy or weak reception is usually due to defective tubes, the tubes making poor contact with sockets or grid clips making poor contact with the caps of the tubes. Tubes may be checked very easily by replacing with other tubes which are known to be good. Do not attempt to make any adjustments on the vibrator.

ALIGNING INSTRUCTIONS:

CAUTION: No aligning adjustments should be attempted without first thoroughly checking over all other possible causes of trouble, such as run down battery, defective tubes, poor installations, open or grounded antenna systems, defective condensers and resistors.

In order to properly align this chassis, an oscillator (generator) is necessary.

All adjustments should be made with a non-metallic screw driver.

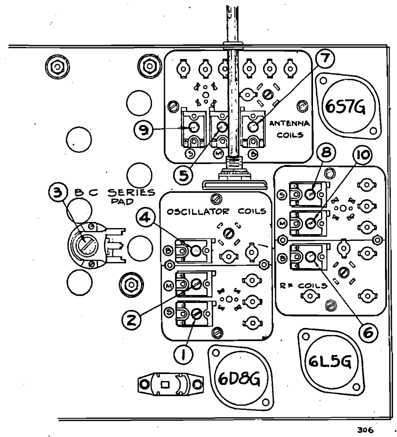

FIG. 3.—BOTTOM VIEW SHOWING TRIMMERS

RESONANCE INDICATOR:

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the two plate terminals of the type 19 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

DUMMY ANTENNAS:

The following dummy antennas are used in aligning and are referred to in the following alignment instructions as "Dummy 1", "Dummy 2", and "Dummy 3".

Dummy 1: (I.F.)—Consists of a .1 mfd. condenser connected in series with the external oscillator.

Dummy 2: (Broadcast)—Consists of a 200 mmfd. condenser and a 20 ohm resistor connected in series with each other and in series with the external oscillator.

Dummy 3: (Middle and Short Wave)—Consists of a .1 mfd. condenser and a 400 ohm resistor connected in series with each other and in series with the external oscillator.

ALIGNING I.F. TRANSFORMERS: (465 K.C.):

Part No. 108-92 Output I.F. Transformer
Part No. 108-93 Input I.F. Transformer

These I.F. transformers have two adjustments, both of which are accessible from the top of chassis (see top view).

1. With volume control full on, (the extreme right of its rotation), the band changing switch in the broadcast position, (extreme left of its rotation), and with the variable condenser set to approximately 1400 kilocycles, make the following adjustments:
   (a) Connect external oscillator set at 465 kilocycles, in series with "Dummy 1", to the control grid cap of the type 6S7G tube, and adjust the output I.F. transformer (No. 108-92) to resonance.
   (b) With "Dummy 1" still connected, move oscillator output clip from grid of 6S7G to grid cap to 6D8G and adjust input I.F. transformer (No. 108-93) to resonance.

SHORT WAVE BAND ALIGNMENT:

5.35 to 18.1 Megacycles

1. With band changing switch in the short wave position, extreme right of its rotation, and with external oscillator set at 18 megacycles and connected in series with "Dummy 3" to the antenna and ground posts, make the following adjustments:
   (a) Move dial pointer to 18 megacycles and adjust short wave oscillator trimmer (adjustment number 1) to resonance.
   (b) Re-set external oscillator to 17 megacycles and pick up signal by rotating variable condenser and adjust short wave R.F. trimmer (adjustment number 8), and short wave antenna trimmer (adjustment number 9), to resonance.
   (c) Re-set external oscillator and check set at 18.1 megacycles and 6 megacycles for band coverage and sensitivity.

NOTE: It is extremely necessary in making all of these adjustments that the fundamental oscillator signal be tuned in and not the image frequency which will fall below the fundamental on the receiver dial. As an example of this a fundamental 18.3 megacycle signal can be tuned in not only at 18.3 on the dial but also at approximately 17.4 megacycles.

MIDDLE WAVE BAND ALIGNMENT:

1690 to 5500 Kilocycles

1. With band changing switch in the middle wave position, center of its rotation, and with external oscillator set at 5.5 megacycles and connected in series with "Dummy 3" to the antenna and ground posts make the following adjustments:
   (a) Move dial pointer to 5.5 megacycles and adjust middle wave oscillator trimmer (adjustment number 2) to resonance.
   (b) Re-set external oscillator to 5 megacycles and pick up signal by rotating variable condenser and adjust middle wave R.F. trimmer (adjustment number 10), and middle wave antenna trimmer (adjustment number 5), to resonance.
   (c) Re-set external oscillator and check sensitivity at 1700 kilocycles.

BROADCAST BAND ALIGNMENT:

540 to 1720 Kilocycles

1. With band changing switch in the broadcast position, extreme left of its rotation, and with gang condenser in its minimum capacity position, plates entirely out of mesh, and with external oscillator connected in series with "Dummy 2" to antenna and ground posts, make following adjustments:
   (a) Set external oscillator to 1720 K.C. and adjust broadcast oscillator trimmer to resonance. (Adjustment number 4; see bottom view of coil assembly, Fig. 3)
   (b) Re-set external oscillator to 1400 K.C., rotate variable gang condenser and pick up signal. Adjust broadcast R.F. trimmer (adjustment number 6) and broadcast antenna trmmer (adjustment number 7), to resonance.
   (c) Re-set external oscillator to 600 K.C., and adjust broadcast series pad (adjustment number 3), to resonance by rotating condenser to approximately 600 K.C., rocking it slowly to and fro until by adjusting series pad maximum output is attained. This adjustment is located on the bottom of the chassis directly under the variable gang condenser. (See bottom view of chassis, Fig. 3).
   (d) Repeat adjustments "a" and "b" until sensitivity is at its maximum.
   (e) Check for tracking and sensitivity at 1400, 1000, and 600 kilocycles. **Under no circumstances bend plates of variable condenser sections to correct tracking.**

MODEL D 734
Notes, Alignment

WESTERN AUTO SUPPLY CO.

PILOT LAMP AND FUSE

PILOT LAMP—A 6-8 volt type lamp is used (Bulb No. 116-13 Bulb).

Fuse—A15 ampere automobile fuse is used. CAUTION: BE SURE THE FUSE SHIELD IS ON THE FUSE BEFORE THE LATTER IS INSERTED IN THE RECEPTACLE.

DESCRIPTION

Model No. 567 is a five-tube superheterodyne receiver having a tuning range of 530 K.C. to 1550 K.C., operates from a 6.0 volt storage battery and uses the automotive type 6.3 volt tubes. The "B" supply is obtained from a vibrator with a tube rectifier.

The I.F. frequency used is 465 K.C., the R.F. end of the receiver consisting of a high gain iron core antenna coil which gives high signal to noise ratio. The I.F. transformers are designed to give high gain and selectivity and yet to have a broad nose for ease of tuning and hi-fidelity response. They are of the air core type and wound with solid wire to give *minimum* drift and variation of gain due to climatic changes.

This receiver has been carefully designed to facilitate servicing, the top and bottom covers are both removable and are fastened in place by spring clips, self tapping screws and trimount buttons.

All adjustments are accessible and any part replaceable without removing the chassis from the case.

TUBE COMPLEMENT

The tube complement of this chassis consists of the following octal base glass and metal tubes which are interchangeable with metal tubes.

1—Type No. 6A8 Pentagrid Converter (composite first detector and oscillator)
1—Type No. 6K7—Remote Cut-off Pentode as an I.F. Amplifier (465 K.C.)
1—Type No. 6Q7—Duplex Diode Triode Second Detector, A.V.C. and First Audio
1—Type No. 6F6—Pentode Output Amplifier
1—Type No. 6X5—High Vacuum Rectifier.

ANTENNA CONNECTION

Insert the antenna plug in cable into the chassis. The wire at the other end of the antenna cable is connected to the lead-in wire from the antenna. Keep the antenna cable as far away from car wiring as possible and ground the pigtail of the antenna cable shield at the antenna end.

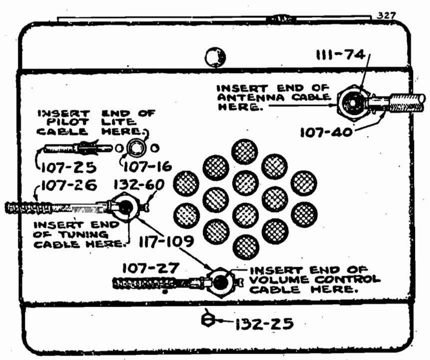

FIG. 1—SIDE VIEW

A 24 inch shielded antenna cable is regularly supplied. If a roof antenna is used, this cable will be long enough in practically all cases to reach the corner post or column at which the antenna lead comes down. The shielded cable should be pushed up into the column as far as possible. The reason for this is that ignition interference may be picked up by any unshielded portion of the antenna cable.

If an under car or running board antenna is used, the shielding must be extended to the antenna in all cases. The pigtail on the end of the antenna cable shield must be well grounded at the extreme antenna end. If it is necessary to extend the antenna cable shielding as described on following page, be sure that a pigtail is put on the end of the shielded extension and that it is well grounded at the extreme antenna end.

To extend the antenna cable shielding, the antenna lead wire should be covered with heavy insulation, such as loom, to properly separate the shielding from the wire. Then connect the two wires together and connect the two shields together, care being taken that no strand of the shield touches the antenna wire.

Aerials suitable for steel roof and convertible cars can be purchased from your dealer. They should be mounted as far to the rear of the car as possible.

The majority of 1937 cars have steel roofs, and a running board or other type car antenna must be used. The 1936 Chrysler Motors cars (except Plymouth—but including Chrysler, Dodge and DeSoto) have a steel roof separated from the body proper, which is used as an antenna. Other cars without steel roofs such as Ford and Plymouth have a built-in roof antenna.

SERVICE NOTES

Voltages taken from different points of circuit to chassis are measured with volume control full on, all tubes in their sockets and speaker connected, with a volt meter having a resistance of 1000 ohms per volt. These voltages are clearly indicated on the circuit diagram.

In order to prevent signal from acting upon A.V.C. and affecting accuracy of voltage measurements, aerial and ground leads should be short circuited while making measurements.

All voltages are to be measured with 6.3 volts input to receiver. Resistances of coils and transformer windings are indicated in ohms on schematic circuit diagram.

To check for open by-pass condensers, shunt each condenser with another condenser of the same capacity and voltage rating, which is known to be good, until the defective unit is located.

Failure to operate, noisy or weak reception is usually due to defective tubes, the tubes making poor contact with sockets or grid clips making poor contact with the caps of the tubes. Tubes may be checked very easily by replacing with other tubes which are known to be good. If fuse blows out frequently and insulating sleeve has been properly placed over fuse, the trouble is probably in the vibrator, it should be replaced. Do not attempt to make any adjustments on the vibrators.

ALIGNING INSTRUCTIONS

All of the adjustments have been very carefully set with signal generators at the factory and require no further adjustment, unless it becomes necessary to replace a coil or transformer, or if the adjustments have been tampered with in the field. Under no circumstances attempt any adjustments without first making certain that adjustment is necessary and only after voltages, tubes and condensers have been checked and found to be normal. To properly re-align this receiver a test oscillator, as well as an output meter, must be used.

DUMMY ANTENNAS

The dummy antennas referred to in the following instructions are:

"I.F. Dummy" —A .5 mfd. condenser connected in series with the test oscillator output lead.

"Broadcast Dummy"—A 175 mmfd. condenser connected in series with the output lead of the test oscillator.

RESONANCE INDICATOR

Use as a resonance indicator an output meter connected across the primary of the speaker input transformer, or by means of an adapter between the plate and screen terminals of the type 6F6 output tube. Maximum deflection of the meter indicates resonance. Use only enough signal to get a readily readable output. A low range output meter or the low scale of a multi-range meter should be used.

I.F. ALIGNMENT: (465 K.C.)

1. With variable condenser in its minimum capacity position (plates entirely out of mesh) and with volume control full on, connect test oscillator set at 465 K.C. in series with I.F. dummy antenna, to grid of 6K7 I.F. tube.
2. Adjust trimmer condensers of output I.F. transformer No. 108-95 to resonance with oscillator.
3. Move test oscillator connection to grid of 6A8 tube and adjust trimmer condensers of input I.F. transformer No. 108-96 to resonance with oscillator. See top view for location of these transformers. There are two adjustments on each and they are accessible from the top of the transformer shield and should be adjusted with an insulated screw driver.

BROADCAST ALIGNMENT

1. With variable condenser in its minimum capacity position, connect test oscillator set at 1550 K.C. in series with broadcast dummy to the antenna lead of receiver.
2. Adjust oscillator trimmer of variable condenser to resonance. (This adjustment is on the section of the gang condenser nearest to the drive—see top view, **Fig. 2**).
3. Shift test oscillator to 1400 K.C. and pick up signal by rotating condenser and adjust antenna trimmer to resonance (see top view, **Fig. 2**).
4. Re-set test oscillator to 600 K.C. and rotate variable condenser to 600 K.C. Adjust series pad rocking gang condenser to and fro at the same time adjusting series pad for maximum gain. This adjustment is accessible from the top of chassis (see top view).
5. Go back and check 1400 K.C. If adjustment is made here, check 600 K.C. again.
6. Check for sensitivity at 1000 K.C. by setting test oscillator to this frequency and picking up the signal by rotating variable condenser. Under no circumstances bend plates of variable condenser sections to correct tracking.

DIAL ADJUSTMENT

Tune set to some station of a known frequency (between 800 and 1200 K.C.) hold selector knob, then with a screw driver adjust the slotted screw on the back of the control head, and in that way adjust the dial pointer to the correct frequency setting.

LINE-UP CAPACITOR ADJUSTMENTS

ADJUSTMENT OF I.F. (465 KC.)

1. Set the volume control to maximum position, the tone control to treble position, the wave-change switch on broadcast and the dial indicator at approximately 600 KC.
2. Connect the output meter to the terminals of the voice coil.
3. Set the test oscillator to 465 KC. and apply the test signal to the grid of the type 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmer condensers #36 and #37 to maximum output.
5. Apply the test signal to the grid of the type 6A8 first detector-oscillator tube and adjust trimmer condensers #22 and #23 to maximum output.
6. Connect the test oscillator to the antenna of the receiver and with a strong input signal adjust wave trap trimmer condenser #6 to minimum output.

BROADCAST BAND ADJUSTMENT

1. Set the test oscillator and dial indicator to 1400 KC.
2. Apply the test signal to the antenna of the receiver through a .0002 mfd. condenser.
3. Adjust oscillator trimmer condenser #14 until the signal is received.
4. Adjust the preselector trimmer condenser #5 to maximum output.
5. Set test oscillator and dial indicator to 600 KC. and adjust the oscillator series condenser #16 until the signal is received. Tune the receiver to a slightly lower frequency and readjust trimmer #16 to maximum output. If the sensitivity increases, continue this procedure in the same direction until maximum sensitivity is reached. If the sensitivity decreases, try this procedure at slightly higher frequencies until maximum sensitivity is reached.
6. Return test oscillator and dial indicator to 1400 KC. and check adjustment of the oscillator and preselector trimmer condensers.

ADJUSTMENT OF GREEN BAND

1. Set the wave-change switch to the Green Band position.
2. Set the test oscillator and dial indicator to 4000 KC. and adjust the oscillator trimmer condenser #13 until the signal is received.
3. Adjust the preselector trimmer condenser #4 to maximum output.
4. Check the sensitivity and calibration over scale.

ADJUSTMENT OF RED BAND

1. Set the wave-change switch to the Red Band position.
2. Set the test oscillator and dial indicator to 15,000 KC. and adjust the oscillator trimmer condenser #12 until the signal is received. Two positions may be found at which the signal may be tuned in. Use the position with the lower capacity trimmer setting or with the alignment screw turned farther out.
3. Adjust the preselector trimmer #3 to maximum output.
4. Check the receiver over scale for calibration and sensitivity.

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes .... 1 #6A8, 1 #6K7, 1 #6H6, 1 #6F5, 1 #25A6, 1 #25Z6, 1 #K42C (Ballast) in Model WR-116, 1 #K42E (Ballast) in Model WR-316 - Total 7
Power Supply Characteristics .... 105-125 volts D.C. or 105-125 volts, 50-60 cycle A.C.
Power Consumption .... 52 Watts
Maximum output .... 1.0 Watts
Maximum Undistorted Output .... 0.75 Watts
Tuning Ranges .... (White Band - 540 to 1550 K.C.
(Green Band - 1500 to 4500 K.C.
(Red Band - - 5500 to 16500 K.C.
Line-Up Frequencies .... I.F. 465 K.C., 1400 K.C., 600 K.C., 4000 K.C., 15000 K.C.

All service parts for Model WR-316 are the same as for Model WR-116 except for the following:

Dia. #	Part #	Description of Parts	List Price
32	CW 2-25	.25 mfd., 200 V. condenser	$ .20
43	VR 9535	1/2 meg. volume control	1.10
44	RE 9527	5000 ohm, 1/4 W. resistor	.10
45	CW 2-05	.05 mfd., 200 V. condenser	.15
70		On-Off switch - part of VR 9535	
72	SK 9538	Speaker assembly (14" Dia.)	10.00
73	DM 956	Diaphragm and voice coil assembly	1.25
74	TR 9556	Output transformer	1.35
80	CL 9556	Field coil	1.60

(WR-116)

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes ...... 2 #6K7, 1 #6A8, 1 #6C5, 1 #6H6, 1 #6F5, 2 #6F6, 1 #6G5, 1 #5Y3 - Total 10
Power Supply .... 105 to 125 volts, 50 to 60 cycles
Power Consumption .... 80 Watts
Maximum Undistorted Output .... 4.5 Watts
Maximum Output .... 6.5 Watts
Tuning Ranges .... (Green Band - 150 to 390 KC.
(White Band - 525 to 1800 KC.
(Blue Band - 1750 to 6000 KC.
(Red Band - - 5800 to 18500 KC.
Line-Up Frequencies .. I.F. 465 KC.,350 KC.,165 KC.,1600 KC.,570 KC.,5500 KC.,1900 KC., 17000 KC., and 6000 KC.

LINE-UP CAPACITOR ADJUSTMENTS

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full and turn tone control to bass position.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC. and adjust its output to produce a measurable reading on output meter when test signal is applied to the grid of 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmers #53 and #55 for maximum output reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 first detector and adjust #47 and #48 for maximum output.

ADJUSTMENT OF GREEN BAND

1. Set wave change switch to Green Band position.
2. Set test oscillator and dial indicator to 350 KC.
3. Apply test signal to antenna terminal of the chassis through a .0002 mfd. series condenser and adjust #44, #23, and #12 for maximum output.
4. Set test oscillator and dial indicator to 165 KC. and adjust #45 for maximum output, at the same time rocking the variable tuning condenser.
5. Return to 350 KC. setting with both test oscillator and dial indicator and repeat adjustment of #44, #23 and #12 for accuracy.

ADJUSTMENT OF BROADCAST BAND

1. Set wave change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 KC. and adjust #42, #21 and #10 for maximum output.
3. Set test oscillator and dial indicator to 570 KC., and adjust #41 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 1600 KC. setting and make readjustment of #42, #21 and #10.

ADJUSTMENT OF BLUE BAND

NOTE: In adjusting the Blue and Red Bands, a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave change switch to Blue Band position.
2. Set test oscillator and dial indicator to 5500 KC. and adjust #38, #19 and #8 for maximum output.
3. Set test oscillator and dial indicator to 1900 KC. and adjust #39 for maximum output, at the same time rocking the variable tuning condenser.

ADJUSTMENT OF RED BAND

1. Set wave change switch to Red Band position.
2. Set test oscillator and dial indicator to 17000 KC. and adjust #34, #16 and #5 for maximum output.
3. Set test oscillator and dial indicator to 6000 KC. and adjust #36 for maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #34, #16 and #5.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents making the condenser appear to be defective. If left in this position too long the condenser may be injured.

WESTINGHOUSE ELEC. & MFG. CO.

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes .... 1 #6A8G, 1 #6K7, 1 #6Q7G, 1 #6Y6G, 1 #5Y3G - Total 5
Power Supply Characteristics .... 105-125 volts, 50-60 cycle A.C.
Power Consumption .... 45 Watts
Total Power Output .... 3.3 Watts
Undistorted Power Output .... 1.6 Watts
Tuning Ranges .... (Broadcast Band 535 to 1550 KC. (Short-wave Band 1550 to 3600 KC.
Line-Up Frequencies .... I.F. 455 KC., 1400 KC.

GENERAL DESCRIPTION

This model is a five-tube, alternating current, two-band superheterodyne receiver, designed to operate over the standard broadcast band extending from 535 to 1550 KC., and a short-wave band extending from 1550 to 3600 KC.

LINE-UP CAPACITOR ADJUSTMENTS

To properly align the circuits of this receiver, it is essential to use a high grade modulated test oscillator, the output of which can be continuously varied and reduced sufficiently to prevent overload as the individual circuits of the receiver are brought into alignment. A conventional output meter should be connected across the terminals of the speaker voice coil to indicate when the individual circuits are correctly aligned. The sensitivity of the meter must be sufficient to give satisfactory readings with low input signals.

Before attempting to align the receiver, the service man should familiarize himself with the general layout of the chassis, location of the various tubes and alignment condensers.

ALIGNMENT OF I.F. (455 KC.)

1. Set the volume control to maximum position, the wave-change switch to standard broadcast band, and the dial pointer to approximately 600 KC.

2. Connect the output meter across the voice coil terminals of the speaker.

3. Set the test oscillator to 455 KC., and adjust its output to produce a measureable reading on the output meter when the test signal is applied to the grid of the type 6A8G first detector-oscillator tube through a 0.5 mfd. blocking condenser.

4. Adjust the four I.F. trimmer condensers underneath the chassis (under the square coil housings) to maximum output.

ALIGNMENT OF OSCILLATOR AND R.F.

1. Check the pointer setting to be sure that it is exactly horizontal when the tuning condenser is completely closed.

2. Set the test oscillator and dial indicator to 1400 KC., and adjust the oscillator trimmer condenser (rear section of gang) to maximum output.

3. Apply the test signal to coil end of the antenna cable through a .0001 mfd. blocking condenser and adjust trimmer condenser (front section of gang) to maximum output.

4. Check sensitivity over the band.

5. Turn wave-change switch to the short-wave band and check the sensitivity over scale.

TRAP ALIGNMENT

This receiver is provided with a tuned trap (top section of antenna coil near gang condenser) which is adjusted to eliminate signals at the I.F. frequency. This trimmer does not need to be adjusted unless there is code interference, in which case adjustment is made to eliminate the undesired signal. The models with the suffix "S" are built without the tuned trap. Viewing the antenna coil from the top, it will be seen that the five lugs are somewhat grouped. The first lug at the left of the open space is #1, #2-3-4-5 being counted in a clockwise direction. The models with the trap are connected: antenna to #1 lug, ground to #2 lug and the trimmer condenser between lugs #1 and #4. The models without the trap are connected: ground to #1 lug, antenna to #5 lug and the fixed condenser between lugs #4 and #5. One model may be readily converted to the other by obtaining the opposite type of condenser and making the above wiring changes.

PARTS LIST

ELECTRICAL SPECIFICATIONS

Type and Number of Tubes ... 2 #6K7,1 #6A8,1 #6H6,1 #6F5,1 #6F6,1 #6G5,1 #5Y3 - Total 8
Power Supply .... 105 to 125 volts, 50 to 60 cycles A.C.
Power Consumption .... 60 Watts
Maximum Output .... 3.3 Watts
Maximum Undistorted Output .... 2.5 Watts
Tuning Ranges .... (White Band - 525 to 1800 KC. (Green Band - 1750 to 6000 KC. (Red Band - - 5800 to 18500 KC.
Line-Up Frequencies .. I.F.465KC.,1600KC.,570 KC.,5500 KC.,1900 KC.,17000 KC.,&6000 KC.

LINE-UP CAPACITOR ADJUSTMENTS

ADJUSTMENT OF I.F. (465 KC.)

1. Set volume control on full; turn tone control to the bass position, the wave change switch on broadcast and the dial indicator at approximately 600 KC.
2. Connect output meter across voice coil of speaker.
3. Set test oscillator to 465 KC. and adjust its output to produce a measureable reading on output meter when test signal is applied to the grid of the 6K7 I.F. tube through a .5 mfd. blocking condenser.
4. Adjust trimmers #44 and #51 to maximum output, reducing output of test oscillator as required.
5. Apply test signal to grid of 6A8 detector-oscillator and adjust #38 and #40 to maximum output.

ADJUSTMENT OF BROADCAST BAND

1. Set wave change switch to the White or Broadcast Band position.
2. Set test oscillator and dial indicator to 1600 KC.
3. Apply test signal to antenna terminal of chassis through a .0002 mfd. series condenser and adjust #26, #13 and #3 to maximum output.
4. Set test oscillator and dial indicator to 570 KC. and adjust #28 to maximum output, at the same time rocking the variable tuning condenser.
5. Return to 1600 KC. setting with both test oscillator and dial indicator and readjust #26, #13 and #3 for accuracy.

ADJUSTMENT OF GREEN BAND

NOTE: In adjusting the two short-wave bands (Green and Red) a .0002 mfd. condenser and a 400 ohm resistor connected in series should be inserted in the high side of the test oscillator leads. This condenser-resistor combination is the approximate equivalent of a short-wave antenna.

1. Set wave change switch to the Green Band position.
2. Set test oscillator and dial indicator to 5500 KC. and adjust #31, #15 and #7 to maximum output.
3. Set test oscillator and dial indicator to 1900 KC. and adjust #34 to maximum output, at the same time rocking the variable tuning condenser.
4. Return to 5500 KC. setting and make readjustment of #31, #15 and #7.

ADJUSTMENT OF RED BAND

1. Set wave change switch to the Red Band position.
2. Set test oscillator and dial indicator to 17000 KC. and adjust #30, #14 and #6 to maximum output.
3. Set test oscillator and dial indicator to 6000 KC. and adjust #35 to maximum output, at the same time rocking the variable tuning condenser.
4. Return to 17000 KC. setting and make readjustment of #30, #14 and #6.

IMPORTANT: While testing or making repairs on this receiver, the chassis should not be turned upside down or on its side for any long period of time while the set is turned on as the chemicals in the electrolytic filter condenser will come out through the air vents making the condenser appear to be defective. If left in this position too long the condenser may be injured.

NOTE

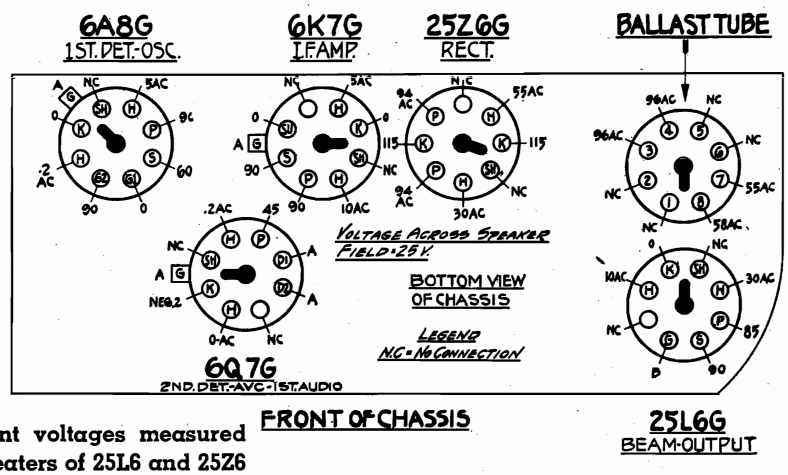
Voltages measured from socket contacts to chassis using a 1000 ohm per volt meter. Antenna disconnected — volume control on full.

Line voltage 115 v. Consumption 55 watts.

Power output 1.6 watts.

(A) Bias for 6A8 — 6K7 and 6Q7 measured at 6Q7 cathode.

(B) Bias for 25L6 measured at point C on 6Q7 socket.



Filament voltages measured across heaters of 25L6 and 25Z6 is 22 volts A.C. Other tubes 6 v A.C.

Operation	Connect Test Oscillator to	Dummy Antenna	Set Test Osc. to	Band	Set Dial At	Adjust Trimmers	Purpose

NOTE

Voltages measured from socket contacts to chassis using a 1000 ohm per volt meter with chassis operating on 110 volt A.C.

Antenna disconnected — volume control on full.

Line voltage 115 v. Consumption 18 watts.

Battery voltage at chassis 6v.

Consumption — switch on normal 2.3 amperes.

Consumption — switch on conserv. 1.95 amperes.

Power Output 1 watt.

(A) Bias for 6D8 and 6S7 measured at K contacts of respective sockets which is +1.8 volts.

(B) Bias for 6G6 tubes measured at K contact of sockets which is +7 volts.

(C) Bias for 6T7 triode measured at K contact of same socket which is +1 volt.

MODEL 9S365
Chassis 5906
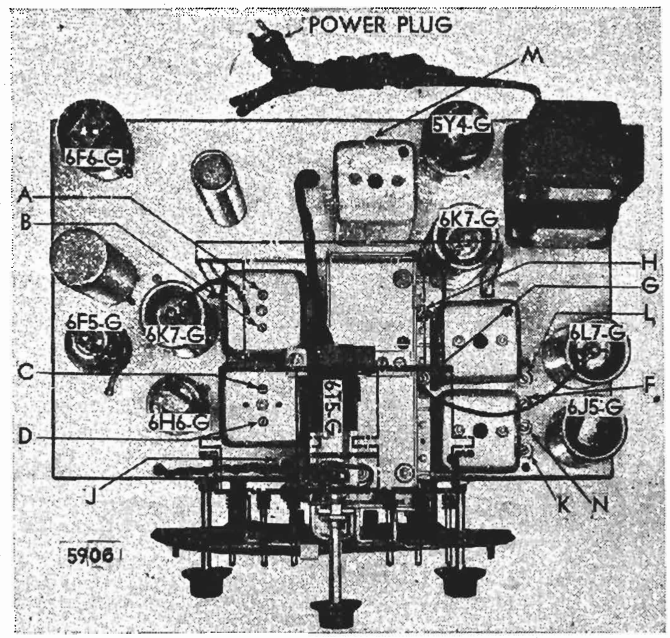
Voltage, Socket
Trimmers, Alignment

ZENITH RADIO CORP.

Model 9S365
CHASSIS No. 5906



Location of Tubes and Trimmers

NOTE

Voltages measured with a 1000 ohm per volt meter from chassis to socket contacts. Antenna disconnected — volume control on full.

Line voltage 115 v. Consumption 75 watts.
Power Output 4.5 watts.

(A) Bias for 6A8 — 6K7 R.F. and I.F. and 6H6 measured at X is—2.6 volts.

(B) Bias for 6F5 measured at X and Y is—4 volts.

(C) Bias for 6F6 measured across XY and Z is—16 volts.

ZENITH RADIO CORP.

ZENITH
AUTOMATIC TUNING SYSTEM

The Zenith automatic tuning system is designed so as to be very simple in adjustment, and to remain in adjustment regardless of changes in humidity, temperature or vibration. This system makes use of the fact that the inductance of a winding varies directly with any change in the permeability of the core material of the coil. A switch is incorporated in each receiver which allows the normal tuned circuits, consisting of a coil and variable condenser in the oscillator, first detector, and, in some cases, the R.F. section of the receiver to be disconnected and replaced by very small fixed windings which may be tuned over a considerable range of frequency by means of a change in the core material.

Specially prepared iron slugs which have very low losses at radio frequency are so arranged that they may be mechanically moved in and out of the field of the afore mentioned coils. The permeability of these iron slugs is naturally much higher than that of air, and as they are moved in or out of the field of the coil, the inductance and natural period of the coil varies accordingly. It is quite easy to arrange such coils and iron slugs so that they may be tuned in tandem, that is, two or more iron slugs moved simultaneously into corresponding coils. This allows the receiver to be designed having only one tuning adjustment for each bank of coils and corresponding button.

As you will see on the circuit above, one button can be pressed to disconnect all automatic coils, and allows the normal tuning system of a coil and variable condenser to operate. On those receivers having short wave band, this switch is a part of the band switch. When the band switch is turned to the automatic position, or, in the smaller receivers, when one of the automatic buttons is pushed, this tuned circuit is disconnected, and the automatic coils are in circuit. The range of each set of coils will vary from 300 k.c. to 600 k.c., depending over which portion of the broadcast band they are designed to operate, and after being adjusted for a certain station within their range will come into operation whenever the corresponding button is pushed in.

The antenna is coupled to the input of the 1st detector by means of a 50 mmfd. condenser (C2) and an antenna compensating condenser (C5) is used to compensate for variations in antenna capacity. This condenser is preset at the factory, and under most conditions it will not be necessary to change it. However, where there is a seeming lack of sensitivity when tuning automatically, the condenser may very easily be reset by setting one of the automatic buttons at approximately the center of the broadcast band, tuning the button to a point where no station is heard, and readjusting the antenna compensating condenser to a point where the background noise is loudest. The button may then be re-set for whatever station is desired. This setting of the antenna condenser will be effective over the entire broadcast band and for all buttons.

In the oscillator circuit, it is necessary to alter the tuning curve so as to provide for tracking between the oscillator and first detector circuits. In the normal tuned circuit, this may be easily accomplished by means of a trimmer and padding condenser working in conjunction with the oscillator section of the variable condenser. However, as no variable condenser is used with the iron core coils, a different method must be resorted to. A small winding connected in series with the grid end of the automatic windings, and so placed as not to be affected by the iron core will, if properly designed, alter the shape of the tuning curve at the high frequency portion of the coil's range. Also, when two inductances are connected in parallel, the maximum inductance is limited by the size of the smaller of the two inductances. The upper portion of coil No. 3 in the above drawing is the padder winding, and also serves as a means of coupling to the oscillator plate circuit, and when used in conjunction with the smaller winding mentioned above alters the shape of the tuning curve so as to allow excellent tracking.

Variations in humidity and temperature are compensated for by means of condenser C6 which consists of a small fixed condenser composed of silver surfaces sprayed on a special ceramic tube which changes its capacity in the opposite way from any changes in the coil, and will compensate for the same.

This automatic system is remarkably simple and trouble free, and once set up for a customer should not require any further attention until it is desired to reset for other stations which can be easily accomplished by the customer himself.

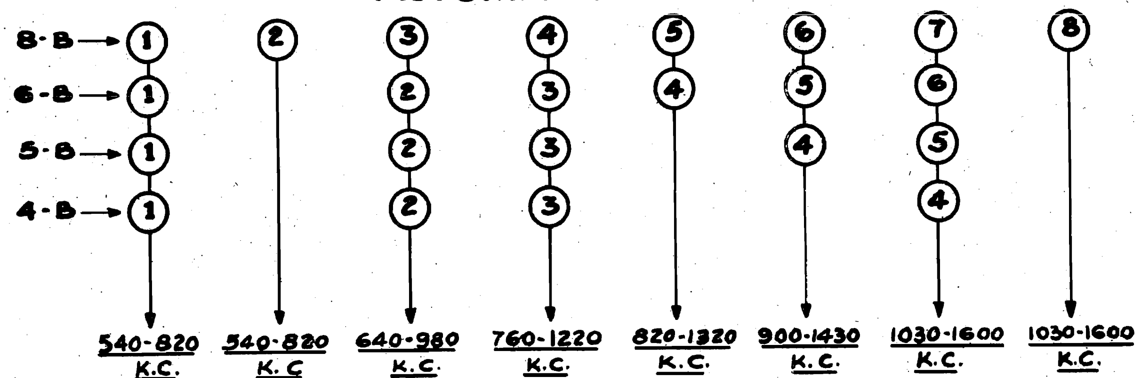
ZENITH RADIO CORP.

AUTOMATIC RANGES



NOTE—Buttons numbered from left to right, or top to bottom as they appear on receivers, except on model 6B321 (Chassis 5653) and Models 6S322 and 6S357 (Chassis 5654) which are reversed.

ALIGNMENT INSTRUCTIONS

The proper procedure for the correct alignment of each chassis is outlined on the page opposite each circuit diagram.

The operations are outlined in consecutive order, and the instructions are under the following headings —

OSC. CONNECTED TO — tells where the output of the service oscillator is to be connected.

DUMMY — gives the proper capacity or resistance which should be connected in series with the service oscillator output.

TEST OSC. — Set test oscillator to frequency shown.

BAND — Set the receiver band switch to the position shown.

DIAL — The receiver should be set at the frequency shown.

TRIMMER — This column tells which trimmer (or trimmers) are to be adjusted for each operation. The chassis drawing has each trimmer indicated by a letter corresponding to the instructions.

PURPOSE—This column tells what is being accomplished by each operation.

If these instructions are carefully followed each chassis will be easily and correctly realigned.

SERVICE HINTS

Chassis	Complaint	Cause and Remedy
5907 & 1206 only	Distortion	Very much like blocking AVC action. Can usually be traced to open filter section.
1502 only	Won't log	Can be traced to loose PK screw in gang hub gear.
5714 only	Noisy automatic or automatic dead	Dirt on contacts or warped strip. Shorted at switch to ground or shorted compensating condenser.
	Automatic dead 1 or more positions Automatic weak	Open coils — usually broken leads or poor contact at switch. Open leads to R. F. section of automatic or leaky or open compensating condenser. Padder loose — out of adjustment or all plates not soldered.
	Eye flutters	Open filter.
	Eye overlaps on strong signal	Open AVC resistors
	No eye action	Shorted condenser (C7.)
	Chirps on medium to loud signal	Leaky condenser across speaker
Radiorgan	No effect	Insulation on 33m resistor cut through and shorts to cathode lug. Open leads, poor contact at switch, open condenser. 5714 only — plate lead of I.F. too far away from chassis. Push down close to metal base.
	Too much change on some, none on others.	Condenser shorted or leads shorting to switch.
	Tone changes with different settings of volume control.	Defective volume control or shorted terminal either of tone switch or volume control. Poor contacts and defective or shorted volume control taps.
	Noisy when tuning	Dirty wipers or gang plates. Flywheel touching band switch lug. Volume control or drive shaft not making good contact to ground. 5714 — Volume control shaft and drive shaft out of line.
	Volume control has two peaks and distorts at low volume.	Isolate 6F5 grid circuit from I.F. plate leads. (Later sets have I.F. plate lead shielded.)
5714 only	Set whistles at medium volume. Noisy between signals	Open filter condenser. —Loose connection or open condenser across RF choke.
Battery Sets	Hash	Loose cover of power pack.
	Hash on automatic position.	Automatic assembly touching power pack. Insulate at point of contact.

Service Notes
Police Receiver Model PR-4

This is a conventional universal receiver of the single fixed-frequency type. The three tuned circuits are aligned by means of double adjustable pads adjacent to the coils. The tube sockets are inverted and care should be taken when replacing tubes not to damage the socket prongs. Grounding of the shields is accomplished by means of metal strips contacting the tubes' cathode prongs and clamped by means of rings to the base of the shields. The volume control should be set somewhere below its spill-over point. The condenser block contains the two 12 MFD as well as the two 5 MFD sections. While the aligning is done at the factory before shipment it is suggested that re-alignment be made at the point of installation before putting into service. An outside antenna is required for satisfactory operation in most locations. This receiver is designed to operate on 105 to 120 volts A.C. or D.C.

Belmont 589 Series "A"

The Issue "B" of this chassis has a 0.05-mf, 400-volt condenser in parallel with the 5-mf condenser, C-10. See schematic on *page 8-5 of Rider's Volume VIII.* This new condenser has a Part No. 100-13 and is identified as C-20.

The unidentified trimmer condenser connected between the lower end of the secondary of T-1 and ground has been given a schematic number, C-21. The unidentified trimmer between the lower end of the oscillator primary (T-2) and ground is C-22. C-21 has a range from 1 to 10 mmf and C-22 from 2 to 20 mmf. Both these condensers are in the same unit, the part number of which is 124-30C.

These two trimmers being in the same unit change the bottom layout of the chassis shown on page 8-5. The adjustment nearer the trimmer marked "ANT-17 MC-TRIMMER" in the layout is the 1400-kc antenna trimmer, C-21, and the one nearer the broadcast series padder is the 1720-kc oscillator trimmer, C-22.

These changes apply to receivers having a serial number above 8E-189200.

Continental 78,780

Models 77 and 770, *page 8-20 of Rider's Volume VIII,* employ an electrodynamic loud speaker. Models 78 and 780 use exactly the same chassis as the Model 77, but in this case the speaker is an 8-inch permanent-magnet type. Please add this information to your index under Continental Radio & Television Corp.

Crosley 163

The following notations should be made on the schematic of this set, which will be found on *page 3-33 of Rider's Volume III and on page 757 of the Rider Combination Manual.*

Draw a connection between the lower end of the secondary of the first i-f transformer and the arm of the volume control. A 10,000-ohm resistor should be shown between the B plus lead going to the primary of the first i-f transformer and the cathode of the 78 i-f tube. No connection should be shown between the windings of the second i-f transformer. The value of the resistor in the cathode circuit of the 77 second detector is 150,000 ohms.

Emerson Chassis AS

In sets having serial numbers above 1,294,500, the 150,000-ohm resistor, R8, was changed to 50,000 ohms and the 240-ohm resistor, R10, was changed to 310 ohms.

In sets with serial numbers above 1,294,700, C31 was changed from 0.002-mf to 0.006-mf. The speaker was changed from Part No. 4FS-274 to 4SS-278.

See schematic diagram on *page 8-49 of Rider's Volume VIII.*

Emerson Chassis F

The accompanying schematic shows the changes that were made in the circuit of receivers carrying serial numbers above 862,650. The schematic of those sets having serial numbers under 862,650 will be found on *page 7-25 in Rider's Volume VII.* Note that a 6Q7G has been substituted for the 75 second detector and that the 43 output tube has been replaced by a 25B5 in this later chassis.

Below will be found the voltage readings for those chassis having serial numbers above 862,650:

Tube	*Plate*	*Screen*	*Cathode*	*Osc. Plate*	*Fil.*
6A7	112	34	2.4	67	6.3
6D6	112	90	4.2	..	6.3
6Q7G	52	..	1.2	..	6.3
25B5	102	112	0	..	25

Voltage across speaker field, 126.
Voltage across filter choke, 10.
Voltage drop across ballast resistor (R-18) is 49 volts between pins 3 and 8.

The alignment data on the early chassis also applies to this receiver. See *page 7-26 in Rider's Volume VII* for these and other instructions.

•

Emerson Chassis H

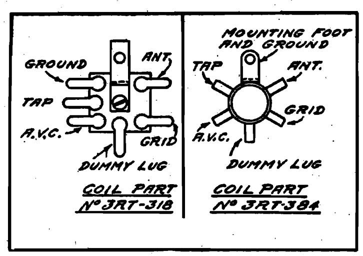
In the portable model (H-137), after approximately 135 hours of service the initial fresh battery performance may be restored by shifting the 67½-volt lead, which is brown, to the 90-volt terminal of the "B" batteries. This will increase the screen voltage to about its normal value.

The alignment of this chassis is conventional, using the i-f peak of 456-kc for the four i-f trimmers, the locations for which will be found on *page 7-39 of Rider's Volume VII,* and 1500-kc for the aligning of the oscillator, r-f, and antenna trimmers with a 0.0002-mf condenser as a dummy antenna.

Emerson AC Chassis

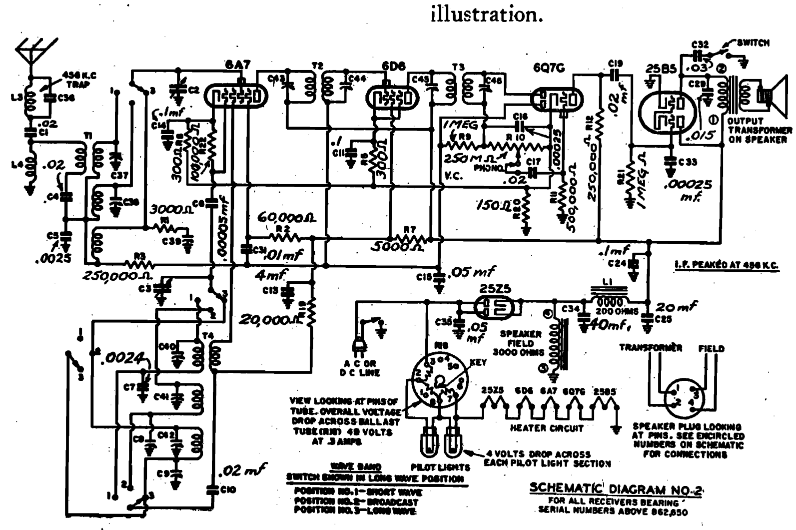
Please make a note on *page 8-9 of Rider's Volume VIII* of the following change which was received too late for inclusion.

In receivers with serial numbers above 1,335,494 a new antenna coil



Lug arrangement of old and new antenna coils in Emerson AC Chassis.

(Part No. 3RT-384) was substituted for the one having the Part No. 3RT-318. These two coils are interchangeable and the lug arrangements of both coils are shown in the accompanying illustration.



The revised schematic for Emerson models F117, F122, F133, F135, and F141 carrying serial numbers above 862,650. One of the major changes is the substitution of a 6Q7G for the 75 second detector.

Emerson Chassis C

The revisions of this chassis as noted on page 6 of the February 1937 issue of SUCCESSFUL SERVICING and subsequently published on *Changes page 8-1 of Rider's Volume VIII,* have another change. The 0.01-mf condenser, No. 55, which was connected across the primary of the output transformer, is now connected from the plate of the 6L6 output tube to ground.

Also on receivers having serial numbers above 880,050 the short-wave antenna and detector coil trimmers, C6 and C9 (see schematic on *page 7-36 of Rider's Volume VII*) are mounted on their respective coils. C6 is connected directly across the secondary of the short-wave antenna coil, T3, and is not returned to ground, as shown on the schematic.

Emerson U-154

In receivers having serial numbers above 1,173,551, the pre-selector coil was changed from Part No. 3UT-331 to 3UT-365; the oscillator coil was changed from Part No. 3UT-325 to 3UT-366; and the three-gang variable condenser from Part No. 3VC-319A to 3VC-359. This substitution of the variable condenser necessitates a change in the alignment. On *page 8-34 of Rider's Volume VIII* the signal generator frequency for the r-f and oscillator alignment is designated as 1530 kc. This is used on those sets having a variable condenser with the part number of 3VC-319 or 3VC-319A. When this number is 3VC-359, the signal frequency is 1570 kc.

The following changes were made to receivers having serial numbers above 1,171,661: The first i-f transformer was changed from Part No. 3UT-332 to 3UT-369. A small capacity coupler was added between the oscillator (central) and i-f (front) sections of the variable condenser. These sections are C3 and C2 respectively on the schematic diagram shown on *page 8-33 of Rider's Volume VIII.* The 0.003-mf condenser, C-22, is now connected between the plate of the 41 output tube and B+ instead of ground, as it is shown in the schematic.

On sets having serial numbers above 949,553, the cathode of the 6D6 a-f amplifier tube is connected to the cathodes of the 6D6 i-f amplifier and the 76 second detector tubes through a 1000-ohm series resistor and not connected directly as shown in the schematic.

Emerson Chassis D

In receivers having serial numbers above 850,000, a 15,000-ohm resistor has been connected from the tap on the volume control to ground. This is a 1/4-watt carbon resistor, Part No. KR-63.

In receivers having serial numbers above 864,755, the resistor, R-20 that is connected from the cathode of the 6C5 phase inverter tube to ground, has been changed from 5000 ohms to 10,000 ohms.

Please make these changes on the schematic of this chassis on *page 7-37 of Rider's Volume VII.*

Emerson AR Combination Chassis

We received too late for publication in *Volume VIII of Rider's Manuals* data on Models AR-165, AR-166, and AR-177 in which are incorporated the Chassis AR with a phonograph. The service notes on the AR chassis which may be found on *Emerson pages 8-41 to 8-44 in Rider's Volume VIII,* apply to the early production of these combination models, less, of course, the phonograph connections. The later models (those after serial No. 1,326,-200) have two 41 tubes in push-pull, instead of the single 41 in the output; also a 6Q7G is substituted for the 76 second detector and avc. This new tube is also used as an audio amplifier.

Emerson Chassis AF

The 0.25-mf condenser, C-17, that was connected between the negative side of the filament and ground, has been eliminated and now this side of the filament is grounded to the chassis. This applies to those receivers having serial numbers above 1,244,716. The schematic of this set will be found on *page 8-45 of Rider's Volume VIII.*

Grigsby-Grunow 310-B Chassis

Please change the value of C-16 of the *early* model from 11 mf to 0.11 mf. The parts list in which this error appears is on *Majestic page 3-22 of Rider's Volume III and page 1214 of the Rider Combination Manual.*

Emerson C134LW, C136LW, C138LW, C139LW, C140LW and C142LW

The schematic is the same as is given in *Rider's Vol. VII, page 7-36,* with the exception that C11 is a 0.00005-mf. fixed condenser shunted by a trimmer, C50, which is part of the long-wave coil assembly. The r-f. primary of T5, position 2, is shunted by a fixed condenser of 0.0001 mf. (C45), and a 2000-ohm resistor (R30).

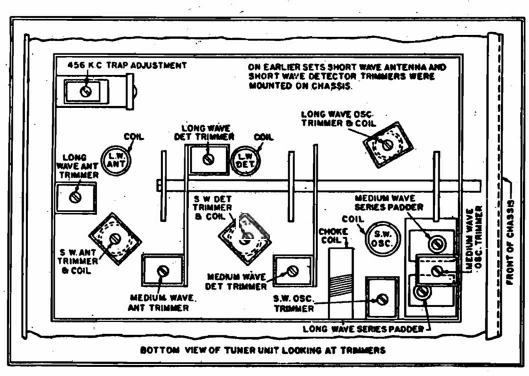
The Long-Wave band has been substituted for the Police band in position 2. T2 is a long-wave antenna coil, T5 is the long-wave detector coil, and T8 is the long-wave oscillator coil.

C6 and C9 trimmers were supplied separately and later incorporated as part of SW Antenna and Detector coil assemblies.

The alignment of the long-wave band is as follows:

Set the wave-band switch at the long-wave (central) position and the pointer to 150. Feed 150 kc. through a standard dummy antenna to the antenna terminal and adjust the long-wave series padder for maximum response. Move the pointer to 345, feed 345 kc. and adjust the long-wave oscillator trimmer. Then adjust the r-f. trimmer, and next the antenna trimmer for maximum response. Return to 150 kc. and re-adjust the long-wave series padder for maximum response. Return to 345 kc. and re-adjust all three trimmers. Return again to 150 and check the alignment. Repeat the entire procedure until no appreciable re-adjustment is required.

The layout of the tuner unit is shown below for this long-wave chassis.



The chassis layout of the long-wave Emerson chassis used in models C134LW, C136LW, C138LW C139LW, C140LW, and C142LW shown at the left differs from the chassis which includes the police band instead of the long-wave band.

G.E. D-51, D-52

A switch is provided in these chassis which is used to cut in and out a series audio coupling condenser between the plate of the 6B7 second detector-avc-af tube and the control grid of the 41 output tube. In most cases it has been found best to allow this switch to remain closed all the time; therefore, its usefulness can be increased by making the following changes:

Disconnect the two wires connected to the switch, S2 in the schematic found on *RCA page 6-9 in Rider's Volume VI,* and after soldering them together, tape them.

Connect a wire from the control grid cap connector of the 6B7 to one terminal of the switch. To the other terminal of S2, connect one side of a 0.0015-mf condenser and connect the other side of the condenser to the case of the receiver.

This procedure provides a two-point tone control which is extremely effective in reducing the tube hiss on weak signals. When the incoming signal is strong, the condenser may be switched out of the circuit, which gives the best fidelity. This type of tone control is more effective in reducing noise than the usual type of control connected across the output of the 41 power amplifier.

Motorola 5T-71A

The schematic for this chassis is the same as that shown on *page 3-2 in Rider's Volume III and on page 1054 in the Rider Combination Manual,* with the following changes:

The 0.25-megohm and 1-megohm resistors in series in the plate circuit of the third 24 r-f tube and the 0.1-mf by-pass condenser from their junction, have been replaced with a choke having the same parts number as the one shown in the grid circuit of the 171A output tube. This choke is connected directly between the plate of the 24 tube and the +B lead.

The choke in the grid circuit of the output tube has been replaced with a 0.2-megohm resistor.

Mid-West 7-36

As was noted on *page 7-2 in Rider's Volume VII,* the tube complement of the late model of this receiver was changed, four metal tubes being employed. Below will be found the voltage data for both the early and the late models.

Early 7-36

Tube		Plate	Screen	Cathode	Supp.	Grid
58	R-F	235	80	0	0	AVC
56	Osc.	120	—	1	—	—
58	Mixer	215	80	1	1	AVC
58	1st I-F	190	80	0	0	AVC
55	2nd Det	35	—	0	0	
2A5	Output	220	245	0	0	17.5
80	Rect	240 volts from filter				

Filament voltage, 2.5

Late 7-36

Tube		Plate	Screen	Supp.	Cathode
6K7	R-F	225	100	0	0
6K7	Mixer	225	100	3	3
6C5	Osc	150	0	0	0
85	2nd Det-AF	30 0	0	0	0
42	Output	225	250	0	0
80	Rect	250 A-C			

Filament voltage, 5.9 Volume control at maximum

Arvin Chassis 518

In order to correct the calibration of the dial, the following procedure is to be used:

Rotate the dial pointer to 550 kc. Press with the thumb on the dial face above its center. Rotate the tuning knob while preventing the dial pointer from moving. This will enable the position of the dial pointer to be varied with respect to the tuning condenser and makes it possible to readjust the calibration without removing the chassis from its cabinet.

For other servicing data see *pages 8-10, 8-12, and 8-13 in Rider's Volume VIII.*

G.E. B-40

The schematic of this receiver, which is the same as RCA M-34, is shown on *RCA page 3-14 of Rider's Volume III and page 1854 of the Rider Combination Manual.* The change explained below will increase the audio gain on medium and strong signals and also improve the A.V.C. action. The partial schematic shown herewith are the original and revised circuits.

Interchange the connections at the terminal board of the red and green wires from the volume control. This places the grid coupling condenser in the circuit of the movable arm of the volume control. Then disconnect the green A.V.C. lead from the terminal board. (This lead is connected to the second terminal from the end on the bottom side of the terminal strip.) Solder a small 2-megohm resistor to this lead and solder the other end of the resistor to the lug on the terminal board to which the green lead from the volume control is attached.

Lafayette M-31 (1935)

Please make this change on the lower schematic on *Lafayette page 8-6 in Rider's Volume VIII:* A connection should be made where the lead from B+ crosses the lead from the plate of the 58. A jumper appears there in the schematic.

Philco 602

The tap between the voice coil and the hum bucking coil should be grounded to minimize hum. See schematic on *page 7-83 of Rider's Volume VII.*

The 133-15 ohms resistor, No. 36, has a part number 33-3235 instead of 33-3225.

Beginning with Run No. 3, the tuning condenser assembly was changed to a vernier type. The part number of this condenser, scale, and pointer remain the same.

The 1-megohm resistor, No. 40 had a rating of ¼ watt. This should be replaced with a ½ watt resistor of the same resistance value; the Part No. 33-510344.

Philco 270

Please make a note in your Index to Rider's Manuals that the parts list of Model 70 applies to the schematic of Model 270, found on *page 1-28 of the revised edition of Rider's Volume I; on page *466-C of the early edition; and on page 1657 of the Rider Combination Manual.*

Philco 116

A 50-mmf. condenser has been added from the end terminal of condenser No. 63 (see schematic on *page 6-11 of Rider's Volume VI*) to ground. This addition was made to prevent oscillation.

As of Run No. 14, the 1-megohm resistor, No. 81, has been changed from Part No. 4409 to 33-510344.

A change has been made in the design of the volume control, No. 66 on the schematic, the old part number was 33-5022 and this has been replaced with Part No. 33-5153.

The Model K-17 speaker, Part No. 36-1025, is used on the new Model 116-B. The cone assembly number is 02996; the field coil and pot assembly is 36-3104.

Philco 116X

The resistance of the field coil, No. 95 on the schematic shown on *page 6-13 of Rider's Volume VI,* is shown as 1125 ohms. Change notes from the manufacturer state that this value is 1450 ohms.

The volume control No. 68 has been changed from Part No. 33-5110 to 33-5155.

Philco I-F Transformers

The i-f transformers of several models have been changed and are listed below. In each case the new part number of the first i-f transformer is 32-2296 and that of the second i-f transformer is 32-2298.

Model	*Parts List on Page*	*Rider's Volume*
37-33	7-15	VII
37-34	8-17	VIII
37-38*	7-17	VII
37-623	7-55	VII
37-624	8-23	VIII

The second i-f transformer has a tertiary winding which is connected in series with the screen-grid circuit of the 1D5G i-f tube.

*In order to prevent oscillation in the i-f circuit of Model 37-38, a tubular condenser, Part No. 30-4020, 0.05 mf, is connected from the screens of the 1C7G detector-oscillator and the 1D5G i-f tubes to ground.

Philco 37-9, Code 121

Run No. 2. Condenser No. 35 has been changed from 16 mf to 18 mf, Part No. 30-2194.

To improve the operation of the i-f circuit, a 0.1-mf condenser, Part No. 30-4455, has been connected from the red lead of the primary of the i-f transformer, No. 53, to ground.

To prevent distortion at minimum volume, the green-white wire connecting the center lug of the volume control, No. 67, to the automatic tuning dial a-f switch, No. 93, must be kept clear of the compensator, No. 54, and the diode circuit of the 6Q7G.

Run No. 3. Condensers 70 and 70A have been replaced by 8- and 10-mf condensers respectively, Part No. 30-2201. The 8-mf condenser, No. 72, has been replaced by a 18-mf condenser, Part No. 30-2200.

The schematic of this receiver will be found on *page 8-11 of Rider's Volume VIII.* Note that the dial calibration notes of Model 37-10, see *page 8-15,* can be used for calibrating the dial of Model 37-9.

Philco 38-39

In order to reduce maximum volume buzz, the following parts were changed: the 11.7-ohm resistor, No. 22, was changed to 12.3 ohms; the 2-megohm resistor, No. 30, was changed to 4 megohms; and the 160,000-ohm resistor, No. 27, was changed to 240,000 ohms. See schematic on *page 8-75 of Rider's Volume VIII.*

Philco 38-4, 38-5

When either of these models are operated on 25 cycles, a power transformer, Part No. 32-7598 must be employed. Also a 0.1-mf condenser must be connected across the speaker field coil, No. 65.

In order to reduce station rumble in the Model 38-4, the following parts were changed: the 0.01-mf condenser, No. 36, was changed to 0.0015 mf. and the 40,000-ohm resistor, No. 38, changed to 32,000 ohms.

In order to reduce frequency drift at the high-frequency end of the broadcast tuning range, in Run No. 3 the compensator No. 16, 1500 kc, Part No. 31-6196, was replaced with Part No. 31-6206, and two condensers, Part No. 30-1097, are connected in parallel with the new condenser. The range 1 oscillator transformer, No. 15, was changed from Part No. 32-2631 to 32-2894.

In Run No. 4 of 38-4 and Run No. 2 of 38-5, the 70,000-ohm resistor, No. 19, was changed to 51,000 ohms to improve the performance of the oscillator circuit on the short-wave bands. For schematic see *page 8-61 in Rider's Volume VIII.*

Philco 38-7, Codes 121,124

Run No. 2. To provide uniform performance of the oscillator circuit, a 20-ohm resistor was connected in series with the cathode of the 6A8G detector-oscillator tube. See schematic on *page 8-65 of Rider's Volume VIII.*

In order to reduce bass response, the following parts were changed in the Code 124 chassis:

Condenser, No. 24, was changed from 0.01 mf to 0.001 mf, Part No. 30-4201. Resistor, No. 32, was changed from 51,000 ohms to 40,000 ohms, Part No. 33-340339. Condenser, No. 38, was changed from 0.006 mf to 0.01 mf, Part No. 30-4479.

Run No. 3. To reduce frequency drift further at the high-frequency end of the broadcast range, the compensator, No. 7A, was replaced with Part No. 31-6206. Also a new thermal compensator was connected in parallel with compensator, No. 7A and mounted near resistor No. 12. The resistor is mounted in the chassis with a mounting clamp and an asbestos insulator. The resistor must be mounted like this or else the thermal compensator will not function properly.

Run No. 4. The thermal compensator added to the chassis in Run No. 3, was replaced by two fixed condensers, Part No. 30-1097.

Run No. 5. The 20-ohm resistor added in Run No. 2 was removed.

The part numbers of Nos. 26, 39, and 48 found in the list of parts on *page 8-66* are correct for Models 38-8 and 38-9. The correct part numbers for Model 38-7, both codes, follow:

No. 26, Volume Control, Part No. 33-5225; No. 39, Tone Control, Part No. 42-1347; and No. 48, Range Switch, Part No. 42-1339.

Philco 38-8, Code 121

Run No. 2. In order to increase the sensitivity of the shadowmeter, the following changes were made: Resistor, No. 12, was changed from 10,000 ohms to 13,000 ohms, Part No. 33-313639 and condenser, No. 17, was changed from 0.05 mf to 0.25 mf, Part No. 30-4134. See schematic on *page 8-65 of Rider's Volume VIII.*

Run No. 3. To provide uniform performance of the oscillator circuit, a 20-ohm resistor was connected in series with the cathode of the 6A8G detector-oscillator tube.

Run No. 4. In order to increase the a-f response in the high frequencies, condenser No. 40, was changed from 0.008 mf to 0.004 mf, Part No. 30-4456.

Run No. 5. The 20-ohm resistor added in Run No. 3, was removed.

Philco 610

We have been advised by the manufacturer that the following changes should be made in the schematic numbers of this model found on *page 6-19 of Rider's Volume VI:* the schematic number 54 should be changed to 41; No. 41 to 56; No. 56 to 54; No. 39 to 40; and No. 40 to 39. This will make the numbers of the wiring diagram, the base view, and the parts list agree.

Beginning with Run No. 15, the oscillator circuit of the second type of this chassis (*see page 7-87 of Rider's Volume VII*) was changed to improve the oscillator action at 6.0 mc. Resistors No. 17 and No. 18 (51,000 ohms and 25,000 ohms) were removed. A 32,000-ohm resistor (Part No. 33-332133) was added from the switch terminal side of condenser No. 7 in the antenna circuit to ground. A 20-ohm resistor, Part No. 33-020133 was connected between the 6A7 cathode and ground.

Philco 38-38

Beginning with Run No. 3, the 8000-ohm resistor, No. 21, was removed from the 90-volt tap and reconnected to the 135-volt tap of the battery cable. At the same time the value of this resistor was changed from 8000 to 25,000 ohms, Part No. 33-325339. The battery cable assembly was changed also to Part No. 41-3394.

In Run No. 4, the 900-ohm resistor No. 38 was changed to 2000 ohms, Part No. 33-220339. This change was made to decrease current drain on the "BC" battery. For schematic see *page 8-73 of Rider's Volume VIII.*

Philco 511, 521

The model 521 is for operation on 25-40 cycles and is similar to the model 511 (60-cycle operation) except as noted below. Please add 521 to the designation on *page 8-107 in Rider's Volume VIII.*

A change in the wiring has been made. The primary of the third r-f transformer instead of going to the left side of the resistor No. 17 now is connected to the other end. Plate voltage for the r-f tubes obtained from the point marked "D" in the voltage divider, No. 37, now is fed in to the resistors Nos. 7, 12, and 17 through

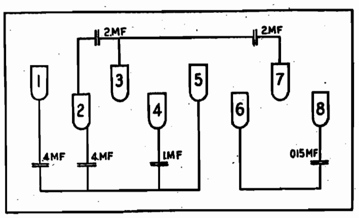


Fig. 2. Filter condenser pack of Philco Model 511 for 60-cycle operation.

the left end of this combination immediately below the first r-f tube. The primary of this r-f transformer now is connected to the right side of No. 7 in the schematic. In other words, the lead marked "D" at the right end of the three series resistors now is at the left end.

The accompanying partial schematic Fig. 1 of the power pack and filter carries various numberings, which correspond to those of Figs. 2 and 3 and show the capacity values of the filter condenser packs No. 35 used for model 511 and 521 respectively. Note that the connections of the 1-mf condenser, 4-5, have been changed from the way they are shown in the schematic on page 8-107. Instead of terminal 4 of No. 35 being connected to terminal 3 of No. 37 it is connected to terminal 1 of No. 35.

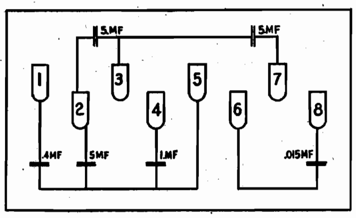

Fig. 3. Filter condenser pack of Philco Model 521 for 25-cycle operation.

The voltage readings are as follows:

Type	*Circuit*	*Fil.*	*Plate*	*Grid*	*Plate MA*
26	1, 2, 3 r-f, 1 a-f	1.62	98	6	4
27	Detector	2.65	38	..	1.5
71	2 a-f	5.26	148	29	17
80	Rect.	5.26	375 a-c	Ea.pl.30	

The voltages at the terminals of the power transformer, No. 34, are:

Terminals	*A-C Volts*
1-3	375
4-6	4.85
7-10	4.8
8-11	1.55
9-12	2.47

In the bottom view of the chassis on page 8-107, the voltage divider (in the lower left corner) has its terminals numbered corresponding to those numbers in the accompanying schematic. Some chassis of both models have been assembled with a resistor, Part No. 3088W, which does not include the detector plate section of 70,000 ohms; on other chassis Part No. 3088 is used. A separate resistor of 70,000 ohms value, Part No. Z-129, is mounted at the end of the sub-base. In this case, the terminals marked 3 and 4 in the layout must be disregarded. The values of the voltage divider sections of Part No. 3088 are as follows:

1-2	16,500 ohms
2-3	5,500 "
4-5	70,000 "
6-7	375 "
7-8	1,500 "

The values of the sections of Part No. 3088W are the same with the exceptions that section 4-5 is omitted as explained above, and the value of 7-8 is 1,590 ohms. The resistance of the volume control, No. 1, is 10,000 ohms and the value of the three resistors, Nos. 7, 12, and 17, is 100 ohms each.

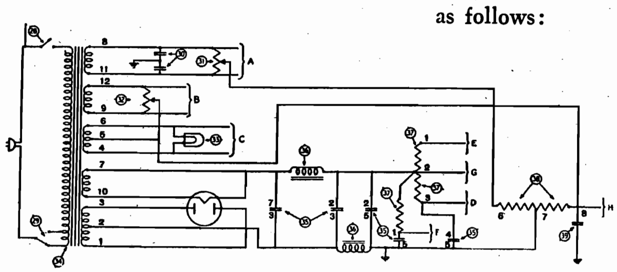

Fig. 1. Schematic of the power pack and filter used in Philco Models 511 and 521. The condenser values for each model can be found in Figs. 1 and 3 above.

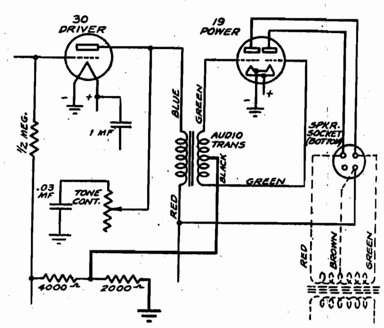
Sentinel 65B

The "B" battery drain of the early production of Model 65B sets can be reduced by about 20% and a corresponding increase in battery life obtained by adding the 2000-ohm and 4000-ohm resistors as shown in the accompanying partial schematic. It is also necessary to change the connection of the black wire, which is shown going to ground from the tap on the secondary of the output transformer on *page 8-27 in Rider's Volume VIII.* This ground connection is changed to the junction of the two resistors mentioned above. This change puts a 3-volt bias on the 19 tube and reduces the "B" battery drain to 18-20 ma.



The addition of the two resistors reduce the battery drain in Sentinel Model 65B.

This change is incorporated in late production receivers and these will be stamped with the letter "A" on the chassis.

Silvertone 4428A, 4448A, etc.

Due to variations in the 6D8G first detector-oscillator tube, whistles and oscillations may occur at the high-frequency end of the Foreign band. To correct such oscillations, change the value of the oscillator grid leak, R-4, from 50,000 ohms to 25,000 ohms. See schematic on *page 7-61 of Rider's Volume VII.*

Chassis in which this change has already been made in production are rubber-stamped with the letter "D" or some following letter on the chassis identification sticker.

Philco 38-2

For 25-cycle operation, the following parts must be changed in addition to the power transformer: the 0.25-mf condenser, No. 98 on the schematic on *page 8-55 of Rider's Volume VIII,* is removed and replaced with a 1 mf-0.5 mf, part No. 30-4549. The white wires of this condenser are connected across the choke, No. 99, and the red wire to the junctions of Nos. 59, 60, and 66 (in the plate circuit of the 1st a-f tube). Also remove the 8-mf electrolytic condenser, No. 96, and replace it with a 16-mf electrolytic condenser, Part No. 30-2200.

Beginning with Run No. 2, the i-f circuit has been changed to use permeability-tuned i-f transformers. These changes and the locations of the compensators are shown on the accompanying partial schematic and layout. Note that the schematic numbers of parts differ from those in the schematic on *page 8-55.* The wires from each circuit, however, have been marked indicating the connecting points on the schematic in Rider's Volume VIII.

The compensators are adjusted as follows: The range switch of the receiver is set in the broadcast position; the volume control at maximum; the magnetic tuning switch to "off"; and the tone control in the first position. The signal generator is set at 470 kc.

Using a 0.1-mf condenser as a dummy antenna, connect the signal generator to the grid of the 6A8G detector-oscillator tube and connect the cable ground to the set chassis. Set the attenuator of the signal generator for maximum output and adjust the i-f compensators as follows:

1. Turn compensator 1XB in until the output meter reading decreases almost to zero.
2. Now adjust the compensator 1XA and 1XC for maximum output; then readjust 1XB for maximum output.
3. Turn compensator 2XC in about three turns; then adjust 2XA and 2XB for maximum output. The adjustment procedure for 2XC is the same as that given at the bottom of *page 8-56 in Rider's Volume VIII* headed "Magnetic Tuning Circuit Adjustments."

In Run No. 3, a 250-mmf condenser, Part No. 30-1032, was connected from the screen of the 6U7G to ground to prevent parasitic oscillations.

Beginning with Run No. 4, the 6U7G r-f tube was replaced with a 6K7G to eliminate parasitic oscillations. In addition to the tube change, the green wire connecting the screen contact of the 6U7G and condenser 6 (0.05 mf) was increased in length. This wire should circle around the 6U7G socket towards the front of the r-f unit and then back to condenser No. 6. Place the wire as close to the base as possible.

The 250-mmf condenser that was added in Run No. 3 (see above) was removed in this run.

Philco 38-9, Code 121

In Run No. 2, a 20-ohm resistor was connected in series with the cathode of the 6A8G detector-oscillator tube to provide uniform performance of the oscillator circuit. The next run, this resistor was removed. See schematic on *page 8-65 of Rider's Volume VIII.*

Stromberg 150L

Complaints have been received now and then about there being too little bass response in this receiver. If more bass is desired, the following changes in the bass control circuit can be made:

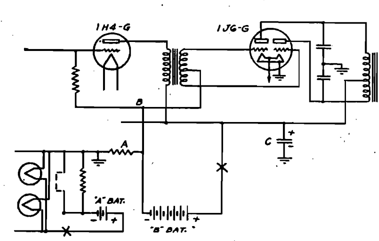
Remove the 10,000-ohm resistor, No. 189 in the schematic on *page 8-7, 8 in Rider's Volume VIII,* and replace it with a 47,000-ohm unit, Part No. 26353. Also replace the 0.04-mf condenser, No. 110 in the volume control circuit, with one having a capacity of 0.01 mf, Part No. 25149.

Note that these changes are not essential except when more bass response in this model is requested.

Zenith 5F233, 5F251

Complaints of short B-battery life or poor tone quality in 4- and 5-tube 2-volt receivers can be corrected by eliminating the C battery and converting the circuit to automatic bias and by by-passing the plate voltage in the set with an electrolytic condenser. The partial schematic diagram shown herewith shows where the changes are made in the chassis No. 5522 (used in the models mentioned above) as an example. *See page 8-5 in Rider's Volume VIII.*

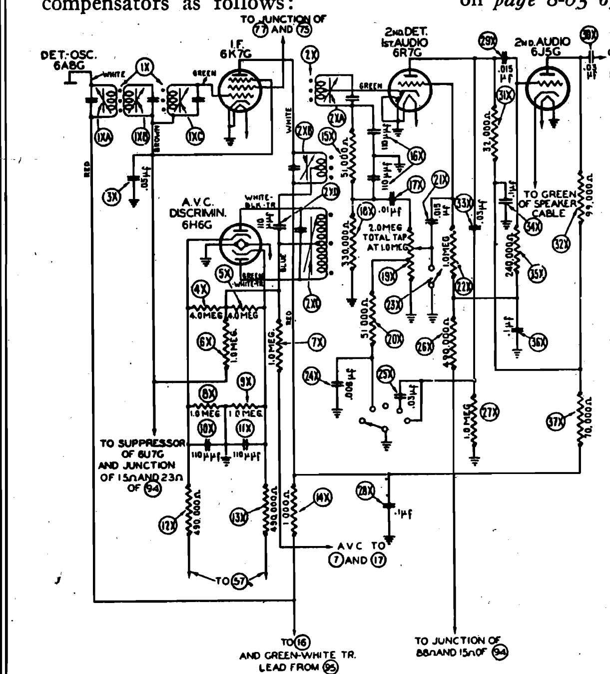
Disconnect the negative B-battery yellow lead where it connects to the chassis inside the chassis base. Connect a 300-ohm resistor (¼-watt) in series with this lead to ground. See "A" in schematic. Run the bias lead from the grid of the 1H4G and the grid of the 1J6G to the yellow B lead under the chassis. Disregard the green lead as the C-battery is omitted. See "B" in schematic.



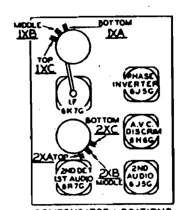
Partial schematic of Zenith 5F233, 5F251

Connect an 8-mf, 150-volt electrolytic condenser from +B to ground after the B circuit switch so that it is not connected across the B batteries when the receiver is turned off. See "C" in schematic.

These changes allow the bias voltage to drop automatically as the B voltage decreases and thereby preserves the tone quality. Originally the bias voltage remained constant when the B voltage dropped. The batteries should be useable down to about 50 volts or a 135-volt drop.



The circuit of the Philco model 38-2 was changed when permeability tuned i-f transformers were substituted for those previously used. Note that the parts numbers in the revised partial schematic at the left, do not correspond with the numbers on the schematic on page 8-55 of Rider's Volume VIII, but that the leads going to the parts of the circuit not shown, employ the original numbering.



COMPENSATOR LOCATIONS.

RCA 85K

This is a console model employing a chassis similar to Model 85T1, the service data for which will be found on *pages 8-112 to 8-114 in Rider's Volume VIII.* These service data apply to Model 85K with the following exceptions.

The loud speaker used is No. 84091-1 and its cable connects to the chassis as follows: Brown lead (L13) to positive (center) terminal of C24; Brown-black lead (L13-T2) to "SG" terminal of the 42 output tube; Black lead (T2) to "P" terminal of the same tube. The resistance values for this speaker are: field coil (L13), 1300 ohms; voice coil (L11), 2.4 ohms; hum neutralizing coil (L12), 0.16 ohm; output transformer (T2) primary, 520 ohms and the secondary, 0.37 ohm. The voice coil impedance is 2.6 ohms at 400 cycles.

The following corrections should be made in the service data and they apply to all models 85T1 and 85K:

The resistance of the antenna coil, L2, should be changed from 0.07 ohm to 1.3 ohms in the large schematic at the top of *page 8-113* and in the small diagram marked "Ant. Coil Connections" on the same page.

In the small schematic marked "Record Player Connections" a shield extension should be shown on the cable and connected to the chassis.

In the voltage diagram on *page 8-114* the voltage from the negative terminal of C24 to chassis should be designated as –17 volts. The voltage from the negative terminal of C10 should be 0 volts instead of –17. The value of C8 has been changed from 450 mmf to 470 mmf. Make this change on both diagrams on *page 8-113.*

Different power transformers (T1) are used in Model 85K. Stock No. 30607 is rated at 105-125/200-250 volts, 50-60 cycles and Stock No. 30571 is rated at 105-125 volts, 25-60 cycles. The complete speaker has a stock number 14613 and the output transformer (T2), 14615.

RCA 6K10, 6T10, 8T10, 9K10

These receivers are similar to models 6K2, 6T2, 8T, and 9K2 respectively, except for cabinet design. The servicing data, as published on the following pages in *Rider's Volume VII,* applies to these new model numbers: 6T10 and 6K10, *page* 7-41; 8T10, *page* 7-56; and 9K10, *page* 7-99.

Bosch 10 (Essex)

It has been brought to our attention that several errors appeared in the schematic of this receiver, which appeared on *page 3-6 of Rider's Volume III and on page 2490 of the Rider Combination Manual.* Please make the following corrections on the schematics on the above-mentioned pages.

The cathode of the 27 second detector should be grounded.

A connection should be indicated at the junction of the leads from R7 and R8. In others words, both of these resistors should be connected to the grid of the 27 A.V.C. tube.

A connection should be indicated at the point where the lead from R5 (in the plate circuit of the 58 first i-f tube) and the lead from the primary of the input pushpull transformer intersects the lead from the junction of R2 and R12 to the primary of the second i-f transformer.

The midpoint of the resistor R18, which is across the power transformer secondary supplying the heaters, should be grounded.

A connection should be indicated at the intersection of the leads from the screens of the 51 first detector and the first i-f tube, a 58.

RCA 6K1, 7X1, 8K1

Model 6K1 is similar to Model 6K (for schematic see *page 7-37 in Rider's Volume VII*) except for the following changes: A 5W4 rectifier is used instead of the 5Z4; R-15 in the heater circuit is omitted; a three-point tone control is used instead of the variable control, R-14; and different power transformers are used.

The tone control is connected as follows: Looking at the control (Part No. 13681) from the rear and starting from counter-clockwise lug, lug No. 1 goes to a 0.017-mf condenser, C-30 (Part No. 11451); the other side of this condenser connects to the chassis. Lug No. 2 goes to the junction of C-20 (0.01 mf) and R-9 (27,000 ohms). The third lug is not used. Lug No. 4 connects directly to the plate contact of the 6F6 output tube.

The d-c resistance of the power transformers are: Part No. 12644 (105-125 volts, 50-60 cycles) primary, 8.6 ohms and secondary 745 ohms; Part No. 12645 (105-125 volts, 25-60 cycles) primary 12.9 ohms and secondary, 1120 ohms; Part No. 12646 (100-130/140-160/195-250 volts, 40-60 cycles) primary, 24.5 ohms and secondary 760 ohms. The voltages for the 5W4 rectifier are: Plate to plate, 692 volts and plate to chassis ground, 346 volts. Other voltages remain the same.

The service data found on *pages 7-37 to 7-40 in Rider's Volume VII* are applicable to Model 6K1.

Model 7X1 is identical to Model 7X (see *page 8-33 in Rider's Volume VIII*) except for cabinet design. Model 8K1 is the same as Model 8K (see *page 7-56 in Rider's Volume VII*) except for cabinet design.

RCA 5M, 6M, 6M2

On the first production of these receivers (*below* serial number 200,000), two types of variable condensers are used. These differ only in the method of mounting the drive gear. Stock Nos. 12221 and 12222 gears are used only with the tuning condenser *not* having a tapped shaft. The gears used with a tapped shaft have the following numbers: 13145 and 13146.

The following parts are in addition to those listed for the above models, which will be found on *pages* 7-13 *and* 7-28 *of Rider's Volume VII*:

13147—Pinion gear and slotted shaft assembly and 13152—on-off operating switch. These are for the control box assemblies.

13006—Tuning and volume control flexible shaft sleeve.

11984—3-contact male connector for reproducer cable, No. 12525.

The second production run of these models (*above* serial number 200,000) used a tuning drive mechanism with a tuning drive ratio of 16 to 1. The following parts are applicable to hese receivers:

13371—3-gang variable tuning condenser.

13372—Tuning condenser shaft drive gear for above.

13373—Tuning condenser worm gear and mounting bracket for above.

13414—Control box complete, less flexible shafts.

Wells-Gardner 5 Tube AC-DC Models

Due to variations in 6J7 tube characteristics, distortion may be encountered at medium or low volume levels. This can be remedied by changing the .5 megohm 2nd detector screen series resistor (R5) to a .7 megohm resistor. This same result, of course, can be obtained by placing an additional .2 megohm resistor in series with the .5 megohm resistor.

Later production models have the .7 megohm resistor.

RCA D 22-1

The 800-8500-ohm resistor, No. 44-45, in the filter circuit of the 5Z3 rectifier, Tube No. 14, has been changed from its original location at the rear of the chassis to the front apron of the chassis near the power transformer. See the chassis wiring diagram on *page 6-137 of Rider's Volume VI.* The electrical connections remain the same.

Chevrolet 601574

The schematic for receivers having serial numbers under 0374000 appears on *United Motor page 6-33 in Rider's Volume VI.* Receivers having serial numbers above 0374000 have the following changes incorporated in the chassis:

Resistor No. 44 in the screen circuit of the 6F7 has been changed from 30,000 to 25,000 ohms.

Condenser No. 29 has been changed from 867 mmf to 950 mmf.

Condensers No. 18C (0.05 mf) and No. 28 (750 mmf) have been eliminated.

Resistor No. 42 in the diode circuit of the 6B7 has been changed from 150,000 to 250,000 ohms.

The volume control, No. 54, has been changed from 0.5 megohm to 1.5 megohms.

The lower end of the primary winding of the second i-f transformer, No. 9, now has a 1000-ohm resistor, No. 48, connected between it and the +B lead. This is located perpendicular to and immediately above resistor No. 42. See the top view of the parts layout on *United Motor page 6-34 in Rider's Volume VI.*

The output tube has been changed from a 41 type to a 42.

Wells-Gardner 6C1

The "B" issue of this series of auto radio receivers has several changes incorporated in it and its data differ from those shown on *pages 8-17 to 8-19 in Rider's Volume VIII.* This issue can be identified by the issue letter which is stamped on the top of the chassis base and on the tube layout label on the chassis case cover. Specify this letter if parts be ordered.

The gang condenser used in the new issue does not have the cut-plate oscillator section. The new part number for the gang condenser is 14A77. A padding condenser (600 kc) was added in series with the oscillator section of this gang condenser and the oscillator coil. The padder is a part of the 2nd i-f trimmer unit and is mounted in the coil can. In other words, the 30-100 mmf condenser, C-14, and the new 900-1300-mmf condenser are mounted in the same can and have a part number 17A79.

The capacity C-15 shown within a dotted circle on the schematic in the 2nd i-f coil assembly, has been changed to an actual part and has a part number 47X57.

The following parts have been changed in the late issue and below will be found the new parts numbers:

T1 Antenna Transformer and Can Assembly 9A859

T2 R-f Transformer and Can Assembly 9A860

T3 Oscillator Coil and Can Assembly 9A862

T5 2nd I-F Transformer and Can Assembly 9A858

The 2000-mmf molded condenser in the plate circuit of the 41 output tube has been changed, to a 0.002-mf, 1000-volt tubular condenser, Part No. 46X-219. A 15-ampere fuse is now used instead of one rated at 20 amperes. The 25-inch volume or tuning control flexible drive shaft has been changed, the Part No. now being 18A49. The changes in this last paragraph apply to all issues of the 6C1 receivers; not just the "B" issue like those above.

RCA 85T1, U-101, U-103

The 450-mmf condenser, C-1, which is connected in the oscillator grid circuit, has been changed to 470 mmf. It is not ordinarily required to replace this in the field, except where trouble might be experienced during re-alignment of the oscillator circuit; in which case tracking will be facilitated if the original unit is replaced with the 470-mmf type, Stock No. 30396. The schematic of model 85T1 will be found on *page 8-113* and that of the other two models on *page 8-147, both being in Rider's Volume VIII.*

United Motors 980393 B-O-P

Please add this note to the data on *United Motors page 8-31 in Rider's Volume VIII.* If the receiver does not oscillate at all or oscillates on one end of the dial only, try a new 36 as an oscillator. If this does not cure the trouble, check resistor R-1-A (the 4200-ohm resistor in the cathode circuit of the 36 detector-oscillator) and condensers C-3 (735 mmf) and C-10 (0.002 mf). As the capacities of these condensers are rather critical, they should be tested by replacement. If these tests do not locate the trouble, it will be necessary to replace the oscillator coil.

Zenith 462

Although several minor changes in the circuit of this automobile receiver were made during production, the schematic on *page 4-3 of Rider's Volume IV* will coincide with most of these sets that have been marketed.

During a portion of the production, the suppressor grids were removed from the cathodes and tied to the grid returns thereby placing the A.V.C. voltage on the suppressor grids. Also a change was made in the first i-f stage, a 6C5 being used instead of a 6D6. This was to eliminate the tendency towards howling.

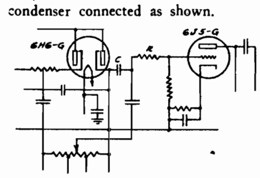
Zenith 668

Please make a note on *Zenith page 6-1 of Rider's Volume VI* that the chassis of this set and that of Model 666 are the same except for some mechanical parts changes. An 8-inch dynamic speaker (Part No. 49-114) is used instead of the 6-inch speaker in the Model 666. The output transformer is not included in the 8-inch speaker assembly and its part number is 95-285. A speaker cable (Part No. 52-69) is used in the Model 668 that is not used in the Model 666. The part number of the complete speaker assembly is S-3665.

Zenith 15-Tube Receivers

In some of these receivers distortion has developed when using the set at low volume. This has been found due to some r.f. getting through to the a-f system.

The correction is an r-f filter in the a-f grid circuit as shown in the accompanying schematic. This consists of a 150,000-ohm resistor and a 0.0005-mf condenser connected as shown.



C and R form the r-f filter. For values, see above

Microphonism or a-f tube noise can be corrected by interchanging the 6J5 1st a-f tube or by replacing it with a 6C5G. The latter appears to give slightly less hum and has lower microphonic characteristics.
